Uniform Medical Plan Pre-authorization List

The Uniform Medical Plan (UMP) Pre-authorization List includes services and supplies that require pre-authorization or notification for UMP members.

How to submit a pre-authorization request or notification

Expedited requests

Use this process only when the member or his/her physician believes that waiting for a decision under the standard time frame could place the member's life, health or ability to regain maximum function in serious jeopardy.

- Availity Essentials: Read the information carefully to ensure your request meets the qualifications, then check the box on the form to attest that it is an expedited request.
- Via fax using the appropriate pre-authorization request form below

Online

- Submit an electronic pre-authorization request, and supporting clinical documentation through Availity Essentials>Patient Registration>Authorizations & Referrals>Authorizations
    - Learn more about submitting requests through Availity
- Sleep medicine: Sign in to the Carelon Medical Benefits Management (Carelon) Provider Portal
- Radiology program: Sign in to the Carelon Provider Portal or choose to be routed from Availity's electronic authorization tool via single sign-on.

Note: Check the status of your requests using the same platform you used to submit the request:

- Requests submitted through Carelon are updated on Carelon's portal: **ProviderPortal.com**.
- Requests submitted through Availity Essentials are updated in Availity: **availity.com**.

Fax

Submit the appropriate pre-authorization request form only if unable to submit online or if submitting an expedited request:

- Medical services (PDF)
- NICU/PICU Notification of Admission Form (PDF)
- Durable medical equipment (DME) (PDF)
- Skilled nursing facility (SNF), long term acute care (LTAC) and inpatient rehabilitation (PDF)
- Behavioral health facility submission forms. Tip: Download the form and then fill it out to avoid browser discrepancies.
    - Initial Request Form (PDF) (can be added to an Availity submission)
    - Concurrent Request Form (PDF)
    - Stepdown Request Form (PDF)
    - Discharge Notification Form (PDF)
- Applied Behavioral Analysis (ABA) Initial Request Form (PDF)
- Applied Behavioral Analysis (ABA) Concurrent Request Form (PDF)
- Transcranial Magnetic Stimulation (rTMS) Request Form (PDF) for initial and ongoing services

Direct clinical information reviews (MCG Health)

For select CPT codes, Availity's electronic authorization tool automatically routes you to MCG Health's website where you can document specific clinical criteria for your patient. If all criteria are met, you will see the approval on the Auth/Referral Dashboard soon after you click submit. Once all criteria are documented, you will then be routed back to Availity Essentials to attach supporting documentation and submit the request. Documenting complete and accurate clinical information for your patients helps to reduce the overall time it takes to review a request. View the services that may receive automated approval (PDF).

Type of service or request	Online	Phone	Fax (only if unable to submit online)
Skilled nursing facility only	Submit an electronic pre-authorization request through Availity Essentials	1 (844) 600-4376	1 (855) 848-8220
Long term acute care		1 (800) 423-6884	1 (855) 848-8220

Expedited requests		1 (800) 423-6884	1 (844) 679-7764
Radiology program Codes requiring authorization are listed in the Radiology section below	Request pre-authorization from Carelon View workarounds for Carelon system outages	1 (877) 291-0509	
Sleep Medicine Codes requiring authorization are listed in the Sleep Medicine section below	Request pre-authorization from Carelon View workarounds for Carelon system outages	1 (877) 291-0509	
Inpatient concurrent review			
for: • Skilled nursing facilities (SNF) • Inpatient hospital continued stay • Inpatient rehabilitation (IPR) • Long-term acute care hospitalizations (LTACH) Notifications for: • Inpatient admissions for SNF/IPRL/LTACH/IP Hospital • Inpatient discharges for SNF/IPRL/LTACH/IP Hospital		1 (800) 423-6884	1 (855) 848-8220
Clinical Records for: • SNF stays • LTACH stays • IPR stays		1 (800) 423-6884	1 (844) 629-4404

Washington State Health Technology Clinical Committee (HTCC) Assessments

Under state law, the Uniform Medical Plans (UMP Achieve 1, UMP Achieve 2, UMP Classic, UMP Select, UMP CDHP, UMP High Deductible, UMP Plus – Puget Sound High Value Network, and UMP Plus – UW Medicine ACN) must comply with decisions made by the Health Technology Clinical Committee (HTCC). The HTCC is a committee of independent health care professionals that reviews selected health technologies (services) to determine the conditions, if any, under which the service will be included as a covered benefit and, if covered, the criteria the plan must use to decide whether the service is medically necessary. These services may include medical or surgical devices and procedures, medical equipment, and diagnostic tests. In public meetings, the HTCC considers public comments and scientific evidence regarding the safety, medical effectiveness, and cost-effectiveness of the services in making its determination. Final decisions and ongoing reviews may be accessed on the HTCC website.

Criteria established by the HTCC supersede Regence Medical Policy.

Procedures that are subject to HTCC decision and require pre-authorization can be found on the UMP Pre-authorization List below.

Procedures denied due to an HTCC decision will be member responsibility.

Important pre-authorization reminders

1. Failure to pre-authorize services subject to pre-authorization requirements will result in an administrative denial, claim non-payment and provider and facility write-off. Members may not be balance billed.
2. Before requesting pre-authorization, please verify member eligibility and benefits via the Availity Portal as the member contract determines the covered benefits.
3. Verify that you are an in-network provider for each member to help reduce his or her out-of-pocket expense.
4. If services are to be rendered in a facility, the pre-authorization request submitted should designate the facility where the treatment will occur to ensure proper reconciliation with related inpatient claims.

5. HTCC Decisions, Medical policies, MCG and CMS criteria may be used as the basis for service coverage determinations, including length of stay and level of care. Visit MCG's website for information on purchasing their criteria, or contact us and we will be happy to provide you with a copy of guidelines for specific services.
6. Emergency services do not require pre-authorization, but are subject to hospital admission notification requirements (see below).
7. The member's contract language will apply.
8. Please note that a pre-authorization does not guarantee payment for requested services. (See #2 above). Our reimbursement policies may affect how claims are reimbursed. Payment of benefits is subject to pre-payment and/or post-payment review, and all plan provisions, including, but not limited to, eligibility for benefits and our Coding Toolkit clinical edits.
9. Investigational and cosmetic services and supplies are typically contract exclusions and are ineligible for payment. Unlisted codes may be used for potentially investigational services and are subject to review. Please refer to the Clinical Edits by Code list for additional information. View a sample non-covered member consent form (PDF).
10. Pre-authorization requirements are not dependent upon site of service. All CPT and HCPCS codes listed on our pre-authorization lists require pre-authorization. View list below for complete requirements.

Type of review	Timeframe	Additional time allowed for review if additional information is needed*:
Urgent/Expedited	Electronic submissions: 1 calendar day, excluding holidays Non-electronic submissions: 2 calendar days	Electronic submissions: 1 calendar day, excluding holidays Non-electronic submissions: 2 calendar days
Standard initial	Electronic submissions: 3 calendar days, excluding holidays Non-electronic submissions: 5 calendar days	Electronic submissions: 3 calendar days, excluding holidays Non-electronic submissions: 4 calendar days
Concurrent	24 hours	72 hours

	Must notify within 24 hours for newborn intensive care unit (NICU) or pediatric intensive care unit (PICU) admission. Exception: Maternity notifications are required on day 6.	

Pre-authorization review timeframes

If Pre-Authorization requests are received requesting urgent/expedited review timeframes and the documentation provided does not meet the urgent/expedited criteria, the review will be reclassified to a standard review and standard timeframes will apply.

Urgent/expedited criteria is defined as one or more of the following:

- The member's life, health or ability to regain maximum function is in serious jeopardy.
- The member's psychological state is putting the life, health or safety of the member or others is in serious jeopardy.
- The member will be subjected to severe pain that cannot be adequately managed without the service.

Payment implications for failure to pre-authorize services

Failure to secure approval for services subject to pre-authorization or concurrent review authorization will result in claim non-payment and provider write-off. Our members must be held harmless and cannot be balance billed.

Please note the following:

- Hospital claims for elective services that require pre-authorization will be reimbursed based upon the member's contract only when the physician or other health care professional has completed and received approval of the pre-authorization for the services. We therefore strongly suggest that facilities develop a method to ensure that required pre-authorization requests have been submitted by

the physician or other health care professional and approved prior to admission of the patient.

- If the physician or other health care professional follows the pre-authorization requirements outlined on our pre-authorization lists, they will not be subject to any pre-authorization penalties for failure of the facility to provide the required inpatient admission and discharge notification. Stays that extend beyond the pre-authorized number of days require admission notification and concurrent review. If a facility fails to receive authorization for additional days, the additional days will be provider liability.
- A pre-authorization does not guarantee payment for requested services. Health Plan reimbursement policies may affect how claims are reimbursed and payment of benefits is subject to all plan provisions, including eligibility for benefits. Services must always be covered benefits and medically necessary.
- If an elective service that requires pre-authorization needs to occur during the course of an inpatient admission, and that need could not be foreseen prior to admission, the facility or provider can request pre-authorization for the service while the member is inpatient (before the service occurs). If pre-authorization does not occur during the stay, services are subject to review post-service for medical necessity.

Pre-authorization exception

There may be exceptions to obtaining pre-authorization. The six situations listed below may apply as part of our Extenuating Circumstances Policy Criteria (PDF):

1. Member presented with an incorrect member ID card or member number or indicated they were self-pay, and that no coverage was in place at the time of treatment, or the participating provider or facility is unable to identify from which carrier or its designated or contracted representative to request a pre-authorization.
2. Natural disaster prevented the provider or facility from securing a pre-authorization or providing hospital admission notification.
3. Member is unable to communicate (e.g., unconscious) medical insurance coverage. Neither family nor collateral support present can provide coverage information.
4. Compelling evidence the provider attempted to obtain pre-authorization. The evidence shall support the provider followed our policy and that the required information was entered correctly by the provider office into the appropriate system.
5. A surgery which requires pre-authorization occurs in an urgent or emergent situation. Services are subject to review post-service for medical necessity.
6. A participating provider or facility is unable to anticipate the need for a pre-authorization before or while performing a service or surgery.

Learn how to notify us about an extenuating circumstance (PDF) prior to claim submission, or how to appeal a claim that has been administratively denied.

Inpatient admissions

See below for substance use disorder and mental health admissions.

Hospital admissions

- Pre-authorization is required for elective inpatient admissions.
- Notification of hospital admission and discharge required within 1 calendar day, regardless of federal holidays or day of the week.
- Elective early delivery, prior to 39 weeks gestation, is not a covered benefit (not applicable to emergency delivery or spontaneous labor).
- Notification is required via electronic medical record, when available. If electronic medical records are not available, notifications are required via fax or by calling 1 (800) 423-6884. Providers should not call Customer Service to notify of patient admissions or discharge. Learn more about this requirement in the Facility Guidelines section of our Administrative Manual.
- Concurrent medical necessity review is required and must include diagnosis and clinical information regarding the member's current inpatient stay. A census list, admission notice, diagnosis code alone or a face sheet without clinical information is not considered adequate for concurrent review. Failure to provide required records may result in a reduction in or denial of benefits.

Inpatient hospice

- Notification of admission or discharge is necessary within 24 hours of admission or discharge (or one business day, if the admission or discharge occurs on a weekend or a federal holiday). Notification of inpatient hospice admission and discharge required within 24 hours, regardless of federal holidays or day of the week.
- Notification is required via electronic medical record, when available. If electronic medical records are not available, notifications are required via fax. Learn more about this requirement.

Long-Term Acute Care Facility (LTAC)

- Pre-authorization is required prior to patient admission.

Rehabilitation

- Pre-authorization is required prior to patient admission.

Skilled Nursing Facility (SNF)

- Pre-authorization is required prior to patient admission.

Extracorporeal Circulation Membrane Oxygenation (ECMO) for the Treatment of Respiratory Failure in Adults (PDF)

- 33946, 33947, 33948, 33949, 33952, 33954, 33956, 33958, 33962, 33964, 33966, 33984, 33986, 33987, 33988, 33989
- Subject to review.

Substance use disorder and mental health

Pre-authorization is required for the services listed below. For select CPT codes, including transcranial magnetic stimulation services, Availity's electronic authorization tool automatically connects to MCG Health's website where specific clinical criteria can be documented for your patient. If all criteria are met, an approval will be received on the Auth/Referral Dashboard. **Emergency inpatient services do not require pre-authorization and are subject to admission notification requirements.**

- **Inpatient: Psychiatric or ASAM 4.0 detoxification**
  - Notification of admission must be received within 24 hours of admission or the next business day (whichever comes first). Medical necessity review will be conducted.
- **Sub-acute detoxification or ASAM level 3.7**
  - Notification of admission must be received within 24 hours of admission or the next business day (whichever comes first)
  - Initial assessment and initial treatment plan must be received within:
    - Two business days for inpatient or residential substance use disorder treatment services
    - Three business days for withdrawal management services
- **Residential treatment: substance use disorders or ASAM level 3.5**
  - Notification of admission must be received within 24 hours of admission or the next business day (whichever comes first)
  - Initial assessment and initial treatment plan must be received within:
    - Two business days for inpatient or residential substance use disorder treatment services
    - Three business days for withdrawal management services
- **Residential treatment: Psychiatric**
  - Requires pre-authorization before the member is admitted for services. Under certain circumstances, pre-authorization requests can be made within 24 hours of admission or the next business day.
- **Partial hospitalization: Psychiatric or ASAM level 2.5 for substance use disorders**
  - Request for authorization is required no later than the day of admission.
- **Intensive outpatient: Psychiatric or ASAM level 2.1 for substance use disorders**
  - Request for authorization is required no later than the day of admission.

Medical necessity for behavioral health services is determined by:

- Behavioral health medical policies
- The American Society of Addiction Medicine's (ASAM) criteria (PDF) for chemical dependency services

View our resources and forms for behavioral health facilities and our behavioral health medical policies.

Applied Behavior Analysis (ABA) Therapy

ABA Therapy is for the treatment of Autism Spectrum Disorders (ASD) when medically necessary.

- Procedure codes 0362T, 0373T, 97151, 97152, 97153, 97154, 97155, 97156, 97157, 97158
- Procedure codes 97151, 97152, and 0362T: Pre-authorization is not required when 97151, 97152, and 0362T are used for **initial** ABA assessments, but pre-authorization is required when 97151, 97152, and 0362T are used for ABA **reassessments**.
- Pre-authorization is only required for UMP members age 18 and older. Use the Availity Authorization tool if you are uncertain if pre-authorization is required for a member.

The following clinical providers, with expertise in using evidenced-based tools to establish or confirm the diagnosis of autism and experience in developing multidisciplinary autism treatment plans, can provide the diagnostic assessment, comprehensive evaluation report, and recommend treatment approach:

- Psychiatrist
- Neurologist
- Pediatric Neurologist
- Developmental Pediatrician
- Doctorate level psychologist
- Advanced registered nurse practitioner

Initial pre-authorizations must contain the following information; View specific details on what each of these below items need to contain (PDF)

- Pre-authorization request form (or equivalent information)
- Clinical evaluation, which includes confirmation of an ASD diagnosis, and recommended treatment approach from a clinician meeting the criteria above (clinical evaluation needs to have been completed within the 12 months prior to the initial pre-authorization request)
- Written Clinical Order, Directive, or Prescription for ABA Therapy services from a clinician meeting the criteria above
- ABA initial report that includes an ABA assessment treatment plan (to be completed by the Lead Behavior Therapist). This sample ABA assessment and treatment plan form (PDF) can be filled out and submitted or used as a reference tool.

A cover letter may be submitted; however, it is not required. A sample cover letter template (PDF) is provided for your reference. Other supporting documentation may be submitted.

View ABA therapy clinical considerations (PDF) for information about hours of service and documentation requirements.

Concurrent Review

The following document should be submitted within five business days prior to the end of a current authorization:

- Updated ABA assessment treatment plan (to be completed by the Lead Behavior Therapist). This sample ABA assessment and treatment plan form (PDF) can be filled out and submitted or used as a reference tool.
- A new Pre-authorization request form (PDF) (or equivalent information).

View ABA therapy clinical considerations (PDF) for information about hours of service and documentation requirements.

Following the submission of the concurrent review documentation, the plan may request additional information prepared and submitted by a clinician meeting the above clinical criteria. The plan will specify what must be included in this report which is intended to assess progress and prospective treatment in further detail and may include a written Clinical Order, Directive or Prescription for ABA Therapy services.

Initial Treatment Request

Procedure codes: 0362T, 0373T, 97151, 97152, 97153, 97154, 97155, 97156, 97157, 97158

- Procedure codes 97151, 97152, and 0362T: pre-authorization is not required when 97151, 97152, and 0362T are used for initial ABA assessments, but pre-authorization is required when 97151, 97152, and 0362T are used for ABA reassessments during course of treatment.
- Pre-authorization is only required for members age 18 and older. Use the Availity Authorization tool, availity.com, if you are uncertain if pre-authorization is required for a member.
- ABA therapy must be recommended or prescribed by a licensed provider experienced in the diagnosis and treatment of autism.

View documentation requirements in our Applied Behavior Analysis for the Treatment of Autism Spectrum Disorder (PDF) medical policy which should include:

- Clinical evaluation, which includes confirmation of an ASD diagnosis, and recommended treatment approach from a clinician meeting the criteria above.
- ABA initial report that includes an ABA assessment treatment plan (to be completed by the Lead Behavior Therapist).
- A cover letter may be submitted; however, it is not required. A sample cover letter template (PDF) is provided for your reference. Other supporting documentation may be submitted.

Concurrent Treatment Request (Reauthorization)

- Updated clinical documents should be submitted within 14 days of end of a current authorization.
- A new Pre-authorization request form (PDF) (or equivalent information).

- Following the submission of the concurrent review documentation, the plan may request additional information prepared and submitted by a clinician meeting the above clinical criteria. The plan will specify what must be included in this report which is intended to assess progress and prospective treatment in further detail and may include a written Clinical Order, Directive or Prescription for ABA Therapy services.

- Review the codes requiring authorization or notification in the Sleep Medicine section.

Genetic testing

In compliance with WA HB 1689, guideline-recommended biomarker testing in patients with recurrent, relapsed, refractory, or metastatic cancer (including stage 3 or 4) will not require prior authorization for Washington members. This does not include non-specific molecular pathology codes (81400-81408).

Diagnosis codes Z800-Z803, Z8041 and Z8042 will no longer be exempted from pre-authorization for Washington members.

- 0232U, 0234U, 0235U, 0238U, 0244U, 81201, 81202, 81203, 81210, 81212, 81215, 81216, 81217, 81225, 81228, 81229, 81235, 81243, 81244, 81250, 81252, 81253, 81254, 81257, 81275, 81276, 81292, 81293, 81294, 81295, 81296, 81297, 81298, 81299, 81300, 81302, 81303, 81304, 81311, 81314, 81317, 81318, 81319, 81321, 81322, 81323, 81324, 81325, 81326, 81341, 81349, 81350, 81351, 81352, 81401,

81402, 81403, 81404, 81405, 81406, 81407, 81408, 81419, 81441, 81470, 81471, S3800, S3840, S3844, S3845, S3846, S3849, S3850, S3853, S3865, S3866
- UMP is subject to HTCC Decision (PDF) for code 81225.
- Code 81225 will deny as not a covered benefit when billed with the following diagnosis: depression, mood disorders, psychosis, anxiety, ADHD and substance use disorders

Genetic Testing for Biallelic RPE65 Variant-Associated Retinal Dystrophy (PDF) - GT21

- 81406

Gene Expression Profiling for Melanoma (PDF) - GT29

- 81552

BRAF Genetic Testing to Select Melanoma or Glioma Patients for Targeted Therapy (PDF) - GT41

- 81210

Assays of Genetic Expression in Tumor Tissue as a Technique to Determine Prognosis in Patients with Breast Cancer (PDF) - GT42

- 81522
- UMP is subject to HTCC Decision (PDF) for codes 81518, 81519, 81520, 81521, 81523, 81541, 81542, 81551, S3854, 0262U, 0045U, 0047U, 0067U and 0009U
- Apply the Regence medical policy Assays of Genetic Expression in Tumor Tissue as a Technique to Determine Prognosis in Patients with Breast Cancer (PDF) for conditions/treatments not addressed in the HTCC decision (e.g. BluePrint, and TargetPrint.)

Diagnostic Genetic Testing for Genetic Testing for FMR1 and AFF2 Variants (Including Fragile X and Fragile XE Syndromes) (PDF) - GT43

- 81243, 81244

Noninvasive Prenatal Testing to Determine Fetal Aneuploidies, Microdeletions, Single-Gene Disorders, and Twin Zygosity (PDF) - GT44

- 81408, 81243

Genetic Testing for CADASIL Syndrome (PDF) - GT51

- 81406

Diagnostic Genetic Testing for α-Thalassemia (PDF) - GT52

- 81257, 81258, 81259, 81269, 81404

Genetic Testing; Primary Mitochondrial Disorders (PDF) - GT54

- 0417U, 81401, 81403, 81404, 81405, 81440, 81460, 81465

Targeted Genetic Testing for Selection of Therapy for Non-Small Cell Lung Cancer (NSCLC) (PDF) - GT56

- 0022U, 81210, 81235, 81275, 81276, 81404, 81405, 81406

Genomic Microarray Testing

- UMP is subject to HTCC Decision (PDF) for codes 81228, 81229, 81349, S3870, 0156U, 0209U, 0318U

Genetic Testing for Myeloid Neoplasms and Leukemia (PDF) - GT59

- 81120, 81121, 81351, 81352, 81401, 81402, 81403, 81450, 81451, 81455, 81456

Genetic Testing for PTEN Hamartoma Tumor Syndrome (PDF) - GT63

- 0235U, 81321, 81322, 81323

Genetic Testing for Evaluating the Utility of Genetic Panels (PDF) - GT64

- 81201, 81202, 81203, 81210, 81225, 81228, 81229, 81235, 81243, 81244, 81250, 81252, 81253, 81254, 81257, 81275, 81276, 81288, 81292, 81293, 81294, 81295, 81296, 81297, 81298, 81299, 81300, 81302, 81303, 81304, 81311, 81314, 81317, 81318, 81319, 81321, 81322, 81323, 81324, 81325, 81326, 81349, 81350, 81401, 81402, 81403, 81404, 81405, 81406, 81407, 81408, 81412, 81432, 81433, 81434, 81437, 81438, 81440, 81441, 81443, 81450, 81451, 81455, 81456, 81460, 81465, 81470, 81471
- UMP is subject to HTCC Decision (PDF) for code 81225
- Code 81225 will deny as not a covered benefit when billed with the following diagnosis: depression, mood disorders, psychosis, anxiety, ADHD and substance use disorders.

Genetic Testing for Methionine Metabolism Enzymes, including MTHFR (PDF) - GT65

- 81401, 81403, 81404, 81405, 81406

Genetic Testing for the Diagnosis of Inherited Peripheral Neuropathies (PDF) - GT66

- 81403, 81404, 81405, 81406, 81324, 81325, 81326, 81448

Genetic Testing for Rett Syndrome (PDF) - GT68

- 0234U, 81302, 81303, 81304, 81404, 81405, 81406

Genetic Testing for Duchenne and Becker Muscular Dystrophy (PDF) - GT69

- 0218U, 81161, 81408

Fetal RHD Genotyping Using Maternal Plasma (PDF) - GT74

- 81403

Genetic Testing for Macular Degeneration (PDF) - GT75

Laboratory

Circulating Tumor DNA and Circulating Tumor Cells for Management (Liquid Biopsy) of Solid Tumor Cancers (PDF)

- 0239U, 0242U, 0326U, 0388U, 0409U, 0428U, 81462, 81463, 81464

Laboratory Tests for Organ Transplant Rejection (PDF)

- 81595

Measurement of Serum Antibiodies to Selected Biologic Agents (PDF)

- 80145, 80230, 80280

Maternity

Elective early delivery, prior to 39 weeks' gestation, is not a covered benefit (not applicable to emergency delivery or spontaneous labor).

Medicine

Bioengineered Skin and Soft Tissue Substitutes and Amniotic Products (PDF)

- A4100, A6460, A6461, Q4100, Q4101, Q4102, Q4105, Q4106, Q4107, Q4114, Q4116, Q4121, Q4122, Q4128, Q4132, Q4133, Q4151, Q4154, Q4159, Q4186, Q4187

Confocal Laser Endomicroscopy (PDF)

- 43206, 43252, 88375

Coverage of Treatments Provided in a Clinical Trial (PDF)

- S9990, S9991, S9988

Digital Therapeutic Products (PDF)

- 98978, A9291, A9292, E1905

Digital Therapeutic Products for Attention Deficit Hyperactivity Disorder (PDF)

- 98978, A9291

Digital Therapeutic Products for Chronic Low Back Pain (PDF)

- 98978, A9291, E1905

Digital Therapeutic Products for Post-traumatic Stress Disorder and Panic Disorder (PDF)

- A9291

Digital Therapeutic Products for Substance Use Disorders (PDF)

- 98978, A9291

Digital Therapeutic Products for Amblyopia (PDF)

- A9292

Hyperbaric Oxygen Therapy for Tissue Damage, Including Wound Care and Treatment of Central Nervous System Conditions (PDF)

- UMP is subject to HTCC Decision (PDF): 99183, G0277
- Regence medical policy is used only to determine units of treatment, criteria for diabetic "standard wound therapy" and to address any conditions not addressed in the HTCC decisions under the HTCC "limitations of coverage" or "non-covered indicators".

In Vivo Analysis of Colorectal Lesions(PDF)

- 88375

Intensity Modulated Radiotherapy (IMRT)

- UMP is subject to HTCC Decision (PDF): 77301, 77338, 77385, 77386, G6015, G6016

Laser Interstitial Thermal Therapy (PDF)

- 61736, 61737

Low-Level Laser Therapy (PDF)

- 97037

Neurofeedback (PDF)

- 90875, 90876. 90901

Orthopedic Applications of Stem-Cell Therapy, Including Bone Substitutes Used with Autologous Bone Marrow (PDF)

- 38206, 38232, 38241

Progenitor Cell Therapy for the Treatment of Damaged Myocardium Due to Ischemia (PDF)

- 38205, 38206, 38240, 38241

Charged-Particle (Proton or Helium Ion) Radiotherapy

- UMP is subject to HTCC Decision (PDF) - 77520, 77522, 77523, 77525
    - Pre-authorization is not required for members under 21 years of age
- When the following codes are used for Charged-Particle (Proton or Helium Ion) Radiotherapy with SRS or SBRT, use HTCC Decision (PDF): 32701, 61796, 61797, 61798, 61799, 61800, 63620, 63621, 77301, 77338, 77371, 77372, 77373, 77432, 77435, G0339, G0340

Radioembolization, Transarterial Embolization (TAE) and Transarterial Chemoembolization (TACE) (PDF)

- 37243, 79445, C9797, S2095
- Note: Ovarian and Internal Iliac Vein Embolization as a Treatment of Pelvic Congestion Syndrome (PDF) is considered investigational.

Sleep Medicine

- View the Sleep Medicine Management Program for notification or authorization requirements.
- Review the codes requiring authorization or notification in the Sleep Medicine section.

Tinnitus: Non-invasive, non-pharmacologic treatments

- UMP is subject to HTCC Decision (PDF) for codes 0552T, 90832, 90833, 90834, 90836, 90837, 90838, 90867, 90868, 90869, 96156, 96158, 96159, 96160, 96161, 96164, 96165, 96167, 96168, 96170, 96171, S8948

- Pre-authorization is only required within tinnitus diagnosis codes: H93.11, H93.12, H93.13, H93.19, H93.A1, H93.A2, H93.A3, H93.A9
- Codes 0552T and S8948, when billed without a tinnitus diagnosis, will be denied as investigational based on Regence Medical Policy Low Level Laser Therapy
- Note: Codes 90867 and 90868, when billed with chronic migraine and chronic tension headaches, is not a covered benefit per HTCC Decision (PDF)

NOTE: For treatment of Tinnitus with transcranial magnetic stimulation (codes 90867, 90868, 90869) for members age 17 years and under, use Transcranial Magnetic Stimulation as a Treatment of Depression and Other Disorders (PDF)

Transcranial Magnetic Stimulation as a Treatment of Depression and Other Disorders (PDF)

- UMP is subject to HTCC Decision (PDF) for codes 90867, 90868, 90869
    - Per the HTCC, TMS for treatment resistant major depressive disorder (MDD) in UMP members age 18 or older is a covered benefit with conditions.
    - TMS for treatment resistant major depressive disorder (MDD) in UMP members age 17 and younger refer to Regence medical policy.
    - TMS for treatment of obsessive-compulsive disorder (OCD), generalized anxiety disorder (GAD), post-traumatic stress disorder (PTSD), smoking cessation, and substance use disorder (SUD) are not covered for all UMP members per the HTCC.
- Apply the Regence medical policy Transcranial Magnetic Stimulation as a Treatment of Depression and Other Disorders (PDF) for code 0858T.

Gender Affirming Interventions for Gender Dysphoria (PDF)

- 15775, 15776, 17380, 55970, 55980
- Codes 55970 and 55980 are non-specific. The specific procedure code(s) must be requested in place of these non-specific codes.
- 11920, 11921, 15771, 15773, 15774, 15825, 15828, 15829, 17999, 19303, 19316, 19318, 19325, 19350, 21125, 21127, 21137, 21139, 21141, 21142, 21143, 21145, 21146, 21147, 21188, 21193, 21194, 21195, 21196, 21208, 53400, 53405, 53410, 53415, 53420, 53425, 53430, 54125, 54400, 54401, 54405, 54520, 54660, 54690, 55175, 55180, 56625, 56800, 56805, 57106, 57110, 57291, 57292, 57295, 57296, 57335, 57426, 58353, 58356, 58563, C1813, C2622, L8600
- Use code 17999 to request laser hair removal.
- Gender affirming surgical interventions for gender dysphoria require pre-authorization. Codes for specific procedures might also be listed as requiring pre-authorization in other medical policies, including but not limited to:
    - Abdominoplasty - 15830
    - Adipose-derived Stem Cell Enrichment in Autologous Fat Grafting to the Breast - 15771
    - Breast Reconstruction - 19316, 19318, 19325, 19350, L8600
    - Blepharoplasty and Brow Lift - 15820, 15821, 15822, 15823, 67900, 67901, 67902, 67903, 67904, 67906, 67908, 67909, 67950
    - Chin Implants - 21120, 21121, 21122, 21123, 21209
    - Collagen Injections - 11950, 11951, 11952, 11954

- Cosmetic and Reconstructive Procedures - 15771, 15773
- Endometrial Ablation - 58353, 58356, 58563
- Panniculectomy - 15830
- Reconstructive Breast Surgery, Mastopexy, and Management of Breast Implants - 15771
- Rhinoplasty - 30400, 30410, 30420, 30430, 30435, 30450

Pharmacy

UMP has a separate vendor – Washington State Rx Services – for their prescription drug benefit. Pre-authorization is necessary for certain injectable drugs that are not normally approved for self-administration when obtained through a retail pharmacy, a network mail-order pharmacy, or a network specialty pharmacy. These drugs are indicated on the UMP Preferred Drug List.

Drugs usually payable under the member's medical benefit and pre-authorized will continue with the same Regence process.

Hemophilia Clotting Factors

Hemophilia clotting factor codes J7170. J7201, J7202, J7203, J7204, J7205, J7207, J7208, J7210 require pre-authorization and if approved will be covered under the Medical benefits for the following groups. For all other groups please use the pharmacy link above.

- ATI Specialty Alloys and Components (group #10015713)
- WA State Health Care Authority (group # 10003948)
- Rin Tinto (grandfathered plan codes only) (groups #10021209 & 10019119)
- OTET (group #10007445)
- Northwest Evaluation Association (NWEA) (group #10002570)
- Utah Valley University (group #10042213)
- Encoder Products (group #10040552)
- Eagle Eye Produce Inc (group #10040165)

Infusion Drug Site of Care

Certain provider administered infusion medications covered on the medical benefit are subject to the Site of Care Program (dru408) medication policy (PDF). This policy does not apply to members covered under UMP Plus plans.

Radiology

Contact Regence for pre-authorization for the following codes:

Coronary Artery Calcium Scoring

- UMP is subject to HTCC Decision (PDF): S8092
- **Note**: 75571 for Cardiac Artery Calcium Scoring is not a covered benefit - reference HTCC Decision.

Wireless Capsule Endoscopy for Gastrointestinal (GI) Disorders (PDF)

- 0651T, 91110, 91111, 91113

Carelon Medical Benefits Management (Carelon)

We partner with Carelon to administer our Advanced Imaging Authorization radiology program.

- Login to Carelon's ProviderPortal
- Phone 1 (877) 291-0509

Note: If HTCC criteria is used for pre-authorization, see below links to that criteria. If there are no HTCC criteria or HTCC is out of scope for request, Carelon criteria will apply.

Contact Carelon to request pre-authorization for the following codes: 70336, 70480, 70481, 70482, 70490, 70491, 70492, 70496, 70498, 70544, 70545, 70546, 70547, 70548, 70549, 70551, 70552, 70553, 71250, 71260, 71270, 71271, 71275, 71550, 71551, 71552, 71555, 72125, 72126, 72127, 72128, 72129, 72130, 72131, 72132, 72133, 72141, 72142, 72146, 72147, 72148, 72149, 72156, 72157, 72158, 72159, 72191, 72192, 72193, 72194, 72195, 72196, 72197, 72198, 73200, 73201, 73202, 73206, 73218, 73219, 73220, 73221, 73222, 73223, 73225, 73700, 73701, 73702, 73706, 73718, 73719, 73720, 73721, 73722, 73723, 73725, 74150, 74160, 74170, 74174, 74175, 74176, 74177, 74178, 74181, 74182, 74183, 74185, 74712, 75559, 75563, 75572, 75573, 75574, 75580, 75635, 76391, 77078, 77084, 78012, 78013, 78014, 78015, 78016, 78018, 78070, 78071, 78072, 78075, 78102, 78103, 78104, 78185, 78195, 78201, 78202, 78215, 78216, 78226, 78227, 78230, 78231, 78232, 78258, 78261, 78262, 78264, 78265, 78266, 78278, 78290, 78291, 78300, 78305, 78306, 78315, 78429, 78430, 78431, 78432, 78433, 78445, 78451, 78452, 78453, 78454, 78456, 78457, 78458, 78459, 78466, 78468, 78469, 78472, 78473, 78579, 78580, 78481, 78582, 78483, 78491, 78492, 78494, 78597, 78598, 78600, 78601, 78605, 78606, 78610, 78630, 78635, 78645, 78650, 78660, 78700, 78701, 78707, 78708, 78709, 78725, 78740, 78761, 78800, 78801, 78802, 78803, 78804, 78830, 78831, 78832, 93303, 93304, 93306, 93307, 93308, 93312, 93313, 93314, 93315, 93316, 93317, 93350, 93351, 95782, 95783, 95805, 95807, 95808, 95810, 95811, E0470, E0471, E0561, E0562, E0601, 0042T, 0648T, 0649T

HTCC decisions administered by Carelon:

- Breast MRI
  - UMP is subject to HTCC Decision (PDF): 77046, 77047, 77048, 77049
  - HTCC criteria applies to all member requests regardless of gender
- Cardiac Magnetic Resonance Angiography (CMRA)
  - UMP is subject to HTCC Decision (PDF): 75557, 75561
- Functional Neuroimaging for Primary Degenerative Dementia or Mild Cognitive Impairment
  - UMP is subject to HTCC Decision (PDF): 70554, 70555, 78608, 78609

    - Please see Carelon criteria for pre-authorization requirements for indications other than primary degenerative dementia or mild cognitive impairment
- Imaging for Rhinosinusitis
    - UMP is subject to HTCC Decision (PDF): 70450, 70460, 70470, 70486, 70487, 70488, 70540, 70542, 70543
    - Please see Carelon criteria for pre-authorization requirements for indications other than Rhinosinusitis
- Noninvasive Cardiac Imaging for Coronary Artery Disease
    - UMP is subject to HTCC Decision (PDF): 75574, 75580, 78429, 78430, 78431, 78432, 78433 78451, 78452, 78453, 78454, 78459, 78466, 78468, 78469, 78472, 78473, 78481, 78483, 78491, 78492, 78494, 93350, 93351
- Positron Emission Tomography (PET) Scans for Lymphoma
    - UMP is subject to HTCC Decision (PDF): 78811, 78812, 78813, 78814, 78815, 78816

Sleep Medicine

We partner with Carelon to administer our Sleep Medicine program.

- Login to Carelon's ProviderPortal
- Phone 1 (877) 291-0509
- View workarounds for Carelon system outages

Contact Carelon to request pre-authorization for the following codes: 95782, 95783, 95805, E0470, E0471

Carelon uses HTCC to pre-authorize sleep medicine diagnosis and equipment. Also refer to the Surgery section for additional information about pre-authorization requirements related to surgery for Sleep Apnea Diagnosis and Treatment.

HTCC decisions administered by Carelon:

- Sleep Apnea – Diagnosis and Equipment
    - UMP is subject to HTCC Decisions (PDF): 95807, 95808, 95810, 95811, E0561, E0562, E0601
    - Please see Carelon criteria for indications other than Sleep Apnea

Surgery

Ablation of Primary and Metastatic Liver Tumors (PDF)

- 47370, 47371, 47380, 47381. 47382, 47383

Adipose-derived Stem Cell Enrichment in Autologous Fat Grafting to the Breast (PDF)

- 15769, 15771, 15772, 11950, 11951, 11952, 11954

- Note: Codes 19380 and 19499 do not require pre-authorization but are considered, and will deny as, investigational when used for autologous fat grafting and adipose-derived stem cell enrichment for augmentation or reconstruction of the breast

Autologous Chondrocyte Implantation for Focal Articular Cartilage Lesions (PDF)

- J7330, S2112

Balloon Dilation of the Eustachian Tube (PDF)

- 69705, 69706

Balloon Ostial Dilation for Treatment of Sinusitis (PDF)

- 31295, 31296, 31297, 31298

Bariatric Surgery (PDF)

- 43771, 43848, 43860, 43886
- UMP is subject to HTCC Decision (PDF): 43644, 43772, 43773, 43774, 43775, 43820, 43845, 43846, 43887, 43888
- Bariatric surgery and HTCC guidelines apply, in order to establish eligibility for surgery and medical necessity.

Blepharoplasty, Repair of Blepharoptosis, and Brow Ptosis Repair (PDF)

- 15820, 15821, 15822, 15823, 67900, 67901, 67902, 67903, 67904, 67906, 67908, 67909, 67950

Bronchial Valves (PDF)

- 31647, 31648, 31649, 31651

Cardiac Stenting

- UMP is subject to HTCC Decision (PDF): 92928, 92933, 92937, 92941, 92943
- Pre-authorization is not required for members being treated for a condition other than stable angina

Carotid Artery Stenting

- UMP is subject to HTCC Decision (PDF): 37215, 37216, 37217, 37246, 37247, C7532

Catheter Ablation Procedures for Supraventricular Tachyarrhythmias (SVTA)

- UMP is subject to HTCC Decision (PDF): 93653, 93655, 93656, 93657

Cervical Fusion for Degenerative Disc Disease

- UMP is subject to HTCC Decision (PDF): 22551, 22552, 22554, 22853, 22854, 22859, 22600

Chemical Peels (PDF)

- 15788, 15789, 15792, 15793, 17360

Cochlear Implant (PDF)

- For Bilateral Cochlear Implants, UMP is subject to HTCC Decision.
  For Unilateral Cochlear Implants and replacement requests, UMP follows Regence Medical Policy.
- 69930, L8614, L8619, L8627, L8628

Cosmetic and Reconstructive Procedures (PDF)

- 11920, 11921, 11922, 11950, 11951, 11952, 11954, 15769, 15771, 15772, 15773, 15774, 17106, 17107, 17108, 19355, 21230, 21244, 21245, 21246, 21248, 21249, 21295, 21296, 41510, 49250, 54360, 67950, 69300, G0429
- Pre-authorization is required EXCEPT when services are rendered in association with breast reconstruction and nipple/areola reconstruction following mastectomy for breast cancer.
- Note: Codes 19380 and 19499 do not require pre-authorization but are considered, and will deny as, investigational when used for autologous fat grafting and adipose-derived stem cell enrichment for augmentation or reconstruction of the breast

Cryosurgical Ablation of Miscellaneous Solid Tumors Outside of the Liver (PDF)

- 31641, 32994, 50542

Deep Brain Stimulation (PDF)

- 61850, 61860, 61863, 61864, 61867, 61868, 61885, 61886, C1820, L8679, L8680, L8685, L8686, L8687, L8688, L8682, L8683
- Deep brain stimulation is not a covered benefit for treatment-resistant depression, per HTCC Decision (PDF).
- Note: HTCC decision applies to UMP members age 18 and older. Refer to Regence Medical Policy for UMP members age 17 and younger

Discography

- UMP is subject to HTCC Decision (PDF): 62290, 72295

Endometrial Ablation (PDF)

- 58353, 58356, 58563

Facet Neurotomy

- UMP is subject to HTCC Decision (PDF): 64633, 64634, 64635, 64636

Gastric Electrical Stimulation (PDF)

- 43647, 43881, 64590, 64595, E0765, C1767, L8679, L8680, L8685, L8686, L8687, L8688

Gastroesophageal Reflux Surgery (PDF)

- 43279, 43280, 43281, 43282, 43325, 43327, 43328, 43332, 43333, 43334, 43335, 43336, 43337

Hip Surgery for Femoroacetabular Impingement Syndrome (FAI)

- UMP is subject to HTCC Decision (PDF): 29914, 29915, 29916

Hypoglossal Nerve Stimulation (PDF)

- 64568, 64582, 64583, C1767

Implantable Peripheral Nerve Stimulation and Peripheral Subcutaneous Field Stimulation (PDF)

- 64585, 64590, 64595, 64596, 64597, 64598, L8679, L8680, L8683

Laser Treatment for Port Wine Stains (PDF)

- 17106, 17107, 17108

Leadless Cardiac Pacemakers (PDF)

- 0823T, 0825T, 33274

Left-Atrial Appendage Closure Devices for Stroke Prevention in Atrial Fibrillation (PDF)

- 33340

Lumbar Fusion for Degenerative Disc Disease

- UMP is subject to HTCC Decision (PDF): 22533, 22558, 22612, 22630, 22633, 22853, 22854, 22859
- Lumbar Fusion for degenerative disc disease uncomplicated by comorbidities is not a covered benefit per HTCC Decision; This includes diagnosis codes M51.35, M51.36, M51.37
  Note: This decision does not apply to patients with the following conditions: radiculopathy, spondylolisthesis (>grade 1), severe spinal stenosis, acute trauma or systemic disease affecting spine, e.g., malignancy
- UMP is subject to HTCC Decision (PDF) for Bone Morphogenic Protein
- Bone morphogenetic protein-7 (rhBMP-7) is not a covered benefit
- HTCC for bone morphogenetic protein does not apply to those under age 18

Magnetic Resonance (MR) Guided Focused Ultrasound (MRgFUS) and High Intensity Focused Ultrasound (HIFU) Ablation (PDF)

- 0398T, 55880

Microwave Tumor Ablation (PDF)

- 32998, 50592

Negative Pressure Wound Therapy for Home Use (NPWT) (PDF)

- UMP is subject to HTCC Decision (PDF): 97605, 97606, 97607, 97608, A6550, E2402
- View the HTCC Decision: Definition of "Complete Wound Therapy Program" (PDF)
- View the NPWT FDA Safety Communication

Occipital Nerve Stimulation (PDF)

- 61885, 61886, 64553, 64568, 64569, 64585, 64590, 64596, 64597, 64598
- C1820, L8679, L8680, L8682, L8683, L8685, L8686, L8687, L8688

- Occipital Nerve Stimulation is considered investigational for all indications, including but not limited to headaches
- Note: These codes may overlap with the codes in the Vagus Nerve Stimulation Medical Policy so to ensure proper adjudication of your claim, please call for pre-authorization on all of the above codes.

Orthognathic surgery (PDF)

- 21085, 21110, 21120, 21121, 21122, 21123, 21125, 21127, 21141, 21142, 21143, 21145, 21146, 21147, 21150, 21151, 21154, 21155, 21159, 21160, 21188, 21193, 21194, 21195, 21196, 21198, 21206, 21208, 21209, 21210, 21215, 21230, 21295, 21296
- Codes 21145, 21196, 21198 require pre-authorization EXCEPT when the procedure is performed for oral cancer diagnosis codes: C01, C02-C02.9, C03-C03.9, C04-C04.9, C05-C05.9, C06, C06.2, C06.9, C09-C09.9, C10-C10.0, C41-C41.1, C46.2, D00-D00.00, D10, D10.1-D10.9, D16.4-D16.5, D37-D37.0, D49-D49.0

Osteochondral Allograft/Autograft Transplantation (OAT)

- UMP is subject to HTCC Decision (PDF): 27415, 27416, 29866, 29867

Ovarian, Internal Iliac and Gonadal Vein Embolization, Ablation, and Sclerotherapy (PDF)

- 37241

Percutaneous Angioplasty and Stenting of Veins (PDF)

- 37238, 37239, 37248, 37249

Panniculectomy (PDF)

- 15830

Pectus Excavatum and Carinatum Surgery (PDF)

- 21740, 21742, 21743

Phrenic Nerve Stimulation for Central Sleep Apnea (PDF)

- C1823

Radiofrequency Ablation (RFA) of Tumors Other Than the Liver (PDF)

- 20982, 31641, 32998, 50542, 50592, 58580, 58674

Reconstructive Breast Surgery/Mastopexy, and Management of Breast Implants (PDF)

- 11920, 11921, 15769, 15771, 15772, 19316, 19318, 19325, 19328, 19330, 19340, 19342, 19350, 19355, 19370, 19371, L8600
- Pre-authorization is required EXCEPT when services are rendered in association with breast reconstruction and nipple/areola reconstruction following mastectomy for breast cancer. However, if autologous fat grafting with adipose-derived stem cell

enrichment is used for augmentation or reconstruction of the breast it would be considered investigational.
- Note: Codes 19380 and 19499 do not require pre-authorization but are considered, and will deny as, investigational when used for autologous fat grafting and adipose-derived stem cell enrichment for augmentation or reconstruction of the breast.

Reduction Mammaplasty (PDF)

- 19318

Responsive Neurostimulation (PDF)

- 61850, 61860, 61863, 61864, 61885, 61886, 61889, 61891, L8680, L8686, L8688

Rhinoplasty (PDF)

- 30120, 30400, 30410, 30420, 30430, 30435, 30450

Sacral Nerve Neuromodulation (Stimulation) for Pelvic Floor Dysfunction (PDF)

- 0786T, 0787T, 0788T, 0789T, 64561, 64581, 64585, 64590, 64595, 64596, 64597, 64598, C1767, L8679, L8680, L8682, L8683, L8685, L8686, L8687, L8688
- Note: Please submit your pre-authorization request for the temporary trial period of sacral nerve neuromodulation AND the permanent placement at the same time, as these are treated as one combined episode.
- Treatment of chronic neuropathic pain is not a covered benefit, per HTCC Decision for codes 0786T, 0787T, 0788T, 0789T

Sacroiliac Joint Fusion (PDF)

- UMP is subject to HTCC Decision (PDF): 27278, 27280, 27279
- For indications not addressed in the HTCC, the Regence Medical Policy will apply

Spinal Cord and Dorsal Root Ganglion Stimulation (PDF)

- 0784T, 0785T, 0786T, 0787T, 0788T, 0789T, 63650, 63655, 63685, C1767, C1820, C1822, C1826, L8679, L8680, L8685, L8686, L8687, L8688
- Note: Please submit your pre-authorization request for the temporary trial AND the permanent placement at the same time.
- Spinal cord stimulation for the treatment of chronic neuropathic pain is not a covered benefit, per HTCC Decision for the following procedure and device codes; 0784T, 0785T, 0786T, 0787T, 0788T, 0789T, 63650, 63655, 63685, C1767, C1820, C1822, C1826, L8679, L8680, L8685, L8686, L8687, L8688 when associated diagnosis codes are included:
    - G60.9
    - G89.28-G89.29
    - M47.20-M47.28
    - M47.811-M47.819
    - M48.062
    - M50.10-M50.13
    - M50.121-M50.123
    - M54.10-M54.13

    - M51.14-M51.17
    - M54.16-M54.17
    - M54.30-M54.32
    - M54.40-M54.42
    - M54.5
    - M79.2
    - G89.4
    - M96.1
- If treatment is for other than this indication, Regence medical policy applies.

Spinal Injections

- Spinal Injections for UMP members are subject to HTCC Decision (PDF)
- Notes:
    - CPT 62292 for Therapeutic Medial Branch Nerve Block, Intradiscal and Facet Spinal Injections are not a covered benefit, reference the HTCC Decision (PDF):
    - CPT 27096, 62320, 62321, 62322, 62323, 64451, 64479, 64480, 64483, 64484, 64490, 64491, 64492, 64493, 64494, 64495 and G0260 may be subject to HTCC Decision. Pre-authorization is not required but may be subject to HTCC Decision (PDF) and require a provider attestation.
    - Attestation is needed for timely and accurate processing of claims
        - Use the electronic authorization tool on the Availity Portal and select the attestation criteria during the clinical documentation process on MCG Health
        - If an attestation is not completed pre-service using the Availity tool, fax the completed attestation form (PDF) to 1 (877) 357-3418
    - This coverage policy does not apply to those with systemic inflammatory disease such as ankylosing spondylitis, psoriatic arthritis or enteropathic arthritis

Spinal Surgery - Artificial Disc Replacement

- UMP is subject to HTCC Decision (PDF): 22856, 22858, 22861, 0095T, 0098T
- Lumbar artificial disc is not a covered benefit: 22857, 22860, 22862, 22865, 0163T, 0164T, 0165T

Stereotactic Radiation Surgery and Stereotactic Body Radiation Therapy

- UMP is subject to HTCC Decision (PDF): 32701, 61796, 61797, 61798, 61799, 61800, 63620, 63621, 77301, 77338, 77371, 77372, 77373, 77432, 77435, C9794, C9795, G0339, G0340
- This determination is specific to the treatment of localized prostate cancer, non-small cell and small cell lung cancer, pancreatic adenocarcinoma, oligometastatic disease, hepatocellular carcinoma, cholangiocarcinoma, Central Nervous System (CNS) primary and metastatic tumors, cancers of spine/paraspinal structures, as well as primary bone, head and neck, adrenal, melanoma, Merkel cell, breast, ovarian, and cervical cancers.
- Regence medical policies:

    - Stereotactic Radiosurgery and Stereotactic Body Radiation Therapy of Intracranial, Skull Base, and Orbital Sites (PDF)
    - Stereotactic Radiosurgery and Stereotactic Body Radiation Therapy for Tumors Outside of Intracranial, Skull Base, or Orbital Sites (PDF)

Surgery for Lumbar Radiculopathy

- UMP is subject to HTCC Decision (PDF): CPT 62380, 63030, 63035, 63042, 63044, 63047, 63048, 63056, 63057, 63090, 63091
- NOTES:
    - Pre-authorization is required only with diagnosis codes M47.20, M47.25, M47.26, M47.27, M47.28, M51.15, M51.16, M51.17, M51.26, M51.27, M54.10, M54.15, M54.16, M54.17, M54.18, M54.30, M54.31, M54.32, M54.40, M54.41, M54.42
    - CPT 62380 when billed without one of the listed diagnosis will be denied as an investigational denial based on Regence Medical Policy Automated Percutaneous and Percutaneous Endoscopic Discectomy

Surgical Treatments for Hyperhidrosis (PDF)

- 32664, 64818, 69676
- Code 32664 only requires pre-authorization for hyperhidrosis diagnoses L74.510 L74.511, L74.512, L74.513, L74.519, L74.52, R61

Surgical Treatments for Lymphedema and Lipedema (PDF)

- Code 15832, 15833, 15834, 15835, 15836, 15837, 15838, 15839, 15876, 15877, 15878, 15879 requires pre-authorization for Lipedema only with diagnosis codes Q82.0, R60.0, R60.9

Sleep Apnea Diagnosis and Treatment

- UMP is subject to HTCC Decision (PDF): 21121, 21122, 21141, 21145, 21196, 21198, 21199, 21685, 41120, 42140, 42145, 42160
- Codes 21145, 21196, 21198, 41120, 42160 do not require pre-authorization when the procedure is performed for oral cancer diagnosis codes: C01, C02-C02.9, C03-C03.9, C04-C04.9, C05-C05.9, C06, C06.2-C06.9, C09-C09.9, C10-C10.0, C41-C41.1, C46.2, D00-D00.00, D10, D10.1-D10.9, D16.4-D16.5, D37-D37.0, D49-D49.0
- HTCC does not apply to those under age 18. See Regence medical policy Surgeries for Snoring, Obstructive Sleep Apnea Syndrome, and Upper Airway Resistance Syndrome (PDF)

Temporomandibular Joint (TMJ) Surgical Interventions

- Visit MCG's website for information on purchasing their criteria, or contact us for a copy of the specific guideline.
- 21010 - MCG A-0522
- 21050 - MCG A-0523
- 29800, 29804 - MCG A-0492
- 21240, 21242, 21243 - MCG A-0523

Transcatheter Aortic-Valve Implantation for Aortic Stenosis (PDF)

- 33361, 33362, 33363, 33364, 33365, 33366

Transcutaneous Bone Conduction and Bone-Anchored Hearing Aids (PDF)

- 69714, 69710, 69716, 69717, 69719, 69726, 69729, 69730, L8690, L8691, L8692, L8694

Transesophageal Endoscopic Therapies for Gastroesophageal Reflux Disease (GERD) (PDF)

- 43192, 43201, 43236
- Note: Codes 43201 and 43236 may also be used for the administration of Botox for indications unrelated to GERD. Botox requires pre-authorization by Regence. Learn more about submitting a pre-authorization request for Boxtox.

Transurethral Water Vapor Thermal Therapy and Transurethral Water Jet Ablation (Aquablation) of the Prostate (PDF)

- 0421T, 53854, C2596

Upper Endoscopy for Gastroesophageal Reflux Disease (GERD) and Gastrointestinal (GI) Symptoms

- Upper Endoscopy for GERD and GI Symptoms for UMP members are subject to HTCC Decision (PDF)
- CPT 43200, 43202, 43235, 43237, 43238, 43239, 43242 and 43259 do not require pre-authorization, but may be subject to HTCC Decision and require a provider attestation
- Attestation is needed for timely and accurate processing of claims for adults (members 18 years and older):
    - Use the electronic authorization tool on the Availity Portal and select the attestation criteria during the clinical documentation process on MCG Health
    - If an attestation is not completed pre-service using the Availity tool, fax the completed attestation form (PDF) to 1 (877) 357-3418.

Vagus Nerve Stimulation (PDF)

- 0720T, 61885, 61886, 64553, 64568, 64569, C1822, E0735, L8679, L8680, L8682, L8683, L8685, L8686, L8687, L8688, C1827
- UMP is subject to HTCC Decision (PDF): for treatment of epilepsy and depression: 0720T, 61885, 61886, 64553, 64568, C1822, E0735, L8679, L8680, L8682, L8683, L8685, L8686, L8687, L8688, C1827
- If treatment is for other than these indications, Regence medical policy applies.
- The HTCC does not apply to members under age 4. Please use Regence Medical Policy for requests for members under age 4.

Varicose Vein Treatment (PDF)

- UMP is subject to HTCC Decision (PDF): 0524T, 36465, 36466, 36470, 36471, 36475, 36476, 36478, 36479, 36482, 36483, 37700, 37718, 37722, 37735, 37760, 37761, 37765, 37766, 37780, 37785, S2202
- Notes:

    - Requests for multiple treatment sessions should refer to Regence medical policy
    - Code 37241 is not appropriate to use in the coding of varicose vein treatment

Ventral (Including Incisional) Hernia Repair (PDF)

- 15734, 49591, 49593, 49595, 49613, 49615, 49617, 49621
- Pre-authorization for 15734 required only with diagnosis code K42.0, K42.1, K42.9 K43.0, K43.1, K43.2 K43.6, K43.7, K43.9, K45.0, K45.1, K45.8, K46.0, K46.1, K46.9 or M62.0 for component separation technique (CST)
- Pre-authorization for codes 49591, 49593, 49595, 49613, 49615, 49617, 49621 only required with diagnoses codes K43.2 and K43.9 for ventral hernia repair

Transplants and ventricular assist devices

Transplants - Cell

- 38205, 38206, 38232, 38240, 38241, 38242, 38243, S2140, S2142, S2150
- Stem Cell Therapy for Musculoskeletal Condition is subject to HTCC Decision (PDF) criteria: 38205, 38206, 38212, 38215, 38230, 38232, 38240, 38241
- Regence medical policy criteria will be used for codes and conditions not reviewed by the HTCC criteria

Transplants - Islet Transplantation (PDF)

- 48160, 0584T, 0585T, 0586T, G0341, G0342, G0343

Utilization management

Air Ambulance Transport (PDF)

- A0435, A0430, S9960
- Pre-authorization is required prior to elective fixed wing air ambulance transport.
- Emergency air ambulance transports may be reviewed retrospectively for medical necessity.

Uniform Medical Plan

ABA Assessment and Treatment Plan

This report is confidential and for professional use only. The content may not be divulged to any person or agency without consent of the parent, legal guardian, or patient, as appropriate. Fax to Regence BlueShield **1-888-496-1540** *or by mail to: Regence BlueShield PO Box 1271 MS E9H, Portland, OR 97207-1271*

Patient Name:	**Treatment Agency Name:**
Patient Birth Date:	**Lead Behavior Therapist Name:**
UMP ID Number (Include Alpha Characters):	**Therapist Assistant Name(s):**

RECOMMENDED TREATMENT HOURS/SESSIONS

	Direct Patient Support - hours (weekly)	**Caregiver/Parent Training - 1 session per day (monthly)**
Recommended Hours and Setting (indicate # of Sessions for Caregiver/Parent Training)	*e.g., 10 hours in home* *2 hours in community*	

	Program Supervision - **includes observation of the treatment being delivered, observation of the child in his/her natural setting, and communication with BCBAs/Techs delivering ABA services.** **(weekly)**	**ABA treatment day program in a clinic or outpatient hospital setting (weekly)**
Recommended Hours and Setting	*e.g., 10 hours in home* *2 hours in community*	

Rationale for this treatment plan should be reflected in the body of the report below, as well as the severity ratings on the Applied Behavior Analysis Authorization Request Form submitted with this treatment plan.

BACKGROUND AND HISTORY *Indicate at least the following or indicate NA.*

Past psychiatric history:

For diagnosis of autism spectrum disorder, include date of diagnosis and diagnosing provider name. Also include initial diagnosis documentation and comorbid diagnoses if this is an initial preauthorization request.

Chief Complaint and History of Present Illness (HPI): *Include all core deficit areas of autism, challenging behaviors, adaptive, motor, vocational, and cognitive skills, and any other related relevant areas. In addition to addressing the chief complaint, one should be able to understand the patient's level of functioning by reading this section. Please provide a detailed summary of information below for both Preauthorization and Concurrent review requests.*

Social Communication: *includes persistent deficits in social communication and social interaction, as outlined in DSM-5*

Behavior: *includes restricted interests and repetitive behaviors, as well as related challenging behaviors (e.g., tantrums, aggression, etc.)*

Adaptive skills:

Motor:

Vocational:

Cognitive:

Family history: *Focus on relevant family psychiatric history and related family training in support of performing ABA therapy*

Social history: *Information about where the patient lives, with whom, as well as any other relevant information about social context or stressors.*

Medical history:

Active medical problems:

Current medical providers:

Current medications, dose, purpose, and potential major side effects:

Allergies, special diets, etc.:

Past medical problems:

Educational History: *Summarize past and current educational plan, including what services are being provided in the educational setting. Discuss whether functional behavior assessments, behavior plans, and/or aversive plans have been used in the school setting. State where the information was obtained (e.g., review of records, interview, etc.).*

History:

Current:

Past and Current Services: *Outline all additional services being provided outside school through any other agency or funding source. Include frequency, provider, and funding source.*

Ensure there is not redundancy with recommended ABA treatment plan.

Outline previous courses of ABA therapy; including dates, setting, and the outcome.

ASSESSMENTS COMPLETED FOR EVALUATION

Measures used: *Discuss all sources of information used in evaluating the patient, including standardized (norm-referenced) and curriculum-based measures, interviews (e.g., parent, caregivers, teacher), direct observation at home/school/community, etc. Please complete the Applied Behavior Analysis Authorization Form and attach to this treatment plan.*

Evaluation Findings: *Briefly summarize findings, including test scores if available. Summary can be brief; a couple sentences per measure. E.g., Vineland-II results demonstrated delays in communication and socialization are present. Tables and score reports can be used if easier to present information. Present in appendices if desired. Briefly summarize findings derived from observations in natural settings (e.g., home, school).*

Functional behavior assessment/analysis findings: *Functional assessment or analysis results should be included here. The following components should be included:*

1) *Operational definition of behavior*

2) *Hypotheses or analysis about functions supported by indirect and direct assessment results*

3) *Functional assessment or analysis data to support function hypotheses or analyses*

4) *Baseline data, including frequency, duration, and intensity data, as appropriate to behavior.*

Include assessment of risk (e.g., due to elopement or other unsafe behavior) as appropriate.

Goal domains derived from assessment: *Include statement about how the information obtained supports goals in specific areas. E.g., Assessment information suggests CHILD needs treatment goals in the areas of Social Communication, Behavior, Adaptive skills, Motor skills, Vocational skills, and Cognitive skills.*

TREATMENT PLAN IMPLEMENTATION

Treatment Plan: *This section should include a brief overview of the treatment plan, including:*

1) *How ABA will be applied to the patient (e.g., ABA as applied to CHILD will include home and community based 1-1 intervention for (x) hours per week to target social, communication, and adaptive goals)*

2) *Whether a positive behavior support plan is required to address challenging behaviors*

3) *The parent/caregiver training plan*

4) *How the treatment plan will be coordinated with other providers, including school (e.g., speech pathologist, medical providers, outpatient psychologist, teachers, etc.).*

Goals and objectives can be found in Appendices A, B and C of this report.

Maintenance/Generalization/Discharge Plan: *This section should include a statement about how maintenance and generalization will be addressed, how services will be reduced or transitioned to the parents and/or how the patient will be transitioned into other less intensive services (e.g., school, outpatient, etc.). This should be more specific as the patient progresses in therapy. The transition or discharge plan should be specific, data driven, and include criterion for discharge.*

Goals and objectives can be found in Appendix D of this report.

Appendix A: Goals and Objectives for Skill Acquisition

Include goals and objectives in all relevant areas. Goals should be worded in such a way that they can be measured to track progress. Objectives should be clear steps toward a goal. Goals and objectives should be worded in such a way that they are easily interpretable to readers who are not familiar with behavioral terminology (i.e., parents, case managers, etc). The specified domains were decided upon by the HCA and include social communication, behavior (restricted interests, repetitive behaviors, other challenging behaviors), adaptive, motor, vocational, and cognitive. Broadly defined, all relevant goals (e.g., play skills, self-help, etc.) should fit into one of these categories. Goals for reduction of problem behavior should be outlined in Appendix B: Positive Behavior Support Plan.

Skill Acquisition Goals: *All skill acquisition goals and their corresponding objectives should be outlined here. Goals should be organized by skill area (e.g., social communication), should be titled with a short 2-3 word title, should include a broad goal that demonstrates the expected outcome, and then be broken down into specific objectives(also titled) that clearly outline target skills to be taught (e.g., within communication, expressive labels and requesting might be two specific objectives). Objectives should be measurable and measurement strategies, including mastery criteria, should be clearly stated (e.g., mastery criteria are met when a correct response occurs on 9 out of 10 opportunities across three sessions). Goals should be written in a manner that is consistent with how the therapists are taking data so data can easily be reported back for utilization review of progress. If progress will be documented by using a formal assessment tool (e.g., a measure associated with a curriculum), this should be stated in how the goal is written (e.g., patient will show improvement according to the ____ assessment).*

If the patient is receiving ABA therapy services primarily to address reduction of challenging behaviors, this section may be marked NA and the Positive Behavior Support Plan should be outlined in Appendix B.

Appendix B: Positive Behavior Support Plan

Positive Behavior Support (PBS) Plan for Reducing Challenging Behaviors: *Should follow from functional assessment/analysis results discussed above and include, 1)operational definitions of behaviors, 2) a brief statement of identified functions of behavior, 3) suggested parent/caregiver/staff response to behaviors when they occur, 4) recommended antecedent interventions to prevent behaviors, 5) plan for teaching replacement behaviors with clear goals, 6) statement about how the proposed interventions were derived from the functional assessment/analysis, 7) plan for coordinating PBS Plan across settings.*

If the patient has minimal challenging behaviors and the primary focus of their ABA treatment plan is on skill acquisition, this section may be marked NA and the skill acquisition goals should be outlined in Appendix A.

Appendix C: Parent/Caregiver Training Goals

This section should address caregiver goals for skill acquisition (e.g., parents will learn to implement the PBS Plan). It should include clear goals and objectives, written in the same format as the patient's skill acquisition goals.

All children should have parent/caregiver training goals in their treatment plan, regardless of the nature of the child's goals/objectives. If the treatment plan is for an adult or an individual living in a group setting, this portion of the plan should focus on training caregivers. This section may not be marked NA.

Medical Policy Manual Allied Health, Policy No. 32

Biofeedback

Effective: April 1, 2023

Next Review: August 2023
Last Review: December 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Biofeedback is intended to increase awareness and control of certain body functions normally considered to be outside conscious control.

MEDICAL POLICY CRITERIA

Note: Services described in this medical policy are not routinely reviewed; however, claims may be subject to audit including but not limited to review of member benefit application, medical appropriateness, frequency utilization, documentation requirements, accurate code selection, and reimbursement. Some devices or services may be subject to the health plan's reimbursement policy manual or may not be covered based on benefit contracts. Claim adjudication is also subject to claim processing guidelines and provider contracts.

I. Biofeedback as part of the overall treatment plan may be **medically necessary** for one or more of the following indications:

   A. Migraine or tension headaches

B. Stress and/or urge urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT)

C. Dyssynergia-type constipation in adults when all of the following criteria (1.-3.) are met:

1. Symptoms of functional constipation that meet all of the following ROME IV criteria (see Policy Guidelines)
2. Objective physiologic evidence of pelvic floor dyssynergia when one or both of the following criteria are met:
   a. Inappropriate contraction of the pelvic floor muscles
   b. Less than 20% relaxation of basal resting sphincter pressure by manometry, imaging, or EMG
3. Failed 3-month trial of standard treatments for constipation including laxatives, dietary changes, and pelvic floor exercises

II. Unsupervised biofeedback in the home setting is considered **investigational** for all indications.

III. Biofeedback is considered **investigational** for all other indications, including but not limited to the following: chronic pain, fecal incontinence, encopresis, and constipation other than dyssynergia type in adults, fibromyalgia, headaches other than migraine and tension (e.g., cluster headaches), myalgia or muscle pain, neck pain, orofacial pain, shoulder pain, temporomandibular joint disorders, and urinary disorders not meeting criteria, including but not limited to: post- prostatectomy urinary dysfunction, urinary incontinence not administered in conjunction with pelvic floor muscle training (PFMT), urinary retention, vesicoureteral reflux and voiding dysfunction.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Rome IV diagnostic criteria for functional constipation are as follows:[1]

1. Must include 2 or more of the following:
   a. Straining during more than one-fourth (25%) of defecations
   b. Lumpy or hard stools (Bristol Stool Form Scale1-2) for more than one-fourth (25%) of defecations
   c. Sensation of incomplete evacuation for more than one-fourth (25%) of defecations
   d. Sensation of anorectal obstruction/blockage for more than one-fourth (25%) of defecations
   e. Manual maneuvers to facilitate more than one-fourth (25%) of defecations (e.g., digital evacuation, support of the pelvic floor)
   f. Fewer than 3 spontaneous bowel movements per week
2. Loose stools are rarely present without the use of laxatives
3. Insufficient criteria for irritable bowel syndrome.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical documenting symptoms and treatment specific to policy criteria
- If for constipation, three months of chart note documentation. Indicate if symptom onset is at least six months prior to diagnosis (please include dates).
- Clinical documentation with physiologic evidence of pelvic floor dyssynergia

BACKGROUND

Biofeedback is a technique intended to teach patients self-regulation of certain physiologic processes not normally considered to be under voluntary control. The technique involves the feedback of a variety of types of information not normally available to the patient, followed by a concerted effort on the part of the patient to use this feedback to help alter the physiological process in some specific way. Biofeedback training is done either in individual or group sessions, alone, or in combination with other behavioral therapies designed to teach relaxation. A typical program consists of 10 to 20 training sessions of 30 minutes each. Training sessions are performed in a quiet, non-arousing environment. Subjects are instructed to use mental techniques to affect the physiologic variable monitored, and feedback is provided for successful alteration of that physiologic parameter. The feedback may be in the form of lights or tone, verbal praise, or other auditory or visual stimuli.

REGULATORY STATUS

A variety of biofeedback devices are cleared for marketing though the Food and Drug Administration's (FDA) 510(k) process. The FDA defines a biofeedback device as "an instrument that provides a visual or auditory signal corresponding to the status of one or more of a patient's physiological parameters (e.g., brain alpha wave activity, muscle activity, skin temperature, etc.) so that the patient can control voluntarily these physiological parameters." Freespira from Palo Alto Health Sciences, Inc. is an example of a biofeedback device that has received FDA approval (K180173).

EVIDENCE SUMMARY

There are several methodologic challenges that arise in assessing biofeedback for any indication. For example, most interventions that include biofeedback are multimodal and include relaxation and behavioral instruction which may have effects separate from those that may occur due to biofeedback. While studies may report a beneficial effect of multimodality treatment, without appropriate control conditions, it is difficult to isolate the specific contribution of biofeedback to the overall treatment effect. In addition, behavioral therapies (non-drug treatments including biofeedback) result in both nonspecific and specific therapeutic effects. Nonspecific effects, sometimes called the placebo effect, occur as a result of therapist contact,

positive expectancies on the part of the patient and therapist, and other beneficial effects that occur as a result of being a patient in a therapeutic environment. Specific effects are those that occur only because of the active treatment, above any nonspecific effects that may be present.

In order to isolate the independent contribution of biofeedback on health outcomes (specific effects) and properly control for nonspecific treatment effects, well-designed randomized controlled trials (RCT) with the following attributes are necessary:

- Randomization helps to achieve equal distribution of individual differences by randomly assigning patients to either biofeedback or sham-biofeedback treatment groups. This promotes the equal distribution of patient characteristics across the two study groups. Consequently, any observed differences in the outcome may, with reasonable assuredness, be attributed to the treatment under investigation.
- A comparable sham control group helps control for expected high placebo effects as well as for the variable natural history of the condition being treated.
- Blinding of study participants, caregivers, and investigators to active or sham assignments helps control for bias for or against the treatment. Blinding assures that placebo effects do not get interpreted as true treatment effects.
- Small studies limit the ability to rule out chance as an explanation of study findings.
- Follow-up periods must be long enough to determine the durability of any treatment effects.

Therefore, the focus of the evidence review for biofeedback for all indications is on RCTs with the attributes noted above.

ASTHMA

SYSTEMATIC REVIEWS

Yorke (2015) published a SR of studies evaluating nonpharmacologic interventions for the treatment of adults with asthma.[2] The literature search, conducted through May 2014, identified 23 studies for inclusion. The nonpharmacologic interventions were organized into groups: relaxation-based therapies (n=9 studies); cognitive behavioral therapies (n=5 studies); biofeedback techniques (n=3 studies); and mindfulness (n=1 study). Five studies incorporated multicomponent interventions. The three biofeedback RCTs used different techniques: exhaled carbon dioxide capnography (pooled n=12)[3]; HRV using a physiograph (pooled n=94 patients)[4]; and respiratory sinus arrhythmia by electrocardiographic feedback and muscle tension by electromyography (EMG; pooled n=17 patients).[5] Common outcomes in the 3 studies included peak expiratory flow and respiratory impedance. Two of the trials reported on medication use. While differences were detected in exhaled carbon dioxide, HRV, and muscle tension, no changes in forced expiratory volume in one second (FEV_1) were found and medication use decreased in only one trial. Reviewers concluded that larger sample sizes were needed to demonstrate effects and that, while certain parameters that patients received biofeedback on may have differed between treatment groups, those differences did not translate into meaningful clinical benefits.

RANDOMIZED CONTROLLED TRIALS

Lehrer and colleagues[4] reported the results of 94 asthma patients randomized to one of the following four groups:

1. "Full protocol" including heart rate variability (HRV) biofeedback and training in pursed-lips abdominal breathing with prolonged exhalation;
2. HRV biofeedback alone;
3. Placebo biofeedback involving bogus "subliminal suggestions designed to help asthma", with no other details provided and no actual suggestions given plus biofeedback training to alternately increase and decrease frontal EEG alpha rhythms; and
4. A waiting list control group.

Although reported improvement was greater in the two treatment groups, scientific conclusions cannot be drawn from this data due to several limitations, as discussed in the Background section above, including possible selection bias due to lack of randomization, short study duration, lack of follow-up to assess long-term effects, and differences between groups in task involvement and assessment frequency. The authors concluded that further research is needed. They advise caution in the use biofeedback for the treatment of asthma until the mechanisms of action are better understood and the long-term effects have been documented.

SECTION SUMMARY

There is insufficient evidence from SRs and RCTs that biofeedback improves outcomes in individuals with asthma. Additional evidence is needed from well-designed comparative studies.

AUTISM SPECTRUM DISORDER

Autism Spectrum Disorders (ASD) can vary in severity of disease and therefore treatments utilized to treat the disease, making it difficult to isolate outcomes associated with biofeedback. The following literature review for biofeedback as a treatment of ASD focuses on SRs and RCTs.

SYSTEMATIC REVIEW

Coben and Myers (2010) reviewed the literature on EEG biofeedback for ASDs.[6] The authors identified two published small, non-RCTs evaluating EEG biofeedback in the treatment of ASDs. As described in the review, a study published by Jarusiewicz and colleagues in 2002 compared treatment with 20 to 69 sessions of biofeedback in 12 autistic children to a matched control group that did not receive biofeedback. Mean reduction in autistic symptoms, as measured by the Autism Treatment Evaluation Checklist (ATEC), was 26% in the biofeedback group and 3% in the comparison group; this difference was statistically significant. The other study was published by Coben and Padolsky in 2007. It compared 20 sessions of EEG biofeedback in 37 patients to a waiting-list control group. After treatment, parents reported reduction in symptoms in 89% of the treatment group compared to 17% of the control group (p-value not reported). Studies differed in their biofeedback protocols and number of sessions. The review article concluded that RCTs are needed to determine the effectiveness of biofeedback to treat ASDs.

RANDOMIZED CONTROLLED TRIALS

Yang (2015) conducted a RCT to explore the effects of visual condition and target size during four reach-to-grasp tasks between 20 autistic and 20 matched control children subjects.[7] The autistic children showed longer movement time, larger normalized jerk score, more movement when compared to controls, especially in non-visual feedback and small target blocks. This study is limited by the small sample size and other methodological considerations making it hard to determine the efficacy of visual effects for autism.

Kouijzer (2013) published a RCT evaluating electroencephalography (EEG) biofeedback as a treatment for ASD.[8] The trial included 35 teenagers between 12 and 18 years-old with confirmed diagnoses of ASD. Participants were randomly assigned to receive EEG biofeedback (n=13), skin conductance biofeedback (n=12), or a waiting-list control group (n=13). The biofeedback interventions included 40 sessions provided twice a week. Patients and parents in the biofeedback groups but not on the waiting-list were blinded to treatment allocation. The primary outcome measure was change in symptoms at three months as measured by the total score on the Social Communication Questionnaire (SCQ) which has a potential range of 0 to 36. In the primary analysis, the investigators only included participants who successfully influenced their EEG activity (called “EEG-regulators”) in the primary analysis. The justification for this was to be able to identify the specific effects of biofeedback on symptoms. Among the 19 of 35 (54%) regulators, there was no statistically significant difference in the SCQ scores between participants treated with EEG- or skin-conductance biofeedback. The investigators evaluated non-specific effects of EEG biofeedback by examining the SCQ scores among EEG-non-regulators as rated by the parents. There was no statistically significant difference in scores among participants in the EEG biofeedback group, the skin conductance biofeedback group and the control group.

SECTION SUMMARY

There is insufficient evidence from SRs and RCTs that biofeedback improves outcomes in individuals with ASDs. The scientific evidence on the effectiveness of biofeedback for treatment of autism consists of one small RCT and a limited number of small, non-randomized studies. The RCT did not report a significant benefit of biofeedback on autism-related symptoms.

BELL’S PALSY (IDIOPATHIC FACIAL PARALYSIS)

SYSTEMATIC REVIEWS

A 2011 Cochrane SR of physical therapy modalities for the treatment of Bell’s palsy.[9] The authors identified two case series and one small RCT. However, no analysis of these studies was performed because they did not meet the minimum methodological quality to be included in the review.

Cardoso (2008) examined the effects of facial exercises associated either with mirror or EMG biofeedback with respect to complications of delayed recovery in Bell's palsy.[10] Patients with unilateral idiopathic facial palsy treated with facial exercises associated with mirror and/or EMG biofeedback were included in this review. Four studies (n=132) met the eligibility criteria. The studies described mime therapy versus control (n=50), mirror biofeedback exercise versus control (n=27), "small" mirror movements versus conventional neuromuscular retraining (n=10), and EMG biofeedback plus mirror training versus mirror training alone. The treatment length varied from one to twelve months. The authors concluded that “…because of the small number of RCTs, it was not possible to analyze if the exercises, associated either with mirror

or EMG biofeedback, were effective. In summary, the available evidence from ran RCTs is not yet strong enough to become integrated into clinical practice."

RANDOMIZED CONTROLLED TRIALS

No RCTs identified after the above SRs.

SECTION SUMMARY

Current evidence from small RCTs with variable biofeedback protocols and type of comparison interventions is insufficient to permit conclusions on the impact of biofeedback on Bell's palsy.

BRUXISM AND SLEEP BRUXISM

SYSTEMATIC REVIEWS

Manfredini (2015) published a SR which included 14 studies, 12 of the studies were RCTs.[11] Two of the studies evaluated bruxism. The authors concluded that the potential benefit of biofeedback (BF) and cognitive-behavioral (CB) approaches to sleep bruxism management is not fully supported.

Wang (2013) published a SR of RCT and non-RCTs on biofeedback treatment for sleep bruxism.[12] The full text of 17 articles was reviewed and seven studies with a total of 240 participants met the inclusion criteria. Studies were generally small; onlytwo included more than 50 participants. Four studies used audio biofeedback, two used contingent electrical stimulation and 1 used visual biofeedback. Treatment duration ranged from one night to six weeks. In four of the studies, the duration of treatment was two weeks. Three of the studies were considered to be at moderate risk of bias and the other four were considered to be at high-risk of bias. The primary outcome of the analysis was the number of sleep bruxism episodes per hour detected by EMG recording. Only two studies (total n=27) reported this outcome and had data suitable for meta-analysis. A pooled analysis did not find a statistically significant difference between the biofeedback and control groups; mean difference: -4.47 (95% CI: -12.33 to 3.38). Findings were not pooled for any other outcomes.

RANDOMIZED CONTROLLED TRIALS

Sato (2015) published a RCT limited in size on the use of EMG biofeedback training for daytime clenching and its effect on sleep bruxism.[13] Patients were monitored for five hours of daytime and night time and were randomized to EMG biofeedback (n=7) or to a control group (n=5). Patients in the biofeedback group received a small auditory signal in the daytime when clenching activity was detected. There were significant decreases in EMG events during weeks two and three in the biofeedback group during the daytime, and the decreases in events carried over into the night time. There were no decreases in EMG events in the control group.

SECTION SUMMARY

There is insufficient evidence from SRs and RCTs that biofeedback improves outcomes in individuals with bruxism. Additional evidence is needed from well-designed comparative studies.

CHRONIC PAIN (NON-HEADACHE)

As discussed in the Background section above, the focus of the evidence review was on RCTs. This study design is particularly important when studying treatments for pain. The most clinically relevant outcomes of therapy for pain are improvement in symptoms, function, and quality of life. These outcomes are subjective and can be influenced by nonspecific effects such as placebo response and the natural history of the disease. Randomized treatment allocation and the inclusion of a control group are needed to isolate the effect of biofeedback therapy.

GENERAL NON-HEADACHE PAIN

Systematic Reviews

A Cochrane SR by Williams on psychological therapies (cognitive-behavioral therapy [CBT] and behavioral therapy, including biofeedback) for chronic non-headache pain in adults was updated in 2012.[14] Forty-two trials provided analyzable data, thirteen of which had not been included in previous updates of this review. The SR found that although the quality of trial design had improved over time, the quality of treatments, reporting, or both had not improved. CBT (not behavioral therapy) had weak effects in improving pain, but only immediately following treatment. CBT also had small effects on pain-related disability, altering mood, and catastrophizing outcomes compared with usual treatment or waiting list patients, with some maintenance at six months follow-up. However, it was not possible to isolate the results for the individual components of CBT, including biofeedback. Behavioral therapy had no effect on mood but showed an effect on catastrophizing immediately post-treatment. The authors recommended against future general RCTs, recommending instead, studies to identify which components of CBT work for which type of patient.

Another Cochrane SR review by Eccleston and colleagues evaluated psychological therapies for the management of chronic and recurrent pain in children and adolescents. Included studies were RCTs with at least 10 participants in each arm. Although psychological therapies were found to improve pain, only one of the five studies on non-headache pain evaluated biofeedback.

Polermo conducted an SR of RCTs to update previously published SRs on psychological therapies for management of chronic non-headache pain in children and adolescents was published by Palermo and colleagues in 2010.[15] RCTs included in previous SRs were automatically eligible for inclusion in this SR. The review did not identify any new RCTs that had not been included in previous SRs. It was not possible to isolate the results of the individual components of the psychological therapies, including biofeedback.

Randomized Controlled Trials

No RCTs were identified that were published after the above SRs.

ARTHRITIS

Systematic Reviews

Richards (2017) published a SR evaluating the application of real-time biofeedback to reduce knee adduction movement (KAM) during gait training, for patients with knee osteoarthritis (KOA).[16] Twelve studies met the inclusion criteria. The authors concluded there are limited controlled studies, but found value for further research in the outcomes of biofeedback to reduce KAM.

In a SR with meta-analysis of psychological interventions for rheumatoid arthritis including relaxation, biofeedback, and cognitive-behavioral therapy, Astin and colleagues concluded that psychological interventions may be important adjunctive therapies in rheumatoid arthritis treatment.[17] In the 25 studies analyzed, significant pooled effect sizes were found for pain after an intervention. However, the same effect was not seen long term, and the meta-analysis did not isolate biofeedback from other psychological interventions. Therefore, the specific effects of biofeedback, as discussed in the Background section above, could not be isolated.

Randomized Controlled Trials

Eid (2016) published a RCT that evaluated the outcomes of electromyographic (EMG) biofeedback training on pain, quadriceps strength and functional ability for 11 boys and 25 girls with polyarticular juvenile rheumatoid arthritis (JRA).[18] Children were assigned to the EMG biofeedback group (n=18) or the control group (n=18). Treatments occurred over 12 weeks, with evaluation at six and 12 weeks. Both groups showed significant improvement at 12 weeks.

FIBROMYALGIA

Systematic Reviews

In 2015 a Cochrane SR was published by Theodom examining mind and body therapy for fibromyalgia. Sixty-one trails were included in the review.[19] The study participants were predominately women and their nature of fibromyalgia varied from mild to severe across the study population. No adverse events were reported. The authors found there was very low quality evidence that biofeedback in comparison to usual care controls had an effect on physical functioning, (SMD -0.1,95% CI-0.4 to 0.3, - 1.2% absolute change, 1 oint shift on a 0-100 scale) pain(SMD -2.6, 95% CI -91.3 to 86.1, -2.6% absolute change, and mood ((SMD 0.1, 95% CI -0.3 to 0.5, 1.9% absolute change, less than 1 point shift on a 0 to 90 scale) post-intervention. Due to the very low quality evidence, it is unclear what role biofeedback has fibromyalgia.

In 2013 Glombiewski published the results of a meta-analysis that included three studies on EEG-biofeedback (neurofeedback) and four studies on EMG-biofeedback for fibromyalgia (N=321).[20] Studies in which biofeedback was evaluated only as part of multicomponent interventions were excluded from the review. A sham intervention was used as a control condition in four studies, two using EEG biofeedback and two using EMG- biofeedback. A pooled analysis was conducted for each therapy. EMG-biofeedback was reported to have significantly reduced pain intensity compared to control groups (effect size, Hedges *g*: 0.86, 95% CI, 0.11 to 0.62). Pooled analyses of studies of EMG and EEG biofeedback did not find a significant benefit of the intervention on other outcomes including sleep problems, depression and health-related quality of life. None of the studies included in this review were high quality, with risk of bias assigned by the authors as either unclear or high for all included studies. In addition, all of the studies reported on short-term outcomes, resulting in a lack of evidence on whether longer-term outcomes are improved. The authors recommended further research focused on long-term effects and predictors of treatment response.

Randomized Controlled Trials

No RCTs identified after the SR above.

KNEE PAIN

Systematic Reviews

A number of SRs have been published that included trials of biofeedback in the treatment of anterior knee pain[21], patellofemoral pain syndrome,[22] and in post-meniscal repair rehabilitation.[22] Mixed results have been reported by the SRs, but no standardized treatment protocols or patient selection criteria have been established for biofeedback for knee pain of any etiology.

Randomized Controlled Trials

No RCTs were published after the above SR.

LOW BACK PAIN

Systematic Review

Sielski (2017) published a SR evaluating the impact of biofeedback for chronic back pain.[23] Twenty-one studies met all inclusion criteria, one of which had to be biofeedback at least 25% of the time. Outcomes were determined for pain, disability, depression, reduced muscle tension, and coping skills. The authors concluded that although the outcomes of biofeedback are promising, the SR had limitations including heterogeneity of how biofeedback and back pain were defined and the positive results should be interpreted with caution.

Qaseem (2017) published a guideline from the American College of Physicians (ACP) that by using the ACP was based on a SR of RCTs and SRs published through April 2015.[24] For patients with acute or sub-acute low back pain, biofeedback was not mentioned. For patients with chronic low back pain the recommendation was to initially try nonpharmacological treatments including biofeedback based on “low quality evidence”. For patients with chronic low back pain who have not responded to nonpharmacological treatments, pharmacological treatment may be considered.

Haines (2017) published an economic evaluation that was done alongside a pilot randomized trial that evaluated motion-sensor biofeedback for sub-acute and chronic low back pain over 12 months.[25] Patients received motion-sensor biofeedback with guideline based care (n=38) or guideline based care alone (n=45) over ten weeks and completed a three, six, and 12 month assessment. The authors concluded that motion-sensor biofeedback is both clinically and economically effective, but more studies are needed.

Daffada (2015) conducted a SR to identify and assess the current evidence regarding the effectiveness of interventions (i.e. graded motor imagery and mirror visual feedback) which target cortical remapping in the management of chronic low back pain (CLBP).[26] Five articles were included in the review, which were comprised of three RCTs, one randomized cross-over study, and one multiple case study design. Although the authors report these interventions, including visual feedback, could be effective, the paucity of literature, small sample sizes, and methodological constraints of the studies included in the review make it difficult to determine the effectiveness of the interventions in the management of CLBP.

A 2010 Cochrane review[27] on behavioral treatments for chronic low-back pain included a meta-analysis of three small RCTs[28-31] comparing electromyography (EMG) biofeedback to a waiting-list control group. These studies were graded as low to very low quality due to methodological limitations and imprecision. In the pooled analysis there were a total of 34 patients in the intervention group and 30 patients in the control group. The standard mean

difference in short-term pain was -0.80 (95% confidence interval [CI]:-1.32 to -0.28); this difference was statistically significant favoring the biofeedback group. One additional RCT was not included in the pooled analysis due to differences in reporting.[28] This small RCT (n=44) was determined to have a low risk of bias and reported no significant differences in outcomes between groups. The Cochrane review did not conduct meta-analyses of trials comparing biofeedback to sham biofeedback.

Randomized Controlled Trials

Tan (2015) conducted a four arm RCT of hypnosis compared with biofeedback for 100 veterans adults with chronic low back pain (CLBP).[32] Group one included an eight-session self-hypnosis training intervention without audio recordings for home practice; group two consisted of an eight-session self-hypnosis training intervention with recordings; group three had a two-session self-hypnosis training intervention with recordings and brief weekly reminder telephone calls; and group four had an eight-session active biofeedback control intervention. All four groups reported significant pre-to post-treatment improvements in pain intensity, pain interference, and sleep quality. This study was limited by the small sample size and other methodological constraints making it hard to determine the efficacy of biofeedback for adults with CLBP.

In a 2010 study published after the above Cochrane SR, Kapitza compared the efficacy of respiratory biofeedback to sham biofeedback in 42 patients with lower back pain.[33] All participants were instructed to perform daily breathing exercises with a portable respiratory feedback machine; exercises were performed for 30 minutes on 15 consecutive days. Patients were randomized to an intervention group that received visual and auditory feedback of their breathing exercises or a control group that received a proxy signal imitating breathing biofeedback. Patients recorded pain levels in a diary three times a day, measuring pain on a visual analogue scale (VAS). Both groups showed reduction in pain levels at the end of the intervention period and at the three month follow-up, but there were no significant differences in pain between groups. For example, the mean change in pain with activity three months after the intervention was a reduction in 1.12 points on a 10-point VAS scale in the intervention group and 0.96 points in the sham control group; $p>0.05$. The mean change in pain at rest after three months was a reduction of 0.79 points in the intervention group and 0.49 points in the control group; $p>0.05$.

Another 2010 RCT, by Glombiewski, assessed whether the addition of EMG biofeedback to CBT improved outcomes in 128 patients with lower back pain.[34] Patients with musculoskeletal pain of the low, mid, or upper back, with pain duration of at least six months on most days of the week, were randomized to CBT, CBT plus biofeedback, or a waiting-list control; 116 patients began the 1-hour weekly sessions (17-25 treatments) and were included in the final analysis. CBT alone included breathing exercises and progressive muscle relaxation; biofeedback was used for 40% of the CBT treatment time in the combined treatment condition. Both treatments were found to improve outcomes including pain intensity compared to a waiting-list control (moderate effect size of 0.66 for pain intensity in the CBT plus biofeedback group). However, the addition of biofeedback did not improve outcomes over CBT alone.

NECK AND SHOULDER PAIN

Systematic Reviews

Campo (2021) published a systematic review and meta-analysis that evaluated the effectiveness of biofeedback for improving pain, disability, and work ability in adults with neck pain.[35] The review included 15 RCTs with eight studies utilizing EMG biofeedback and seven studies pressure biofeedback. There was no restriction on the control intervention (eg, no treatment, placebo, active treatment) or co-intervention, provided the independent effects of biofeedback could be elucidated. Results suggest that biofeedback has a moderate effect on reducing short-term disability and a small effect on reducing intermediate-term disability with no effect on pain or work ability in the short- and intermediate-term. Of note, there were a variety of control interventions across included studies (eg, exercise, electroacupuncture, electrotherapy, education) with few studies directly comparing biofeedback to no treatment or placebo.

Kamonseki (2021) completed a systematic review and meta-analysis of 5 RCTs (N=272) that examined the effects of EMG biofeedback for shoulder pain and function.[36] Very-low quality of evidence found that electromyographic biofeedback was not superior to control for reducing shoulder pain (standardized mean differences = -0.21, 95% confidence interval: -0.67 to 0.24, p=0.36) or shoulder function (standardized mean differences = -0.11, 95% confidence interval: -0.41 to 0.19, p=0.48). The authors state the very low quality of evidence does not permit a definitive recommendation regarding EMG biofeedback in the treatment of shoulder pain.

Shearer (2016) published a SR evaluating the impact of psychological interventions, one of which was biofeedback for neck pain and associated disorders (NAD) and whiplash disorders.[37] The SR included RCTs, cohort and case control studies. No clear positive effects were seen for biofeedback and the authors noted more sound methodological research is needed.

Hesselstrand (2015) published a SR of 19 studies called Occupational Therapy Interventions in Chronic Pain-A SR.[38] One RCT addressed surface EMG biofeedback training for persons with neck and shoulder complaints after whiplash-associated disorders, concerning activities of daily living and pain. The SR concluded that no support exists for the effectiveness of electromyographic biofeedback training as a supplement and that more studies are needed to confirm this result.

Randomized Controlled Trial

Ma (2011) published an RCT that included 72 patients with chronic (at least three months) computer work-related neck and shoulder pain.[39] Patients were randomized to one of four six-week interventions: Biofeedback, exercise, passive treatment (e.g., hot packs), or a control group receiving only an educational pamphlet. Members of the biofeedback group were given a portable EMG biofeedback machine and were instructed to use it for two hours daily while performing computer work. The active exercise group was given an exercise routine to perform on their own for no longer than 20 minutes, four times a day. Sixty of 72 (83%) participants were available for the post-intervention follow-up assessment (n=15 per group). At the end of the intervention, the average VAS score and neck disability index (NDI) scores were significantly lower in the biofeedback group than in the other three groups. For example, the mean VAS post-intervention was 1.87 (standard deviation [SD]: 0.74) in the biofeedback group and 2.10 (SD: 1.34) in the active exercise group ($p< 0.05$).

This study found a short-term benefit of a biofeedback intervention, but the magnitude of difference in the VAS scores and the NDI index was small and of uncertain clinical significance. In addition, there were several methodologic limitations. The study was of small

size and had a substantial number of dropouts; data were available on only 39 of 72 (54%) participants at six months. The interventions were not balanced in intensity, as the biofeedback intervention was more intensive (two hours per day) than the other interventions, such as the passive treatment arm, which received two 15-minute sessions per week. Long-term data were not available due to the low follow-up rate, which at six months was too small for meaningful analysis.

OROFACIAL PAIN (INCLUDING TEMPOROMANDIBULAR JOINT DISORDER)

Systematic Reviews

A 2011 Cochrane SR identified 17 trials evaluating non-pharmacological psychological interventions for adults with chronic orofacial pain (e.g., temporomandibular joint (TMJ) disorder).[40] For the outcome short-term pain relief (three months or less), there was a significantly greater reduction in pain with interventions that combined CBT and biofeedback compared to usual care (two studies). However, there was not a significant benefit of a combined CBT/biofeedback on longer-term i.e., six-month pain relief, and there were no studies that compared CBT alone to CBT combined with biofeedback. For biofeedback-only interventions, a pooled analysis of two studies on short-term pain relief did not find a significant benefit compared to usual care. There was only one study reporting long-term pain relief after a biofeedback-only intervention, so a pooled analysis could not be conducted. The authors concluded that there is weak evidence to support psychosocial interventions for managing chronic orofacial pain and the most promising evidence is for CBT, with or without biofeedback. They noted that the trials in the review were few in number and had a high risk of bias, and they recommended additional high-quality trials.

The conclusions of the Cochrane review are similar to previous SRs on treatment of TMJ disorder. The reviews also concluded that there is weak evidence that psychosocial/physical therapy interventions, including biofeedback among others, are beneficial for treating TMJ but that there were few studies and they tended to be of poor methodologic quality. For example, Medlicott and colleagues recommended caution in interpreting results due to heterogeneity in study design and interventions used.[41] Since biofeedback was not isolated from other therapies, no conclusions could be reached for biofeedback alone. Based on two poor-qualityRCTs, McNeely and colleagues concluded that biofeedback did not reduce pain more than relaxation or occlusal splint therapy for TMJ, but did improve oral opening when compared with occlusal splints.[42]

Randomized Controlled Trials

No RCTs identified after the above SR.

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Systematic Reviews

No SRs were identified for biofeedback for the treatment of SLE.

Randomized Controlled Trial

In an RCT of 92 patients with Systemic Lupus Erythematosus (SLE), Greco and colleagues reported that patients treated with six sessions of biofeedback-assisted cognitive-behavioral treatment for stress reduction had a statistically significant greater improvement in pain post

treatment than a symptom-monitoring support group (p=0.044) and a usual care group (p=0.028).[43] However, these improvements in pain were not sustained at a nine-month follow-up and further studies are needed to determine the incremental benefits of biofeedback-assisted cognitive-behavioral treatment over other interventions in SLE patients.

RECURRENT ABDOMINAL PAIN

Systematic Reviews

No SRs were identified using biofeedback for the treatment of recurrent abdominal pain.

Randomized Controlled Trial

Humphrey's and Everts randomly assigned 64 patients with recurrent abdominal pain to groups treated with: 1) increased dietary fiber; 2) fiber and biofeedback; 3) fiber, biofeedback, and cognitive-behavioral therapy; and 4) fiber, biofeedback, cognitive-behavioral therapy, and parental support.[44] The three multi-component treatment groups were similar and had better pain reduction than the fiber-only group. This study does not address placebo effects. In a SR of recurrent abdominal pain therapies in children, Weider and colleagues concluded that behavioral interventions (cognitive-behavioral therapy and biofeedback) had a general positive effect on nonspecific recurrent abdominal pain and were safe.[45] However, the specific effects of biofeedback were not isolated in this SR.

VESTIBULODYNIA/VULVODYNIA/VULVAR VESTIBULITIS

Systematic Reviews

Morin published a SR to evaluate the outcomes of different physical therapies, one of which was biofeedback for women with provoked vestibulodynia.[46] The SR included RCTs, prospective and retrospective studies, case reports and study protocols, most of which had methodological limitations. The authors concluded more well designed RCTs are needed.

Randomized Controlled Trial

An RCT by Bergeron of 78 patients with vulvar vestibulitis compared biofeedback, surgery and cognitive-behavioral therapy.[47] Surgery patients had significantly better pain scores than patients who received biofeedback or cognitive-behavioral therapy. No placebo treatment was used.

OTHER CHRONIC PAIN

Other pain for which there are no publications sufficient to demonstrate the effectiveness of biofeedback include muscle pain or myalgia.

SECTION SUMMARY

The current evidence base is insufficient to allow scientific conclusions concerning the contribution of biofeedback to improvements in health outcomes for the treatment of chronic non-headache pain. [Headache is discussed separately below]

DEPRESSION, ANXIETY, AND POST-TRAUMATIC STRESS DISORDERS

Systematic Reviews and Technology Assessments

In 2018, the Canadian Agency for Drugs and Technology in Health (CADTH) published an updated “Post-Traumatic Stress Disorder: Summary of Evidence of the Clinical Effectiveness of Treatments”.[48] They reviewed 26 treatments, one of which was biofeedback. They continued their stance that there is no evidence-based guidelines for the treatment of any mood or anxiety disorders. Additional well-designed, controlled clinical studies are needed to determine the clinical effectiveness of biofeedback on PTSD.

A 2017 CADTH evidence report on biofeedback for mood and anxiety disorders states the following:[49]

> Evidence from single randomized controlled trials suggests that compared with no treatment there is a statistically significant improvement in symptoms with neurofeedback treatment in patients with post-traumatic stress disorder (PTSD) or generalized anxiety disorder (GAD).
>
> A single randomized controlled trial (RCT) showed that for patients with PTSD there was improvement in symptoms with biofeedback (BF) plus treatment as usual (TAU) and also with TAU alone but the improvement occurred faster in the BF plus TAU group.
>
> A single RCT showed that for patients with PTSD there were no between group differences for BF and various mindfulness related treatment modalities. A single RCT showed that for patients with major depressive disorder, there was a statistically significant improvement in depression with BF plus TAU.
>
> Results need to be interpreted in the light of limitations (such as small sample size, lack of randomization details, lack of reporting of adverse events, lack of long-term data).
>
> No relevant studies on the clinical effectiveness of biofeedback using home equipment for treatment of PTSD, GAD, or depression without continued support from health professionals were identified.
>
> No relevant evidence based guidelines regarding the use of neurofeedback or biofeedback for the treatment of PTSD, GAD, or depression were identified.

Goessl (2017) published a SR on the effect of heart rate variability (HRV) biofeedback training in patients with stress and anxiety.[50] HRV is a measure of cardiac vagal tone. Low HRV is associated with certain psychological states such as anxiety. The literature search identified 24 studies (total N=484 patients), published between 1976 and 2015, for inclusion. Sample sizes ranged from five to 106 patients (median, 14 patients). The Cochrane risk of bias tool was used to assess study quality. Many studies had high or unclear risk of bias due to the following factors: inadequate randomization descriptions, improper randomization, undescribed allocation concealment, and missing data that was either not described or mishandled; 13 studies included a comparison group (six waitlist, three standard of care, two sham, one daily thought record, one progressive muscle relaxation). The average within-group effect size among the 24 studies, measured by Hedges’ *g*, was 0.81, indicating a large effect on anxiety. The average between-group effect size among the 13 studies with comparators, also measured by Hedges’ *g*, was 0.83, indicating HRV had a larger effect on anxiety than the comparators.

Schoenberg and David (2014) published a systematic review (SR) on biofeedback for psychiatric disorders, one of which was anxiety.[51] They identified 227 articles and 63 met the criteria for review. The authors concluded that development of standardized controlled

methodology protocols tailored for specific disorders and guidelines are needed to determine the benefit of biofeedback on health outcomes for those with anxiety.

Randomized Controlled Trials

In addition to those included in the systematic reviews, the following RCTs have been published. Maynart (2021) compared respiratory and heart rate biofeedback plus usual care to usual care alone in 36 patients with moderate to severe depression or dysthymia.[52] After six weeks (six sessions of biofeedback training), the biofeedback plus usual care group had less severe depression as measured by the Beck Depression Inventory (BDI) than the usual care alone group.

A preliminary open-label RCT by Park and Jung (2020) compared respiratory sinus arrhythmia biofeedback plus usual care to usual care alone in 30 patients with major depressive disorder.[53] After four weeks (six sessions of biofeedback), the biofeedback plus usual care group had greater improvements in Hamilton Depression Rating Scale (HAM-D) scores compared to the group receiving usual care alone. Improvements in other clinical measures, including the BDI, were not significantly different between groups.

Chen (2016) published an RCT comparing diaphragmatic breathing relaxation (DBR) with routine respiration activities in the treatment of 46 patients with anxiety.[54] DBR is a technique that uses diaphragm muscle contractions to force air downward into the body, increasing diaphragm length and breathing efficiency. Outcomes were anxiety level, measured by Beck Anxiety Inventory, and four physiological measures (skin conductivity, peripheral blood flow, heart rate, breathing rate). All patients participated in an individualized eight-week course in breathing relaxation, but only 30 completed it. Fifteen were randomized to DBR training and 15 to routine breathing relaxation training. Researchers and patients were blinded to randomization, with only the trainer being aware of group allocation. After eight weeks, the DBR group experienced statistically significant decreases in Beck Anxiety Inventory scores compared with baseline, while the control group did not experience significant decreases from baseline. The DBR group also experienced significant improvements in all four physiological measurements, while the control group did not. The authors noted this therapy is promising, but more well-controlled studies are needed.

A RCT by Meuret (2010) included 41patients with panic disorder and agoraphobia who were randomized to receive four weeks of capnometry-assisted respiratory training (Freespira) or cognitive training.[55] Although capnometry-assisted respiratory training, but not cognitive training, was associated with a shift from hypocapnic to normocapnic levels, reductions in panic symptom severity and panic-related cognitions was well as improvements in perceived control were significant and comparable in both treatment groups.

FECAL INCONTINENCE AND CONSTIPATION

The relevant clinical outcome in studies of biofeedback as a treatment of fecal incontinence, encopresis, and constipation should be the overall change in the bowel symptoms. Reduction in episodes of fecal incontinence, encopresis, and constipation, and an increase in voluntary bowel movements as a result of biofeedback are the primary clinical outcomes of interest. Patient symptoms are usually assessed through diary, questionnaire, or interview. However, changes in anorectal physiological assessment (e.g., anal pressure, sensory threshold) often do not correlate with symptom relief (i.e., clinical outcomes).

FECAL INCONTINENCE IN ADULTS

Systematic Reviews

A 2014 Cochrane SR of RCTs compared one method of biofeedback to sham-biofeedback, no treatment, or another method of biofeedback in adults (> 18 years of age) with chronic idiopathic (functional) constipation.[56] Seventeen RCTs (25 individual reports) were included (N=931); biofeedback was compared to conventional nonsurgical treatment in 7 studies[57-63], to different methods of biofeedback in six studies[64-69], to surgical intervention in two studies[70, 71], to sham treatment in one study[72] and to electrical stimulation in one crossover study[73, 74]. No studies compared biofeedback to no treatment. Meta-analysis was not possible due to between-study heterogeneity and evidence was rated as low or very low quality due poor methodological quality with high risk of bias. The length of follow-up was determined to be inadequate in many RCTs. There was significant heterogeneity between groups and between studies that precluded meta-analysis. These included between-group differences at baseline, between-study differences in symptoms measured, symptom measurement tools used, and difference in protocols for biofeedback including the type of biofeedback, the number, frequency, and duration of sessions, and patient education (e.g., diet, normal bowel function, lifestyle advice). In addition, the review noted that many of the included RCTs were likely to be underpowered to detect between-group differences. The authors concluded that there is insufficient evidence to allow conclusions on the efficacy and safety of biofeedback for chronic constipation.

This Cochrane SR also reviewed four prior SRs[75-78] of RCTs that included systematic literature searches. The review reported methodological limitations in all four of these SRs including incomplete reporting of review methods, limited or non-comprehensive literature search strategies, failure to exclude non-SRs, and meta-analyses of heterogeneous studies. These reviews all reported generally poor quality evidence and the need for further research.

A 2013 SR by Vonthein et al. identified 13 RCTS on biofeedback, electrical stimulation, or the combination for treatment of fecal incontinence.[79] Ten RCTs included comparisons of biofeedback and an alternative treatment; some of the biofeedback interventions also involved other components such as sensory training and pelvic floor exercises. A meta-analysis of studies comparing biofeedback to a control intervention significantly favored biofeedback (relative risk, 2.12; 95% CI, 1.42 to 3.16). This study did not attempt to isolate the effect of biofeedback in multicomponent interventions that included pelvic floor exercise or other treatments.

In 2012, an updated Cochrane SR of randomized and quasi-randomized trials for biofeedback and/or sphincter exercises for the treatment of fecal incontinence in adults was published.[80] Almost half of the 21 trials were considered low risk for bias. Due to the variety of different treatment combinations, treatment delivery techniques, and outcome measures, comparison between studies was difficult. In addition, most studies reported immediate post-treatment outcomes with follow-up of only a few weeks. The authors reached the following conclusions:

- Biofeedback or electrical stimulation “may offer an advantage over exercises alone” in patients who have failed conservative management (e.g., diet changes, medications).
- Biofeedback following surgical sphincter repair does not improve health outcomes.
- The evidence does not permit conclusions about best practices in the clinical setting, including but not limited to the technique for biofeedback delivery and which patients are suitable for and most likely to benefit from biofeedback.

- Biofeedback is unlikely to cause harm as no study has reported any adverse events or worsening of symptoms.
- There is a need for large, long-term, well-designed RCTs that use validated outcome measures to compare outcomes of biofeedback with other treatments.

Randomized Controlled Trials

One new RCT was published after the above SRs. Damon randomized 157 patients with fecal incontinence to either a treatment group (n=77) receiving perineal retraining including biofeedback and standard conservative treatment, or a control group (n=80) receiving standard conservative treatment.[81] This RCT reported only short-term outcomes, with a follow-up of four months. The perineal retraining group had a significantly higher success rate than the control group for daily stool frequency, leakage, and urgency (57% versus 37%, respectively; $p<0.021$). However, there was no significant difference in quality of life scores between the two groups.

FECAL INCONTINENCE IN CHILDREN

Systematic Reviews

A 2011 updated Cochrane SR[82] combined the results of nine trials that compared conventional treatment (i.e., laxatives, toilet training, and dietary advice) with versus without biofeedback in children with fecal incontinence.[83-91] The majority of the trials included fewer than 50 participants. Pooling of data was difficult due to the variety of outcome measures; the only outcome reported by all nine trials was the number of children not cured or improved. Combined results of nine trials showed higher rather than lower rates of persisting symptoms of fecal incontinence up to 12 months when biofeedback was added to conventional treatment. In addition, any short-term benefit from biofeedback training did not correspond with later treatment success. The authors concluded that there is no evidence that biofeedback training added any benefit to conventional treatment in the management of functional fecal incontinence in children.

These results confirm the conclusions of prior versions of this Cochrane SR and other SRs.[92-94]

Randomized Controlled Trials

Since the above SRs, one additional randomized trial was published in which the authors reported that the results at six-months follow-up did not differ between biofeedback and customary care.[83]

CONSTIPATION IN ADULTS

Systematic Review

For the treatment of constipation, a SR of 11 RCTs found a benefit of biofeedback as a treatment of constipation in adults.[75] Conclusions of the SR were limited by variability in patient populations, comparison treatments, and outcomes measures. However, detailed examination of several well-conducted RCTs focusing on patients with dyssynergia-type constipation suggested benefits in a sub-group of patients who met criteria similar to trial participants.[58, 59, 72] Studies for other types of constipation were limited to poorly-designed

RCTs and case series. These unreliable studies do not permit conclusions on the effect of biofeedback on other types of constipation in adults.

Randomized Controlled Trials

Hart (2012) published an RCT that studied anorectal biofeedback (AB) for constipation. Twenty-one patients with pelvic floor dyssynergia were randomized into two groups.[59] One group learned to isolate the anal sphincter using an electromyography probe and the other learned to relax trapezius or temporalis muscles with EMG feedback. The authors concluded that although the sample size was statistically underpowered, AB produced clinical improvements in the severity of constipation. The authors also noted there were several study limitations, including patient selection and long-term follow-up; thus, the evaluation of long-term effects on health outcomes needs to be determined in future studies.

CONSTIPATION IN CHILDREN

Systematic Reviews

A systematic review conducted by Wegh (2021) assessed the effectiveness of nonpharmacological interventions for functional constipation in children.[95] Studies included in the review were RCTs that enrolled children aged 0 to 18 years with functional constipation as defined by Rome III or IV criteria and reported defecation outcomes and/or QOL outcomes. The review included three RCTs comparing biofeedback alone with biofeedback in conjunction with laxative use. The trials were all assessed as having a high risk of bias. Meta-analysis found no difference between groups in study-defined treatment success (risk difference, 0.23; 95% CI, -0.08 to 0.54) and heterogeneity was high (I^2=86%). Other clinical outcomes and harms of treatment were not reported.

Randomized Controlled Trials

A RCT conducted by Van Ginkel (2001) evaluated biofeedback in the treatment of constipation in children.[96] Groups included standard treatment i.e., education, laxatives (n=111) or standard treatment plus two sessions of anorectal manometry (n=91). Manometry measurements were viewed by the child and parent during measurement sessions and the data discussed after each session with instructions in home exercises. At six weeks follow-up, there was no significant different in success between the standard treatment group (4%) and the biofeedback group (7%). At the final 104 week follow-up, 43%of the standard treatment group and 35% of the biofeedback group were considered treatment successes. This difference was not significant. The authors noted that 30% of the randomized patients were missing at the final follow-up.

Section Summary

The current evidence from several well-designed, well-conducted RCTs is sufficient to determine that biofeedback as a treatment of dyssynergia-type constipation may be beneficial in adult patients who meet the policy criteria.

The evidence base is insufficient to draw conclusions or demonstrate a significant health benefit as a result of biofeedback treatments for the treatment of incontinence or constipation other than dyssynergia-type constipation in adults. The evidence is limited to data from studies with significant methodological limitations including inadequate randomization, lack of a

placebo control group, heterogeneity between patient groups and between study protocols, and short-term follow-up periods.

HEADACHE

TENSION AND MIGRAINE HEADACHE

Systematic Reviews

Sullivan (2016) published a SR to evaluate the outcomes of psychological interventions, one of which was biofeedback for migraines.[97] Twenty-four studies were reviewed. The authors noted there were methodological limitations from the study review and that biofeedback was not superior to relaxation training or cognitive behavioral therapy.

A number of other SRs, including two Cochrane SRs, have reported small beneficial effects in children and medium to large beneficial effects in adults when biofeedback is used in conjunction with other prevention measures such as relaxation techniques.[15, 98-104]

Randomized Controlled Trials

Despite the poor quality of case series and RCTs, biofeedback has evolved into a standard of care as part of comprehensive regimens, including medication and relaxation techniques, for treatment and prevention of tension-type headaches, and the prevention of migraine headaches.

Data from case series and RCTs is difficult to interpret due to poor study design, high drop-out rates, and inconsistent outcomes.[105-110]

OTHER HEADACHE

The evidence is insufficient to determine the effect of biofeedback for the prevention or treatment of headaches other than migraine and tension headaches, including but not limited to cluster headaches.

SECTION SUMMARY

Despite the poor quality of studies, biofeedback has evolved into a standard of care as part of comprehensive regimens, including medication and relaxation techniques, for treatment and prevention of tension-type headaches and the prevention of migraine headaches.

There is not enough research to show that biofeedback improves outcomes in patients with headaches other than migraine and tension headaches.

HYPERTENSION

SYSTEMATIC REVIEWS

Nagele (2014) published a SR with meta-analysis on stress-reduction techniques in adults with essential hypertension.[111] The review included SRs and RCTs with a no-treatment control group and at least 24 weeks follow-up that were published through September 2012. Outcomes of interest were mortality, cardiovascular morbidity/mortality, end-stage renal disease, health related quality of life, adverse events, change in blood pressure, and changes in antihypertensive medication. Biofeedback was one of a number of the stress-reduction

techniques included in the review. The review found that data were not reported for most of the patient-relevant outcomes. No benefit was found for use of antihypertensives. Some beneficial effect was found for lowering blood pressure; however, studies were limited by methodological limitations such as heterogeneity between studies, short-term follow-up. The authors concluded that a beneficial effect of stress-reduction techniques on hypertension remains unproven.

In a 2010 SR, Greenhalgh concluded, "…we found no convincing evidence that consistently demonstrates the effectiveness of the use of any particular biofeedback treatment in the control of essential hypertension when compared with pharmacotherapy, placebo, no intervention or other behavioral therapies."[112] Trials generally had small sample sizes; only four included more than 100 patients. Trials included a variety of biofeedback techniques, and some included more than one modality. Results were not pooled due to differences in interventions and outcomes and the generally poor quality of the studies. Only one trial was identified that compared a biofeedback combination intervention to sham biofeedback, and this study did not find a significant difference in the efficacy of the two interventions. Only four studies on biofeedback alone and four on a combined biofeedback intervention reported data beyond six months; most of these found no significant differences in efficacy between the biofeedback and control groups.

Rainforth reviewed RCTs and all previous meta-analyses related to stress reduction programs including biofeedback.[113] Each type of therapy was analyzed separately. No significant reduction in blood pressure was achieved using biofeedback alone or biofeedback combined with relaxation training.

RANDOMIZED CONTROLLED TRIALS

Wang (2016) published an RCT evaluating the effect of direct blood pressure biofeedback on patients with prehypertension or stage I hypertension.[114] A trained nurse instructed patients in blood pressure self-regulation by using slow diaphragmatic breathing and passive attitude. During the eight-week training (one session per week), patients in the treatment group received real-time blood pressure feedback signals (n=29) and controls received pseudo-feedback signals (n=28). Outcomes were systolic and diastolic blood pressure, measured at baseline and one and eight weeks after training. Both groups significantly decreased blood pressure following training. The decreases were equal in magnitude, suggesting that blood pressure self-regulation training can effectively lower blood pressure, regardless of the type of feedback signal.

Landman (2013) conducted a randomized, double-blind, sham-controlled trial comparing the effects on blood pressure of lowering breathing frequency in patients with type two diabetes and hypertension using active (n=21) and sham (n=24) biofeedback.[115] The changes in systolic blood pressure from baseline favored the control group while differences in diastolic blood pressure favored the intervention group. However, these differences from baseline, and the differences between the two groups were not statistically significant.

SECTION SUMMARY

Although there are RCTs evaluating biofeedback for treating hypertension, evidence is insufficient due to the shortage of studies isolating the effect of biofeedback, the generally poor quality of the trials, and the variability among interventions.

INSOMNIA

SYSTEMATIC REVIEWS

No SRs were identified using biofeedback for the treatment of insomnia.

RANDOMIZED CONTROLLED TRIALS

No RCTs were identified using biofeedback for the treatment of insomnia.

MOTOR FUNCTION AFTER STROKE, INJURY, OR LOWER LIMB SURGERY

SYSTEMATIC REVIEWS

Several SRs have been published; none of these conducted quantitative pooling of results due to heterogeneity among study populations, interventions, and outcome measures.

Knee Injury

A 2010 SR by Silkman evaluated the effectiveness of electromyography (EMG) biofeedback for improving muscle function during knee rehabilitation after injury.[116] Four RCTs that compared knee rehabilitation exercise programs with and without biofeedback were identified. Sample sizes in individual studies ranged from 26 to 60 patients. Two of the four studies found a statistically significantly greater benefit in the programs that included biofeedback, and the other two did not find a significant difference between groups. The positive studies assessed intermediate outcomes e.g., contraction values of the quadriceps muscles. None of the studies were designed to assess functional outcomes.

Post-Stroke Motor Function

Stanton (2017) updated a SR published in 2011 which evaluated the effect of biofeedback on lower-limb activities in patients who have had a stroke.[117] Only high-quality RCTs or quasi-RCTs with Physiotherapy Evidence Database (PEDro) scores greater than four were included. The literature search, conducted through September 2015, identified 18 trials (total N=429 patients) for inclusion. Training activities were walking (nine trials), standing (eight trials), and standing up (one trial). Trials were small, with study populations ranging from 12 to 50 patients. Biofeedback techniques included weight distribution from a force platform or sensor (11 trials), muscle activity from EMG (three trials), linear gait parameters (three trials), and joint angle from a goniometer (one trial). Visual feedback was used in seven trials, auditory in seven trials, and a combination of visual/auditory in four trials. Pooled standardized mean difference of the short-term effect of biofeedback from 17 trials (n=417) was significant (0.50; 95% confidence interval [CI], 0.3 to 0.7). Long-term effects could not be calculated because only four trials provided that information.

Stanton (2011) conducted a SR with meta-analysis of RCTs evaluating biofeedback to improve activities involving lower limb function after stroke.[118] A total of 22 trials with 591 participants met inclusion criteria. All of the trials had relatively small sample sizes; the largest trial had 54 participants and 15 trials had 30 or fewer participants. The majority of trials (n=17) compared biofeedback plus usual therapy to usual therapy alone. The specific interventions varied; the types of biofeedback included biofeedback of ground reaction force from a force platform with visual and/or auditory feedback (13 trials), muscle activity via visual and/or auditory feedback (five trials), joint position from an electrogoniometer via visual and/or auditory feedback (three

trials), and limb position via auditory feedback one trial). The duration of interventions ranged from two to eight weeks, and intensity ranged between one to five days per week.

A pooled analysis of data from 17 trials on short-term effect (i.e. one month or less) found that biofeedback significantly improved lower limb activities compared to usual care or placebo (standardized mean difference [SMD]: 0.41; 95% CI: 0.21 to 0.62). Outcomes included activities such as directional control during standing, weight distribution between the lower limbs, and gait parameters such as stride length. There was heterogeneity among studies. Trials did not report functional outcomes such as ability to perform activities of daily living (ADL). A sensitivity analysis determined that the heterogeneity was best explained by study quality. When lower quality trials were excluded, biofeedback was still found to improve lower limb activity compared to control conditions (SMD: 0.49, 95% CI: 0.22 to 0.75). A sub-group analysis was also done by type of activity. There was only one high-quality trial on standing up (n=40). A pooled analysis of five high-quality trials on short-term effect found that biofeedback significantly improved standing outcomes compared to control (SMD: 0.42, 95% CI: 0.05 to 0.78). A pooled analysis of four short-term trials on walking also found better outcomes with biofeedback compared to control (SMD: 0.57, 95% CI: 0.10 to 1.03). Five high-quality trials with a total sample size of 136 contributed data to an analysis of long-term term efficacy i.e., one-five months after cessation of the intervention. In this pooled analysis, biofeedback was found to improve outcomes compared to control (SMD: 0.41, 95% CI: 0.06 to 0.75).

A Cochrane SR that assessed EMG biofeedback for the recovery of motor function after stroke was published in 2007.[119] It included 13 randomized or quasi-randomized studies with a total of 269 patients. All of the trials compared EMG biofeedback plus standard physiotherapy to standard physiotherapy; in addition to standard physiotherapy, several studies also included a sham biofeedback group. The studies tended to be small and poorly designed. The authors did not find support for EMG biofeedback to improve motor power, functional recovery, or gait quality when compared to physiotherapy alone.

A 2010 SR by Zijlstra searched for studies evaluating biofeedback-based training to improve mobility and balance in adults older than 60 years of age.[120] Although the review was not limited to studies on motor function after stroke, more than half of the studies included older adults post-stroke. For inclusion in this review, studies needed to include a control group of patients who did not receive biofeedback and to assess at least one objective outcome measure. A total of 97 potentially relevant articles were identified, and 21 (22%) studies, including 17 RCTs, met the selection criteria. Twelve of the 21 (57%) studies included individuals post-stroke; three included older adults who had lower-limb surgery and six included frail older adults without a specific medical condition. Individual studies were small with sample sizes that ranged from five to thirty patients. The added benefit of using biofeedback could be evaluated in 13 of 21 (62%) studies. Nine of the 13 studies found a significantly greater benefit with interventions that used biofeedback compared to control interventions. However, the outcomes assessed were generally not clinical outcomes but were laboratory-based measures related to executing a task, e.g., moving from sitting to standing in a laboratory setting and platform-based measures of postural sway. The applicability of improvements in these types of measures to clinical outcomes such as the ability to perform activities of daily living or the rate of falls is unknown. Only one study cited in this review reported an improvement in fall rates, and this trial could not isolate the effect of biofeedback from other components of treatment. In addition, only three studies reported long-term outcomes, and none of these reported a significant effect of biofeedback. Conclusions about the efficacy of biofeedback for improving mobility and balance in older adults cannot be drawn

from these data due to the lack of evidence on clinical outcomes. Other methodologic limitations included limited data on the durability of effects and the inability to isolate the effect of biofeedback in many studies.

RANDOMIZED CONTROLLED TRIALS

Kim (2017) published a RCT on the effect of EMG on upper-extremity functions in patients who have had a stroke.[121] Patients were randomized to traditional rehabilitation therapy (n=15) or traditional rehabilitation therapy plus EMG biofeedback training (n=15). Upper-limb function was measured by Fugl-Meyer Assessment (FMA) and Manual Function Test (MFT), and activities of daily living were measured using the FIM instrument. Both FMA and MFT scores improved significantly more in the patients receiving EMG biofeedback. However, there was not a significant difference in functional independence measurement (FIM) score improvement between groups.

Yang (2016) published a limited in size RCT on the effect of biofeedback weight-bearing training on the ability to sit/stand/sit and on stability among patients who have had a stroke.[122] Patients were randomized to biofeedback weight-bearing training (n=15) or functional weight-bearing training (n=15). Outcomes were time to sit/stand/sit and stability (measured by BioRescue, which detects an area of center of pressure). Comparison statistics were calculated for pre- and post training results, and between treatment groups. Both outcomes significantly improved in the biofeedback group but not in the control group.

Ghomashchi (2016) published a RCT evaluating the effect of visual biofeedback on postural balance disorders in patients who have had a stroke.[123] Patients received conventional physical therapy and balance training exercises. During balance training, 16 patients were randomized to visual biofeedback and 15 patients to no visual information. Outcomes were the center of pressure and approximate entropy. Both groups experienced improvements in postural control, with no significant differences between rehabilitation methods.

In a small RCT published after the above SR, Barcala randomized 20 adults with hemiplegia following stroke to balance training with visual biofeedback or to conventional physical therapy alone.[124] Patients received interventions twice a week for five weeks. Both groups demonstrated significant improvement, but no statistically significant differences were found between the two groups.

SECTION SUMMARY

The evidence on biofeedback for improving motor function after stroke is limited by small studies, most of which are methodologically limited. There is variability in the type, duration, and intensity of interventions. Conclusions about the efficacy of biofeedback for improving mobility and balance in older adults cannot be drawn from the current evidence base.

MOVEMENT DISORDERS

SYSTEMATIC REVIEWS

A Cochrane SR assessing EMG biofeedback for the recovery of motor function after stroke included thirteen randomized or quasi-randomized studies.[119] The authors reported that EMG biofeedback did not improve motor power, functional recovery, or gait quality when compared to physiotherapy alone, although the results were limited due to small, poorly designed trials. Use of different assessment scales made pooling data for meta-analysis impossible.

RANDOMIZED CONTROLLED TRIALS

No RCTs identified after the above SR.

SECTION SUMMARY

The current evidence base is insufficient to draw conclusions regarding the role of biofeedback for the treatment of movement disorders.

MULTIPLE SCLEROSIS

SYSTEMIC REVIEWS

No SRs were identified for biofeedback for the treatment of multiple sclerosis.

RANDOMIZED CONTROLLED TRIAL

van der Logt (2016) published a crossover study that evaluated the effect of vibrotactile biofeedback for trunk sway on balance control in patients with multiple sclerosis.[125] Ten patients performed a series of stance and gait tasks while trunk sway was measured using a SwayStar device attached to the waist. Patients underwent the series of tasks with and without an add-on to the SwayStar device, which provided patients with direction-specific vibrotactile feedback during the tasks. When patients performed the tasks with vibrotactile biofeedback, there was a general reduction in trunk sway, though not all the reductions differed significantly with trunk sway when performing the tasks without vibrotactile biofeedback. Studies with larger sample sizes are needed.

A 2015, MacKay published results from an (RCT) that evaluated the addition of biofeedback to standard care in 40 patients with relapsing-remitting multiple sclerosis patients to help improve emotional symptoms, coping, and fatigue in patients with multiple sclerosis.[126] The standard care psychosocial intervention consisted of relaxation, mindfulness, social support, and education. All patients attended a one-hour training and assessment sessions at weekly intervals. During the first session, all patients had training in mindfulness breathing exercises and progressive muscle relaxation techniques. Patients randomized to the biofeedback arm received additional instruction on use of biofeedback equipment for self-regulation. Following the 3 weekly sessions, patients were instructed to practice the exercises at home, with or without use of biofeedback equipment. Outcomes included breathing rate and anxiety, depression, fatigue, and muscle tension measures. At the end of treatment, there were not statistically significant differences between groups in any outcomes. However, some variables were marginally significant. The difference between the intervention and control group in breathing rate was 3.06 (95% CI, -0.17 to 6.280; p=0.06) and the difference in muscle tension was -13.91 (95% CI, -30.06 to 2.25; p=0.09). This study is limited by the small sample size, and other methodological constraints that make it hard to determine the efficacy of biofeedback for anxiety, fatigue, and stress in patients with multiple sclerosis.

SECTION SUMMARY

There is not enough research to show that biofeedback improves health outcomes for the treatment of multiple sclerosis. Additional well-designed, comparative studies are needed.

ORTHOSTATIC HYPOTENSION IN PATIENTS WITH A SPINAL CORD INJURY

SYSTEMATIC REVIEW

Gillis conducted a SR to identify and describe the body of literature pertaining to nonpharmacologic management of orthostatic hypotension during the early rehabilitation of persons with a spinal cord injury.[127] Participants with any level or degree of completeness of spinal cord injury and any time elapsed since their injuries were included. Interventions must have measured at least systolic blood pressure and have induced orthostatic stress in a controlled manner and have attempted to control orthostatic hypotension during an orthostatic challenge. Four distinct nonpharmacologic interventions for orthostatic hypotension were identified: application of compression and pressure to the abdominal region and/or legs, upper body exercise, functional electrical stimulation applied to the legs, and biofeedback. Methodologic quality varied dramatically between studies. The authors concluded that "…The clinical usefulness of compression/pressure, upper body exercise and biofeedback for treating OH [orthostatic hypotension] has not been proven."

RANDOMIZED CONTROLLED TRIALS

No RCTs identified after the above SR.

SECTION SUMMARY

There is insufficient evidence from high-quality comparative studies to permit conclusions about the impact of biofeedback on orthostatic hypotension in patients with a spinal cord injury.

PRETERM BIRTH PREVENTION

SYSTEMATIC REVIEWS

No SRs were identified for biofeedback used to prevent preterm birth.

RANDOMIZED CONTROLLED TRIALS

In 2014, Siepmann published data on 48 women who had experienced threatened preterm labor between the 24th and 32nd gestational week.[128] Twenty-four patients received six biofeedback sessions over two weeks, and the other 24 patients were in a usual care group. Preterm delivery occurred in three patients (13%) in the biofeedback group and eight patients (33%) in the control group; the difference between groups was not statistically significant ($p>0.05$). Other gestational outcome data, such as the gestational duration and birthweight, also did not differ significantly between groups.

SECTION SUMMARY

There is insufficient evidence that biofeedback is effective in preventing preterm birth in pregnant women with a history of threatened preterm labor.

RAYNAUD'S PHENOMENON

SYSTEMATIC REVIEWS

No SRs were identified for biofeedback for Raynaud's phenomenon.

RANDOMIZED CONTROLLED TRIALS

The Raynaud's Treatment Study Investigators conducted a randomized comparison of sustained-release nifedipine and thermal biofeedback in 313 patients with primary Raynaud's phenomenon.[129] In addition to these two treatment groups, there were two control treatments: pill placebo and EMG biofeedback. EMG biofeedback was chosen as a control because it did not address the physiological mechanism of Raynaud's phenomenon. Nifedipine significantly reduced Raynaud's attacks compared with placebo pill ($p<0.001$), but thermal biofeedback did not differ from EMG biofeedback ($p=0.37$). Better outcome for nifedipine relative to thermal biofeedback was nearly significant ($p=0.08$). With a larger sample size, the rate of 56% fewer attacks with nifedipine relative to thermal biofeedback would likely have been statistically significant. Thus, it cannot be concluded that thermal biofeedback is as effective as this form of medical therapy.

A 2009 SR identified five RCTs that reported a variety of outcomes. A pooled analysis from four RCTs (total n=110) on the change in frequency of attacks favored the sham control group over the biofeedback group.[130]

SECTION SUMMARY

There is insufficient evidence from a small number of RCTs that biofeedback is effective as a treatment of Raynaud's disease. A meta-analysis of the available RCTs did not find that biofeedback was more effective than the control intervention.

STRESS REDUCTION

SYSTEMIC REVIEWS

No SRs were identified for biofeedback for stress reduction.

RANDOMIZED CONTROLLED TRIALS

A 2015 Van der Zwan published an RCT comparing the efficacy of self-help physical activity (PA), mindfulness meditation (MM), and heart rate variability biofeedback (HRV-BF) in reducing stress and its related symptoms.[131] This study, which was limited in size and objective outcomes indicated that all interventions were equally effective in reducing stress and its related symptoms. The current evidence base is insufficient to permit conclusions on the impact of biofeedback on stress reduction.

SECTION SUMMARY

There is not enough research to show that biofeedback improves health outcomes for stress reduction. Additional well-designed, comparative studies are needed.

TINNITUS

SYSTEMATIC REVIEWS

No SRs were identified for biofeedback for tinnitus.

RANDOMIZED CONTROLLED TRIALS

Weise investigated the efficacy of a biofeedback-based cognitive-behavioral treatment for tinnitus in Germany. Tinnitus patients (n=130) were randomly assigned to an intervention or a wait-list control group.[132] Treatment consisted of 12 sessions of a biofeedback-based

behavioral intervention over a three-month period. The primary outcome measures were global tinnitus annoyance and a daily rating of tinnitus disturbance measured by a Tinnitus Questionnaire (TQ) and a daily diary using visual analog scale (VAS) scores. Patients in the wait-list group participated in the treatment after the intervention group had completed the treatment. Results showed improvements regarding the following: tinnitus annoyance; diary ratings of loudness; feelings of controllability; changes in coping cognitions; changes in depressive symptoms; TQ: total score (range 0–84) pre-assessment mean 54.7, post-assessment mean 32.52; TQ: emotional distress (range 0–24) pre-assessment mean 16.00, post-assessment mean 8.15; and diary: loudness VAS (range 0–10) pre-assessment mean 5.68, post-assessment mean 4.38. Improvements were maintained over a six-month follow-up period in which variable effect sizes were observed. The study did not investigate the possible additive effect of biofeedback with cognitive-behavioral therapy and did not include an active treatment control group.

SECTION SUMMARY

The current evidence base is insufficient to draw conclusions regarding the role of biofeedback for the treatment of tinnitus.

URINARY DISORDERS

POST-PROSTATECTOMY URINARY INCONTINENCE

Systematic Reviews

Hsu (2016) published a SR evaluating pelvic floor muscle training (PFMT) with biofeedback in men who had radical prostatectomy.[133] Thirteen trials met reviewers' inclusion criteria. However, on closer inspection, not all trials included a biofeedback intervention, and other trials did not compare PFMT alone to PFMT plus biofeedback. Thus, conclusions about the added efficacy of biofeedback cannot be determined from the results of this SR.

In 2015 a Cochrane SR was conducted by Anderson to determine the effectiveness of conservative management interventions for urinary incontinence in men after a prostatectomy, which updated the 2012 review by Campbell et all.[134, 135] Conservative therapies include pelvic floor muscle training with or without feedback, electrical stimulation, extra-corporeal magnetic innervation, compression devices, lifestyle changes, or a combination of methods. Fifty randomized and quasi-Rs were included in the review; however, just eight of these trials examined biofeedback compared to pelvic floor muscle training. Per the rating of moderate quality studies, the authors found no evidence that pelvic floor muscle training with or without biofeedback was better than control for men who had urinary incontinence up to 12 months after radical prostatectomy.

A SR of PMFT to improve post-prostatectomy urinary incontinence identified three studies (281 men) that focused on the incremental value of biofeedback over written/verbal PME.[136] Although PPMFT appeared to reduce the time to recover continence compared to no training, there was no evidence for an advantage of training with biofeedback over written/verbal instructions. None of the individual trials found a statistically significant difference in outcomes between groups.

A 2003 randomized trial by Wille randomized 139 men prior to radical prostatectomy to one of three groups.[137] Group one received verbal and written instructions about PFMT from a

physical therapist. Group two received PFMT instruction and instruction on using an electrical stimulation device. Group three received the previous two intervention components and training on using biofeedback with the electrical stimulation device. Patients had regular contact with a health care provider for the first five weeks after surgery. In the immediate postsurgical period, 20.5% in group one, 22.9% in group two, and 20.7% in group three were continent (p=0.815). After six and 12 months, continence rates remained similar among the groups. Twelve-month continence rates were 88% in group one, 81% in group two, and 88.6% in group three (p=0.524).

Bales (2000) randomized 100 men scheduled to undergo radical prostatectomy to PFMT plus biofeedback intervention (n=50) or to a control group (n=50) that received written and brief verbal instructions performing PFMT [138] The intervention consisted of a single session with a trained nurse two to four weeks before surgery. Three men dropped out of the PFMT plus intervention group. At six months after surgery, the incidence of urinary incontinence was 94% (44/47) in the PFMT plus biofeedback group and 96% (948/40) in the control group. The difference between groups was not statistically significant.

Randomized Controlled Trials

Oh (2020) randomized 84 patients undergoing robot-assisted laparoscopic radical prostatectomy to receive biofeedback with an extracorporeal perineometer plus PFMT or PFMT alone.[139] Although the average urine loss volume was lower in the biofeedback plus PFMT group compared to PFMT alone at month 1 after catheter removal (p=0.028), there was no difference between groups at months 2 or 3 after catheter removal. At study end (month 3), the percentage of continent patients was not significantly different between the biofeedback plus PFMT group (67.5%) and PFMT alone (61.9%).

A 2013 trial by Dijkstra-Eshuis compared the impact of preoperative pelvic floor muscle training (PFMT) with biofeedback (n=65) to standard care (n=56) on postoperative SUI in men undergoing laparoscopic radical prostatectomy.[140] Patients in the intervention group received four weekly sessions of biofeedback-assisted muscle training before surgery. Patients assigned to the control group did not have a presurgical intervention. The primary outcome was the rate of continence one year after surgery. Among the 74 patients available for follow-up analysis, 66% in the intervention group and 80% in the control group were continent at one year. The investigators originally planned to enroll 248 patients. However, an interim analysis after 122 patients were enrolled showed no significant benefit for the intervention group, even if the trial was completed as planned and therefore the trial was halted prematurely.

In 2012, Tienforti compared biofeedback (a session before and after surgery) in combination with written/verbal instructions on performing pelvic floor muscle exercises to a control intervention of written/verbal instructions alone.[141] The study included 34 patients, 32 of whom (16 in each group) were available for the final 6-month analysis. By six months, 10 of 16 patients (62.5%) in the treatment group and one of sixteen patients (6.3%) in the control group had achieved continence; this difference was statistically significant (p value not reported). The mean number of incontinence episodes per week was also significantly lower in the intervention group (2.7) than the control group (13.1) at six months.

STRESS, URGE OR MIXED URINARY INCONTINENCE

Systematic Reviews

Zhu (2022) performed a meta-analysis of 17 RCTs in postpartum women with lower urinary tract symptoms.[142] Fifteen studies (n=1965) compared PMFT plus biofeedback and electrical stimulation with PMFT alone. The analysis reported a significantly greater likelihood of achieving a therapeutic effect with combined PFMT plus biofeedback and electrical stimulation versus PMFT alone (risk ratio, 1.20; 95% confidence interval [CI], 1.15 to 1.24; I^2=0%). Pelvic floor muscle strength was also significantly higher with combination therapy (p<0.0001), but there was high heterogeneity among studies for this outcome (I^2=66%). Limitations of this analysis include risk of bias, lack of blinding, and heterogeneity in the definition of therapeutic effect.

Wu (2021) conducted a meta-analysis (N=21 studies; 13 RCTs, 8 nonrandomized) of PMFT with biofeedback versus PMFT alone in women with stress incontinence or pelvic floor dysfunction.[143] Most studies were conducted in China and none were from the U.S. There was a significant benefit of PMFT with biofeedback compared to PMFT alone in patients with both urinary incontinence (odds ratio, 4.82; 95% CI, 2.21 to 10.51; I^2=85.3%; n=11 studies) and pelvic floor dysfunction (odds ratio, 2.81; 95% CI, 2.04 to 3.86; I^2=13.1%; n=6 studies). Analyses of quality of life and quality of sexual life results were limited by substantial heterogeneity (>80%). Limitations of this analysis include an unclear, moderate, or high risk of bias in all studies and use of Kegel exercises only in some studies rather than a complete PMFT program.

An updated Agency for Healthcare Research and Quality (AHRQ) SR and comparative effectiveness report of nonsurgical treatments for urinary incontinence in women was published by Blak (2018).[144] Biofeedback was considered among nonpharmacological behavioral therapy approaches. The report evaluated 42 studies that compared 19 active nonpharmacological interventions (including combinations of nonpharmacological interventions) with each other. One study reported statistically significant improvements in the daily activities domain with PFMT and biofeedback compared with PFMT alone, and one study reported significant improvements in distress for bladder training combined with PFMT and biofeedback when compared to bladder training, however, nine studies either reported discordant or nonsignificant differences across all other domains for this comparison. No adverse events were reported for any of the studies evaluating biofeedback. The report concludes that behavioral therapy, alone or in combination with other interventions, is generally more effective than other first- and second-line interventions alone for both stress and urgency UI.

A SR by Mateus-Vasconcelos (2018) assessed various physiotherapy methods to strengthen the pelvic floor muscles for women with stress urinary incontinence.[145] Their review included six studies which were RCTs, quasi-experimental trials, and systematic reviews. One study (an uncontrolled RCT) included biofeedback as a comparator; the effectiveness of pelvic floor muscle training (PFMT) with biofeedback (group n=6) to PFMT with palpation (group n=5) was evaluated. The exercises for the biofeedback group consisted of achieving the same number of rapid and slow contractions of the same duration as that achieved during the PERFECT scheme (8 series). The palpation group strengthened the pelvic floor muscles while a physiotherapist performed palpations on the central perineal tendon and vagina (4 sessions). At the end of treatment, there was no statistical difference in improvement between the biofeedback group and the palpation group in power, endurance, or rapidity of contractions. This RCT was limited in its small sample size and lack of control group and masking of assessors.

Oliveira (2017) published a SR that evaluated the protocols and/or PFMT parameters for women with stress urinary incontinence.[146] Seven studies were included, two of which involved biofeedback. The authors concluded that strengthening exercises for pelvic floor training combined with biofeedback was the most effective training protocol, but because of the limited studies and heterogeneity of the intervention protocols they could not identify what the most effective training protocol would be.

Moroni (2016) published a SR of 37 RCTs on conservative treatment of stress urinary incontinence in women.[147] Five trials (N=250) were identified that compared PFMT plus biofeedback with biofeedback alone. A pooled analysis of four studies found significantly more urine loss as measured by a posttreatment pad test with PFMT alone than with PFMT plus biofeedback (mean difference [MD], 0.90; 95% confidence interval [CI], 0.71 to 1.10). Reviewers noted that the difference between groups was likely not clinically significant because there was only about a one-gram difference. Moreover, the finding was largely due to the effect of one study. Results on other outcomes (eg, quality of life, number of incontinence episodes) could not be pooled due to imprecision of the estimates.

A 2011 Cochrane SR evaluated feedback or biofeedback in conjunction with pelvic floor muscle training (PFMT) for treating urinary incontinence (UI) in women.[148] The review included RCTs in women with stress, urge or mixed UI in which at least two arms of the study included exercise training and at least one arm included feedback and/or biofeedback. Feedback was defined as verbal feedback by a clinician, whereas biofeedback involved use of an instrument or device. After examining 36 full-text articles, 24 trials were found to meet the review's inclusion criteria and 17 contributed data to the analysis of at least one primary outcome measure. Sixteen of the 24 trials included a comparison of PFMT plus biofeedback to PFMT alone; nine of these included the same PFMT programs in both groups. The primary outcomes of the review were quality of life and improvement or cure. Nine trials used one of several validated quality-of-life instruments; however, only four of these reported data in a form that could be used for meta-analysis. Thus, quality-of-life results were not pooled. Data were pooled for the other primary outcome, improvement or cure, but there were a sufficient number of studies only for the comparison between PFMT with and without biofeedback. In a pooled analysis of seven studies, there was a significant reduction in the proportion of women reporting 'no improvement or cure' when biofeedback was added to muscle exercise (risk ratio [RR]: 0.75, confidence interval [CI]: 0.66 to 0.86). The authors noted that there may have been other differences between groups, such as more frequent contact with a healthcare professional or a greater number of treatment sessions, which might partially explain the difference in the improvement or cure rate in women who did or did not receive biofeedback. Moreover, when only the outcome 'no cure' was examined, there was not a significant difference between groups that did and did not receive biofeedback (5 studies: RR: 0.92, 95% CI: 0.81-1.05). Among secondary outcomes, a pooled analysis of seven trials did not find a significant difference in leakage episodes in a 24-hour period after treatment (mean difference: -0.01, 95% CI: -0.21 to 0.01). For the outcomes frequency and nocturia, data could not be combined but the review authors reported that the pattern was one of no difference between groups.

A number of significant design flaws in the 24 trials that met inclusion criteria (N=1583 women) limit the reliability of the reported outcomes. These flaws included:

- It was common for the women in the biofeedback arm to have more contact with healthcare professionals than those who did not receive biofeedback;

- Many of the trials were at moderate to high risk of bias; and
- There was significant variation in the regimens proposed for feedback and biofeedback, and the intervention's purpose and composition were often unclear.

The authors concluded that feedback or biofeedback may provide additional benefit to pelvic floor muscle exercises (PME) alone; however, further research is needed to differentiate whether the beneficial effect was due to feedback, biofeedback, or some other difference between the trial arms.

Randomized Controlled Trials

Hagen (2020) conducted a multicenter RCT in 600 women with stress or mixed urinary incontinence. Participants were randomized to 16 weeks of PMFT with electromyographic biofeedback or PMFT alone. Both groups received supervised PMFT during clinic appointments and a home PMFT regimen. The mean number of appointments attended was about four in both groups. Urinary incontinence symptoms (self-reported at month 24 via the International Consultation on Incontinence Questionnaire on Urinary Incontinence Short Form [ICIQ-UI-SF]) were similar in both groups (mean difference, -0.09; 95% CI, -0.92 to 0.75; p=.84). ICIQ-UI-SF scores were also similar between groups at earlier times (6 and 12 months). At 24 months, the proportion of patients who achieved the study's definition of cure, improvement, and symptoms that were very much better or much better was similar between groups. Pelvic floor muscle strength and endurance was assessed at 6 months, with similar findings in both groups. A limitation of this study is the short duration of the intervention compared to the length of follow-up.

A double-blind, sham-controlled RCT by Terlikowski (2013) compared transvaginal electrical stimulation (TVES) with active (n=68) or sham (n=34) EMG-biofeedback in premenopausal women with stress urinary incontinence (SUI).[149] The group receiving active biofeedback had significantly better results than the sham group for reduction in urinary leakage, pelvic floor muscle strength, and incontinence-related quality of life. No significant between group difference was found in urodynamic data. The authors concluded that TVES with active EMG biofeedback "is a trustworthy method for treating premenopausal women with stress urinary incontinence; however reliability needs to be established."

Other RCTs comparing the efficacy of PFMT alone with PFMT with biofeedback have been published. Statistically significant differences in outcomes between interventions were not consistently found, however, sample sizes were small (<25 per group) and thus the studies may have been underpowered.

VOIDING DYSFUNCTION

Systematic Reviews

Fazeli published a SR with meta-analysis to better understand how biofeedback has been used to treat children, up to age 18, with symptoms of bladder dysfunction not responding to standard therapy alone.[150] Five eligible studies were included in the SR. Four of the studies were pooled in the meta-analysis for a total of 382 participants. The overall proportion of cases with resolved incontinence at six months was similar in biofeedback and control groups (OR1.37 [95% CI 0.64 to 2.93], RD 0.0.7 [-0.9, 0.23]). There was no significant different in mean maximum urinary flow rate mean difference 0.50 ml, range -0.56 to 1.55) or likelihood of

urinary tract infection (OR 1.30 [95% CI 0.65 to 2.58]). This SR was limited by the paucity of research, high quality studies, and small sample sizes.

Randomized Controlled Trials

In 2015, Sener published results from a retrospective RCT that compared the outcomes of four biofeedback sessions (group one; n=20) with six to ten biofeedback sessions (group two; n=20) on treating children with dysfunctional voiding. [151] Normalized voiding after the treatment was determined in 18 subjects from group one, and 19 subjects in group two. Fifteen out of the 40 total study sample were determined to have reflux. At the six month evaluation of group one, voiding dysfunction had resolved in seven, had improved in three, and persisted in one. In group two, voiding dysfunction had resolved in ten, improved in three. This study is limited by a small sample size and other methodological constraints that make it difficult to determine the efficacy of biofeedback for children with dysfunctional voiding.

In 2015, Minardi published results from a four arm RCT to evaluate the therapeutic effects of tamsulosin and biofeedback on recurrent urinary tract infections in 155 women with dysfunctional voiding.[152] The study consisted of four groups: group one received uroflowmetry biofeedback, group two received α1-adrenoceptor antagonists, group three received uroflowmetry biofeedback combined with α1-adrenoceptor antagonists, and group four received no treatment. Patients were evaluated by the American Urological Association Symptom Index. Urodynamics was carried out in patients of groups one, two and three at three, six and 12 months, whereas urodynamics was only carried out at 12 months in group four. The incidence of storage and emptying symptoms, mean post-void residual, mean flow rate, flow time, voiding volume, and urinary tract infections decreased at three, six, and twelve month for all four groups. This study was limited by the small sample size, attrition, and other methodological constraints making it hard to determine the efficacy of biofeedback for women with recurrent urinary tract infections and dysfunctional voiding.

OTHER URINARY INCONTINENCE

Systemic Reviews

No SRs were identified for biofeedback for the treatment of other urinary incontinence.

Randomized Control Trials

An RCT of 74 patients with multiple sclerosis reported that the addition of neuromuscular electrical stimulation with biofeedback training resulted in 85% incontinence reduction, compared to a 47% incontinence reduction in the control group trained only with biofeedback.[153]

Section Summary

The available evidence for the use of biofeedback in the treatment of stress and/or or urge urinary incontinence in female patients includes several RCTs and SRs. Although there is some heterogeneity across these studies, there is enough research to show that biofeedback improves outcomes in women with urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT). The current evidence base is insufficient to draw conclusions regarding the role of biofeedback for the treatment of urinary incontinence other than in this setting.

OTHER INDICATIONS

Other indications for which there are no clinical trial publications sufficient to demonstrate the effectiveness of biofeedback include, but are not limited to the following:

- Cardiovascular disorders
- Chronic fatigue syndrome
- Chronic obstructive pulmonary disease (COPD)
- Epilepsy[154]
- Facial palsy
- Hand hemiplegia
- Low vision
- Side-effects of cancer chemotherapy

PRACTICE GUIDELINE SUMMARY

AMERICAN ACADEMY OF SLEEP MEDICINE (AASM)

In 2008, an AASM special committee released a guideline on evaluation and management of chronic insomnia in adults.[155] The AASM considers biofeedback as one of a number of common therapies that are "effective and recommended in the treatment of chronic primary and comorbid (secondary) insomnia (Guideline)" The AASM definition for guideline is "a patient-care strategy, which reflects a moderate degree of clinical certainty. The term guideline implies the use of Level two Evidence (RCTs with high alpha and beta error) or a consensus of Level three Evidence (non-randomized concurrently controlled studies)."

AMERICAN COLLEGE OF GASTROENTEROLOGY

In 2014, the American College of Gastroenterology (ACG) published guidelines on the management of fecal incontinence.[156] The guideline indicated that pelvic floor rehabilitation techniques (eg, biofeedback, therapeutic exercises) are effective in patients with fecal incontinence who do not respond to conservative measures (strong recommendation, moderate quality of evidence).

AMERICAN COLLEGE OF OBSTETRICIANS AND GYNECOLOGISTS (ACOG)[157]

In 2015 ACOG reaffirmed their 2009 clinical practice guidelines on urinary incontinence in women. Biofeedback was not included in these recommendations.

AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians published a guideline titled "Noninvasive Treatments for Acute, Subacute, and Chronic Back Pain: a Clinical Practice Guideline From the American College of Physicians". The guideline stated low quality evidence supports biofeedback for chronic low back pain.

AMERICAN COLLEGE OF OCCUPATIONAL AND ENVIRONMENTAL MEDICINE (ACOEM)

In 2020, the ACOEM updated their guideline on noninvasive and minimally invasive management of low back disorders.[158] The role of biofeedback is not addressed in this updated guideline.

AMERICAN GASTROENTEROLOGICAL ASSOCIATION (AGA)

The updated AGA position statement (2013) on constipation considers biofeedback a possible treatment for patients with dyssynergia-type constipation with severe symptoms and proven pelvic floor dysfunction "to train patients to relax their pelvic floor muscles during straining and to correlate relaxation and pushing to achieve defecation (Strong Recommendation, High-Quality Evidence)."[159, 160]

The following statement on biofeedback was included: "Pelvic floor retraining by biofeedback therapy rather than laxatives is recommended for defecatory disorders (Strong Recommendation, High-Quality Evidence)."

AMERICAN HEART ASSOCIATION

A 2013 the American Heart Association published a statement based on a systematic literature review on alternatives to diet and medication for lowering blood pressure (BP) in patients with hypertension.[161] The report found meta-analyses to have had mixed results, though some recent trials showed reduction in BP with certain biofeedback techniques. However, recommendations for any specific techniques could not be made due to the paucity of data. The statement recommended that biofeedback could be considered for treatment of hypertension. This recommendation was rated as Class IIB, Level of Evidence B recommendation, defined as usefulness/efficacy less well-defined based on conflicting evidence from a single RCT or nonrandomized studies; additional studies with broad objectives needed.

AMERICAN NEUROGASTROENTEROLOGY AND MOTILITY SOCIETY

In 2015, the American Neurogastroenterology and Motility Society and the European Society of Neurogastroenterology and Mobility jointly published consensus-based guidelines on biofeedback therapy for anorectal disorders.[162] The guidelines included the following recommendations:

- "Biofeedback is recommended for the short-term and long-term treatment of constipation with dyssynergic defecation."
- "Biofeedback therapy is recommended for the short-term and long-term treatment of fecal incontinence"
- "Biofeedback therapy is not recommended for the routine treatment of children with functional constipation, with or without overflow fecal incontinence."

AMERICAN SOCIETY OF COLON AND RECTAL SURGEONS (ASCRS)

In 2016, ASCRS published guidelines on the evaluation and management of constipation.[163] The guideline states that biofeedback therapy is a first-line treatment for symptomatic pelvic floor dyssynergia (strong recommendation, moderate quality of evidence).

An American Society of Colon and Rectal Surgeons practice parameter recommended biofeedback "as an initial treatment for motivated patients with incontinence with some voluntary sphincter contraction. Biofeedback may be considered a first-line option for many patients with fecal incontinence who have not responded to simple dietary modification or medication. Supportive counseling and practical advice regarding diet and skin care can improve the success of biofeedback. Biofeedback may be considered before attempting sphincter repair or for those who have persistent or recurrent symptoms after sphincter repair. It may have a role in the early postpartum period in females with symptomatic sphincter weakness. Biofeedback and a pelvic floor exercise program can produce improvement that lasts more than two years. Biofeedback home training is an alternative to ambulatory training programs, especially in the elderly." The authors assigned a level of evidence of III and grade of recommendation B, defined as well-designed, quasi-experimental nonrandomized studies with generally consistent findings.

AMERICAN UROLOGICAL ASSOCIATION AND THE SOCIETY OF URODYNAMICS, FEMALE PELVIC MEDICINE & UROGENITAL RECONSTRUCTION (AUA/SUFU)[164]

The 2014 AUA/SUFU evidence-based practice guidelines recommended offering behavioral therapies (e.g., bladder training, bladder control strategies, pelvic floor muscle training) as first line therapy to all patients with overactive bladder. This recommendation was rated as a Standard, defined as a directive statement that an action should or should not be taken. The strength of evidence was rated as Grade B (moderate quality; moderate certainty). Biofeedback was included among a number of other modalities as a component of behavioral therapies. The guideline reported that the limited literature did not show any single component of behavioral therapy to be essential to efficacy or to be superior in efficacy.

TENSION AND MIGRAINE HEADACHES

Clinical practice guidelines from professional associations include biofeedback in their recommendations for prevention of tension and migraine headaches.[165-168] The associations included the American Academy of Neurology, the National Institute of Neurologic Disorders and Stroke, the U.S. Headache Consortium, and the European Federation of Neurological Societies.

NATIONAL INSTITUTE FOR CLINICAL EXCELLENCE

In 2017, the National Institute for Clinical Excellence (NICE) issued evidence-based guidance on constipation in children and young people, which was reaffirmed in 2014.[169] The guidance indicated that biofeedback should not be used for ongoing treatment.

SUMMARY

It appears that biofeedback may improve health outcomes for some people for prevention of tension-type and migraine headaches. Clinical guidelines based on research recommend biofeedback for people with tension and migraine headaches. Therefore, biofeedback may be considered medically necessary when policy criteria are met.

There is enough research to show that biofeedback improves health outcomes for people with dyssynergia-type constipation. Clinical guidelines based on research recommend biofeedback for pelvic floor training for dyssynergia constipation in adults. Therefore,

biofeedback may be considered medically necessary when policy criteria are met.

There is enough research to show that biofeedback improves outcomes in individuals with stress and/or urge urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT). Clinical practice guidelines recommended behavioral therapies including biofeedback as to patients with overactive bladder. Therefore, biofeedback may be considered medically necessary in individuals with stress and/or urge urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT).

There is not enough research to show that biofeedback improves health outcomes for people with the variety of investigational indications listed in the criteria. In addition, no clinical guidelines based on research recommend biofeedback for these indications. Therefore, biofeedback is considered investigational for all other indications.

Administrative Guidelines to Determine Dental vs Medical Services

Effective: March 1, 2024

Next Review: November 2024
Last Review: January 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Coverage under medical or dental benefits is determined by the condition that is being diagnosed and treated, regardless of whether the service is provided by a dentist or a medical doctor.

MEDICAL POLICY CRITERIA

Notes: Member contracts for covered services vary. Member contract language takes precedence over medical policy. Medical necessity criteria must also be met when applicable.

I. Services are considered under medical benefits if the condition being diagnosed and treated is one which is non-contiguous to the teeth and/or gums or is systemic. (See Policy Guidelines for examples of medical services)

II. Services are considered under dental benefits when the condition being diagnosed and treated is contiguous or localized to the teeth and/or gums or when services are intended to restore lost function of the teeth. (See Policy Guidelines for examples of dental services)

III. General anesthesia services and related facility charges provided in conjunction with **any** (i.e., covered or excluded) dental procedure that is *performed in a hospital or in an ambulatory surgery* center are eligible for coverage under the medical benefit when one or more criteria below (A - C) are met:

A. The patient is under the age of seven, with a dental condition that cannot be safely and effectively treated in a dental office; or

B. The patient is physically or developmentally disabled, with a dental condition that cannot be safely and effectively treated in a dental office; or

C. The patient has a medical condition that the physician determines would place him/her at undue risk if the dental procedure is performed in a dental office. The procedure must be approved by the patient's physician.

Reimbursement Note:

If anesthesia is processed under the medical benefit, it is subject to anesthesia guidelines and must be performed by an independent anesthetist/anesthesiologist. Anesthesia will not be reimbursed to the physician or dentist performing the procedure. The dental procedure may be performed by a dentist or other appropriate provider.

IV. General anesthesia services by a medical provider *provided in a dental office* in conjunction with any covered dental procedure are eligible for coverage under the medical benefit when either criteria 1 or 2 below is met:

A. The patient is under the age of seven; or

B. The patient is physically or developmentally disabled.

Reimbursement Note:

When anesthesia services are provided by a dentist or under the direct supervision of a dentist, the anesthesia services as well as the dental procedure are eligible for dental coverage if applicable. The dentist must have appropriate state certification to perform general anesthesia. When anesthesia services are provided by an anesthesia provider (such as an anesthesiologist or CRNA), the anesthesia services are eligible for medical coverage if applicable.

V. Hospitalization with or without general anesthesia for non-preventive necessary dental treatment is eligible for coverage under the medical benefit when a patient has an existing medical condition for which dental treatment in an office setting is contraindicated and medical necessity exists for hospitalization and/or general anesthesia. Examples of such medical conditions include but are not limited to hemophilia or malignant hyperthermia.

VI. Non-dental services provided in conjunction with any dental procedure are considered **not medically necessary** when Criterion III. IV .or V. is not met.

POLICY GUIDELINES

Examples of **medical services** include but are not limited to:

- Treatment of a blocked salivary gland billed by a dentist

- Cleft palate obturator devices made by a dentist to allow for proper swallowing
- Closure of a cleft palate defect and, for defects extending into the maxilla, associated dental work and orthodontia
- Construction and management of a Tongue Retaining Device (TRD)/sleep apnea appliance, when provided by a dentist as a treatment of documented obstructive sleep apnea
- Soft tissue biopsies (tongue, cheeks, lips and floor of the mouth) except for gum tissues
- Hospital emergency room treatment for a serious condition that is related to the teeth, gums or contiguous structures, such as an acute abscess that results in an extraction

  Note: Facility and professional physician ER charges are covered by medical benefits; however, follow-up services related to dental treatment are covered under dental benefits, if available.
- Conditions where there is documentation of a direct link between destroyed bone or gums and chemotherapy or radiation and when there is documentation that the teeth were in reasonable condition prior to the initiation of the treatment(s)
- Treatment of leukoplakia or pigmented tissue, when confirmed on pathology as malignant

Examples of **dental services** include but are not limited to:

- Initial dental implants and implant removal due to infection caused by the implant
- Initial and replacement crowns
- Pathology studies for tooth-related conditions, such as apical cysts and odontogenic cysts
- Biopsies with extractions for cellulitis localized to the gums
- Dental evaluation and treatment related to other conditions, such as prior to transplantation or chemotherapy, including:
- Prophylactic work-up (i.e., exam, x-rays)
- Dentition history
- Prophylactic extractions of teeth which are necessary due to dental caries or periodontal infection

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and physical indicating if the condition is localized to the teeth and/or gums or contiguous structures. Or, indicate if non-contiguous to the teeth/gums or is systematic. Specify in detail. Indicate place of service (e.g., office, ER) and contributing factors such as cancer treatment or radiation etc.
- If general anesthesia is being used, indicate in the chart notes if the member is physically or developmentally disabled and has a documented dental condition that is

not safe to treat in the dental office or the member has a documented condition that will place him/her at undue risk if in the dental office.

CODES

NOTE: This code list is not intended to be an all-inclusive list, and the absence of a code from this medical policy does not imply coverage.

Codes	Number	Description
CPT	21245	Reconstruction of mandible or maxilla, subperiosteal implant; partial
	21246	Reconstruction of mandible or maxilla, subperiosteal implant; complete
	21248	Reconstruction of mandible or maxilla, endosteal implant (eg, blade, cylinder); partial
	21249	Reconstruction of mandible or maxilla, endosteal implant (eg, blade, cylinder); complete
	40899	Unlisted procedure, vestibule of mouth
	41800	Drainage of abscess, cyst, hematoma from dentoalveolar structures
	41805	Removal of embedded foreign body from dentoalveolar structures; soft tissues
	41806	Removal of embedded foreign body from dentoalveolar structures; bone
	41820	Gingivectomy, excision gingiva, each quadrant
	41821	Operculectomy, excision pericoronal tissues
	41822	Excision of fibrous tuberosities, dentoalveolar structures
	41823	Excision of osseous tuberosities, dentoalveolar structures
	41825	Excision of lesion or tumor (except listed above), dentoalveolar structures; without repair
	41826	Excision of lesion or tumor (except listed above), dentoalveolar structures; with simple repair
	41827	Excision of lesion or tumor (except listed above), dentoalveolar structures; with complex repair
	41828	Excision of hyperplastic alveolar mucosa, each quadrant (specify)
	41830	Alveolectomy, including curettage of osteitis or sequestrectomy
	41850	Destruction of lesion (except excision), dentoalveolar structures
	41870	Periodontal mucosal grafting
	41872	Gingivoplasty, each quadrant (specify)
	41874	Alveoloplasty, each quadrant (specify)
	41899	Unlisted procedure, dentoalveolar structures

Uniform Medical Plan

ASD DOCUMENTATION REQUIREMENTS

Documentation of the diagnosis of an Autism Spectrum Disorder will be based on criteria defined by the most current DSM version (such as DSM-5 299.00). The diagnosis must be made by a neurologist, pediatric neurologist, developmental pediatrician, psychiatrist, or doctorate level psychologist for an Autism Spectrum Disorder (ASD).

For a diagnosis to be accepted there must be:

- Documentation of the confirmed presence of the core symptoms of autism: communication, behavioral, and social impairments; AND
- Documentation of the tool **and/or** observations used to make/confirm the diagnosis.

To determine eligibility for services, there must be a report documenting a diagnostic assessment, comprehensive evaluation, and treatment plan with recommendations. The report must include these elements:

Specific to Diagnostic Assessment & Comprehensive Evaluation Report (cannot be more than a year old)

For children who are current patients, it is acceptable to send the initial evaluation, most current notes or recent evaluation, as well as a letter certifying the diagnosis and providing any other required elements below that are not in other documentation being submitted. The letter should serve as an addendum and refer to the documentation being submitted, rather than reiterate this content. The following documentation is required:

a. Documentation of routine developmental surveillance performed by providers at well child visits; Examples of source documentation are: IEP, primary care practitioner or health care provider who referred the child, e.g. Occupational therapist, etc. if available;

b. Audiology and vision assessment results if available; or that vision and hearing were determined to be within normal limits during assessment and not a barrier to completing a valid evaluation;

c. If applicable, name of screening questionnaire, date completed, and significant results;

d. If applicable, documentation of formal diagnostic procedures performed by an experienced clinician, including name of measure, date and results, including scores. Examples of diagnostic measures are:
    - Autism Diagnostic Observation Schedule (ADOS);
    - Autism Diagnostic Interview (ADI);

e. Documentation of formal cognitive and/or developmental assessment performed by a qualified clinician, including name of measure, dates, results, and standardized scores providing verbal, nonverbal, and full scale scores, as available. Examples are:
    - Mullen;
    - Weschler; or
    - Bayley;

01/22/2014

f. Documentation of formal adaptive behavior assessment performed by a qualified clinician, including name of measure, dates, results, and standardized scores providing scores for each domain as available. Examples are:

- Vineland Adaptive Behavior Scales; or
- Adaptive Behavior Assessment System (ABAS);

e. Documentation of the observed or family reported behaviors having an adverse impact on development, communication and of the injurious behavior, as applicable;

f. Expanded laboratory evaluation, if clinically indicated;

g. Documentation of less intrusive or less intensive behavioral interventions have been tried and not been successful; **OR** that there is no equally effective and substantially less costly alternative available for reducing interfering behaviors, increasing pro-social behaviors, or maintaining desired behaviors, if ABA is included on the treatment plan;

Specific to Treatment Plan with Recommendations:
(If child not a new patient, can be in prescription.)

A multi-disciplinary Individualized Treatment Plan (ITP) with recommendations that consider the full range of autism treatments with ABA as one treatment component, if clinically indicated;

The Prescription must include these elements:

a. The order or prescription for ABA for the child, without specifying hours or how services are to be provided;

b. Documentation that the child's behaviors are having an adverse impact on development and/or communication, and/or demonstrating injurious behavior, such that

- The child cannot adequately participate in home, school, or community activities because behavior interferes; OR
- The child presents a safety risk to self or others;

c. A statement that the requested ABA services will result in measurable improvement in the child's behavior and/or skills.

Aversion Therapy for Chemical Dependency

Effective: February 1, 2021

Next Review: October 2021
Last Review: December 2020

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Aversion therapy is an in-patient substance abuse treatment strategy that has been used for alcohol and cocaine dependence at the Schick Shadel Hospitals (Universal Health Inc.). The treatment generally includes aversion counter conditioning designed to make the sight, smell, taste and thought of the alcohol and/or cocaine unpalatable.

MEDICAL POLICY CRITERIA

Aversion therapy and pentothal interviews are considered **investigational** for all indications including but not limited to the treatment of chemical dependency.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

CROSS REFERENCES

None

BACKGROUND

Aversion therapy is an in-patient substance abuse treatment strategy that has been used for many years for alcohol and cocaine dependence at the Schick Shadel Hospitals (Universal

Health Services, Inc.). The treatment generally includes a 10-day in-patient stay during which the patient receives aversion counter conditioning designed to make the sight, smell, taste and thought of the alcohol and/or cocaine unpalatable. Narcotherapy (pentothal interview) is a component of the aversion therapy program designed to gather initial psychological diagnostic information and to monitor the development of aversion to the addictive substances. Under light anesthesia, patients are queried about the level of desire for each type of substance. Aversion therapy with pentothal interview is provided within a comprehensive treatment program that includes detoxification, counseling, addiction education, and introduction to a 12-step program for follow-up care.

EVIDENCE SUMMARY

Currently, the components of standard outpatient substance abuse therapy consist of individual, group and family psychotherapy, relapse prevention therapy, and introduction to a 12-step program for follow up. Agonist substitution therapy (methadone or levo-alpha-acetyl-methadol [LAAM]) and medications to decrease the reinforcing effects of abused substances, also known as withdrawal drugs (e.g., naltrexone, clonidine/naltrexone, buprenorphine), may also be included as a component of standard therapy.

Long-term outcomes from prospective, randomized controlled trials comparing aversion therapy to standard substance abuse therapy are needed to demonstrate the independent contribution of aversion therapy in the overall treatment program.

RANDOMIZED CONTROLLED TRIALS

There are no randomized controlled trials comparing aversion therapy or pentothal interviews to other treatments for chemical dependency.

NONRANDOMIZED STUDIES

The available published evidence consists of outcomes from patients treated at Schick Shadel Hospitals which are summarized below.

In a pilot study, by Frawley and Smith, 20 patients (9 treated for cocaine only and 11 treated for cocaine/alcohol) completed a program which included chemical aversion therapy to develop a conditioned aversion to the sight, smell, and taste of a cocaine substitute (tetracaine, mannitol, and quinine with Psychem).[1] Ninety-five percent of patients were followed up in six months with a total abstinence rate from cocaine of 56% in the cocaine only group and total abstinence from cocaine of 70% for the cocaine/alcohol group. After 18 months out of the ninety percent of patients that were followed up, 38% of the cocaine only group had been totally abstinent (75% were currently abstinent) and 50% of the cocaine/alcohol group had been totally abstinent (80% were currently abstinent).

Smith and Frawley reported outcomes for 200 patients randomly selected from a group of patients that completed an initial 10 days of treatment at a Schick Shadel Hospital in 1983.[2] During the initial 10-day hospitalization, patients received 5 days of aversion therapy and 5 days of narcotherapy, given on alternating days. This was followed at 30-day and 90-day intervals with 2-day inpatient admissions for reinforcement treatment consisting of 1 day each of aversion therapy and narcotherapy. Follow up was by telephone interview at 12-months. Of the 200 patients, 20% were lost to follow up. In addition, 22 patients were known to have relapsed prior to the 12-month telephone interview.

The same authors followed several other groups of patients for up to 20 months post-aversion therapy, reported in 1990 and 1993.[3 4] Patients in these cohorts were addicted to alcohol alone, cocaine alone, cocaine and alcohol, or cocaine and marijuana. As with the first study, there was either significant loss to follow-up (29%-36%) or small initial sample size (n=20) and therefore conclusions about the study effects could not be determined.

In a 1991 retrospective matched case-control study, 249 patients in the Schick Shadel System were matched to an equal number of patients in the alcohol treatment database and were followed for up to 12 months.[5] As with previous studies there was significant patient attrition: only 33% (248/754) of patients who were contacted for participation remained in the study at 6 months and at 12 months another 17% (41/248) were lost to follow-up.

Based on the same study described above, the same 249 patients were compared for faradic aversion and chemical aversion.[6] The two groups were separately analyzed and authors concluded that no significant differences in outcomes were found.

SECTION SUMMARY

Conclusions concerning the impact of aversion therapy and narcotherapy on health outcomes cannot be reached from the current evidence base. The evidence is limited due to methodological limitations including but not limited to lack of randomization, selection bias (individuals may not be representative of all those with chemical dependency issues), high loss to follow-up, and the inability to isolate the independent contribution of aversion therapy and pentothal interview from the overall substance abuse treatment program.

PRACTICE GUIDELINE SUMMARY

There are no evidence-based clinical practice guidelines that recommend the use of aversion therapy for the treatment of chemical dependency.

SUMMARY

The use of aversion therapy has been proposed as an alternative treatment for chemical dependency. There is not enough research to show that aversion therapy improves health outcomes. More research is needed with longer term follow-up. In addition, no evidence-based clinical practice guidelines recommend aversion therapy. Therefore, aversion therapy is considered investigational for all indications.

Applied Behavior Analysis for the Treatment of Autism Spectrum Disorder

Effective: June 1, 2023

Next Review: April 2024
Last Review: April 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Applied Behavior Analysis (ABA) is an umbrella term describing principles and techniques used in the assessment, treatment, and prevention of challenging behaviors and the promotion of new desired behaviors. The goal of ABA is to teach new skills, promote generalization of these skills, and reduce challenging behaviors with systematic reinforcement.

MEDICAL POLICY CRITERIA

Note: This policy only applies to member contracts that are subject to preauthorization for Applied Behavior Analysis for the Treatment of Autism Spectrum Disorder, as specified by their group plan. Please check the preauthorization website for the member contract to confirm requirements.

I. Initiation of Applied Behavior Analysis (ABA)-based therapy may be considered **medically necessary** when all of the following criteria (A. - C.) are met:

A. An ABA assessment has been documented and all of the following criteria (1. - 3.) are met:

1. The member has a diagnosis of an Autism Spectrum Disorder according to

the DSM (Diagnostic and Statistical Manual of Mental Disorders), either the DSM-IV or DSM-5 (see Policy Guidelines), by a licensed provider experienced in the diagnosis and treatment of autism; and

2. The Autism Spectrum Disorder (ASD) related symptoms and behaviors are impairing the member's communication, social and/or behavioral functioning such that the member is a safety risk to self or others and/or is unable to participate in age-appropriate home or community activities; and
3. ABA therapy must be recommended or prescribed by a licensed provider experienced in the diagnosis and treatment of autism.

B. Based upon the recommendation or prescription from the prescribing provider, a documented individualized treatment plan (ITP) is prepared by the treating provider who is certified to provide ABA therapy. An ITP shall be documented in the medical record; and

C. The individualized treatment plan (ITP) shall include all of the following (1. - 7.):

1. A detailed description of specific behaviors targeted for therapy. Targeted behaviors must be those which prevent the member from participating in age-appropriate home or community activities and/or are presenting a safety risk to self or others; and
2. For each targeted behavior, an objective baseline measurement using standardized instruments that include frequency, intensity and duration; and
3. A detailed description of treatment interventions and techniques specific to each of the targeted behaviors, including the frequency and duration of treatment for each intervention which is designed to improve the member's ability to participate in age-appropriate home or community activities and/or reduce the safety risk to self or others; and
4. Where there was a prior course of ABA therapy, documentation will specify the anticipated benefit of an additional course of treatment; and
5. A description of training and participation of family (parents, legal guardians and/or active caretakers as appropriate) in setting baseline and demonstrating progress toward treatment goals that directly support member's ITP; and
6. Clinical justification for the number of days per week and hours per day of direct ABA services provided to the member and the family, and the hours per week of direct face-to-face supervision of the treatment being delivered and observation of the child in their natural setting; and
7. Individualized and measurable discharge and/or transition criteria.

II. Continuation of ABA-based therapy may be considered **medically necessary** when there has been functional and measurable progress in the ITP goals, demonstrated when all of the following criteria (A. - D.) are met:

A. Member continues to meet Criteria I.B. and I.C. above; and

B. Data on targeted behaviors is documented by the individuals who are delivering the prescribed or recommended ABA therapy to the member during each ABA session. The treating provider who is certified to provide ABA therapy will

routinely collate and evaluate the data from all sessions and conduct a case review and treatment plan review; and

C. Progress toward each of the defined goals in the ITP is assessed and documented for each targeted behavior regarding whether clinically significant improvements are achieved and sustained both during treatment sessions and outside the treatment setting (e.g. home/community). Progress toward the ITP goals is measured using the same indices utilized for baseline measurements in the ITP; and

D. Objective measurements using standardized instruments that include frequency, intensity, and duration and evaluation to occur at a minimum of every six months.

III. Initial or continued ABA-based therapy for all indications is considered **not medically necessary** when the above applicable criteria are not met.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

APPLICABLE BENEFITS

This policy applies to member contracts with applicable benefits subject to the following:

- Washington's Mental Health Parity Act (RCW 48.44); or
- Oregon's Mental Health Parity Act (ORS 743.168) effective August 8, 2014; or
- Idaho's Clarification Regarding Coverage of Treatments for Autism Spectrum Disorder (Bulletin No. 18-02), or
- Utah's Autism Services Amendment, SB 57 (UCA 31A-22-642) effective 2016.

CERTIFIED PROVIDERS

Treating providers who are certified to provide ABA therapy include a qualified Lead Behavior Analysis Therapist (LBAT), and in Idaho, a credentialed provider with a Board-Certified Behavioral Analysis (BCBA) certification issued by the Behavioral Analyst Certification Board.

TREATMENT EXPECTATIONS

At least every three months, the LBAT, or in Idaho, a credentialed provider with a Board Certified Behavioral Analysis (BCBA) certification issued by the Behavioral Analyst Certification Board, should assess the member and update the individualized treatment plan (ITP) as indicated by the member's response to therapy and obtain review by the Prescribing Provider or another licensed provider who has experience in the diagnosis and treatment of autism.

LIST OF INFORMATION NEEDED FOR REVIEW

SUBMISSION OF DOCUMENTATION

The following information may be required for review of ABA services:

Initiation

- Documentation of the following from the prescribing provider (Criteria I.A.1. and I.A.2., above):
  - Diagnosis of Autism Spectrum Disorder (ASD)
  - ASD is impairing the member's functioning such that the member is a safety risk and/or is unable to participate in age-appropriate activities
- Written recommendation, clinical order, or prescription for ABA services from the provider (Criteria I.A.3., above)
- Individualized treatment plan (ITP) with the information listed in Criteria I.C.1.-7., above
- List of specific services requested with the number of units/hours requested per specified period of time

Continuation

The following documentation should be submitted within five business days prior to the end of a current authorization:

- Updated ITP with the information listed in Criteria II.A.-C., above

CROSS REFERENCES

1. Applied Behavior Analysis Initial Assessment for the Treatment of Autism Spectrum Disorder, Behavioral Health, Policy No. 33

BACKGROUND

AUTISM SPECTRUM DISORDER

Autism Spectrum Disorder (ASD) is a neurodevelopment disorder characterized by impaired social communication and interaction and atypical interests and behavioral patterns. ASD may be accompanied by other conditions, such as epilepsy and cognitive impairment. As defined by the American Psychiatric Association Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-5), ASD includes:[1]

- Autistic Disorder
- Asperger's Disorder
- Pervasive Developmental Disorder, Not Otherwise Specified (PDD-NOS)

Diagnostic criteria for ASD as defined by the DSM-5[1], are listed in Appendix 1.

BEHAVIORAL INTERVENTIONS FOR AUTISM SPECTRUM DISORDER

A number of behavioral interventions (e.g., educational, medical, behavioral, complementary, and other allied health interventions) aiming to improve core social, communication and challenging behaviors are available. Several treatments for ASD have been developed based upon different treatment principles, such as applied behavior analysis (ABA) as described below. With the exception of two treatment therapies (UCLA/Lovaas and Early Start Denver Model), most ABA intervention protocols have not been manualized, resulting in the potential for practice and treatment variation.

Applied Behavior Analysis

ABA may be defined as: “the design, implementation and evaluation of environmental modifications, using behavioral interventions for the treatment of autism spectrum disorder. The goal of the therapy is to produce clinically significant improvements in core deficits associated with autism spectrum disorder (i.e. significant issues with communication, social interaction or injurious behaviors). It includes the use of direct observation, measurement and functional analysis of the relationship between the environment and behavior and uses behavioral stimuli and consequences.”

The majority of the research supporting the use of ABA has been conducted in children; although there is some evidence of the effectiveness of ABA in adults (18 years and older), the evidence is less robust and definitive, warranting closer review.[2, 3]

Early Intensive Behavioral Intervention

Early intensive behavioral interventions incorporate principles of ABA but differ in methods and settings. There are two intensive, manualized ABA-based early intervention programs intended to improve the challenging behaviors specifically associated with ASD that include University of California, Los Angeles (UCLA/Lovaas and the Early Start Denver model).

SUMMARY

Applied Behavior Analysis (ABA) is applied in the assessment, treatment, and prevention of challenging behaviors and the promotion of new desired behaviors. This method of treatment is often used for Autism Spectrum Disorder (ASD). Individual states have mandated requirements for the assessment and treatment of ASD, which the policy criteria align with. Therefore, ABA may be considered medically necessary for the initiation and continuation of treatment for ASD when policy criteria are met. When policy criteria are not met, ABA for ASD is considered not medically necessary.

	97158	Group adaptive behavior treatment with protocol modification, administered by physician or other qualified health care professional, face-to-face with multiple patients, each 15 minutes
HCPCS	None	

APPENDIX 1

Diagnostic and Statistical Manual of Mental Disorders, *5th Edition* (DSM-5)

Autism Spectrum Disorder, 299.00 (F84.0)

Diagnostic Criteria

A. Persistent deficits in social communication and social interaction across multiple contexts, as manifested by the following, currently or by history (examples are illustrative, not exhaustive, see text):

APPENDIX 1

1. Deficits in social-emotional reciprocity, ranging, for example, from abnormal social approach and failure of normal back-and-forth conversation; to reduced sharing of interests, emotions, or affect; to failure to initiate or respond to social interactions.
2. Deficits in nonverbal communicative behaviors used for social interaction, ranging, for example, from poorly integrated verbal and nonverbal communication; to abnormalities in eye contact and body language or deficits in understanding and use of gestures; to a total lack of facial expressions and nonverbal communication.
3. Deficits in developing, maintaining, and understanding relationships, ranging, for example, from difficulties adjusting behavior to suit various social contexts; to difficulties in sharing imaginative play or in making friends; to absence of interest in peers.

Specify current severity:

Severity is based on social communication impairments and restricted repetitive patterns of behavior (see Table 1).

B. Restricted, repetitive patterns of behavior, interests, or activities, as manifested by at least two of the following, currently or by history (examples are illustrative, not exhaustive; see text):

1. Stereotyped or repetitive motor movements, use of objects, or speech (e.g., simple motor stereotypies, lining up toys or flipping objects, echolalia, idiosyncratic phrases).
2. Insistence on sameness, inflexible adherence to routines, or ritualized patterns or verbal nonverbal behavior (e.g., extreme distress at small changes, difficulties with transitions, rigid thinking patterns, greeting rituals, need to take same route or eat food every day).
3. Highly restricted, fixated interests that are abnormal in intensity or focus (e.g., strong attachment to or preoccupation with unusual objects, excessively circumscribed or perseverative interest).
4. Hyper- or hyporeactivity to sensory input or unusual interests in sensory aspects of the environment (e.g., apparent indifference to pain/temperature, adverse response to specific sounds or textures, excessive smelling or touching of objects, visual fascination with lights or movement).

Specify current severity:

Severity is based on social communication impairments and restricted, repetitive patterns of behavior (see Table 1).

C. Symptoms must be present in the early developmental period (but may not become fully manifest until social demands exceed limited capacities, or may be masked by learned strategies in later life).

APPENDIX 1

D. Symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning.

E. These disturbances are not better explained by intellectual disability (intellectual developmental disorder) or global developmental delay. Intellectual disability and autism spectrum disorder frequently co-occur; to make comorbid diagnoses of autism spectrum disorder and intellectual disability, social communication should be below that expected for general developmental level.

Note: Individuals with a well-established DSM-IV diagnosis of autistic disorder, Asperger's disorder, or pervasive developmental disorder not otherwise specified should be given the diagnosis of autism spectrum disorder. Individuals who have marked deficits in social communication, but whose symptoms do not otherwise meet criteria for autism spectrum disorder, should be evaluated for social (pragmatic) communication disorder.

Specify if:

With or without accompanying intellectual impairment

With or without accompanying language impairment

Associated with a known medical or genetic condition or environmental factor

Table 1. Severity levels for autism spectrum disorder

Severity level	Social communication	Restricted, repetitive behaviors
Level 3 "Requiring very substantial support"	Severe deficits in verbal and nonverbal social communizations skills cause severe impairment sin functioning, very limited initiation of social interactions, and minimal response to social overtures from others. For example, a person with few words of intelligible speech who rarely initiates interaction and, when he or she does, makes unusual approaches to meet needs only and responds to only very direct social approaches.	Inflexibility of behavior, extreme difficulty coping with change, or other restricted/repetitive behaviors markedly interfere with functioning in all spheres. Great distress/difficulty changing focus or action.
Level 2 "Requiring substantial support"	Marked deficits in verbal and nonverbal social communication skills; social impairments apparent even with supports in place; limited initiation of social interactions; and reduced or abnormal responses to social overtures from others. For example, a person who speaks simple sentences, whose interaction is limited to narrow special interests, and who has markedly odd nonverbal communication.	Inflexibility of behavior, difficulty coping with change or other restricted/repetitive behaviors appear frequently enough to be obvious to the casual observer and interfere with functioning in a variety of contexts. Distress and/or difficulty changing focus or action.
Level 1 "Requiring support"	Without supports in place, deficits in social communication cause noticeable impairments. Difficulty initiating social interactions, and clear examples of atypical	Inflexibility of behavior causes significant interference with functioning in one or more contexts.

APPENDIX 1		
	or unsuccessful responses to social overtures of others. May appear to have decreased interest in social interactions. For example, a person who is able to speak in full sentences and engages in communication but whose to-and-fro conversation with other fails, and whose attempts to make friends are odd and typically unsuccessful.	Difficulty switching between activities. Problems of organization and planning hamper independence.

Medical Policy Manual Behavioral Health, Policy No. 25

Eating Disorder Inpatient Treatment

Effective: November 1, 2022

Next Review: January 2023
Last Review: October 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Eating Disorder Inpatient (IP) is a 24-hour acute treatment setting that is licensed as a hospital by the appropriate agency and under the direct supervision of an attending psychiatrist or psychiatric extender.

MEDICAL POLICY CRITERIA

Note: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. An Inpatient Hospitalization (IP) admission for an Eating Disorder provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. - B.) are met:

   A. All of the following intensity of service criteria (1. – 12.) are met:

      1. The hospital or inpatient unit is licensed by the appropriate state agency.
      2. There is an expectation that the member's history and physical examination is completed within 24 hours of admission (unless completed within 72 hours prior to admission or if transferred from an acute inpatient level of care).

3. There is an expectation that drug screens and relevant lab tests (electrolytes, chemistry, CBC, thyroid and ECG, etc.) are completed upon admission and as clinically indicated and documented in the medical record.
4. The attending provider is a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) who is responsible for diagnostic evaluation within 24 hours of admission. After the initial diagnostic evaluation, there is an expectation that the physician, or physician extender provides and documents medical monitoring and evaluation daily. The attending provider must be available 24 hour a day, 7 days per week.
5. There is an expectation that within 24 hours of admission, following a multidisciplinary assessment that includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
6. Treatment programing includes an expectation of at least one individual counseling session weekly or more as clinically indicated, which is documented in the clinical record.
7. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
8. Treatment programing is multidisciplinary and includes clinical services provided daily that comprehensively address the needs identified in the member's treatment plan. In addition, the program is operated with licensed clinical staff who are trained and experienced in the medical and psychiatric treatment of Eating Disorders.
9. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
10. On-site registered nursing care is available 24 hours a day, 7 days a week with full capabilities for all appropriate interventions in medical and behavioral health and emergencies that occur on the unit.
11. On-site, licensed clinical staff is available 24 hours a day, seven days a week adequate to supervise the member's medical and psychological needs.
12. There is an expectation that nutritional planning including target weight range and planned interventions by a registered dietitian is undertaken and documented in the medical record.

B. All of the following severity of illness criteria (1. - 2.) are met:
    1. All the following are met (a. –d.):
        a. The member has been given a severe Eating Disorder diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.
        b. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.
        c. The treatment is not primarily for the convenience of the provider or member (e.g., primarily for lack of housing options, respite care, or custodial needs).
        d. Treatment could not be safely provided at a lower level of care or no safe lower level of care is available.
    2. One or more of the following criteria must be met:
        a. The member presents with medical risks due to one or more the following:
            i. Heart Rate: <40 in Adults; <50 in Child/Adolescent
            ii. Blood Pressure: <90/60 mm Hg in Adults; <80/50 mm Hg in Child/Adolescent
            iii. Orthostatic Pulse Increase: (Lying to standing) Change of more than 20 beats per minute
            iv. Orthostatic Blood Pressure Decrease: (Lying to standing) Change of more than 10 mm Hg
        b. The member presents with one or more of the following abnormal labs resulting from disordered eating and require inpatient stabilization:
            i. Low serum glucose: < 60 mg/dl
            ii. Low Potassium (Hypokalemia): <3.2 mEq/L
            iii. Low Phosphorus (Hypophosphatemia): <2.5 mg/dL
            iv. Low Magnesium (Hypomagnesemia): <1.5 mg/dL
            v. Low Sodium (Hyponatremia): <135 mEq/L
        c. The member presents with medical conditions either secondary to or exacerbated by disordered eating such as: severe dehydration with corresponding lab findings, poor liver function, poor kidney function, cardiac abnormalities, uncontrolled or risky diabetes, etc.
        d. The member meets one of the following biometric criteria:
            i. A body mass index (BMI) less than 16 and requires re-feeding
            ii. BMI is greater than or equal to 16, AND there is evidence of one of the following:

a.) The member has been losing >2 lbs per week resulting in physiological abnormalities that require inpatient stabilization; or

b.) Weight loss associated with medical instability that is not primarily due to a general medical condition.

e. The individual's eating disorder symptoms require around the clock medical/nursing intervention for one or more of the following:

i. For issues of imminent risk of harm to self or others.

ii. There is a need to provide immediate interruption of food restriction, excessive exercise, binging/purging, and/or use of laxatives/diet pills/diuretics because acute medical complications are imminent without intervention.

iii. To avoid impending life-threatening complications due to a co-morbid medical condition (e.g., pregnancy, diabetes, etc.).

iv. Due to the severity of food restriction/malnutrition, medically managed re-feeding is indicated to mitigate risks of Refeeding Syndrome.

II. A continued stay in Inpatient Hospitalization (IP) for an Eating Disorder under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – D.) are met:

A. The individual continues to meet admission criteria (I.A. – B.).

B. There is evidence of active discharge planning.

C. Family participation (see Policy Guidelines):

1. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.

2. For children/adolescents: Family treatment will be provided as part of the treatment plan. If Family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within 48 hours of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly or more often if clinically indicated.

D. One or more of the following criteria are met:

1. The active treatment being provided to the member is demonstrating meaningful improvements in the member's clinical status and appears to be helping the member reach a level of stability that step-down to a lower level of care will be possible.

2. If the active treatment being provided to member does not appear to result in clinical improvements (or the member's condition has deteriorated further), the treatment team is actively re-evaluating the treatment plan and adjusting as needed to produce positive outcomes.

3. Member is experiencing complications arising from medications or other treatments (such as Electroconvulsive Therapy) with such severity that require further stabilization and 24-hour observation.
4. The member has developed new symptoms and/or behaviors that require this intensity of service for safe and effective treatment.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

- Pre-Authorization Request Form
- Supporting clinical documentation, including:
  - Initial Psychiatric Evaluation/Intake Assessment
  - Nursing Assessment/ History & Physical (if available)
  - Recent lab results
  - Any additional supporting clinical evidence, if available (example: letters from outpatient providers supporting this level of care)
- Preliminary Individualized Treatment Plan

Request for Extension/Concurrent Review:

- Supporting clinical documentation, including:
  - Recent psychiatric evaluation
  - MD Notes
  - Treatment Plan/Progress Reports
  - Any other supporting clinical evidence

Medical Policy Manual Behavioral Health, Policy No. 26

Eating Disorder Intensive Outpatient

Effective: November 1, 2022

Next Review: January 2023
Last Review: October 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Intensive Outpatient (IOP) is an outpatient program that is licensed as an appropriate facility/agency by the appropriate state agency and is provided under the supervision of a psychiatrist or psychiatric extender. Intensive Outpatient (IOP) is intended to provide treatment on an outpatient basis, does not include boarding/housing and is intended to provide treatment interventions in a structured setting, with patients returning to their home environments each day.

MEDICAL POLICY CRITERIA

Notes: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. An Intensive Outpatient Program (IOP) admission provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

   A. All of the following intensity of service criteria (1. – 9.) are met:

      1. If required by state statute, the facility is licensed by the appropriate state agency. If state license not required, facility is accredited.

2. There is an expectation that drug screens and relevant lab tests (electrolytes, chemistry, CBC, thyroid and ECG, etc.) are completed upon admission and as clinically indicated and are documented in the clinical record.
3. There is an expectation of evaluation by a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) when clinically necessary. The physician, or physician extender will continue to be available throughout the program as medically indicated for face-to-face evaluations.
4. There is an expectation that within 5 days of admission, following a multidisciplinary assessment which includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
5. Treatment programing includes documentation of at least one individual counseling session weekly or more as clinically indicated.
6. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
7. All treatment is supervised by licensed behavioral health practitioners.
8. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
9. There is an expectation that a multidisciplinary treatment program occurs 3 days per week and provides a minimum of 9 hours of weekly clinical services to comprehensively address the needs identified in the member's treatment plan. In addition, the program is operated with licensed clinical staff who are trained and experienced in the medical and psychiatric treatment of Eating Disorders.

B. All of the following severity of illness criteria (1. – 8.) are met:

1. The member has been given a severe Eating Disorder diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.
2. The member is able to actively participate in and comply with treatment in this level of care.
3. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.

4. Members reporting non-acute safety concerns can develop a safety plan and access crisis intervention so that a more intensive level of care can be avoided.
5. The member's family and/or support system is willing to engage in the treatment process through family therapy as appropriate.
6. The member is experiencing significant disruption in multiple areas of functioning due to disordered eating behaviors (e.g., work, school, social relationships, family relationships).
7. Lack of external supports alone is not sufficient for continued treatment at this level of care.
8. Treatment could not be safely provided at a lower level of care or safe lower level of care is not available.

II. A continued stay in an Intensive Outpatient Program (IOP) provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All the following (1. – 5.) must be met:

1. Member continues to meet admission criteria (I.A. –B.).
2. The member and family are involved to the best of their ability in the treatment and discharge planning process.
3. Continued stay is intended to provide active treatment and is not primarily to provide a safe and supportive environment.
4. Family participation (see Policy Guidelines):
    a. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.
    b. For children/adolescents: Family treatment will be provided as part of the treatment plan. If Family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within five days of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly or more often if clinically indicated.
5. There is evidence of active discharge planning.

B. One or more of the following criteria must be met:

1. The treatment being provided to the member is demonstrating meaningful improvements in the member's clinical status and appears to be helping the member reach a level of stability that step-down to a lower level of care will be possible.
2. If the active treatment being provided to member does not appear to result in clinical improvements (or the member's condition has deteriorated further), the treatment team is actively re-evaluating the treatment plan and adjusting as needed to produce positive outcomes.

3. The member has developed new symptoms and/or behaviors that require this intensity of service for safe and effective treatment.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

MULTIDISCIPLINARY TREATMENT PROGRAM

The intent of the standard for nine hours of weekly treatment program (groups, activities and psychotherapies) is that they are evidence-based and are explicitly focused on the alleviation of the current condition as opposed to providing general recreation activities, watching videos, etc. and other facility offerings that are not tied back directly to the treatment plan.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

Medical Policy Manual Behavioral Health, Policy No. 27

Eating Disorder Partial Hospitalization

Effective: November 1, 2022

Next Review: January 2023
Last Review: October 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Partial Hospitalization (PHP) is an outpatient program that is provided under the supervision of an attending psychiatrist or psychiatric extender. Partial Hospitalization (PHP) is intended to provide treatment on an outpatient basis, does not include boarding/housing and is intended to provide treatment interventions in a structured setting, with patients returning to their home environments each day.

MEDICAL POLICY CRITERIA

Note: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. A Partial Hospitalization (PHP) outpatient program admission for an Eating Disorder provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All of the following intensity of service criteria (1. – 12.) are met:

1. If required by state statute, the facility is licensed by the appropriate state agency. If state license not required, facility is accredited.

2. There is an expectation that drug screens and relevant lab tests (electrolytes, chemistry, CBC, thyroid and ECG, etc.) are completed upon admission and as clinically indicated and are documented in the clinical record.
3. The attending provider is a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) who is responsible for diagnostic evaluation within 48 hours of admission. After the initial diagnostic evaluation, there is an expectation that the physician, or physician extender provides and documents monitoring and evaluation as indicated, but no less than weekly.
4. There is an expectation that within 5 days of admission, following a multidisciplinary assessment that includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
5. Treatment programing includes an expectation of at least one individual counseling session weekly or more as clinically indicated, which is documented in the medical record.
6. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
7. All treatment is supervised by licensed behavioral health practitioners.
8. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
9. Treatment programing is multidisciplinary and occurs 5 days per week and provides 25 hours of weekly clinical services to comprehensively address the needs identified in the member's treatment plan. In addition, the program is operated with licensed clinical staff who are trained and experienced in the medical and psychiatric treatment of Eating Disorders.
10. When members are receiving boarding services, during non-program hours the member is allowed the opportunity to:
    a. Function independently.
    b. Develop and practice new recovery skills in the real world to prepare for community re-integration and sustained, community-based recovery.
11. There is an expectation that nutritional planning including target weight range and planned interventions by a registered dietitian is undertaken and documented in the medical record.

12. There is documentation of a safety plan including access for the member and/or family/support system to professional supports outside of program hours.

B. All of the following severity of illness criteria (1. – 2.) are met:

1. All the following are met (a. – h.):

a. The member has been given a severe Eating Disorder diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.

b. The member is able to actively participate in and comply with treatment at this level of care.

c. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.

d. Members reporting non-acute safety concerns can develop a safety plan and access crisis intervention so that a more intensive level of care can be avoided.

e. The member's family and/or support system are willing to participate in the treatment and discharge planning process as appropriate.

f. If member has comorbid medical issues, the issues can be safely managed in a partial hospitalization level of care.

g. Lack of external supports alone is not sufficient for continued treatment at this level of care.

h. Treatment could not be safely provided at a lower level of care or no safe lower level of care is available.

2. One or more of the following are met:

a. The member is demonstrating significant impairments in functioning due to an Eating Disorder not requiring 24-hour monitoring, as evidenced by both (i. – ii.) of the following:

i. The patient's symptoms or behavioral manifestations are of such severity that there is significant interference with one or more of the following:

a.) Family functioning.

b.) Vocational functioning.

c.) Educational functioning.

d.) Other age-appropriate social role functions.

ii. The member is unable to employ the appropriate coping skills outside of a structured setting which puts member at risk of the condition worsening.

b. The member has recently demonstrated non-lethal self-injurious behavior (superficial cutting) or made serious threats of self-harm or harm to others

but does not require 24-hour monitoring.

c. The member's eating disorder is interfering with their ability to manage a serious medical condition which, left unmanaged, could be life-threatening.

II. A continued stay in a Partial Hospitalization (PHP) outpatient program for an Eating Disorder provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All the following (1. – 4.) must be met:

1. Member continues to meet admission criteria (I.A. – B.)
2. The member continues to demonstrate motivation for change, interest in and ability to actively engage in their behavioral health treatment, as evidenced by active participation in groups, cooperation with treatment plan, working on assignments, actively developing discharge plan, and other markers of treatment engagement. If member is not engaged, there are documented interventions by the treatment team to address.
3. Family participation (see Policy Guidelines):
   a. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.
   b. For children/adolescents: Family treatment will be provided as part of the treatment plan. If Family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within 72 hours of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly or more often if clinically indicated.
4. There is evidence of active discharge planning.

B. One or more of the following criteria must be met:

1. The treatment being provided to the member is demonstrating meaningful improvements in the member's clinical status and appears to be helping the member reach a level of stability that step-down to a lower level of care will be possible.
2. If the active treatment being provided to member does not appear to result in clinical improvements (or the member's condition has deteriorated further), the treatment team is actively re-evaluating the treatment plan and adjusting as needed to produce positive outcomes.
3. The member has developed new symptoms and/or behaviors that require this intensity of service for safe and effective treatment.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

WEEKLY TREATMENT PROGRAM

The intent of the standard for twenty-five hours of weekly treatment program (groups, activities and psychotherapies) is that they are evidence-based and are explicitly focused on the alleviation of the current condition as opposed to providing general recreation activities, watching videos, etc. and other facility offerings that are not tied back directly to the treatment plan.

For child and adolescent programs, accredited schooling comprises a portion of the 25 hours per week.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

- Pre-Authorization Request Form
- Supporting clinical documentation, including:
  - Initial Psychiatric Evaluation/Intake Assessment
  - Nursing Assessment/ History & Physical (if available)
  - Recent lab results
  - Any additional supporting clinical evidence, if available (example: letters from outpatient providers supporting this level of care)
- Preliminary Individualized Treatment Plan

Request for Extension/Concurrent Review:

- Supporting clinical documentation, including:
  - Recent psychiatric evaluation
  - MD Notes
  - Treatment Plan/Progress Reports
  - Any other supporting clinical evidence

Medical Policy Manual Behavioral Health, Policy No. 28

Eating Disorder Residential Treatment

Effective: November 1, 2022

Next Review: January 2023
Last Review: October 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Residential treatment (RTC) is a 24-hour sub-acute treatment setting that is licensed as a residential treatment center by the appropriate agency to provide residential treatment and is under 24-hour care with an attending psychiatrist or psychiatric extender available for consultation 24/7.

MEDICAL POLICY CRITERIA

Notes: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. An Eating Disorder Residential Treatment (RTC) program admission provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

   A. All of the following intensity of service criteria (1. – 12.) are met:

      1. The facility is licensed by the appropriate state agency.

      2. There is an expectation that the member's history and physical examination is completed within 48 hours of admission (unless completed within 72 hours

prior to admission or if the member is transferred from an acute inpatient level of care).

3. There is expectation that drug screens and relevant lab tests (electrolytes, chemistry, CBC, thyroid and ECG, etc.) are completed upon admission and as clinically indicated and are documented in the medical record.
4. The attending provider is a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) who is responsible for diagnostic evaluation within 48 hours of admission. After the initial diagnostic evaluation, there is an expectation that the physician, or physician extender provides and documents monitoring and evaluation at least weekly. The attending provider must be available 24 hours per day, 7 days per week.
5. There is an expectation that within 72 hours of admission, following a multidisciplinary assessment that includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
6. Treatment programming includes an expectation of at least one individual counseling session per week, or more as clinically indicated, which is documented in the medical record.
7. There is an expectation that evaluations of the member by a licensed behavioral health provider are performed daily and are documented in the medical record.
8. Treatment programing is multidisciplinary and includes clinical services provided daily that comprehensively address the needs identified in the member's treatment plan. In addition, the program is operated with licensed clinical staff who are trained and experienced in the medical and psychiatric treatment of Eating Disorders.
9. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
10. On-site registered nursing care available 24 hours a day, 7 days a week with full capabilities for all appropriate interventions in medical and behavioral health and emergencies that occur on the unit.
11. On-site, licensed clinical staff is available 24 hours a day, seven days a week adequate to supervise the member's medical and psychological needs.

12. There is an expectation that nutritional planning including target weight range and planned interventions by a registered dietitian is undertaken and documented in the medical record.

B. All of the following severity of illness criteria (1. – 2.) are met:

1. All the following are met (a. – g.):

a. The member has been given a severe Eating Disorder diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.

b. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.

c. The treatment is not primarily for the convenience of the provider or member (e.g. lack of housing options, respite care or custodial needs)

d. The member has significant functional impairment in more than one area that requires 24-hour monitoring and intervention: Home, School/Work, Health/Medical, maintaining safe behaviors towards self or others, inability to maintain healthy eating and exercise behaviors despite active, recent attempts to self-manage in a less restrictive setting.

e. Member is able to function independently and actively participate in group and individual therapy.

f. Treatment could not be effectively provided at a lower level of care (supported by clinical documentation) OR The member's home environment is not conducive to treatment/recovery, such that treatment at a lower level of care is unlikely to be successful OR no safe lower level of care is available.

g. The family members and/or support system are committed to change through participation in the treatment process as appropriate.

2. One or more of the following:

a. Member requires 24-hour structure and supervision at each meal to prevent disordered eating patterns (food restriction, binging/purging, etc.) that member's family or support system are unable to provide at a less restrictive level of care.

b. Member requires 24-hour observation to interrupt/avoid compensatory behaviors such as: excessive exercise, food restriction, purging, taking laxatives/diuretics/diet pills that would otherwise lead to imminent medical risks, complications or deterioration of a co-morbid medical condition.

c. In addition to a primary eating disorder requiring active treatment, member presents with a co-occurring psychiatric disorder requiring active treatment or risk of harm that requires 24-hour supervision.

II. Continued stay in an Eating Disorder Residential Treatment (RTC) program provided under the supervision of an attending psychiatrist may be indicated when all of the following are met (A. – F.):

A. The member continues to meet admission criteria (I.A. – B.).

B. There is reasonable expectation that continued treatment provided at this level of care will produce improvement that is sustainable after discharge.

C. Family participation (see Policy Guidelines):

1. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.

2. For children/adolescents: Family treatment will be provided as part of the treatment plan. If Family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within 72 hours of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly or more often if clinically indicated.

D. The individual and family are involved to the best of their ability in the treatment and discharge planning process.

E. The member continues to demonstrate motivation for change, interest in and ability to actively engage in their behavioral health treatment, as evidenced by active participation in groups, cooperation with treatment plan, working on assignments actively developing discharge plan and other markers of treatment engagement. If member is not engaged, there are documented interventions by the treatment team to address.

F. There is evidence of active discharge planning.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

DAYTIME OUTINGS

For purposes of discharge planning and when clinically indicated, members may participate in daytime outings, during non-program hours, of up to eight hours per outing, with family, guardians, authorized representatives or other supportive individuals, to assess current conflicts, skills development and ability to tolerate a return to his/her living environment and other issues relevant to the unique member.

CUSTODIAL CARE

The following definition of custodial care by the Centers for Medicare & Medicaid Services (CMS) is applicable in support of the policy criteria:[11]

> Custodial care serves to assist an individual in the activities of daily living, such as assistance in walking, getting in and out of bed, bathing, dressing, feeding, and using

the toilet, preparation of special diets, and supervision of medication that usually can be self-administered. Custodial care essentially is personal care that does not require the continuing attention of trained medical or paramedical personnel. In determining whether a person is receiving custodial care, [consider] the level of care and medical supervision required and furnished. [The decision is not based] on diagnosis, type of condition, degree of functional limitation, or rehabilitation potential.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

Medical Policy Manual Behavioral Health, Policy No. 29

Psychiatric Inpatient Hospitalization

Effective: April 1, 2023

Next Review: January 2024
Last Review: February 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Inpatient Psychiatric Hospitalization is a 24-hour acute treatment setting occurring on a locked unit that is licensed as a hospital by the appropriate agency and under the direct supervision of an attending psychiatrist or psychiatric extender.

MEDICAL POLICY CRITERIA

Notes: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. An Inpatient Psychiatric Hospitalization (IP) admission provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

   A. All of the following intensity of service criteria (1. – 11.) are met:

      1. The hospital or inpatient unit is licensed by the appropriate state agency.

      2. There is an expectation that the member's history and physical examination is completed within 24 hours of admission (unless completed within 72 hours prior to admission or if transferred from an acute inpatient level of care).

3. There is an expectation that drug screens and relevant lab tests are completed upon admission and as clinically indicated and are documented in the medical record.
4. The attending provider is a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) who is responsible for diagnostic evaluation within 24 hours of admission. After the initial diagnostic evaluation, there is an expectation that the physician, or physician extender provides and documents medical monitoring and evaluation daily. The attending provider must be available 24 hour a day, 7 days per week.
5. There is an expectation that within 24 hours of admission, following a multidisciplinary assessment that includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, subjects such as identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, potential need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care, and other issues that affect the likelihood of successful community tenure.
6. Treatment programing includes an expectation of at least one individual counseling session per week, or more as clinically indicated, which is documented in the medical record.
7. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
8. Treatment programing is multidisciplinary and includes clinical services provided daily that comprehensively address the needs identified in the member's treatment plan.
9. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
10. On-site registered nursing care is available 24 hours a day, 7 days a week with full capabilities for all appropriate interventions in medical and behavioral health and emergencies that occur on the unit.
11. On-site, licensed clinical staff is available 24 hours a day, 7 days a week adequate to supervise the member's medical and psychological needs.

B. All of the following severity of illness criteria (1. – 2.) are met:

1. All the following (a. – d.) are met:
    a. The member has been given a severe mental health diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.

b. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.

c. The treatment is not primarily for the convenience of the provider or member (e.g., primarily for lack of housing options, respite care, custodial needs or extended discharge planning).

d. Treatment could not be safely provided at a lower level of care or no safe lower level of care is available.

2. One or more of the following must be met:

a. There is significant evidence that member is an imminent risk of harm to self or to others due to one or more of the following reasons:

i. The member has made a recent and serious attempt to substantially harm self or someone else in a way that was intended to be deadly.

ii. The member is verbalizing intent and plan to harm self or someone else in a way that would either be deadly or cause serious bodily harm.

iii. Recent self-injurious behaviors that are substantial enough to require 24-hour observation and safety planning (example: Cutting self substantially enough to require sutures).

iv. Recent violent, impulsive, and/or agitated behavior that cannot safely be controlled outside of 24-hour monitoring and intervention to prevent serious harm to self or others.

b. The member is experiencing severe deterioration in their ability to care for themself due to the severity of their psychiatric condition. Examples of this level of deterioration are:

i. The member is not taking care of basic tasks such as eating, drinking, caring for hygiene or taking prescribed psychiatric medications which contributes to deterioration.

ii. The member is experiencing a recent onset or exacerbation of psychotic symptoms that are resulting in significant deterioration of functioning that can only be safely managed with 24-hour observation and treatment. (Examples include: delusional thinking with limited to no awareness of reality, auditory and/or visual hallucinations, severe paranoia).

c. Member has a comorbid medical condition in addition to active psychiatric symptoms and requires the resources of an inpatient hospital for safe and appropriate treatment.

II. Continued stay in an Inpatient Psychiatric Hospitalization (IP) provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – D.) are met:

A. The individual continues to meet admission criteria (I.A. – B.).

B. There is evidence of active discharge planning.

C. Family participation (see Policy Guidelines):

1. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.
2. For children/adolescents: Family treatment will be provided as part of the treatment plan. If family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within 48 hours of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly or more often if clinically indicated.

D. One or more of the following criteria must be met:

1. The active treatment being provided to the member is demonstrating meaningful improvements in the member's clinical status and appears to be helping the member reach a level of stability that step-down to a lower level of care will be possible.
2. If the active treatment being provided to member does not appear to result in clinical improvements (or the member's condition has deteriorated further), the treatment team is actively re-evaluating the treatment plan and adjusting as needed to produce positive outcomes.
3. Member is experiencing complications arising from medications or other treatments (such as Electroconvulsive Therapy) with such severity that require further stabilization and 24-hour observation.
4. The member has developed new symptoms and/or behaviors that require this intensity of service for safe and effective treatment.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

- o Pre-Authorization Request Form
- o Supporting clinical documentation, including:
  - Initial Psychiatric Evaluation/Intake Assessment
  - Nursing Assessment/ History & Physical (if available)

- Any additional supporting clinical evidence, if available (example: letters from outpatient providers supporting this level of care)

o Preliminary Individualized Treatment Plan

Request for Extension/Concurrent Review:

o Supporting clinical documentation, including:
- Recent psychiatric evaluation
- MD Notes
- Treatment Plan/Progress Reports
- Any other supporting clinical evidence

Medical Policy Manual Behavioral Health, Policy No. 30

Psychiatric Intensive Outpatient

Effective: April 1, 2023

Next Review: January 2024
Last Review: February 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Intensive Outpatient (IOP) is an outpatient program that is licensed as a facility/agency by the appropriate state agency and is provided under the supervision of a psychiatrist or psychiatric extender. Intensive Outpatient (IOP) is intended to provide treatment on an outpatient basis, does not include boarding/housing and is intended to provide treatment interventions in a structured setting, with patients returning to their home environments each day.

MEDICAL POLICY CRITERIA

Note: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. An Intensive Outpatient Program (IOP) admission provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All of the following intensity of service criteria (1. – 11.) are met:

1. If required by state statute, the facility is licensed by the appropriate state agency. If licensure is not required by state, facility is accredited.

2. There is an expectation that drug screens and relevant lab tests are completed upon admission and as clinically indicated and are documented in the clinical record.
3. There is an expectation of evaluation by a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) when clinically necessary. The physician, or physician extender will continue to be available throughout the program as medically indicated for face-to-face evaluations.
4. There is an expectation that within 5 days of admission, following a multidisciplinary assessment which includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
5. Treatment programming includes documentation of at least one individual counseling session per week or more as clinically indicated.
6. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
7. All treatment is supervised by licensed behavioral health practitioners.
8. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
9. There is an expectation that a multidisciplinary treatment program provides a minimum of 9 hours of weekly clinical services for adults or 6 hours for adolescents to comprehensively address the needs identified in the member's treatment plan (see Policy Guidelines).
10. When members are receiving boarding services, during non-program hours the member is allowed the opportunity to:
    a. Function independently; and
    b. Develop and practice new recovery skills in the real world to prepare for community re-integration and sustained, community-based recovery.
11. There is documentation of a safety plan including access for the member and/or family/support system to professional supports outside of program hours.

B. All of the following severity of illness criteria (1. – 8.) are met:

1. The member has been given a severe mental health diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.
2. The member is able to actively participate in and comply with treatment in this level of care.
3. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.
4. Members reporting non-acute safety concerns can develop a safety plan and access crisis intervention so that a more intensive level of care can be avoided.
5. The member's family and/or support system are willing to participate in the treatment process as appropriate.
6. The member is experiencing significant disruption in multiple areas of functioning due to psychiatric condition (e.g. work, school, social relationships, family relationships).
7. Lack of external supports alone is not sufficient for continued treatment at this level of care.
8. Treatment could not be safely provided at a lower level of care or safe lower level of care is not available.

II. Continued stay in an Intensive Outpatient Program (IOP) provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All the following must be met (1. – 5.):

1. Member continues to meet admission criteria (I.A. – B.)
2. The member and family are involved to the best of their ability in the treatment and discharge planning process.
3. Continued stay is intended to provide active treatment and is not primarily to provide a safe and supportive environment.
4. Family participation (see Policy Guidelines):
    a. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.
    b. For children/adolescents: Family treatment will be provided as part of the treatment plan. If Family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within five days of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly or more often if clinically indicated.
5. There is evidence of active discharge planning.

B. One or more of the following must be met:

1. The treatment being provided to the member is demonstrating meaningful improvements in the member's clinical status and appears to be helping the member reach a level of stability that step-down to a lower level of care will be possible.
2. If the active treatment being provided to member does not appear to result in clinical improvements (or the member's condition has deteriorated further), the treatment team is actively re-evaluating the treatment plan and adjusting as needed to produce positive outcomes.
3. The member has developed new symptoms and/or behaviors that require this intensity of service for safe and effective treatment.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

MULTIDISCIPLINARY TREATMENT PROGRAM

The intent of the standard for hours (nine for adults and six for adolescents) of weekly treatment program (groups, activities and psychotherapies) is that they are evidence-based and are explicitly focused on the alleviation of the current condition as opposed to providing general recreation activities, watching videos, etc. and other facility offerings that are not tied back directly to the treatment plan.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

Psychiatric Partial Hospitalization

Effective: April 1, 2023

Next Review: January 2024
Last Review: February 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Partial Hospitalization (PHP) is an outpatient program that is provided under the supervision of an attending psychiatrist or psychiatric extender. Partial Hospitalization (PHP) is intended to provide treatment on an outpatient basis, does not include boarding/housing and is intended to provide treatment interventions in a structured setting, with patients returning to their home environments each day.

MEDICAL POLICY CRITERIA

Note: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. A Partial Hospitalization (PHP) outpatient program admission provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All of the following intensity of service criteria (1. - 11.) are met:

1. If required by state statute, the facility is licensed by the appropriate state agency. If state license is not required, facility is accredited.

2. There is an expectation that drug screens and relevant lab tests are completed upon admission and as clinically indicated and are documented in the medical record.
3. The attending provider is a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) who is responsible for diagnostic evaluation within 48 hours of admission. After the initial diagnostic evaluation, there is an expectation that the physician, or physician extender provides and documents monitoring and evaluation as indicated, but no less than weekly.
4. There is an expectation that within 5 days of admission, following a multidisciplinary assessment which includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
5. Treatment programming includes an expectation of at least one individual counseling session weekly, or more as clinically indicated, which is documented in the medical record.
6. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
7. All treatment is supervised by licensed behavioral health practitioners.
8. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
9. Treatment programing is multidisciplinary and includes 20 hours of clinical services per week to comprehensively address the needs identified in the member's treatment plan.
10. When a member receives boarding services, during non-program hours the member is supported in and allowed the opportunity to:
    a. Function independently.
    b. Develop and practice new recovery skills in the real world to prepare for community re-integration and sustained, community-based recovery.
11. There is documentation of a safety plan including access for the member and/or family or other support system to professional supports outside of program hours.

B. All of the following severity of illness criteria (1. – 2.) are met:

1. All the following (a. – h.) must be met:
    a. The member has been given a severe mental health diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.
    b. The member is able to actively participate in and comply with treatment at this level of care.
    c. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.
    d. Members reporting non-acute safety concerns can develop a safety plan and access crisis intervention so that a more intensive level of care can be avoided.
    e. The member's family and/or support system are willing to participate in the treatment process and discharge planning as appropriate.
    f. If member has comorbid medical issues, they can be safely managed in a partial hospital level of care.
    g. Lack of external supports alone is not sufficient for continued treatment at this level of care.
    h. Treatment could not be safely provided at a lower level of care or no safe lower level of care is available.
2. One or more of the following must be met:
    a. The member is demonstrating significant impairments in functioning due to a psychiatric disorder not requiring 24-hour monitoring, as evidenced by both of the following (i. – ii.):
        i. The patient's symptoms or behavioral manifestations are of such severity that there is significant interference with one or more of the following:
            a.) Family functioning.
            b.) Vocational functioning.
            c.) Educational functioning.
            d.) Other age appropriate social role functions.
        ii. The member is unable to employ the appropriate coping skills outside of a structured setting which puts member at risk of the condition worsening.
    b. The member has recently demonstrated non-lethal self-injurious behavior (example: superficial cutting) or made serious threats of self-harm or harm to others but does not require 24-hour monitoring.
    c. The member's psychiatric condition is interfering with their ability to manage a serious medical condition which, left unmanaged, could be life-threatening.

II. A continued stay in a Partial Hospitalization (PHP) outpatient program provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All the following (1. – 4.) are met:

1. Member continues to meet admission criteria (I.A. - B.).
2. The member continues to demonstrate motivation for change, interest in and ability to actively engage in their behavioral health treatment, as evidenced by active participation in groups, cooperation with treatment plan, working on assignments, actively developing discharge plan and other markers of treatment engagement. If member is not engaged, there are documented interventions by the treatment team to address.
3. Family participation (see Policy Guidelines):
    a. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.
    b. For children/adolescents: Family treatment will be provided as part of the treatment plan. If Family treatment is not rendered, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within five days of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care. Family sessions will occur at least weekly.
4. There is evidence of active discharge planning.

B. One or more of the following criteria must be met:

1. The treatment being provided to the member is demonstrating meaningful improvements in the member's clinical status and appears to be helping the member reach a level of stability that step-down to a lower level of care will be possible.
2. If the active treatment being provided to member does not appear to result in clinical improvements (or the member's condition has deteriorated further), the treatment team is actively re-evaluating the treatment plan and adjusting as needed to produce positive outcomes.
3. The member has developed new symptoms and/or behaviors that require this intensity of service for safe and effective treatment.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

MULTIDISCIPLINARY TREATMENT PROGRAM

The intent of the standard for 20 hours of weekly treatment program (groups, activities and psychotherapies) is that they are evidence-based and are explicitly focused on the alleviation of the current condition as opposed to providing general recreation activities, watching videos, etc. and other facility offerings that are not tied back directly to the treatment plan.

For children and adolescent programs, accredited schooling comprises a portion of the 20 hours of programming.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

- Pre-Authorization Request Form
- Supporting clinical documentation, including:
  - Initial Psychiatric Evaluation/Intake Assessment
  - Nursing Assessment/ History & Physical (if available)
  - Any additional supporting clinical evidence, if available (example: letters from outpatient providers supporting this level of care)
- Preliminary Individualized Treatment Plan

Continued Stay/Concurrent Review:

Medical Policy Manual Behavioral Health, Policy No. 32

Psychiatric Residential Treatment

Effective: April 1, 2023

Next Review: January 2024
Last Review: February 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Residential treatment (RTC) is a 24-hour sub-acute treatment setting that is licensed as a residential treatment center by the appropriate agency to provide residential treatment and is under 24-hour care with an attending psychiatrist or psychiatric extender available for consultation 24/7.

MEDICAL POLICY CRITERIA

Note: Submission of a behavioral health intake form is required for initial intake, concurrent review, stepdown request to a lower level of care, and discharge confirmation.

I. Admission to a Psychiatric Residential Treatment (RTC) program admission provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – B.) are met:

A. All of the following intensity of service criteria (1. – 11.) are met:

1. The facility is licensed by the appropriate state agency.
2. There is an expectation that the member's history and physical examination is completed within 48 hours of admission (unless completed within 72 hours

prior to admission or if the member is transferred from an acute inpatient level of care).

3. There is an expectation that drug screens and relevant lab tests are completed upon admission and as clinically indicated and are documented in the medical record.
4. The attending provider is a psychiatrist, a licensed psychiatric nurse practitioner, or physician assistant with formal practice agreement with a psychiatrist (when permitted by state laws) who is responsible for diagnostic evaluation within 48 hours of admission. After the initial diagnostic evaluation, there is an expectation that the physician, or physician extender provides and documents monitoring and evaluation at least weekly. The attending provider must be available 24 hours per day, 7 days per week.
5. There is an expectation that within 72 hours of admission, following a multidisciplinary assessment that includes input from recent treating providers, an individualized treatment plan (ITP) is developed and documented in the medical record. The ITP should use evidence-based concepts, where applicable, and be amended as needed for changes in the individual's clinical condition. The ITP should include, but is not limited to, identification of key precipitants to current episode of treatment, assessment of psychosocial supports available after discharge, availability of aftercare services in member's home geographic area, need for supportive living placement to continue recovery, need for services for comorbid medical or substance use conditions, contact with aftercare providers to facilitate an effective transition to lower levels of care and other issues that affect the likelihood of successful community tenure.
6. Treatment programming includes an expectation of at least one individual counseling session per week, or more as clinically indicated, which is documented in the medical record.
7. There is an expectation that evaluations of the member are performed daily by a licensed behavioral health provider and are documented in the medical record.
8. Treatment programing is multidisciplinary and includes clinical services provided daily that comprehensively address the needs identified in the member's treatment plan.
9. Mental health and medical services are available on-site (or off-site by arrangement) 24 hours per day, 7 days per week.
10. On-site nursing (e.g., LPNs) is available a minimum of 8 hours a day, 5 days a week. RNs are available 24 hours a day and respond to significant clinical events within one hour.
11. On-site, licensed clinical staff is available 24 hours a day, 7 days a week adequate to supervise the member's medical and psychological needs.

B. All of the following criteria (1. – 7.) are met:

1. The member has been given a severe mental health diagnosis according to the most recent DSM criteria which will be the primary focus of daily active treatment.
2. The member is able to function independently and actively participate in group and individual therapy.
3. There is reasonable expectation that treatment at this level of care will meaningfully impact the presenting symptoms/behaviors leading to the admission.
4. The treatment is not primarily for the convenience of the provider or member (e.g. primarily for lack of housing options, respite care or custodial needs).
5. The member has significant functional impairment in more than one area that requires 24-hour monitoring and intervention: Home, School/Work, Health/Medical, maintaining safe behaviors towards self or others.
6. Treatment could not be effectively provided at a lower level of care (supported by clinical documentation) OR The member's home environment is not conducive to treatment/recovery, such that treatment at a lower level of care is unlikely to be successful OR no safe lower level of care is available.
7. The family members and/or support system are committed to change through participation in the treatment process as appropriate.

II. Continued stay in a Psychiatric Residential Treatment (RTC) program provided under the supervision of an attending psychiatrist or psychiatric extender may be indicated when all of the following (A. – F.) are met:

A. Member continues to meet admission criteria (I.A. – B.)

B. There is reasonable expectation that continued treatment provided at this level of care will produce improvement that is sustainable after discharge.

C. The individual and family are involved to the best of their ability in the treatment and discharge planning process.

D. The member continues to demonstrate motivation for change, interest in and ability to actively engage in their behavioral health treatment, as evidenced by active participation in groups, cooperation with treatment plan, working on assignments actively developing discharge plan and other markers of treatment engagement. If member is not engaged, there are documented interventions by the treatment team to address.

E. Family participation (see Policy Guidelines):

1. For Adults: Family treatment is encouraged when clinically appropriate. Family treatment is available to be provided at an appropriate frequency when clinically warranted.
2. For children/adolescents: Family treatment is being provided at least weekly or more often if clinically indicated. If Family treatment is not provided, the facility/provider specifically lists the contraindications to Family Therapy. The family/support system assessment will be completed within 72 hours of admission with the expectation that family is involved in treatment decisions and discharge planning throughout the course of care.

F. There is evidence of active discharge planning.

POLICY GUIDELINES

FAMILY PARTICIPATION

Family participation may be conducted via telephonic sessions when there is a significant geographic or other limitation.

Custodial Care

The following definition of custodial care by the Centers for Medicare & Medicaid Services (CMS) is applicable in support of the policy criteria:[1]

> Custodial care serves to assist an individual in the activities of daily living, such as assistance in walking, getting in and out of bed, bathing, dressing, feeding, and using the toilet, preparation of special diets, and supervision of medication that usually can be self-administered. Custodial care essentially is personal care that does not require the continuing attention of trained medical or paramedical personnel. In determining whether a person is receiving custodial care, [consider] the level of care and medical supervision required and furnished. [The decision is not based] on diagnosis, type of condition, degree of functional limitation, or rehabilitation potential.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Initial Request:

- Prior Authorization Form
- Initial Psychiatric Evaluation/Intake Assessment
- Other supporting clinical documentation, such as:
  - Nursing Assessment/ History & Physical (if available)
  - Any additional supporting clinical evidence, if available (example: letters from outpatient providers supporting this level of care)
- Preliminary Individualized Treatment Plan

Continued Stay/Concurrent Review:

- Supporting clinical documentation, including:
  - Recent psychiatric evaluation
  - MD Notes
  - Treatment Plan/Progress Reports
  - Any other supporting clinical evidence

Pre-authorization Request Form
Behavioral Health
Fax: 1 (888) 496-1540
Mail to: PO Box 1271, WW5-53
Portland, OR 97207-1271

Instructions: This form should be completed and filled out by the requesting provider. Prior to completing this form, please confirm the patient's benefits, eligibility and whether pre-authorization is required.

Is this for a Medicare Preservice Benefit Organization Determination Request? ☐ Yes ☐ No

Expedited request. I attest that this request meets the definition indicated below by checking the expedited request box. ☐ Fax to 1 (855) 240-6498.

Expedited is defined as: When the member or his/her provider believes that waiting for a decision within the standard timeframe could place the member's life, health or ability to regain maximum function in serious jeopardy.

SECTION 1 – PATIENT INFORMATION

SECTION 4 – DOCUMENTATION SUBMISSION

Please submit the following documentation, as appropriate for this request:

Psychiatric or substance use disorder evaluation or intake assessment including:

- Family history
- Medical, psychiatric and substance use history
- Mental status exam
- Personal and social history (psychosocial)
- History of current complaint/clinical status
- Member's current complaint/clinical status

History and physical/nursing assessment (if available) including:

- Current vitals
- Current medical concerns/risks

Substance use disorders only:

- Clinical Institute Withdrawal Assessment (CIWA) or
- Clinical Opiate Withdrawal Scale (COWS) score or
- Description of active withdrawal symptoms

Any other supporting documents you would like considered, such as letters from outpatient providers, etc.

SAMPLE COVER LETTER

CHILD was formally evaluated on DATE at SITE OF EXAM by PROVIDER. CHILD demonstrated impairments in social interaction, social communication and atypical behavior consistent with an Autism Spectrum Disorder. CHILD's behaviors and/or impairments are having an adverse impact on development and/or communication as documented on DATE by the presence of severe behaviors and/or functional impairments that interfere with CHILD's ability to participate adequately in their home, school or community environments and/or the health and safety of CHILD or others are at significant safety risk. Please see the attached report/COE report/treatment plan and DSM-IV-TR checklist for details.

Applied behavioral analysis services are recommended given the adverse impact of CHILD's behaviors and/or core impairments. CHOOSE HERE [Less intensive behavioral treatment or other therapy has been tried and not been successful, or it is not accessible, or there is no equally effective alternative available for reducing severe interfering or disruptive behaviors, increasing pro-social behaviors, or achieving desired behaviors]; and Applied Behavioral analysis services are reasonably expected to result in a measureable improvement in CHILD's skills and behaviors.

Effective November 21, 2016

Uniform Medical Plan ABA Therapy Clinical Considerations

ABA Therapy hours of service should reflect the number of and type of behavioral targets and key functional skills to be addressed and include a clinical summary justifying the hours requested for each behavioral target. The total hours of ABA Therapy requested should be comprised of fewer than 40 hours per week.

Any requests for greater than 40 hours per week should show documentation as to why more than 40 hours of therapy is medically necessary.

ABA therapy documentation should show the following:

- The client‘s response to ABA therapy services and progress being made
- Meaningful, measurable, and functional improvement, changes, or progress
    - Meaningful changes should be demonstrated by:
        - Data confirming the changes or progress
        - Documentation in charts and graphs
        - Durability over time beyond the end of the actual treatment session
        - Generalizable outside the treatment setting to the client’s residence or the community within which the client resides
- Compliance with treatment plan, including keeping appointments, attending and participating in treatment and family training sessions, completion of homework assignments, and family application of training techniques as directed by the therapy assistant or LBAT.

Regence

Medical Policy Manual Allied Health, Policy No. 32

Biofeedback

Effective: February 1, 2024

Next Review: August 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Biofeedback is intended to increase awareness and control of certain body functions normally considered to be outside conscious control.

MEDICAL POLICY CRITERIA

Note: This policy does not cover biofeedback devices for post-traumatic stress disorder or panic attacks.

I. Biofeedback as part of the overall treatment plan may be **medically necessary** for one or more of the following indications:

   A. Migraine or tension headaches

   B. Stress and/or urge urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT)

   C. Dyssynergia-type constipation in adults when all of the following criteria (1.-3.) are met:

      1. Symptoms of functional constipation that meet <u>all</u> of the following ROME IV criteria (see Policy Guidelines)

2. Objective physiologic evidence of pelvic floor dyssynergia when one or both of the following criteria are met:
    a. Inappropriate contraction of the pelvic floor muscles
    b. Less than 20% relaxation of basal resting sphincter pressure by manometry, imaging, or EMG
3. Failed 3-month trial of standard treatments for constipation including laxatives, dietary changes, and pelvic floor exercises

II. Unsupervised biofeedback in the home setting is considered **investigational** for all indications.

III. Biofeedback is considered **investigational** for all other indications, including but not limited to the following: chronic pain, fecal incontinence, encopresis, and constipation other than dyssynergia type in adults, fibromyalgia, headaches other than migraine and tension (e.g., cluster headaches), myalgia or muscle pain, neck pain, orofacial pain, shoulder pain, temporomandibular joint disorders, and urinary disorders not meeting criteria, including but not limited to: post- prostatectomy urinary dysfunction, urinary incontinence not administered in conjunction with pelvic floor muscle training (PFMT), urinary retention, vesicoureteral reflux and voiding dysfunction.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Rome IV diagnostic criteria for functional constipation are as follows:[1]

1. Must include 2 or more of the following:
    a. Straining during more than one-fourth (25%) of defecations
    b. Lumpy or hard stools (Bristol Stool Form Scale1-2) for more than one-fourth (25%) of defecations
    c. Sensation of incomplete evacuation for more than one-fourth (25%) of defecations
    d. Sensation of anorectal obstruction/blockage for more than one-fourth (25%) of defecations
    e. Manual maneuvers to facilitate more than one-fourth (25%) of defecations (e.g., digital evacuation, support of the pelvic floor)
    f. Fewer than 3 spontaneous bowel movements per week
2. Loose stools are rarely present without the use of laxatives
3. Insufficient criteria for irritable bowel syndrome.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical documenting symptoms and treatment specific to policy criteria
- If for constipation, three months of chart note documentation. Indicate if symptom onset is at least six months prior to diagnosis (please include dates).

- Clinical documentation with physiologic evidence of pelvic floor dyssynergia

BACKGROUND

Biofeedback is a technique intended to teach patients self-regulation of certain physiologic processes not normally considered to be under voluntary control. The technique involves the feedback of a variety of types of information not normally available to the patient, followed by a concerted effort on the part of the patient to use this feedback to help alter the physiological process in some specific way. Biofeedback training is done either in individual or group sessions, alone, or in combination with other behavioral therapies designed to teach relaxation. A typical program consists of 10 to 20 training sessions of 30 minutes each. Training sessions are performed in a quiet, non-arousing environment. Subjects are instructed to use mental techniques to affect the physiologic variable monitored, and feedback is provided for successful alteration of that physiologic parameter. The feedback may be in the form of lights or tone, verbal praise, or other auditory or visual stimuli.

REGULATORY STATUS

A variety of biofeedback devices are cleared for marketing though the Food and Drug Administration's (FDA) 510(k) process. The FDA defines a biofeedback device as "an instrument that provides a visual or auditory signal corresponding to the status of one or more of a patient's physiological parameters (e.g., brain alpha wave activity, muscle activity, skin temperature, etc.) so that the patient can control voluntarily these physiological parameters."

EVIDENCE SUMMARY

There are several methodologic challenges that arise in assessing biofeedback for any indication. For example, most interventions that include biofeedback are multimodal and include relaxation and behavioral instruction which may have effects separate from those that may occur due to biofeedback. While studies may report a beneficial effect of multimodality treatment, without appropriate control conditions, it is difficult to isolate the specific contribution of biofeedback to the overall treatment effect. In addition, behavioral therapies (non-drug treatments including biofeedback) result in both nonspecific and specific therapeutic effects. Nonspecific effects, sometimes called the placebo effect, occur as a result of therapist contact, positive expectancies on the part of the patient and therapist, and other beneficial effects that occur as a result of being a patient in a therapeutic environment. Specific effects are those that occur only because of the active treatment, above any nonspecific effects that may be present.

In order to isolate the independent contribution of biofeedback on health outcomes (specific effects) and properly control for nonspecific treatment effects, well-designed randomized controlled trials (RCT) with the following attributes are necessary:

- Randomization helps to achieve equal distribution of individual differences by randomly assigning patients to either biofeedback or sham-biofeedback treatment groups. This promotes the equal distribution of patient characteristics across the two study groups.

Consequently, any observed differences in the outcome may, with reasonable assuredness, be attributed to the treatment under investigation.

- A comparable sham control group helps control for expected high placebo effects as well as for the variable natural history of the condition being treated.
- Blinding of study participants, caregivers, and investigators to active or sham assignments helps control for bias for or against the treatment. Blinding assures that placebo effects do not get interpreted as true treatment effects.
- Small studies limit the ability to rule out chance as an explanation of study findings.
- Follow-up periods must be long enough to determine the durability of any treatment effects.

Therefore, the focus of the evidence review for biofeedback for all indications is on RCTs with the attributes noted above.

ASTHMA

SYSTEMATIC REVIEWS

Yorke (2015) published a SR of studies evaluating nonpharmacologic interventions for the treatment of adults with asthma.[2] The literature search, conducted through May 2014, identified 23 studies for inclusion. The nonpharmacologic interventions were organized into groups: relaxation-based therapies (n=9 studies); cognitive behavioral therapies (n=5 studies); biofeedback techniques (n=3 studies); and mindfulness (n=1 study). Five studies incorporated multicomponent interventions. The three biofeedback RCTs used different techniques: exhaled carbon dioxide capnography (pooled n=12)[3]; HRV using a physiograph (pooled n=94 patients)[4]; and respiratory sinus arrhythmia by electrocardiographic feedback and muscle tension by electromyography (EMG; pooled n=17 patients).[5] Common outcomes in the 3 studies included peak expiratory flow and respiratory impedance. Two of the trials reported on medication use. While differences were detected in exhaled carbon dioxide, HRV, and muscle tension, no changes in forced expiratory volume in one second (FEV_1) were found and medication use decreased in only one trial. Reviewers concluded that larger sample sizes were needed to demonstrate effects and that, while certain parameters that patients received biofeedback on may have differed between treatment groups, those differences did not translate into meaningful clinical benefits.

RANDOMIZED CONTROLLED TRIALS

Lehrer (2004)[4] reported the results of a study in which 94 asthma patients were randomized to one of the following four groups: “Full protocol” including heart rate variability (HRV) biofeedback and training in pursed-lips abdominal breathing with prolonged exhalation; HRV biofeedback alone; Placebo biofeedback involving bogus “subliminal suggestions designed to help asthma”, with no other details provided and no actual suggestions given plus biofeedback training to alternately increase and decrease frontal EEG alpha rhythms; and waiting list control group. Although reported improvement was greater in the two treatment groups, scientific conclusions cannot be drawn from this data due to several limitations, including possible selection bias due to lack of randomization, short study duration, lack of follow-up to assess long-term effects, and differences between groups in task involvement and assessment

frequency. The authors concluded that further research is needed. They advise caution in the use biofeedback for the treatment of asthma until the mechanisms of action are better understood and the long-term effects have been documented.

SECTION SUMMARY

There is insufficient evidence from SRs and RCTs that biofeedback improves outcomes in individuals with asthma. Additional evidence is needed from well-designed comparative studies.

AUTISM SPECTRUM DISORDER

Autism Spectrum Disorders (ASD) can vary in severity of disease and therefore treatments utilized to treat the disease, making it difficult to isolate outcomes associated with biofeedback. The following literature review for biofeedback as a treatment of ASD focuses on SRs and RCTs.

SYSTEMATIC REVIEW

Coben and Myers (2010) reviewed the literature on EEG biofeedback for ASDs.[6] The authors identified two published small, non-RCTs evaluating EEG biofeedback in the treatment of ASDs. As described in the review, a study published by Jarusiewicz and colleagues in 2002 compared treatment with 20 to 69 sessions of biofeedback in 12 autistic children to a matched control group that did not receive biofeedback. Mean reduction in autistic symptoms, as measured by the Autism Treatment Evaluation Checklist (ATEC), was 26% in the biofeedback group and 3% in the comparison group; this difference was statistically significant. The other study was published by Coben and Padolsky in 2007. It compared 20 sessions of EEG biofeedback in 37 patients to a waiting-list control group. After treatment, parents reported reduction in symptoms in 89% of the treatment group compared to 17% of the control group (p-value not reported). Studies differed in their biofeedback protocols and number of sessions. The review article concluded that RCTs are needed to determine the effectiveness of biofeedback to treat ASDs.

RANDOMIZED CONTROLLED TRIALS

Yang (2015) conducted a RCT to explore the effects of visual condition and target size during four reach-to-grasp tasks between 20 autistic and 20 matched control children subjects.[7] The autistic children showed longer movement time, larger normalized jerk score, more movement when compared to controls, especially in non-visual feedback and small target blocks. This study is limited by the small sample size and other methodological considerations making it hard to determine the efficacy of visual effects for autism.

Kouijzer (2013) published a RCT evaluating electroencephalography (EEG) biofeedback as a treatment for ASD.[8] The trial included 35 teenagers between 12 and 18 years-old with confirmed diagnoses of ASD. Participants were randomly assigned to receive EEG biofeedback (n=13), skin conductance biofeedback (n=12), or a waiting-list control group (n=13). The biofeedback interventions included 40 sessions provided twice a week. Patients and parents in the biofeedback groups but not on the waiting-list were blinded to treatment allocation. The primary outcome measure was change in symptoms at three months as measured by the total score on the Social Communication Questionnaire (SCQ) which has a potential range of 0 to 36. In the primary analysis, the investigators only included participants

who successfully influenced their EEG activity (called “EEG-regulators”) in the primary analysis. The justification for this was to be able to identify the specific effects of biofeedback on symptoms. Among the 19 of 35 (54%) regulators, there was no statistically significant difference in the SCQ scores between participants treated with EEG- or skin-conductance biofeedback. The investigators evaluated non-specific effects of EEG biofeedback by examining the SCQ scores among EEG-non-regulators as rated by the parents. There was no statistically significant difference in scores among participants in the EEG biofeedback group, the skin conductance biofeedback group and the control group.

SECTION SUMMARY

There is insufficient evidence from SRs and RCTs that biofeedback improves outcomes in individuals with ASDs. The scientific evidence on the effectiveness of biofeedback for treatment of autism consists of one small RCT and a limited number of small, non-randomized studies. The RCT did not report a significant benefit of biofeedback on autism-related symptoms.

BELL’S PALSY (IDIOPATHIC FACIAL PARALYSIS)

SYSTEMATIC REVIEWS

A 2011 Cochrane SR of physical therapy modalities for the treatment of Bell’s palsy.[9] The authors identified two case series and one small RCT. However, no analysis of these studies was performed because they did not meet the minimum methodological quality to be included in the review.

Cardoso (2008) examined the effects of facial exercises associated either with mirror or EMG biofeedback with respect to complications of delayed recovery in Bell's palsy.[10] Patients with unilateral idiopathic facial palsy treated with facial exercises associated with mirror and/or EMG biofeedback were included in this review. Four studies (n=132) met the eligibility criteria. The studies described mime therapy versus control (n=50), mirror biofeedback exercise versus control (n=27), "small" mirror movements versus conventional neuromuscular retraining (n=10), and EMG biofeedback plus mirror training versus mirror training alone. The treatment length varied from one to twelve months. The authors concluded that “…because of the small number of RCTs, it was not possible to analyze if the exercises, associated either with mirror or EMG biofeedback, were effective. In summary, the available evidence from ran RCTs is not yet strong enough to become integrated into clinical practice.”

RANDOMIZED CONTROLLED TRIALS

No RCTs identified after the above SRs.

SECTION SUMMARY

Current evidence from small RCTs with variable biofeedback protocols and type of comparison interventions is insufficient to permit conclusions on the impact of biofeedback on Bell’s palsy.

BRUXISM AND SLEEP BRUXISM

SYSTEMATIC REVIEWS

Manfredini (2015) published a SR which included 14 studies, 12 of the studies were RCTs.[11] Two of the studies evaluated bruxism. The authors concluded that the potential benefit of biofeedback (BF) and cognitive-behavioral (CB) approaches to sleep bruxism management is not fully supported.

Wang (2013) published a SR of RCT and non-RCTs on biofeedback treatment for sleep bruxism.[12] The full text of 17 articles was reviewed and seven studies with a total of 240 participants met the inclusion criteria. Studies were generally small; onlytwo included more than 50 participants. Four studies used audio biofeedback, two used contingent electrical stimulation and 1 used visual biofeedback. Treatment duration ranged from one night to six weeks. In four of the studies, the duration of treatment was two weeks. Three of the studies were considered to be at moderate risk of bias and the other four were considered to be at high-risk of bias. The primary outcome of the analysis was the number of sleep bruxism episodes per hour detected by EMG recording. Only two studies (total n=27) reported this outcome and had data suitable for meta-analysis. A pooled analysis did not find a statistically significant difference between the biofeedback and control groups; mean difference: -4.47 (95% CI: -12.33 to 3.38). Findings were not pooled for any other outcomes.

RANDOMIZED CONTROLLED TRIALS

Sato (2015) published a RCT limited in size on the use of EMG biofeedback training for daytime clenching and its effect on sleep bruxism.[13] Patients were monitored for five hours of daytime and night time and were randomized to EMG biofeedback (n=7) or to a control group (n=5). Patients in the biofeedback group received a small auditory signal in the daytime when clenching activity was detected. There were significant decreases in EMG events during weeks two and three in the biofeedback group during the daytime, and the decreases in events carried over into the night time. There were no decreases in EMG events in the control group.

SECTION SUMMARY

There is insufficient evidence from SRs and RCTs that biofeedback improves outcomes in individuals with bruxism. Additional evidence is needed from well-designed comparative studies.

CHRONIC PAIN (NON-HEADACHE)

As discussed in the Background section above, the focus of the evidence review was on RCTs. This study design is particularly important when studying treatments for pain. The most clinically relevant outcomes of therapy for pain are improvement in symptoms, function, and quality of life. These outcomes are subjective and can be influenced by nonspecific effects such as placebo response and the natural history of the disease. Randomized treatment allocation and the inclusion of a control group are needed to isolate the effect of biofeedback therapy.

GENERAL NON-HEADACHE PAIN

Systematic Reviews

A Cochrane SR by Williams on psychological therapies (cognitive-behavioral therapy [CBT] and behavioral therapy, including biofeedback) for chronic non-headache pain in adults was updated in 2012.[14] Forty-two trials provided analyzable data, thirteen of which had not been included in previous updates of this review. The SR found that although the quality of trial

design had improved over time, the quality of treatments, reporting, or both had not improved. CBT (not behavioral therapy) had weak effects in improving pain, but only immediately following treatment. CBT also had small effects on pain-related disability, altering mood, and catastrophizing outcomes compared with usual treatment or waiting list patients, with some maintenance at six months follow-up. However, it was not possible to isolate the results for the individual components of CBT, including biofeedback. Behavioral therapy had no effect on mood but showed an effect on catastrophizing immediately post-treatment. The authors recommended against future general RCTs, recommending instead, studies to identify which components of CBT work for which type of patient.

Another Cochrane SR review by Eccleston and colleagues evaluated psychological therapies for the management of chronic and recurrent pain in children and adolescents. Included studies were RCTs with at least 10 participants in each arm. Although psychological therapies were found to improve pain, only one of the five studies on non-headache pain evaluated biofeedback.

Polermo conducted an SR of RCTs to update previously published SRs on psychological therapies for management of chronic non-headache pain in children and adolescents was published by Palermo and colleagues in 2010.[15] RCTs included in previous SRs were automatically eligible for inclusion in this SR. The review did not identify any new RCTs that had not been included in previous SRs. It was not possible to isolate the results of the individual components of the psychological therapies, including biofeedback.

Randomized Controlled Trials

No RCTs were identified that were published after the above SRs.

ARTHRITIS

Systematic Reviews

Richards (2017) published a SR evaluating the application of real-time biofeedback to reduce knee adduction movement (KAM) during gait training, for patients with knee osteoarthritis (KOA).[16] Twelve studies met the inclusion criteria. The authors concluded there are limited controlled studies, but found value for further research in the outcomes of biofeedback to reduce KAM.

In a SR with meta-analysis of psychological interventions for rheumatoid arthritis including relaxation, biofeedback, and cognitive-behavioral therapy, Astin and colleagues concluded that psychological interventions may be important adjunctive therapies in rheumatoid arthritis treatment.[17] In the 25 studies analyzed, significant pooled effect sizes were found for pain after an intervention. However, the same effect was not seen long term, and the meta-analysis did not isolate biofeedback from other psychological interventions. Therefore, the specific effects of biofeedback, as discussed in the Background section above, could not be isolated.

Randomized Controlled Trials

Eid (2016) published a RCT that evaluated the outcomes of electromyographic (EMG) biofeedback training on pain, quadriceps strength and functional ability for 11 boys and 25 girls with polyarticular juvenile rheumatoid arthritis (JRA).[18] Children were assigned to the EMG biofeedback group (n=18) or the control group (n=18). Treatments occurred over 12 weeks,

with evaluation at six and 12 weeks. Both groups showed significant improvement at 12 weeks.

FIBROMYALGIA

Systematic Reviews

In 2015 a Cochrane SR was published by Theodom examining mind and body therapy for fibromyalgia. Sixty-one trails were included in the review.[19] The study participants were predominately women and their nature of fibromyalgia varied from mild to severe across the study population. No adverse events were reported. The authors found there was very low quality evidence that biofeedback in comparison to usual care controls had an effect on physical functioning, (SMD -0.1,95% CI-0.4 to 0.3, - 1.2% absolute change, 1 oint shift on a 0-100 scale) pain(SMD -2.6, 95% CI -91.3 to 86.1, -2.6% absolute change, and mood ((SMD 0.1, 95% CI -0.3 to 0.5, 1.9% absolute change, less than 1 point shift on a 0 to 90 scale) post-intervention. Due to the very low-quality evidence, it is unclear what role biofeedback has fibromyalgia.

In 2013 Glombiewski published the results of a meta-analysis that included three studies on EEG-biofeedback (neurofeedback) and four studies on EMG-biofeedback for fibromyalgia (N=321).[20] Studies in which biofeedback was evaluated only as part of multicomponent interventions were excluded from the review. A sham intervention was used as a control condition in four studies, two using EEG biofeedback and two using EMG- biofeedback. A pooled analysis was conducted for each therapy. EMG-biofeedback was reported to have significantly reduced pain intensity compared to control groups (effect size, Hedges *g*: 0.86, 95% CI, 0.11 to 0.62). Pooled analyses of studies of EMG and EEG biofeedback did not find a significant benefit of the intervention on other outcomes including sleep problems, depression and health-related quality of life. None of the studies included in this review were high quality, with risk of bias assigned by the authors as either unclear or high for all included studies. In addition, all of the studies reported on short-term outcomes, resulting in a lack of evidence on whether longer-term outcomes are improved. The authors recommended further research focused on long-term effects and predictors of treatment response.

Randomized Controlled Trials

No RCTs identified after the SR above.

KNEE PAIN

Systematic Reviews

A number of SRs have been published that included trials of biofeedback in the treatment of anterior knee pain[21], patellofemoral pain syndrome,[22] and in post-meniscal repair rehabilitation.[22] Mixed results have been reported by the SRs, but no standardized treatment protocols or patient selection criteria have been established for biofeedback for knee pain of any etiology.

Randomized Controlled Trials

No RCTs were published after the above SR.

LOW BACK PAIN

Systematic Review

Sielski (2017) published a SR evaluating the impact of biofeedback for chronic back pain.[23] Twenty-one studies met all inclusion criteria, one of which had to be biofeedback at least 25% of the time. Outcomes were determined for pain, disability, depression, reduced muscle tension, and coping skills. The authors concluded that although the outcomes of biofeedback are promising, the SR had limitations including heterogeneity of how biofeedback and back pain were defined and the positive results should be interpreted with caution.

Qaseem (2017) published a guideline from the American College of Physicians (ACP) that by using the ACP was based on a SR of RCTs and SRs published through April 2015.[24] For patients with acute or sub-acute low back pain, biofeedback was not mentioned. For patients with chronic low back pain the recommendation was to initially try nonpharmacological treatments including biofeedback based on “low quality evidence”. For patients with chronic low back pain who have not responded to nonpharmacological treatments, pharmacological treatment may be considered.

Haines (2017) published an economic evaluation that was done alongside a pilot randomized trial that evaluated motion-sensor biofeedback for sub-acute and chronic low back pain over 12 months.[25] Patients received motion-sensor biofeedback with guideline based care (n=38) or guideline based care alone (n=45) over ten weeks and completed a three, six, and 12 month assessment. The authors concluded that motion-sensor biofeedback is both clinically and economically effective, but more studies are needed.

Daffada (2015) conducted a SR to identify and assess the current evidence regarding the effectiveness of interventions (i.e. graded motor imagery and mirror visual feedback) which target cortical remapping in the management of chronic low back pain (CLBP).[26] Five articles were included in the review, which were comprised of three RCTs, one randomized cross-over study, and one multiple case study design. Although the authors report these interventions, including visual feedback, could be effective, the paucity of literature, small sample sizes, and methodological constraints of the studies included in the review make it difficult to determine the effectiveness of the interventions in the management of CLBP.

A 2010 Cochrane review[27] on behavioral treatments for chronic low-back pain included a meta-analysis of three small RCTs[28-31] comparing electromyography (EMG) biofeedback to a waiting-list control group. These studies were graded as low to very low quality due to methodological limitations and imprecision. In the pooled analysis there were a total of 34 patients in the intervention group and 30 patients in the control group. The standard mean difference in short-term pain was -0.80 (95% confidence interval [CI]:-1.32 to -0.28); this difference was statistically significant favoring the biofeedback group. One additional RCT was not included in the pooled analysis due to differences in reporting.[28] This small RCT (N=44) was determined to have a low risk of bias and reported no significant differences in outcomes between groups. The Cochrane review did not conduct meta-analyses of trials comparing biofeedback to sham biofeedback.

Randomized Controlled Trials

Kent (2023) compared the effectiveness and economic efficiency of Cognitive Functional Therapy (CFT), delivered with or without movement sensor biofeedback, with usual care for patients with chronic, disabling low back pain in a three-arm, unblinded, RCT as part of the (RESTORE) trial.[32] Participants (N=492) were randomly assigned (1:1:1) via a centralized

adaptive schedule to usual care (N=165), CFT only (N=164), or CFT plus biofeedback (N=165). Both interventions were more effective than usual care (CFT only mean difference -4·6 [95% CI -5·9 to -3·4] and CFT plus biofeedback mean difference -4·6 [-5·8 to -3·3]) for activity limitation at 13 weeks (primary endpoint). Effect sizes were similar at 52 weeks.

Tan (2015) conducted a four arm RCT of hypnosis compared with biofeedback for 100 veterans adults with chronic low back pain (CLBP).[33] Group one included an eight-session self-hypnosis training intervention without audio recordings for home practice; group two consisted of an eight-session self-hypnosis training intervention with recordings; group three had a two-session self-hypnosis training intervention with recordings and brief weekly reminder telephone calls; and group four had an eight-session active biofeedback control intervention. All four groups reported significant pre-to post-treatment improvements in pain intensity, pain interference, and sleep quality. This study was limited by the small sample size and other methodological constraints making it hard to determine the efficacy of biofeedback for adults with CLBP.

In a 2010 study published after the above Cochrane SR, Kapitza compared the efficacy of respiratory biofeedback to sham biofeedback in 42 patients with lower back pain.[34] All participants were instructed to perform daily breathing exercises with a portable respiratory feedback machine; exercises were performed for 30 minutes on 15 consecutive days. Patients were randomized to an intervention group that received visual and auditory feedback of their breathing exercises or a control group that received a proxy signal imitating breathing biofeedback. Patients recorded pain levels in a diary three times a day, measuring pain on a visual analogue scale (VAS). Both groups showed reduction in pain levels at the end of the intervention period and at the three month follow-up, but there were no significant differences in pain between groups. For example, the mean change in pain with activity three months after the intervention was a reduction in 1.12 points on a 10-point VAS scale in the intervention group and 0.96 points in the sham control group; $p>0.05$. The mean change in pain at rest after three months was a reduction of 0.79 points in the intervention group and 0.49 points in the control group; $p>0.05$.

Another 2010 RCT, by Glombiewski, assessed whether the addition of EMG biofeedback to CBT improved outcomes in 128 patients with lower back pain.[35] Patients with musculoskeletal pain of the low, mid, or upper back, with pain duration of at least six months on most days of the week, were randomized to CBT, CBT plus biofeedback, or a waiting-list control; 116 patients began the 1-hour weekly sessions (17-25 treatments) and were included in the final analysis. CBT alone included breathing exercises and progressive muscle relaxation; biofeedback was used for 40% of the CBT treatment time in the combined treatment condition. Both treatments were found to improve outcomes including pain intensity compared to a waiting-list control (moderate effect size of 0.66 for pain intensity in the CBT plus biofeedback group). However, the addition of biofeedback did not improve outcomes over CBT alone.

NECK AND SHOULDER PAIN

Systematic Reviews

Campo (2021) published a systematic review and meta-analysis that evaluated the effectiveness of biofeedback for improving pain, disability, and work ability in adults with neck pain.[36] The review included 15 RCTs with eight studies utilizing EMG biofeedback and seven studies pressure biofeedback. There was no restriction on the control intervention (eg, no treatment, placebo, active treatment) or co-intervention, provided the independent effects of

biofeedback could be elucidated. Results suggest that biofeedback has a moderate effect on reducing short-term disability and a small effect on reducing intermediate-term disability with no effect on pain or work ability in the short- and intermediate-term. Of note, there were a variety of control interventions across included studies (eg, exercise, electroacupuncture, electrotherapy, education) with few studies directly comparing biofeedback to no treatment or placebo.

Kamonseki (2021) completed a systematic review and meta-analysis of 5 RCTs (N=272) that examined the effects of EMG biofeedback for shoulder pain and function.[37] Very-low quality of evidence found that electromyographic biofeedback was not superior to control for reducing shoulder pain (standardized mean differences = -0.21, 95% confidence interval: -0.67 to 0.24, p=0.36) or shoulder function (standardized mean differences = -0.11, 95% confidence interval: -0.41 to 0.19, p=0.48). The authors state the very low quality of evidence does not permit a definitive recommendation regarding EMG biofeedback in the treatment of shoulder pain.

Shearer (2016) published a SR evaluating the impact of psychological interventions, one of which was biofeedback for neck pain and associated disorders (NAD) and whiplash disorders.[38] The SR included RCTs, cohort and case control studies. No clear positive effects were seen for biofeedback and the authors noted more sound methodological research is needed.

Hesselstrand (2015) published a SR of 19 studies called Occupational Therapy Interventions in Chronic Pain-A SR.[39] One RCT addressed surface EMG biofeedback training for persons with neck and shoulder complaints after whiplash-associated disorders, concerning activities of daily living and pain. The SR concluded that no support exists for the effectiveness of electromyographic biofeedback training as a supplement and that more studies are needed to confirm this result.

Randomized Controlled Trial

de Oliveira (2022) conducted an RCT in 24 patients with subacromial pain syndrome who received exercise or exercise plus EMG biofeedback for 8 weeks.[40] The primary outcomes were pain and shoulder function. At 8 weeks, pain was better in the exercise-only group (mean numeric pain rating, 0.5 vs 2 with exercise plus biofeedback; p=.01); however, this outcome was not different between groups at other time points. The only other significant finding was forward rotation of the scapula, which was better in the biofeedback group at 12 weeks (p=.006). All other outcomes were similar between groups.

Ma (2011) published an RCT that included 72 patients with chronic (at least three months) computer work-related neck and shoulder pain.[41] Patients were randomized to one of four six-week interventions: Biofeedback, exercise, passive treatment (e.g., hot packs), or a control group receiving only an educational pamphlet. Members of the biofeedback group were given a portable EMG biofeedback machine and were instructed to use it for two hours daily while performing computer work. The active exercise group was given an exercise routine to perform on their own for no longer than 20 minutes, four times a day. Sixty of 72 (83%) participants were available for the post-intervention follow-up assessment (n=15 per group). At the end of the intervention, the average VAS score and neck disability index (NDI) scores were significantly lower in the biofeedback group than in the other three groups. For example, the mean VAS post-intervention was 1.87 (standard deviation [SD]: 0.74) in the biofeedback group and 2.10 (SD: 1.34) in the active exercise group (p< 0.05).

This study found a short-term benefit of a biofeedback intervention, but the magnitude of difference in the VAS scores and the NDI index was small and of uncertain clinical significance. In addition, there were several methodologic limitations. The study was of small size and had a substantial number of dropouts; data were available on only 39 of 72 (54%) participants at six months. The interventions were not balanced in intensity, as the biofeedback intervention was more intensive (two hours per day) than the other interventions, such as the passive treatment arm, which received two 15-minute sessions per week. Long-term data were not available due to the low follow-up rate, which at six months was too small for meaningful analysis.

OROFACIAL PAIN (INCLUDING TEMPOROMANDIBULAR JOINT DISORDER)

Systematic Reviews

A 2011 Cochrane SR identified 17 trials evaluating non-pharmacological psychological interventions for adults with chronic orofacial pain (e.g., temporomandibular joint (TMJ) disorder).[42] For the outcome short-term pain relief (three months or less), there was a significantly greater reduction in pain with interventions that combined CBT and biofeedback compared to usual care (two studies). However, there was not a significant benefit of a combined CBT/biofeedback on longer-term i.e., six-month pain relief, and there were no studies that compared CBT alone to CBT combined with biofeedback. For biofeedback-only interventions, a pooled analysis of two studies on short-term pain relief did not find a significant benefit compared to usual care. There was only one study reporting long-term pain relief after a biofeedback-only intervention, so a pooled analysis could not be conducted. The authors concluded that there is weak evidence to support psychosocial interventions for managing chronic orofacial pain and the most promising evidence is for CBT, with or without biofeedback. They noted that the trials in the review were few in number and had a high risk of bias, and they recommended additional high-quality trials.

The conclusions of the Cochrane review are similar to previous SRs on treatment of TMJ disorder. The reviews also concluded that there is weak evidence that psychosocial/physical therapy interventions, including biofeedback among others, are beneficial for treating TMJ but that there were few studies and they tended to be of poor methodologic quality. For example, Medlicott and colleagues recommended caution in interpreting results due to heterogeneity in study design and interventions used.[43] Since biofeedback was not isolated from other therapies, no conclusions could be reached for biofeedback alone. Based on two poor-quality RCTs, McNeely and colleagues concluded that biofeedback did not reduce pain more than relaxation or occlusal splint therapy for TMJ, but did improve oral opening when compared with occlusal splints.[44]

Randomized Controlled Trials

No RCTs identified after the above SR.

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Systematic Reviews

No SRs were identified for biofeedback for the treatment of SLE.

Randomized Controlled Trial

In an RCT of 92 patients with Systemic Lupus Erythematosus (SLE), Greco and colleagues reported that patients treated with six sessions of biofeedback-assisted cognitive-behavioral treatment for stress reduction had a statistically significant greater improvement in pain post treatment than a symptom-monitoring support group (p=0.044) and a usual care group (p=0.028).[45] However, these improvements in pain were not sustained at a nine-month follow-up and further studies are needed to determine the incremental benefits of biofeedback-assisted cognitive-behavioral treatment over other interventions in SLE patients.

RECURRENT ABDOMINAL PAIN

Systematic Reviews

No SRs were identified using biofeedback for the treatment of recurrent abdominal pain.

Randomized Controlled Trial

Humphrey's and Everts randomly assigned 64 patients with recurrent abdominal pain to groups treated with: 1) increased dietary fiber; 2) fiber and biofeedback; 3) fiber, biofeedback, and cognitive-behavioral therapy; and 4) fiber, biofeedback, cognitive-behavioral therapy, and parental support.[46] The three multi-component treatment groups were similar and had better pain reduction than the fiber-only group. This study does not address placebo effects. In a SR of recurrent abdominal pain therapies in children, Weider and colleagues concluded that behavioral interventions (cognitive-behavioral therapy and biofeedback) had a general positive effect on nonspecific recurrent abdominal pain and were safe.[47] However, the specific effects of biofeedback were not isolated in this SR.

VESTIBULODYNIA/VULVODYNIA/VULVAR VESTIBULITIS

Systematic Reviews

Morin published a SR to evaluate the outcomes of different physical therapies, one of which was biofeedback for women with provoked vestibulodynia.[48] The SR included RCTs, prospective and retrospective studies, case reports and study protocols, most of which had methodological limitations. The authors concluded more well designed RCTs are needed.

Randomized Controlled Trial

An RCT by Bergeron of 78 patients with vulvar vestibulitis compared biofeedback, surgery and cognitive-behavioral therapy.[49] Surgery patients had significantly better pain scores than patients who received biofeedback or cognitive-behavioral therapy. No placebo treatment was used.

OTHER CHRONIC PAIN

Other pain for which there are no publications sufficient to demonstrate the effectiveness of biofeedback include muscle pain or myalgia.

SECTION SUMMARY

The current evidence base is insufficient to allow scientific conclusions concerning the contribution of biofeedback to improvements in health outcomes for the treatment of chronic non-headache pain. [Headache is discussed separately below]

DEPRESSION, ANXIETY, AND POST-TRAUMATIC STRESS DISORDERS

Systematic Reviews and Technology Assessments

In 2018, the Canadian Agency for Drugs and Technology in Health (CADTH) published an updated "Post-Traumatic Stress Disorder: Summary of Evidence of the Clinical Effectiveness of Treatments".[50] They reviewed 26 treatments, one of which was biofeedback. They continued their stance that there is no evidence-based guidelines for the treatment of any mood or anxiety disorders. Additional well-designed, controlled clinical studies are needed to determine the clinical effectiveness of biofeedback on PTSD.

A 2017 CADTH evidence report on biofeedback for mood and anxiety disorders states the following:[51]

> Evidence from single randomized controlled trials suggests that compared with no treatment there is a statistically significant improvement in symptoms with neurofeedback treatment in patients with post-traumatic stress disorder (PTSD) or generalized anxiety disorder (GAD).
>
> A single randomized controlled trial (RCT) showed that for patients with PTSD there was improvement in symptoms with biofeedback (BF) plus treatment as usual (TAU) and also with TAU alone but the improvement occurred faster in the BF plus TAU group.
>
> A single RCT showed that for patients with PTSD there were no between group differences for BF and various mindfulness related treatment modalities. A single RCT showed that for patients with major depressive disorder, there was a statistically significant improvement in depression with BF plus TAU.
>
> Results need to be interpreted in the light of limitations (such as small sample size, lack of randomization details, lack of reporting of adverse events, lack of long-term data).
>
> No relevant studies on the clinical effectiveness of biofeedback using home equipment for treatment of PTSD, GAD, or depression without continued support from health professionals were identified.
>
> No relevant evidence based guidelines regarding the use of neurofeedback or biofeedback for the treatment of PTSD, GAD, or depression were identified.

Goessl (2017) published a SR on the effect of heart rate variability (HRV) biofeedback training in patients with stress and anxiety.[52] HRV is a measure of cardiac vagal tone. Low HRV is associated with certain psychological states such as anxiety. The literature search identified 24 studies (total N=484 patients), published between 1976 and 2015, for inclusion. Sample sizes ranged from five to 106 patients (median, 14 patients). The Cochrane risk of bias tool was used to assess study quality. Many studies had high or unclear risk of bias due to the following factors: inadequate randomization descriptions, improper randomization, undescribed allocation concealment, and missing data that was either not described or mishandled; 13 studies included a comparison group (six waitlist, three standard of care, two sham, one daily thought record, one progressive muscle relaxation). The average within-group effect size among the 24 studies, measured by Hedges' *g*, was 0.81, indicating a large effect on anxiety. The average between-group effect size among the 13 studies with comparators, also measured by Hedges' *g*, was 0.83, indicating HRV had a larger effect on anxiety than the comparators.

Schoenberg and David (2014) published a systematic review (SR) on biofeedback for psychiatric disorders, one of which was anxiety.[53] They identified 227 articles and 63 met the criteria for review. The authors concluded that development of standardized controlled methodology protocols tailored for specific disorders and guidelines are needed to determine the benefit of biofeedback on health outcomes for those with anxiety.

Randomized Controlled Trials

In addition to those included in the systematic reviews, the following RCTs have been published:

Maynart (2021) compared respiratory and heart rate biofeedback plus usual care to usual care alone in 36 patients with moderate to severe depression or dysthymia.[54] After six weeks (six sessions of biofeedback training), the biofeedback plus usual care group had less severe depression as measured by the Beck Depression Inventory (BDI) than the usual care alone group.

A preliminary open-label RCT by Park and Jung (2020) compared respiratory sinus arrhythmia biofeedback plus usual care to usual care alone in 30 patients with major depressive disorder.[55] After four weeks (six sessions of biofeedback), the biofeedback plus usual care group had greater improvements in Hamilton Depression Rating Scale (HAM-D) scores compared to the group receiving usual care alone. Improvements in other clinical measures, including the BDI, were not significantly different between groups.

Chen (2016) published an RCT comparing diaphragmatic breathing relaxation (DBR) with routine respiration activities in the treatment of 46 patients with anxiety.[56] DBR is a technique that uses diaphragm muscle contractions to force air downward into the body, increasing diaphragm length and breathing efficiency. Outcomes were anxiety level, measured by Beck Anxiety Inventory, and four physiological measures (skin conductivity, peripheral blood flow, heart rate, breathing rate). All patients participated in an individualized eight-week course in breathing relaxation, but only 30 completed it. Fifteen were randomized to DBR training and 15 to routine breathing relaxation training. Researchers and patients were blinded to randomization, with only the trainer being aware of group allocation. After eight weeks, the DBR group experienced statistically significant decreases in Beck Anxiety Inventory scores compared with baseline, while the control group did not experience significant decreases from baseline. The DBR group also experienced significant improvements in all four physiological measurements, while the control group did not. The authors noted this therapy is promising, but more well-controlled studies are needed.

FECAL INCONTINENCE AND CONSTIPATION

The relevant clinical outcome in studies of biofeedback as a treatment of fecal incontinence, encopresis, and constipation should be the overall change in the bowel symptoms. Reduction in episodes of fecal incontinence, encopresis, and constipation, and an increase in voluntary bowel movements as a result of biofeedback are the primary clinical outcomes of interest. Patient symptoms are usually assessed through diary, questionnaire, or interview. However, changes in anorectal physiological assessment (e.g., anal pressure, sensory threshold) often do not correlate with symptom relief (i.e., clinical outcomes).

FECAL INCONTINENCE IN ADULTS

Systematic Reviews

A 2014 Cochrane SR of RCTs compared one method of biofeedback to sham-biofeedback, no treatment, or another method of biofeedback in adults (> 18 years of age) with chronic idiopathic (functional) constipation.[57] Seventeen RCTs (25 individual reports) were included (N=931); biofeedback was compared to conventional nonsurgical treatment in 7 studies[58-64], to different methods of biofeedback in six studies[65-70], to surgical intervention in two studies[71, 72], to sham treatment in one study[73] and to electrical stimulation in one crossover study[74, 75]. No studies compared biofeedback to no treatment. Meta-analysis was not possible due to between-study heterogeneity and evidence was rated as low or very low quality due poor methodological quality with high risk of bias. The length of follow-up was determined to be inadequate in many RCTs. There was significant heterogeneity between groups and between studies that precluded meta-analysis. These included between-group differences at baseline, between-study differences in symptoms measured, symptom measurement tools used, and difference in protocols for biofeedback including the type of biofeedback, the number, frequency, and duration of sessions, and patient education (e.g., diet, normal bowel function, lifestyle advice). In addition, the review noted that many of the included RCTs were likely to be underpowered to detect between-group differences. The authors concluded that there is insufficient evidence to allow conclusions on the efficacy and safety of biofeedback for chronic constipation.

This Cochrane SR also reviewed four prior SRs[76-79] of RCTs that included systematic literature searches. The review reported methodological limitations in all four of these SRs including incomplete reporting of review methods, limited or non-comprehensive literature search strategies, failure to exclude non-SRs, and meta-analyses of heterogeneous studies. These reviews all reported generally poor quality evidence and the need for further research.

A 2013 SR by Vonthein et al. identified 13 RCTS on biofeedback, electrical stimulation, or the combination for treatment of fecal incontinence.[80] Ten RCTs included comparisons of biofeedback and an alternative treatment; some of the biofeedback interventions also involved other components such as sensory training and pelvic floor exercises. A meta-analysis of studies comparing biofeedback to a control intervention significantly favored biofeedback (relative risk, 2.12; 95% CI, 1.42 to 3.16). This study did not attempt to isolate the effect of biofeedback in multicomponent interventions that included pelvic floor exercise or other treatments.

In 2012, an updated Cochrane SR of randomized and quasi-randomized trials for biofeedback and/or sphincter exercises for the treatment of fecal incontinence in adults was published.[81] Almost half of the 21 trials were considered low risk for bias. Due to the variety of different treatment combinations, treatment delivery techniques, and outcome measures, comparison between studies was difficult. In addition, most studies reported immediate post-treatment outcomes with follow-up of only a few weeks. The authors reached the following conclusions:

- Biofeedback or electrical stimulation “may offer an advantage over exercises alone” in patients who have failed conservative management (e.g., diet changes, medications).
- Biofeedback following surgical sphincter repair does not improve health outcomes.
- The evidence does not permit conclusions about best practices in the clinical setting, including but not limited to the technique for biofeedback delivery and which patients are suitable for and most likely to benefit from biofeedback.

- Biofeedback is unlikely to cause harm as no study has reported any adverse events or worsening of symptoms.
- There is a need for large, long-term, well-designed RCTs that use validated outcome measures to compare outcomes of biofeedback with other treatments.

Randomized Controlled Trials

One new RCT was published after the above SRs. Damon randomized 157 patients with fecal incontinence to either a treatment group (n=77) receiving perineal retraining including biofeedback and standard conservative treatment, or a control group (n=80) receiving standard conservative treatment.[82] This RCT reported only short-term outcomes, with a follow-up of four months. The perineal retraining group had a significantly higher success rate than the control group for daily stool frequency, leakage, and urgency (57% versus 37%, respectively; $p<0.021$). However, there was no significant difference in quality of life scores between the two groups.

FECAL INCONTINENCE IN CHILDREN

Systematic Reviews

A 2011 updated Cochrane SR[83] combined the results of nine trials that compared conventional treatment (i.e., laxatives, toilet training, and dietary advice) with versus without biofeedback in children with fecal incontinence.[84-92] The majority of the trials included fewer than 50 participants. Pooling of data was difficult due to the variety of outcome measures; the only outcome reported by all nine trials was the number of children not cured or improved. Combined results of nine trials showed higher rather than lower rates of persisting symptoms of fecal incontinence up to 12 months when biofeedback was added to conventional treatment. In addition, any short-term benefit from biofeedback training did not correspond with later treatment success. The authors concluded that there is no evidence that biofeedback training added any benefit to conventional treatment in the management of functional fecal incontinence in children.

These results confirm the conclusions of prior versions of this Cochrane SR and other SRs.[93-95]

Randomized Controlled Trials

Since the above SRs, one additional randomized trial was published in which the authors reported that the results at six-months follow-up did not differ between biofeedback and customary care.[84]

CONSTIPATION IN ADULTS

Systematic Review

For the treatment of constipation, a SR of 11 RCTs found a benefit of biofeedback as a treatment of constipation in adults.[76] Conclusions of the SR were limited by variability in patient populations, comparison treatments, and outcomes measures. However, detailed examination of several well-conducted RCTs focusing on patients with dyssynergia-type constipation suggested benefits in a sub-group of patients who met criteria similar to trial participants.[59, 60, 73] Studies for other types of constipation were limited to poorly-designed

RCTs and case series. These unreliable studies do not permit conclusions on the effect of biofeedback on other types of constipation in adults.

Randomized Controlled Trials

Hart (2012) published an RCT that studied anorectal biofeedback (AB) for constipation. Twenty-one patients with pelvic floor dyssynergia were randomized into two groups.[60] One group learned to isolate the anal sphincter using an electromyography probe and the other learned to relax trapezius or temporalis muscles with EMG feedback. The authors concluded that although the sample size was statistically underpowered, AB produced clinical improvements in the severity of constipation. The authors also noted there were several study limitations, including patient selection and long-term follow-up; thus, the evaluation of long-term effects on health outcomes needs to be determined in future studies.

CONSTIPATION IN CHILDREN

Systematic Reviews

A systematic review conducted by Wegh (2021) assessed the effectiveness of nonpharmacological interventions for functional constipation in children.[96] Studies included in the review were RCTs that enrolled children aged 0 to 18 years with functional constipation as defined by Rome III or IV criteria and reported defecation outcomes and/or QOL outcomes. The review included three RCTs comparing biofeedback alone with biofeedback in conjunction with laxative use. The trials were all assessed as having a high risk of bias. Meta-analysis found no difference between groups in study-defined treatment success (risk difference, 0.23; 95% CI, -0.08 to 0.54) and heterogeneity was high (I^2=86%). Other clinical outcomes and harms of treatment were not reported.

Randomized Controlled Trials

A RCT conducted by Van Ginkel (2001) evaluated biofeedback in the treatment of constipation in children.[97] Groups included standard treatment i.e., education, laxatives (n=111) or standard treatment plus two sessions of anorectal manometry (n=91). Manometry measurements were viewed by the child and parent during measurement sessions and the data discussed after each session with instructions in home exercises. At six weeks follow-up, there was no significant different in success between the standard treatment group (4%) and the biofeedback group (7%). At the final 104 week follow-up, 43%of the standard treatment group and 35% of the biofeedback group were considered treatment successes. This difference was not significant. The authors noted that 30% of the randomized patients were missing at the final follow-up.

Section Summary

The current evidence from several well-designed, well-conducted RCTs is sufficient to determine that biofeedback as a treatment of dyssynergia-type constipation may be beneficial in adult patients who meet the policy criteria.

The evidence base is insufficient to draw conclusions or demonstrate a significant health benefit as a result of biofeedback treatments for the treatment of incontinence or constipation other than dyssynergia-type constipation in adults. The evidence is limited to data from studies with significant methodological limitations including inadequate randomization, lack of a

placebo control group, heterogeneity between patient groups and between study protocols, and short-term follow-up periods.

HEADACHE

TENSION AND MIGRAINE HEADACHE

Systematic Reviews

Sullivan (2016) published a SR to evaluate the outcomes of psychological interventions, one of which was biofeedback for migraines.[98] Twenty-four studies were reviewed. The authors noted there were methodological limitations from the study review and that biofeedback was not superior to relaxation training or cognitive behavioral therapy.

A number of other SRs, including two Cochrane SRs, have reported small beneficial effects in children and medium to large beneficial effects in adults when biofeedback is used in conjunction with other prevention measures such as relaxation techniques.[15, 99-105]

Randomized Controlled Trials

Despite the poor quality of case series and RCTs, biofeedback has evolved into a standard of care as part of comprehensive regimens, including medication and relaxation techniques, for treatment and prevention of tension-type headaches, and the prevention of migraine headaches.

Data from case series and RCTs is difficult to interpret due to poor study design, high drop-out rates, and inconsistent outcomes.[106-111]

OTHER HEADACHE

The evidence is insufficient to determine the effect of biofeedback for the prevention or treatment of headaches other than migraine and tension headaches, including but not limited to cluster headaches.

SECTION SUMMARY

Despite the poor quality of studies, biofeedback has evolved into a standard of care as part of comprehensive regimens, including medication and relaxation techniques, for treatment and prevention of tension-type headaches and the prevention of migraine headaches.

There is not enough research to show that biofeedback improves outcomes in patients with headaches other than migraine and tension headaches.

HYPERTENSION

SYSTEMATIC REVIEWS

Nagele (2014) published a SR with meta-analysis on stress-reduction techniques in adults with essential hypertension.[112] The review included SRs and RCTs with a no-treatment control group and at least 24 weeks follow-up that were published through September 2012. Outcomes of interest were mortality, cardiovascular morbidity/mortality, end-stage renal disease, health related quality of life, adverse events, change in blood pressure, and changes in antihypertensive medication. Biofeedback was one of a number of the stress-reduction

techniques included in the review. The review found that data were not reported for most of the patient-relevant outcomes. No benefit was found for use of antihypertensives. Some beneficial effect was found for lowering blood pressure; however, studies were limited by methodological limitations such as heterogeneity between studies, short-term follow-up. The authors concluded that a beneficial effect of stress-reduction techniques on hypertension remains unproven.

In a 2010 SR, Greenhalgh concluded, "…we found no convincing evidence that consistently demonstrates the effectiveness of the use of any particular biofeedback treatment in the control of essential hypertension when compared with pharmacotherapy, placebo, no intervention or other behavioral therapies."[113] Trials generally had small sample sizes; only four included more than 100 patients. Trials included a variety of biofeedback techniques, and some included more than one modality. Results were not pooled due to differences in interventions and outcomes and the generally poor quality of the studies. Only one trial was identified that compared a biofeedback combination intervention to sham biofeedback, and this study did not find a significant difference in the efficacy of the two interventions. Only four studies on biofeedback alone and four on a combined biofeedback intervention reported data beyond six months; most of these found no significant differences in efficacy between the biofeedback and control groups.

Rainforth reviewed RCTs and all previous meta-analyses related to stress reduction programs including biofeedback.[114] Each type of therapy was analyzed separately. No significant reduction in blood pressure was achieved using biofeedback alone or biofeedback combined with relaxation training.

RANDOMIZED CONTROLLED TRIALS

Wang (2016) published an RCT evaluating the effect of direct blood pressure biofeedback on patients with prehypertension or stage I hypertension.[115] A trained nurse instructed patients in blood pressure self-regulation by using slow diaphragmatic breathing and passive attitude. During the eight-week training (one session per week), patients in the treatment group received real-time blood pressure feedback signals (n=29) and controls received pseudo-feedback signals (n=28). Outcomes were systolic and diastolic blood pressure, measured at baseline and one and eight weeks after training. Both groups significantly decreased blood pressure following training. The decreases were equal in magnitude, suggesting that blood pressure self-regulation training can effectively lower blood pressure, regardless of the type of feedback signal.

Landman (2013) conducted a randomized, double-blind, sham-controlled trial comparing the effects on blood pressure of lowering breathing frequency in patients with type two diabetes and hypertension using active (n=21) and sham (n=24) biofeedback.[116] The changes in systolic blood pressure from baseline favored the control group while differences in diastolic blood pressure favored the intervention group. However, these differences from baseline, and the differences between the two groups were not statistically significant.

SECTION SUMMARY

Although there are RCTs evaluating biofeedback for treating hypertension, evidence is insufficient due to the shortage of studies isolating the effect of biofeedback, the generally poor quality of the trials, and the variability among interventions.

INSOMNIA

SYSTEMATIC REVIEWS

No SRs were identified using biofeedback for the treatment of insomnia.

RANDOMIZED CONTROLLED TRIALS

No RCTs were identified using biofeedback for the treatment of insomnia.

MOTOR FUNCTION AFTER INJURY OR ORTHOPEDIC SURGERY

SYSTEMATIC REVIEWS

Several SRs have been published; none of these conducted quantitative pooling of results due to heterogeneity among study populations, interventions, and outcome measures.

A 2010 SR by Silkman evaluated the effectiveness of electromyography (EMG) biofeedback for improving muscle function during knee rehabilitation after injury.[117] Four RCTs that compared knee rehabilitation exercise programs with and without biofeedback were identified. Sample sizes in individual studies ranged from 26 to 60 patients. Two of the four studies found a statistically significantly greater benefit in the programs that included biofeedback, and the other two did not find a significant difference between groups. The positive studies assessed intermediate outcomes e.g., contraction values of the quadriceps muscles. None of the studies were designed to assess functional outcomes.

RANDOMIZED CONTROLLED TRIALS

Tiryaki (2023) published the results of a RCT comparing the effectiveness of exercise with EMG biofeedback (n=23) to control exercise without biofeedback group (n=23) in patients rehabilitating from a massive rotator cuff tear.[118] The intervention lasted six weeks and the patients were followed for 12 months. Both groups improved similarly on most outcome scores. The biofeedback group had greater change in shoulder flexion strength and patient satisfaction score at six weeks and at 12 months follow-up ($p<0.05$).

MOTOR FUNCTION AFTER STROKE

Stanton (2017) updated a SR published in 2011 which evaluated the effect of biofeedback on lower-limb activities in patients who have had a stroke.[119] Only high-quality RCTs or quasi-RCTs with Physiotherapy Evidence Database (PEDro) scores greater than four were included. The literature search, conducted through September 2015, identified 18 trials (total N=429 patients) for inclusion. Training activities were walking (nine trials), standing (eight trials), and standing up (one trial). Trials were small, with study populations ranging from 12 to 50 patients. Biofeedback techniques included weight distribution from a force platform or sensor (11 trials), muscle activity from EMG (three trials), linear gait parameters (three trials), and joint angle from a goniometer (one trial). Visual feedback was used in seven trials, auditory in seven trials, and a combination of visual/auditory in four trials. Pooled standardized mean difference of the short-term effect of biofeedback from 17 trials (n=417) was significant (0.50; 95% confidence interval [CI], 0.3 to 0.7). Long-term effects could not be calculated because only four trials provided that information.

Stanton (2011) conducted a SR with meta-analysis of RCTs evaluating biofeedback to improve activities involving lower limb function after stroke.[120] A total of 22 trials with 591 participants met inclusion criteria. All of the trials had relatively small sample sizes; the largest trial had 54 participants and 15 trials had 30 or fewer participants. The majority of trials (n=17) compared biofeedback plus usual therapy to usual therapy alone. The specific interventions varied; the types of biofeedback included biofeedback of ground reaction force from a force platform with visual and/or auditory feedback (13 trials), muscle activity via visual and/or auditory feedback (five trials), joint position from an electrogoniometer via visual and/or auditory feedback (three trials), and limb position via auditory feedback one trial). The duration of interventions ranged from two to eight weeks, and intensity ranged between one to five days per week.

A pooled analysis of data from 17 trials on short-term effect (i.e. one month or less) found that biofeedback significantly improved lower limb activities compared to usual care or placebo (standardized mean difference [SMD]: 0.41; 95% CI: 0.21 to 0.62). Outcomes included activities such as directional control during standing, weight distribution between the lower limbs, and gait parameters such as stride length. There was heterogeneity among studies. Trials did not report functional outcomes such as ability to perform activities of daily living (ADL). A sensitivity analysis determined that the heterogeneity was best explained by study quality. When lower quality trials were excluded, biofeedback was still found to improve lower limb activity compared to control conditions (SMD: 0.49, 95% CI: 0.22 to 0.75). A sub-group analysis was also done by type of activity. There was only one high-quality trial on standing up (n=40). A pooled analysis of five high-quality trials on short-term effect found that biofeedback significantly improved standing outcomes compared to control (SMD: 0.42, 95% CI: 0.05 to 0.78). A pooled analysis of four short-term trials on walking also found better outcomes with biofeedback compared to control (SMD: 0.57, 95% CI: 0.10 to 1.03). Five high-quality trials with a total sample size of 136 contributed data to an analysis of long-term term efficacy i.e., one-five months after cessation of the intervention. In this pooled analysis, biofeedback was found to improve outcomes compared to control (SMD: 0.41, 95% CI: 0.06 to 0.75).

A Cochrane SR that assessed EMG biofeedback for the recovery of motor function after stroke was published in 2007.[121] It included 13 randomized or quasi-randomized studies with a total of 269 patients. All of the trials compared EMG biofeedback plus standard physiotherapy to standard physiotherapy; in addition to standard physiotherapy, several studies also included a sham biofeedback group. The studies tended to be small and poorly designed. The authors did not find support for EMG biofeedback to improve motor power, functional recovery, or gait quality when compared to physiotherapy alone.

A 2010 SR by Zijlstra searched for studies evaluating biofeedback-based training to improve mobility and balance in adults older than 60 years of age.[122] Although the review was not limited to studies on motor function after stroke, more than half of the studies included older adults post-stroke. For inclusion in this review, studies needed to include a control group of patients who did not receive biofeedback and to assess at least one objective outcome measure. A total of 97 potentially relevant articles were identified, and 21 (22%) studies, including 17 RCTs, met the selection criteria. Twelve of the 21 (57%) studies included individuals post-stroke; three included older adults who had lower-limb surgery and six included frail older adults without a specific medical condition. Individual studies were small with sample sizes that ranged from five to thirty patients. The added benefit of using biofeedback could be evaluated in 13 of 21 (62%) studies. Nine of the 13 studies found a significantly greater benefit with interventions that used biofeedback compared to control interventions. However, the outcomes assessed were generally not clinical outcomes but were

laboratory-based measures related to executing a task, e.g., moving from sitting to standing in a laboratory setting and platform-based measures of postural sway. The applicability of improvements in these types of measures to clinical outcomes such as the ability to perform activities of daily living or the rate of falls is unknown. Only one study cited in this review reported an improvement in fall rates, and this trial could not isolate the effect of biofeedback from other components of treatment. In addition, only three studies reported long-term outcomes, and none of these reported a significant effect of biofeedback. Conclusions about the efficacy of biofeedback for improving mobility and balance in older adults cannot be drawn from these data due to the lack of evidence on clinical outcomes. Other methodologic limitations included limited data on the durability of effects and the inability to isolate the effect of biofeedback in many studies.

RANDOMIZED CONTROLLED TRIALS

Benfield (2023) published a RC feasibility study comparing dysphagia treatment with usual care with usual care plus sEMG biofeedback as intervention in patients after an acute stroke.[123] Twenty-seven patients (13 biofeedback, 14 control) with average age of 73.3 (Standard Deviation [SD] ± 11.0) and National Institute of Health Stroke Scale (NIHSS) of 10.7 ± 5.1 were recruited 22.4 ± 9.5 days post stroke. A total of 84.6% of participants completed >80% of sessions; failed sessions were mainly due to participant availability, drowsiness or refusal. Sessions lasted for an average of 36.2 ± 7.4 min. Although 91.7% found the intervention comfortable with satisfactory administration time, frequency, and time post stroke, 41.7% found it challenging. There were no treatment-related serious adverse events. There were no differences in the Dysphagia Severity Rating Scale (DSRS) score between the two groups at 2 weeks. Long term data were not provided.

Nordio (2022) published a small RCT comparing surface electromyography (sEMG) biofeedback (N=9) to control treatment (N=7) for rehabilitation of swallowing in post-stroke dysphagia.[124] Functional oral intake scale (FOIS) improved in all patients, regardless of treatment. sEMG-biofeedback rehabilitation led to improvements of the pharyngeal clearance and swallowing safety. The rehabilitative effects appeared stable at 2-months follow-up. Treatment with sEMG biofeedback was not different than control treatment.

Kim (2017) published a RCT on the effect of EMG on upper-extremity functions in patients who have had a stroke.[125] Patients were randomized to traditional rehabilitation therapy (n=15) or traditional rehabilitation therapy plus EMG biofeedback training (n=15). Upper-limb function was measured by Fugl-Meyer Assessment (FMA) and Manual Function Test (MFT), and activities of daily living were measured using the FIM instrument. Both FMA and MFT scores improved significantly more in the patients receiving EMG biofeedback. However, there was not a significant difference in functional independence measurement (FIM) score improvement between groups.

Yang (2016) published a limited in size RCT on the effect of biofeedback weight-bearing training on the ability to sit/stand/sit and on stability among patients who have had a stroke.[126] Patients were randomized to biofeedback weight-bearing training (n=15) or functional weight-bearing training (n=15). Outcomes were time to sit/stand/sit and stability (measured by BioRescue, which detects an area of center of pressure). Comparison statistics were calculated for pre- and post training results, and between treatment groups. Both outcomes significantly improved in the biofeedback group but not in the control group.

Ghomashchi (2016) published a RCT evaluating the effect of visual biofeedback on postural balance disorders in patients who have had a stroke.[127] Patients received conventional physical therapy and balance training exercises. During balance training, 16 patients were randomized to visual biofeedback and 15 patients to no visual information. Outcomes were the center of pressure and approximate entropy. Both groups experienced improvements in postural control, with no significant differences between rehabilitation methods.

In a small RCT published after the above SR, Barcala randomized 20 adults with hemiplegia following stroke to balance training with visual biofeedback or to conventional physical therapy alone.[128] Patients received interventions twice a week for five weeks. Both groups demonstrated significant improvement, but no statistically significant differences were found between the two groups.

SECTION SUMMARY

The evidence on biofeedback for improving motor function after stroke is limited by small studies, most of which are methodologically limited. There is variability in the type, duration, and intensity of interventions. Conclusions about the efficacy of biofeedback for improving mobility and balance in older adults cannot be drawn from the current evidence base.

MOVEMENT DISORDERS

SYSTEMATIC REVIEWS

A Cochrane SR assessing EMG biofeedback for the recovery of motor function after stroke included thirteen randomized or quasi-randomized studies.[121] The authors reported that EMG biofeedback did not improve motor power, functional recovery, or gait quality when compared to physiotherapy alone, although the results were limited due to small, poorly designed trials. Use of different assessment scales made pooling data for meta-analysis impossible.

RANDOMIZED CONTROLLED TRIALS

Yaksi (2022) published a small RCT comparing static posturography-assisted biofeedback exercises and a conventional exercise program in patients (N=40) with Parkinson Disease (PD).[129] No differences were observed between the two groups in any of the outcome measurements before and after the treatment ($p > 0.05$). The authors concluded that static posturography-assisted biofeedback exercises provided no additional benefit.

SECTION SUMMARY

The current evidence base is insufficient to draw conclusions regarding the role of biofeedback for the treatment of movement disorders.

MULTIPLE SCLEROSIS

SYSTEMIC REVIEWS

No SRs were identified for biofeedback for the treatment of multiple sclerosis.

RANDOMIZED CONTROLLED TRIAL

van der Logt (2016) published a crossover study that evaluated the effect of vibrotactile biofeedback for trunk sway on balance control in patients with multiple sclerosis.[130] Ten

patients performed a series of stance and gait tasks while trunk sway was measured using a SwayStar device attached to the waist. Patients underwent the series of tasks with and without an add-on to the SwayStar device, which provided patients with direction-specific vibrotactile feedback during the tasks. When patients performed the tasks with vibrotactile biofeedback, there was a general reduction in trunk sway, though not all the reductions differed significantly with trunk sway when performing the tasks without vibrotactile biofeedback. Studies with larger sample sizes are needed.

A 2015, MacKay published results from an (RCT) that evaluated the addition of biofeedback to standard care in 40 patients with relapsing-remitting multiple sclerosis patients to help improve emotional symptoms, coping, and fatigue in patients with multiple sclerosis.[131] The standard care psychosocial intervention consisted of relaxation, mindfulness, social support, and education. All patients attended a one-hour training and assessment sessions at weekly intervals. During the first session, all patients had training in mindfulness breathing exercises and progressive muscle relaxation techniques. Patients randomized to the biofeedback arm received additional instruction on use of biofeedback equipment for self-regulation. Following the 3 weekly sessions, patients were instructed to practice the exercises at home, with or without use of biofeedback equipment. Outcomes included breathing rate and anxiety, depression, fatigue, and muscle tension measures. At the end of treatment, there were not statistically significant differences between groups in any outcomes. However, some variables were marginally significant. The difference between the intervention and control group in breathing rate was 3.06 (95% CI, -0.17 to 6.280; p=0.06) and the difference in muscle tension was -13.91 (95% CI, -30.06 to 2.25; p=0.09). This study is limited by the small sample size, and other methodological constraints that make it hard to determine the efficacy of biofeedback for anxiety, fatigue, and stress in patients with multiple sclerosis.

SECTION SUMMARY

There is not enough research to show that biofeedback improves health outcomes for the treatment of multiple sclerosis. Additional well-designed, comparative studies are needed.

ORTHOSTATIC HYPOTENSION IN PATIENTS WITH A SPINAL CORD INJURY

SYSTEMATIC REVIEW

Gillis conducted a SR to identify and describe the body of literature pertaining to nonpharmacologic management of orthostatic hypotension during the early rehabilitation of persons with a spinal cord injury.[132] Participants with any level or degree of completeness of spinal cord injury and any time elapsed since their injuries were included. Interventions must have measured at least systolic blood pressure and have induced orthostatic stress in a controlled manner and have attempted to control orthostatic hypotension during an orthostatic challenge. Four distinct nonpharmacologic interventions for orthostatic hypotension were identified: application of compression and pressure to the abdominal region and/or legs, upper body exercise, functional electrical stimulation applied to the legs, and biofeedback. Methodologic quality varied dramatically between studies. The authors concluded that "…The clinical usefulness of compression/pressure, upper body exercise and biofeedback for treating OH [orthostatic hypotension] has not been proven."

RANDOMIZED CONTROLLED TRIALS

No RCTs identified after the above SR.

SECTION SUMMARY

There is insufficient evidence from high-quality comparative studies to permit conclusions about the impact of biofeedback on orthostatic hypotension in patients with a spinal cord injury.

PRETERM BIRTH PREVENTION

SYSTEMATIC REVIEWS

No SRs were identified for biofeedback used to prevent preterm birth.

RANDOMIZED CONTROLLED TRIALS

In 2014, Siepmann published data on 48 women who had experienced threatened preterm labor between the 24th and 32nd gestational week.[133] Twenty-four patients received six biofeedback sessions over two weeks, and the other 24 patients were in a usual care group. Preterm delivery occurred in three patients (13%) in the biofeedback group and eight patients (33%) in the control group; the difference between groups was not statistically significant ($p>0.05$). Other gestational outcome data, such as the gestational duration and birthweight, also did not differ significantly between groups.

SECTION SUMMARY

There is insufficient evidence that biofeedback is effective in preventing preterm birth in pregnant women with a history of threatened preterm labor.

RAYNAUD'S PHENOMENON

SYSTEMATIC REVIEWS

No SRs were identified for biofeedback for Raynaud's phenomenon.

RANDOMIZED CONTROLLED TRIALS

The Raynaud's Treatment Study Investigators conducted a randomized comparison of sustained-release nifedipine and thermal biofeedback in 313 patients with primary Raynaud's phenomenon.[134] In addition to these two treatment groups, there were two control treatments: pill placebo and EMG biofeedback. EMG biofeedback was chosen as a control because it did not address the physiological mechanism of Raynaud's phenomenon. Nifedipine significantly reduced Raynaud's attacks compared with placebo pill ($p<0.001$), but thermal biofeedback did not differ from EMG biofeedback ($p=0.37$). Better outcome for nifedipine relative to thermal biofeedback was nearly significant ($p=0.08$). With a larger sample size, the rate of 56% fewer attacks with nifedipine relative to thermal biofeedback would likely have been statistically significant. Thus, it cannot be concluded that thermal biofeedback is as effective as this form of medical therapy.

A 2009 SR identified five RCTs that reported a variety of outcomes. A pooled analysis from four RCTs (total n=110) on the change in frequency of attacks favored the sham control group over the biofeedback group.[135]

SECTION SUMMARY

There is insufficient evidence from a small number of RCTs that biofeedback is effective as a treatment of Raynaud's disease. A meta-analysis of the available RCTs did not find that biofeedback was more effective than the control intervention.

STRESS REDUCTION

SYSTEMIC REVIEWS

No SRs were identified for biofeedback for stress reduction.

RANDOMIZED CONTROLLED TRIALS

A 2015 Van der Zwan published an RCT comparing the efficacy of self-help physical activity (PA), mindfulness meditation (MM), and heart rate variability biofeedback (HRV-BF) in reducing stress and its related symptoms.[136] This study, which was limited in size and objective outcomes indicated that all interventions were equally effective in reducing stress and its related symptoms. The current evidence base is insufficient to permit conclusions on the impact of biofeedback on stress reduction.

SECTION SUMMARY

There is not enough research to show that biofeedback improves health outcomes for stress reduction. Additional well-designed, comparative studies are needed.

TINNITUS

SYSTEMATIC REVIEWS

No SRs were identified for biofeedback for tinnitus.

RANDOMIZED CONTROLLED TRIALS

Weise investigated the efficacy of a biofeedback-based cognitive-behavioral treatment for tinnitus in Germany. Tinnitus patients (n=130) were randomly assigned to an intervention or a wait-list control group.[137] Treatment consisted of 12 sessions of a biofeedback-based behavioral intervention over a three-month period. The primary outcome measures were global tinnitus annoyance and a daily rating of tinnitus disturbance measured by a Tinnitus Questionnaire (TQ) and a daily diary using visual analog scale (VAS) scores. Patients in the wait-list group participated in the treatment after the intervention group had completed the treatment. Results showed improvements regarding the following: tinnitus annoyance; diary ratings of loudness; feelings of controllability; changes in coping cognitions; changes in depressive symptoms; TQ: total score (range 0–84) pre-assessment mean 54.7, post-assessment mean 32.52; TQ: emotional distress (range 0–24) pre-assessment mean 16.00, post-assessment mean 8.15; and diary: loudness VAS (range 0–10) pre-assessment mean 5.68, post-assessment mean 4.38. Improvements were maintained over a six-month follow-up period in which variable effect sizes were observed. The study did not investigate the possible additive effect of biofeedback with cognitive-behavioral therapy and did not include an active treatment control group.

SECTION SUMMARY

The current evidence base is insufficient to draw conclusions regarding the role of biofeedback for the treatment of tinnitus.

URINARY DISORDERS

POST-PROSTATECTOMY URINARY INCONTINENCE

Systematic Reviews

Hsu (2016) published a SR evaluating pelvic floor muscle training (PFMT) with biofeedback in men who had radical prostatectomy.[138] Thirteen trials met reviewers' inclusion criteria. However, on closer inspection, not all trials included a biofeedback intervention, and other trials did not compare PFMT alone to PFMT plus biofeedback. Thus, conclusions about the added efficacy of biofeedback cannot be determined from the results of this SR.

In 2015 a Cochrane SR was conducted by Anderson to determine the effectiveness of conservative management interventions for urinary incontinence in men after a prostatectomy, which updated the 2012 review by Campbell et all.[139, 140] Conservative therapies include pelvic floor muscle training with or without feedback, electrical stimulation, extra-corporeal magnetic innervation, compression devices, lifestyle changes, or a combination of methods. Fifty randomized and quasi-Rs were included in the review; however, just eight of these trials examined biofeedback compared to pelvic floor muscle training. Per the rating of moderate quality studies, the authors found no evidence that pelvic floor muscle training with or without biofeedback was better than control for men who had urinary incontinence up to 12 months after radical prostatectomy.

A SR of PMFT to improve post-prostatectomy urinary incontinence identified three studies (281 men) that focused on the incremental value of biofeedback over written/verbal PME.[141] Although PPMFT appeared to reduce the time to recover continence compared to no training, there was no evidence for an advantage of training with biofeedback over written/verbal instructions. None of the individual trials found a statistically significant difference in outcomes between groups.

A 2003 randomized trial by Wille randomized 139 men prior to radical prostatectomy to one of three groups.[142] Group one received verbal and written instructions about PFMT from a physical therapist. Group two received PFMT instruction and instruction on using an electrical stimulation device. Group three received the previous two intervention components and training on using biofeedback with the electrical stimulation device. Patients had regular contact with a health care provider for the first five weeks after surgery. In the immediate postsurgical period, 20.5% in group one, 22.9% in group two, and 20.7% in group three were continent (p=0.815). After six and 12 months, continence rates remained similar among the groups. Twelve-month continence rates were 88% in group one, 81% in group two, and 88.6% in group three (p=0.524).

Bales (2000) randomized 100 men scheduled to undergo radical prostatectomy to PFMT plus biofeedback intervention (n=50) or to a control group (n=50) that received written and brief verbal instructions performing PFMT [143] The intervention consisted of a single session with a trained nurse two to four weeks before surgery. Three men dropped out of the PFMT plus intervention group. At six months after surgery, the incidence of urinary incontinence was 94% (44/47) in the PFMT plus biofeedback group and 96% (948/40) in the control group. The difference between groups was not statistically significant.

Randomized Controlled Trials

Oh (2020) randomized 84 patients undergoing robot-assisted laparoscopic radical prostatectomy to receive biofeedback with an extracorporeal perineometer plus PFMT or PFMT alone.[144] Although the average urine loss volume was lower in the biofeedback plus PFMT group compared to PFMT alone at month 1 after catheter removal (p=0.028), there was no difference between groups at months 2 or 3 after catheter removal. At study end (month 3), the percentage of continent patients was not significantly different between the biofeedback plus PFMT group (67.5%) and PFMT alone (61.9%).

A 2013 trial by Dijkstra-Eshuis compared the impact of preoperative pelvic floor muscle training (PFMT) with biofeedback (n=65) to standard care (n=56) on postoperative SUI in men undergoing laparoscopic radical prostatectomy.[145] Patients in the intervention group received four weekly sessions of biofeedback-assisted muscle training before surgery. Patients assigned to the control group did not have a presurgical intervention. The primary outcome was the rate of continence one year after surgery. Among the 74 patients available for follow-up analysis, 66% in the intervention group and 80% in the control group were continent at one year. The investigators originally planned to enroll 248 patients. However, an interim analysis after 122 patients were enrolled showed no significant benefit for the intervention group, even if the trial was completed as planned and therefore the trial was halted prematurely.

In 2012, Tienforti compared biofeedback (a session before and after surgery) in combination with written/verbal instructions on performing pelvic floor muscle exercises to a control intervention of written/verbal instructions alone.[146] The study included 34 patients, 32 of whom (16 in each group) were available for the final 6-month analysis. By six months, 10 of 16 patients (62.5%) in the treatment group and one of sixteen patients (6.3%) in the control group had achieved continence; this difference was statistically significant (p value not reported). The mean number of incontinence episodes per week was also significantly lower in the intervention group (2.7) than the control group (13.1) at six months.

STRESS, URGE OR MIXED URINARY INCONTINENCE

Systematic Reviews

Zhu (2022) performed a meta-analysis of 17 RCTs in postpartum women with lower urinary tract symptoms.[147] Fifteen studies (n=1965) compared PMFT plus biofeedback and electrical stimulation with PMFT alone. The analysis reported a significantly greater likelihood of achieving a therapeutic effect with combined PFMT plus biofeedback and electrical stimulation versus PMFT alone (risk ratio, 1.20; 95% confidence interval [CI], 1.15 to 1.24; I^2=0%). Pelvic floor muscle strength was also significantly higher with combination therapy (p<0.0001), but there was high heterogeneity among studies for this outcome (I^2=66%). Limitations of this analysis include risk of bias, lack of blinding, and heterogeneity in the definition of therapeutic effect.

Wu (2021) conducted a meta-analysis (N=21 studies; 13 RCTs, 8 nonrandomized) of PMFT with biofeedback versus PMFT alone in women with stress incontinence or pelvic floor dysfunction.[148] Most studies were conducted in China and none were from the U.S. There was a significant benefit of PMFT with biofeedback compared to PMFT alone in patients with both urinary incontinence (odds ratio, 4.82; 95% CI, 2.21 to 10.51; I^2=85.3%; n=11 studies) and pelvic floor dysfunction (odds ratio, 2.81; 95% CI, 2.04 to 3.86; I^2=13.1%; n=6 studies). Analyses of quality of life and quality of sexual life results were limited by substantial heterogeneity (>80%). Limitations of this analysis include an unclear, moderate, or high risk of

bias in all studies and use of Kegel exercises only in some studies rather than a complete PMFT program.

An updated Agency for Healthcare Research and Quality (AHRQ) SR and comparative effectiveness report of nonsurgical treatments for urinary incontinence in women was published by Blak (2018).[149] Biofeedback was considered among nonpharmacological behavioral therapy approaches. The report evaluated 42 studies that compared 19 active nonpharmacological interventions (including combinations of nonpharmacological interventions) with each other. One study reported statistically significant improvements in the daily activities domain with PFMT and biofeedback compared with PFMT alone, and one study reported significant improvements in distress for bladder training combined with PFMT and biofeedback when compared to bladder training, however, nine studies either reported discordant or nonsignificant differences across all other domains for this comparison. No adverse events were reported for any of the studies evaluating biofeedback. The report concludes that behavioral therapy, alone or in combination with other interventions, is generally more effective than other first- and second-line interventions alone for both stress and urgency UI.

A SR by Mateus-Vasconcelos (2018) assessed various physiotherapy methods to strengthen the pelvic floor muscles for women with stress urinary incontinence.[150] Their review included six studies which were RCTs, quasi-experimental trials, and systematic reviews. One study (an uncontrolled RCT) included biofeedback as a comparator; the effectiveness of pelvic floor muscle training (PFMT) with biofeedback (group n=6) to PFMT with palpation (group n=5) was evaluated. The exercises for the biofeedback group consisted of achieving the same number of rapid and slow contractions of the same duration as that achieved during the PERFECT scheme (8 series). The palpation group strengthened the pelvic floor muscles while a physiotherapist performed palpations on the central perineal tendon and vagina (4 sessions). At the end of treatment, there was no statistical difference in improvement between the biofeedback group and the palpation group in power, endurance, or rapidity of contractions. This RCT was limited in its small sample size and lack of control group and masking of assessors.

Oliveira (2017) published a SR that evaluated the protocols and/or PFMT parameters for women with stress urinary incontinence.[151] Seven studies were included, two of which involved biofeedback. The authors concluded that strengthening exercises for pelvic floor training combined with biofeedback was the most effective training protocol, but because of the limited studies and heterogeneity of the intervention protocols they could not identify what the most effective training protocol would be.

Moroni (2016) published a SR of 37 RCTs on conservative treatment of stress urinary incontinence in women.[152] Five trials (N=250) were identified that compared PFMT plus biofeedback with biofeedback alone. A pooled analysis of four studies found significantly more urine loss as measured by a posttreatment pad test with PFMT alone than with PFMT plus biofeedback (mean difference [MD], 0.90; 95% confidence interval [CI], 0.71 to 1.10). Reviewers noted that the difference between groups was likely not clinically significant because there was only about a one-gram difference. Moreover, the finding was largely due to the effect of one study. Results on other outcomes (eg, quality of life, number of incontinence episodes) could not be pooled due to imprecision of the estimates.

A 2011 Cochrane SR evaluated feedback or biofeedback in conjunction with pelvic floor

muscle training (PFMT) for treating urinary incontinence (UI) in women.[153] The review included RCTs in women with stress, urge or mixed UI in which at least two arms of the study included exercise training and at least one arm included feedback and/or biofeedback. Feedback was defined as verbal feedback by a clinician, whereas biofeedback involved use of an instrument or device. After examining 36 full-text articles, 24 trials were found to meet the review's inclusion criteria and 17 contributed data to the analysis of at least one primary outcome measure. Sixteen of the 24 trials included a comparison of PFMT plus biofeedback to PFMT alone; nine of these included the same PFMT programs in both groups. The primary outcomes of the review were quality of life and improvement or cure. Nine trials used one of several validated quality-of-life instruments; however, only four of these reported data in a form that could be used for meta-analysis. Thus, quality-of-life results were not pooled. Data were pooled for the other primary outcome, improvement or cure, but there were a sufficient number of studies only for the comparison between PFMT with and without biofeedback. In a pooled analysis of seven studies, there was a significant reduction in the proportion of women reporting 'no improvement or cure' when biofeedback was added to muscle exercise (risk ratio [RR]: 0.75, confidence interval [CI]: 0.66 to 0.86). The authors noted that there may have been other differences between groups, such as more frequent contact with a healthcare professional or a greater number of treatment sessions, which might partially explain the difference in the improvement or cure rate in women who did or did not receive biofeedback. Moreover, when only the outcome 'no cure' was examined, there was not a significant difference between groups that did and did not receive biofeedback (5 studies: RR: 0.92, 95% CI: 0.81-1.05). Among secondary outcomes, a pooled analysis of seven trials did not find a significant difference in leakage episodes in a 24-hour period after treatment (mean difference: -0.01, 95% CI: -0.21 to 0.01). For the outcomes frequency and nocturia, data could not be combined but the review authors reported that the pattern was one of no difference between groups.

A number of significant design flaws in the 24 trials that met inclusion criteria (N=1583 women) limit the reliability of the reported outcomes. These flaws included:

- It was common for the women in the biofeedback arm to have more contact with healthcare professionals than those who did not receive biofeedback;
- Many of the trials were at moderate to high risk of bias; and
- There was significant variation in the regimens proposed for feedback and biofeedback, and the intervention's purpose and composition were often unclear.

The authors concluded that feedback or biofeedback may provide additional benefit to pelvic floor muscle exercises (PME) alone; however, further research is needed to differentiate whether the beneficial effect was due to feedback, biofeedback, or some other difference between the trial arms.

Randomized Controlled Trials

Kannan (2022) published a single blinded three-arm randomized control pilot trial evaluating safety, feasibility, effectiveness of a new biofeedback device (PelviSense; PS) with that of conventional biofeedback (CB) using an intravaginal probe for the treatment of stress urinary incontinence (SUI) in women.[154] Patients (n=51) were randomly allocated to one of three study groups: PS-assisted pelvic floor muscle training (PFMT), CB-assisted PFMT, or PFMT alone. The PFMT adherence was greater in the PS-assisted PFMT group than in the unassisted or CB-assisted PFMT groups. Between-groups analysis revealed significant effects

on improved SUI symptoms, urine loss severity, and PFM strength for the PS-assisted PFMT group compared with the CB-assisted and PFMT alone groups. This pilot study is limited in sample size, study duration, and lack of long-term follow-up.

Sahin (2022) conducted a prospective, randomized study to examine the effect of pelvic floor exercises performed with EMG biofeedback or a vaginal cone in women (N=40) with stress urinary incontinence.[155] Patients were randomly divided into two groups; pelvic floor muscle exercise (PFME) with a vaginal cone at home (N = 20) and PFME with EMG biofeedback in the hospital (N = 20). Both groups improved in the pad test, muscle strength, social anxiety index, quality of life, and treatment satisfaction measurement compared with the pre-treatment period ($p < 0.05$). No significant difference was found between the groups in terms of assessment parameters in intergroup analyses during follow-up ($p > 0.05$).

Hagen (2020) conducted a multicenter RCT in 600 women with stress or mixed urinary incontinence. Participants were randomized to 16 weeks of PMFT with electromyographic biofeedback or PMFT alone. Both groups received supervised PMFT during clinic appointments and a home PMFT regimen. The mean number of appointments attended was about four in both groups. Urinary incontinence symptoms (self-reported at month 24 via the International Consultation on Incontinence Questionnaire on Urinary Incontinence Short Form [ICIQ-UI-SF]) were similar in both groups (mean difference, -0.09; 95% CI, -0.92 to 0.75; p=.84). ICIQ-UI-SF scores were also similar between groups at earlier times (6 and 12 months). At 24 months, the proportion of patients who achieved the study's definition of cure, improvement, and symptoms that were very much better or much better was similar between groups. Pelvic floor muscle strength and endurance was assessed at 6 months, with similar findings in both groups. A limitation of this study is the short duration of the intervention compared to the length of follow-up.

A double-blind, sham-controlled RCT by Terlikowski (2013) compared transvaginal electrical stimulation (TVES) with active (n=68) or sham (n=34) EMG-biofeedback in premenopausal women with stress urinary incontinence (SUI).[156] The group receiving active biofeedback had significantly better results than the sham group for reduction in urinary leakage, pelvic floor muscle strength, and incontinence-related quality of life. No significant between group difference was found in urodynamic data. The authors concluded that TVES with active EMG biofeedback “is a trustworthy method for treating premenopausal women with stress urinary incontinence; however reliability needs to be established.”

Other RCTs comparing the efficacy of PFMT alone with PFMT with biofeedback have been published. Statistically significant differences in outcomes between interventions were not consistently found, however, sample sizes were small (<25 per group) and thus the studies may have been underpowered.

VOIDING DYSFUNCTION

Systematic Reviews

Fazeli published a SR with meta-analysis to better understand how biofeedback has been used to treat children, up to age 18, with symptoms of bladder dysfunction not responding to standard therapy alone.[157] Five eligible studies were included in the SR. Four of the studies were pooled in the meta-analysis for a total of 382 participants. The overall proportion of cases with resolved incontinence at six months was similar in biofeedback and control groups (OR1.37 [95% CI 0.64 to 2.93], RD 0.0.7 [-0.9, 0.23]). There was no significant different in

mean maximum urinary flow rate mean difference 0.50 ml, range -0.56 to 1.55) or likelihood of urinary tract infection (OR 1.30 [95% CI 0.65 to 2.58]). This SR was limited by the paucity of research, high quality studies, and small sample sizes.

Randomized Controlled Trials

In 2015, Sener published results from a retrospective RCT that compared the outcomes of four biofeedback sessions (group one; n=20) with six to ten biofeedback sessions (group two; n=20) on treating children with dysfunctional voiding. [158] Normalized voiding after the treatment was determined in 18 subjects from group one, and 19 subjects in group two. Fifteen out of the 40 total study sample were determined to have reflux. At the six month evaluation of group one, voiding dysfunction had resolved in seven, had improved in three, and persisted in one. In group two, voiding dysfunction had resolved in ten, improved in three. This study is limited by a small sample size and other methodological constraints that make it difficult to determine the efficacy of biofeedback for children with dysfunctional voiding.

In 2015, Minardi published results from a four arm RCT to evaluate the therapeutic effects of tamsulosin and biofeedback on recurrent urinary tract infections in 155 women with dysfunctional voiding.[159] The study consisted of four groups: group one received uroflowmetry biofeedback, group two received α1-adrenoceptor antagonists, group three received uroflowmetry biofeedback combined with α1-adrenoceptor antagonists, and group four received no treatment. Patients were evaluated by the American Urological Association Symptom Index. Urodynamics was carried out in patients of groups one, two and three at three, six and 12 months, whereas urodynamics was only carried out at 12 months in group four. The incidence of storage and emptying symptoms, mean post-void residual, mean flow rate, flow time, voiding volume, and urinary tract infections decreased at three, six, and twelve month for all four groups. This study was limited by the small sample size, attrition, and other methodological constraints making it hard to determine the efficacy of biofeedback for women with recurrent urinary tract infections and dysfunctional voiding.

OTHER URINARY INCONTINENCE

Systemic Reviews

No SRs were identified for biofeedback for the treatment of other urinary incontinence.

Randomized Control Trials

An RCT of 74 patients with multiple sclerosis reported that the addition of neuromuscular electrical stimulation with biofeedback training resulted in 85% incontinence reduction, compared to a 47% incontinence reduction in the control group trained only with biofeedback.[160]

Section Summary

The available evidence for the use of biofeedback in the treatment of stress and/or or urge urinary incontinence in female patients includes several RCTs and SRs. Although there is some heterogeneity across these studies, there is enough research to show that biofeedback improves outcomes in women with urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT). The current evidence base is insufficient to draw conclusions regarding the role of biofeedback for the treatment of urinary incontinence other than in this setting.

OTHER INDICATIONS

Other indications for which there are no clinical trial publications sufficient to demonstrate the effectiveness of biofeedback include, but are not limited to the following:

- Cardiovascular disorders
- Childhood Apraxia of Speech[161]
- Chronic fatigue syndrome
- Chronic obstructive pulmonary disease (COPD)
- Epilepsy[162]
- Facial palsy
- Hand hemiplegia
- Low vision
- Side-effects of cancer chemotherapy

PRACTICE GUIDELINE SUMMARY

AMERICAN ACADEMY OF SLEEP MEDICINE (AASM)

In 2008, an AASM special committee released a guideline on evaluation and management of chronic insomnia in adults.[163] The AASM considers biofeedback as one of a number of common therapies that are “effective and recommended in the treatment of chronic primary and comorbid (secondary) insomnia (Guideline)” The AASM definition for guideline is “a patient-care strategy, which reflects a moderate degree of clinical certainty. The term guideline implies the use of Level two Evidence (RCTs with high alpha and beta error) or a consensus of Level three Evidence (non-randomized concurrently controlled studies).”

AMERICAN COLLEGE OF GASTROENTEROLOGY

In 2014, the American College of Gastroenterology (ACG) published guidelines on the management of fecal incontinence.[164] The guideline indicated that pelvic floor rehabilitation techniques (eg, biofeedback, therapeutic exercises) are effective in patients with fecal incontinence who do not respond to conservative measures (strong recommendation, moderate quality of evidence).

In 2021, the American College of Gastroenterology (ACG) published a guideline on the management of benign anorectal disorders.[165] The guideline notes: "We recommend that instrumented anorectal biofeedback therapy should be used to manage symptoms in DD [defecation disorder] (strong recommendation; minimal risk of harm; quality of evidence: moderate)." Furthermore, the guideline notes the following key concepts related to biofeedback in the setting of DD:

- "Biofeedback should involve 4–6 sessions with well-trained therapists aimed at normalizing rectoanal coordination, ensuring good rectal pressure on strain, sensory retraining, and balloon expulsion retraining.

- Baseline ARM [anorectal manometry] and balloon expulsion is useful to predict the outcome and guide biofeedback therapy
- Defecography (MR [magnetic resonance] or barium) may be indicated in patients with DD who fail conservative therapy and biofeedback."
- The guideline also provides a suggested treatment protocol for anorectal biofeedback.

AMERICAN COLLEGE OF OBSTETRICIANS AND GYNECOLOGISTS (ACOG)[166]

In 2015 ACOG reaffirmed their 2009 clinical practice guidelines on urinary incontinence in women. Biofeedback was not included in these recommendations.

AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians published a guideline titled “Noninvasive Treatments for Acute, Subacute, and Chronic Back Pain: a Clinical Practice Guideline From the American College of Physicians”. The guideline stated low quality evidence supports biofeedback for chronic low back pain.

AMERICAN COLLEGE OF OCCUPATIONAL AND ENVIRONMENTAL MEDICINE (ACOEM)

In 2020, the ACOEM updated their guideline on noninvasive and minimally invasive management of low back disorders.[167] The role of biofeedback is not addressed in this updated guideline.

AMERICAN GASTROENTEROLOGICAL ASSOCIATION (AGA)

The updated AGA position statement (2013) on constipation considers biofeedback a possible treatment for patients with dyssynergia-type constipation with severe symptoms and proven pelvic floor dysfunction “to train patients to relax their pelvic floor muscles during straining and to correlate relaxation and pushing to achieve defecation (Strong Recommendation, High-Quality Evidence).”[168, 169]

The following statement on biofeedback was included: “Pelvic floor retraining by biofeedback therapy rather than laxatives is recommended for defecatory disorders (Strong Recommendation, High-Quality Evidence).”

AMERICAN HEART ASSOCIATION

A 2013 the American Heart Association published a statement based on a systematic literature review on alternatives to diet and medication for lowering blood pressure (BP) in patients with hypertension.[170] The report found meta-analyses to have had mixed results, though some recent trials showed reduction in BP with certain biofeedback techniques. However, recommendations for any specific techniques could not be made due to the paucity of data. The statement recommended that biofeedback could be considered for treatment of hypertension. This recommendation was rated as Class IIB, Level of Evidence B recommendation, defined as usefulness/efficacy less well-defined based on conflicting evidence from a single RCT or nonrandomized studies; additional studies with broad objectives needed.

AMERICAN NEUROGASTROENTEROLOGY AND MOTILITY SOCIETY

In 2015, the American Neurogastroenterology and Motility Society and the European Society of Neurogastroenterology and Mobility jointly published consensus-based guidelines on biofeedback therapy for anorectal disorders.[171] The guidelines included the following recommendations:

- "Biofeedback is recommended for the short-term and long-term treatment of constipation with dyssynergic defecation."
- "Biofeedback therapy is recommended for the short-term and long-term treatment of fecal incontinence"
- "Biofeedback therapy is not recommended for the routine treatment of children with functional constipation, with or without overflow fecal incontinence."

AMERICAN SOCIETY OF COLON AND RECTAL SURGEONS (ASCRS)

In 2016, ASCRS published guidelines on the evaluation and management of constipation.[172] The guideline states that biofeedback therapy is a first-line treatment for symptomatic pelvic floor dyssynergia (strong recommendation, moderate quality of evidence).

An American Society of Colon and Rectal Surgeons practice parameter recommended biofeedback "as an initial treatment for motivated patients with incontinence with some voluntary sphincter contraction. Biofeedback may be considered a first-line option for many patients with fecal incontinence who have not responded to simple dietary modification or medication. Supportive counseling and practical advice regarding diet and skin care can improve the success of biofeedback. Biofeedback may be considered before attempting sphincter repair or for those who have persistent or recurrent symptoms after sphincter repair. It may have a role in the early postpartum period in females with symptomatic sphincter weakness. Biofeedback and a pelvic floor exercise program can produce improvement that lasts more than two years. Biofeedback home training is an alternative to ambulatory training programs, especially in the elderly." The authors assigned a level of evidence of III and grade of recommendation B, defined as well-designed, quasi-experimental nonrandomized studies with generally consistent findings.

AMERICAN UROLOGICAL ASSOCIATION AND THE SOCIETY OF URODYNAMICS, FEMALE PELVIC MEDICINE & UROGENITAL RECONSTRUCTION (AUA/SUFU)[173]

The 2020 AUA/SUFU evidence-based practice guidelines recommended offering behavioral therapies (e.g., bladder training, bladder control strategies, pelvic floor muscle training) as first line therapy to all patients with overactive bladder. This recommendation was rated as a Standard, defined as a directive statement that an action should or should not be taken. The strength of evidence was rated as Grade B (moderate quality; moderate certainty). Biofeedback was included among a number of other modalities as a component of behavioral therapies. The guideline reported that the limited literature did not show any single component of behavioral therapy to be essential to efficacy or to be superior in efficacy.

TENSION AND MIGRAINE HEADACHES

Clinical practice guidelines from professional associations include biofeedback in their recommendations for prevention of tension and migraine headaches.[174-177] The associations included the American Academy of Neurology, the National Institute of Neurologic Disorders and Stroke, the U.S. Headache Consortium, and the European Federation of Neurological Societies.

NATIONAL INSTITUTE FOR CLINICAL EXCELLENCE

In 2017, the National Institute for Clinical Excellence (NICE) issued evidence-based guidance on constipation in children and young people, which was reaffirmed in 2014.[178] The guidance indicated that biofeedback should not be used for ongoing treatment.

SUMMARY

It appears that biofeedback may improve health outcomes for some people for prevention of tension-type and migraine headaches. Clinical guidelines based on research recommend biofeedback for people with tension and migraine headaches. Therefore, biofeedback may be considered medically necessary when policy criteria are met.

There is enough research to show that biofeedback improves health outcomes for people with dyssynergia-type constipation. Clinical guidelines based on research recommend biofeedback for pelvic floor training for dyssynergia constipation in adults. Therefore, biofeedback may be considered medically necessary when policy criteria are met.

There is enough research to show that biofeedback improves outcomes in individuals with stress and/or urge urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT). Clinical practice guidelines recommended behavioral therapies including biofeedback as to patients with overactive bladder. Therefore, biofeedback may be considered medically necessary in individuals with stress and/or urge urinary incontinence when administered in conjunction with pelvic floor muscle training (PFMT).

There is not enough research to show that biofeedback improves health outcomes for people with the variety of investigational indications listed in the criteria. In addition, no clinical guidelines based on research recommend biofeedback for these indications. Therefore, biofeedback is considered investigational for all other indications.

Definitive Lower Limb Prostheses

Effective: April 1, 2024

Next Review: July 2024
Last Review: March 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

A prosthesis is a fabricated substitute for a missing body part. Lower limb prostheses may include a number of components, such as prosthetic feet, ankles, knees, and socket insertions and suspensions. A definitive prosthesis is provided after the surgical wound has healed and the residual limb has matured.

MEDICAL POLICY CRITERIA

Notes:

- This policy does not address microprocessor-controlled prostheses. Please refer to the *Cross References* section below for the appropriate medical policy.
- Preauthorization is only required for definitive (permanent) prostheses. Please check the preauthorization website to confirm requirements.
- This policy does not address preparatory prostheses, which may be considered medically necessary.
- This policy applies to the codes listed in the policy criteria as noted. Unlisted codes should not be used if there is a specific code that is applicable (see Coding Note below).

I. A definitive lower limb prosthesis may be considered **medically necessary** when all of the following criteria (A. – B.) are met:

A. All of the following general criteria are met:

1. The patient is motivated to ambulate using the requested prosthesis; and
2. The prosthesis is furnished incident to a physician's services or on a physician's order; and
3. The residual limb has matured; and
4. The member has been using a prosthesis, has achieved a defined functional state and is cognitively capable of using the prosthesis to ambulate effectively at the determined functional level (K0 – K4); and
5. The member had an in-person medical evaluation with the ordering physician to establish their overall functional capabilities and functional level (K level). (NOTE: The ordering physician might delegate this assessment to a licensed/certified medical professional (LCMP) defined as a physical therapist (PT) or occupational therapist (OT), or physician with training and expertise in the functional evaluation of beneficiaries with amputations.)

B. One or more of the following are met:

1. The request is for a lower limb prosthesis (L5010-L5341).
2. The request is for one of the following prosthetic feet:
   a. Request is for an external keel SACH foot (L5970) or single axis ankle/foot (L5974) for patients demonstrating a functional Level 1 or above.
   b. Request is for a flexible-keel foot (L5972) or multiaxial ankle/foot (L5978) for patients demonstrating a functional Level 2 or greater.
   c. Request is for a flex foot system (L5980), energy storing foot (L5976), multiaxial ankle/foot, dynamic response foot (L5979), or flex walk system or equal (L5981) or shank foot system with vertical loading pylon (L5987) for patients demonstrating a functional Level 3 or above.
3. Request is for one of the following prosthetic knees:
   a. Request is for a high activity knee control frame (L5930) for patients demonstrating a functional Level 4.
   b. Request is for a fluid (hydraulic) or pneumatic knee (L5610, L5613, L5614, L5722 - L5780, L5814, L5822-L5841, L5848) for patients demonstrating a functional Level 3 or above.
   c. Request is for other knee system (L5611, L5616, L5710-L5718, L5810-L5812, L5816-L5818) for patients demonstrating a functional Level 1 or above.
4. Request is for an axial rotation unit (L5982-L5986) or a multiaxial rotation unit with swing phase (L5968) for patients demonstrating a functional level 2 or above.
5. Request is for up to two test (diagnostic) sockets (L5618–L5628) for an

individual prosthetic. Additional documentation of medical necessity is required for more than two test sockets.

6. Request is for prosthesis replacement when one or more of the following criteria are met:
    a. A change in the physiological condition of the patient; or
    b. An irreparable change in the condition of the device, or in a part of the device; or
    c. The condition of the device, or the part of the device, requires repairs and the cost of such repairs would be more than 60 percent of the cost of a replacement device, or, as the case may be, of the part being replaced.
7. Request is for socket replacements (L5700–L5703) when both of the following criteria are met:
    a. The member has an existing prosthesis
    b. One of the following is met:
        i. Changes in the residual limb that cannot be accommodated through the use of socket inserts and/or liners and/or stump stockings, and/or modifications to the existing socket; or
        ii. The existing socket is irreparable due to damage or wear.

II. Definitive prostheses are considered **not medically necessary** if Criterion I. is not met.

III. Replacement is considered **not medical necessary** for the following:
    A. Criterion I. is not met.
    B. Replacement is covered under manufacturer warranty and maintenance services.

IV. Replacement requests for same/similar items which include upgraded features or components (additional or deluxe features which exceed the member's medical need) or upgrades to DME, prosthetics, or orthotics already in use are considered **not medically necessary**.

V. Definitive prostheses are considered **not medically necessary** if the patient's potential functional level is "0."

VI. More than two of the same socket inserts (L5654-L5665, L5673, L5679, L5681, L5683) per individual prosthesis at the same time are considered **not medically necessary**.

VII. Use of a mechanical reel-based socket volume adjustment system, including but not limited to the RevoFit®, is considered **not medically necessary.**

VIII. Prostheses are considered **not medically necessary** if the member is unable or unwilling to use the prosthesis.

IX. Accessories for any non-covered DMEPOS item are considered **not medically necessary** (See the health plan’s Reimbursement Policy for “Associated Claims,” Administrative 119). Note, accessories in this situation would be non-covered regardless of whether the original DMEPOS item was billed to the health plan.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

DEFINITIONS

For purposes of this policy, the following definitions apply:

Preparatory Prosthesis. An unfinished, functional replacement for an amputated limb, fitted and aligned to accelerate the rehabilitation process, control edema, and prepare the residual limb for the external forces associated with wearing a prosthesis on a day to day basis.[1]

Permanent (i.e. definitive) Prosthesis. A permanent prosthesis is an artificial limb used by amputees whose residual limb has matured and the amputee has satisfactorily completed the temporary limb phase. The socket and components are manufactured to provide lasting durability and a proper cosmetic appearance.[2]

Mature Residual Limb: A mature residual limb is defined as one that has healed, reached its optimal volume, and been shaped appropriately to accommodate the chosen socket configuration

FUNCTIONAL CLASSIFICATION LEVELS

Following are the functional classification levels used to determine patient rehabilitation potential:[3]

Functional Classification Levels	
Level 0:	Does not have the ability or potential to ambulate or transfer safely with or without assistance, and a prosthesis does not enhance quality of life or mobility.
Level 1:	Has the ability or potential to use a prosthesis for transfers or ambulation on level surfaces at fixed cadence. Typical of the limited and unlimited household ambulator.
Level 2:	Has the ability or potential for ambulation with the ability to traverse low level environmental barriers such as curbs, stairs or uneven surfaces. Typical of the limited community ambulator.
Level 3:	Has the ability or potential for ambulation with variable cadence. Typical of the community ambulator who has the ability to traverse most environmental barriers and may have vocational, therapeutic, or exercise activity that demands prosthetic utilization beyond simple locomotion.
Level 4:	Has the ability or potential for prosthetic ambulation that exceeds basic ambulation skills, exhibiting high impact, stress, or energy levels. Typical of the prosthetic demands of the child, active adult, or athlete.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and physical/chart notes (including prior prosthetic use)
    - Medical records should document the patient's current functional capabilities and expected functional potential, including an explanation for any difference. Bilateral amputees cannot be strictly bound by functional level classifications.
- Current condition, including the status of the residual limb and the nature of other medical problems
- Functional level
- Desire to ambulate
- Physician's order (if applicable)
- Product information (manufacturer name, model number)
- For replacement items:
    - Comparative limb measurements (if applicable) or specific physiological change that necessitates replacement.
    - The date of service the prosthesis or component was provided.
    - The make/model and serial number (if applicable) for the component(s)
    - Warranty information
    - A repair vs. replacement analysis (i.e. cost to replace vs. cost to repair)

BACKGROUND

In 2005, there were 1.6 million people living with limb loss in the U.S., and the number is predicted to be 3.6 million by 2050.[4] Common causes of lower limb amputation are dysvascular complications from diabetes, arteriosclerosis, smoke, or a combination of factors, and less commonly, traumatic injury, such as motor vehicle and industrial accidents, congenital limb development deficiency, and tumors.[5]

A standard timeline of amputation and prosthetic use includes multiple stages, including recovery and healing, maturation, and prosthetic selection and adjustments. Initially following an amputation, there is a period of limb management, where a variety of dressings may be used. Then a preparatory prosthesis is used while the limb volume stabilizes. Once the residual limb has matured and the patient's functional level has been determined, a definitive prosthesis is fitted.

PRACTICE GUIDELINE SUMMARY

Department of Veterans Affairs and the Department of Defense

A 2017 clinical practice guideline from the Department of Veterans Affairs and the Department of Defense (VA/DoD) included the following recommendation:[5]

- We suggest that in the perioperative phase following amputation, patients receive physical rehabilitation and appropriate durable medical equipment/assistive technology. (Weak strength of evidence)
- We recommend the use of valid, reliable, and responsive functional outcome measures, including, but not limited to, the Comprehensive High-level Activity Mobility Predictor, Amputee Mobility Predictor, 10-meter walk test, and 6-minute walk test. (Strong strength of evidence)
- We suggest the use of a combination of measures with acceptable psychometric properties to assess functional outcomes. (Weak strength of evidence)

SUMMARY

Definitive lower limb prosthetics improve health outcomes for select individuals missing part of a lower limb. Therefore, they may be considered medically necessary when policy criteria are met. When policy criteria are not met, the requested items are considered not appropriate in these individuals and are considered not medically necessary.

CODES

NOTE: All items must be reported with the appropriate Healthcare Common Procedure Coding System (HCPCS) code. Most prosthetics and accessories have an applicable, specific HCPCS code available. Only when there is no appropriate descriptive code to use may an “unlisted code” (e.g., HCPCS codes E1399) be reported. Inappropriate use of unlisted codes or failure to use specific codes when available may result in inaccurate reviews. The health plan will defer to the Medicare Pricing, Data Analysis, and Coding (PDAC) contractor (Palmetto GBA) for proper code assignment of most items.

Codes	Number	Description
CPT	None	
HCPCS	L5010	Partial foot, molded socket, ankle height, with toe filler
	L5020	Partial foot, molded socket, tibial tubercle height, with toe filler
	L5050	Ankle, Symes, molded socket, SACH foot
	L5060	Ankle, Symes, metal frame, molded leather socket, articulated ankle/foot (SACH)
	L5100	Below knee (BK), molded socket, shin, SACH foot
	L5105	Below knee (BK), plastic socket, joints and thigh lacer, SACH foot
	L5150	Knee disarticulation (or through knee), molded socket, external knee joints, shin, SACH foot
	L5160	Knee disarticulation (or through knee), molded socket, bent knee configuration, external knee joints, shin, SACH foot
	L5200	Above knee (AK), molded socket, single axis constant friction knee, shin, SACH foot
	L5210	Above knee (AK), short prosthesis, no knee joint (stubbies), with foot blocks, no ankle joints, each
	L5220	Above knee (AK), short prosthesis, no knee joint (stubbies), with articulated ankle/foot, dynamically aligned, each
	L5230	Above knee (AK), for proximal femoral focal deficiency, constant friction knee, shin, SACH foot
	L5250	Hip disarticulation, Canadian type; molded socket, hip joint, single axis constant friction knee, shin, SACH foot
	L5270	Hip disarticulation, tilt table type; molded socket, locking hip joint, single axis constant friction knee, shin, SACH foot
	L5280	Hemipelvectomy, Canadian type; molded socket, hip joint, single axis constant friction knee, shin, SACH foot
	L5301	Below knee (BK), molded socket, shin, SACH foot, endoskeletal system
	L5312	Knee disarticulation (or through knee), molded socket, single axis knee, pylon, SACH foot, endoskeletal system
	L5321	Above knee (AK), molded socket, open end, SACH foot, endoskeletal system, single axis knee
	L5331	Hip disarticulation, Canadian type, molded socket, endoskeletal system, hip joint, single axis knee, SACH foot
	L5341	Hemipelvectomy, Canadian type, molded socket, endoskeletal system, hip joint, single axis knee, SACH foot
	L5610	Addition to lower extremity, endoskeletal system, above knee (AK), hydracadence system
	L5611	Addition to lower extremity, endoskeletal system, above knee (AK), knee disarticulation, four-bar linkage, with friction swing phase control
	L5613	Addition to lower extremity, endoskeletal system, above knee (AK), knee disarticulation, four-bar linkage, with hydraulic swing phase control
	L5614	Addition to lower extremity, exoskeletal system, above knee (AK), knee disarticulation, four-bar linkage, with pneumatic swing phase control
	L5616	Addition to lower extremity, endoskeletal system, above knee (AK), universal multiplex system, friction swing phase control
	L5700	Replacement, socket, below knee (BK), molded to patient model
	L5701	Replacement, socket, above knee (AK)/knee disarticulation, including attachment plate, molded to patient model
	L5702	Replacement, socket, hip disarticulation, including hip joint, molded to patient model
	L5703	Ankle, Symes, molded to patient model, socket without solid ankle cushion heel (SACH) foot, replacement only

Codes	Number	Description
	L5710	Addition, exoskeletal knee-shin system, single axis, manual lock
	L5711	Additions exoskeletal knee-shin system, single axis, manual lock, ultra-light material
	L5712	Addition, exoskeletal knee-shin system, single axis, friction swing and stance phase control (safety knee)
	L5714	Addition, exoskeletal knee-shin system, single axis, variable friction swing phase control
	L5716	Addition, exoskeletal knee-shin system, polycentric, mechanical stance phase lock
	L5718	Addition, exoskeletal knee-shin system, polycentric, friction swing and stance phase control
	L5722	Addition, exoskeletal knee-shin system, single axis, pneumatic swing, friction stance phase control
	L5724	Addition, exoskeletal knee-shin system, single axis, fluid swing phase control
	L5726	Addition, exoskeletal knee-shin system, single axis, external joints, fluid swing phase control
	L5728	Addition, exoskeletal knee-shin system, single axis, fluid swing and stance phase control
	L5780	Addition, exoskeletal knee-shin system, single axis, pneumatic/hydra pneumatic swing phase control
	L5783	Addition to lower extremity, user adjustable, mechanical, residual limb volume management system
	L5810	Addition, endoskeletal knee-shin system, single axis, manual lock
	L5811	Addition, endoskeletal knee-shin system, single axis, manual lock, ultra-light material
	L5812	Addition, endoskeletal knee-shin system, single axis, friction swing and stance phase control (safety knee)
	L5814	Addition, endoskeletal knee-shin system, polycentric, hydraulic swing phase control, mechanical stance phase lock
	L5816	Addition, endoskeletal knee-shin system, polycentric, mechanical stance phase lock
	L5818	Addition, endoskeletal knee-shin system, polycentric, friction swing and stance phase control

Medical Policy Manual Durable Medical Equipment, Policy No. 37

Power Wheelchairs: Group 3

Effective: November 1, 2023

Next Review: July 2024
Last Review: September 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Power wheelchairs are battery powered mobility devices with integrated or modular seating system, electronic steering and four or more-wheel non-highway construction.

MEDICAL POLICY CRITERIA

Note: This policy only addresses the initial provision of Group 3 power wheelchairs (HCPCS codes K0848-K0864). Replacement of a wheelchair or of wheelchair components, as well as wheelchair accessories, are addressed by a separate medical policy, Durable Medical Equipment, Prosthetic and Orthotic Replacements, Duplicates, Repairs, and Upgrades to Existing Equipment (DME75).

I. Group 3 power wheelchairs (PWC) may be considered **medically necessary** when both of the following Criteria (A. and B.) are met:

A. All of the following general Criteria (1. – 12.) are met:

1. The patient has had a specialty evaluation that was performed by a licensed/certified medical professional, such as a PT or OT, or practitioner who has specific training and experience in rehabilitation wheelchair

evaluations and that documents the medical necessity for the wheelchair and its special features; and

2. The patient has a mobility limitation that significantly impairs their ability to participate in one or more mobility-related activities of daily living (MRADLs) such as toileting, feeding, dressing, grooming, and bathing in customary locations in the home. A mobility limitation is one that:
    a. Prevents the member from accomplishing a MRADL entirely, or
    b. Places the patient at reasonably determined heightened risk of morbidity or mortality secondary to the attempts to perform a MRADL, or
    c. Prevents the member from completing MRADLs within a reasonable time frame.
3. Use of a power wheelchair in the home will significantly improve the patient's ability to participate in MRADLs, with or without caregiver assistance; and
4. The patient does not have sufficient upper extremity function to self-propel an optimally configured manual wheelchair (see Policy Guidelines) in the home to perform MRADLs during a typical day. Notes: Limitations of strength, endurance, range of motion, or coordination, presence of pain, or deformity or absence of one or both upper extremities are relevant to the assessment of upper extremity function; and
5. The underlying condition is not reversible, and the length of need is more than 3 months; and
6. The patient's mobility limitation cannot be sufficiently and safely resolved by the use of an appropriately fitted cane or walker; and
7. The patient's mobility needs cannot be met by a power operated vehicle (POV) (see Policy Guidelines); and
8. The patient has the mental (e.g., cognition, judgment) and physical (e.g., vision) capabilities to safely operate the power wheelchair that is provided in the home setting; or if the patient is unable to safely operate the power wheelchair, the patient has a caregiver who is unable to adequately propel an optimally configured manual wheelchair (see Policy Guidelines), but is available, willing, and able to safely operate the power wheelchair that is provided; and
9. The patient's weight is less than or equal to the weight capacity of the PWC that is provided and greater than or equal to 95% of the weight capacity of the next lower weight class, i.e., a Heavy Duty PWC is covered for a patient weighing 285 – 450 pounds; a Very Heavy Duty PWC is covered for a patient weighing 428 – 600 pounds; an Extra Heavy Duty PWC is covered for a patient weighing 570 pounds or more; and
10. The patient's home provides adequate access between rooms, maneuvering space, and surfaces for the operation of the power wheelchair that is provided; and
11. The patient has not expressed an unwillingness to use a power wheelchair in the home; and

12. Any coverage criteria pertaining to the specific wheelchair type (see below) are met.

B. Any of the following Group 3 power wheelchairs (PWC) may be considered **medically necessary** when all of Criteria A. above are met:

1. A Group 3 PWC with no power options (K0848-K0855) when the patient's mobility limitation is due to a neurological condition, myopathy, or congenital skeletal deformity.
2. A Group 3 PWC with single power option (K0856-K0860) or multiple power option (K0861-K0864) when **both** of the following (a. and b.) are met:
    a. The patient's mobility limitation is due to a neurological condition, myopathy, or congenital skeletal deformity; and
    b. Any one of the following are met:
        i. The patient requires a drive control interface other than a hand or chin-operated standard proportional joystick (examples include but are not limited to head control, sip and puff, switch control); or
        ii. The patient uses a ventilator which is mounted on the wheelchair; or
        iii. The patient has a power tilt or a power recline seating system and the system is being used on the wheelchair and one of the following are met:
            a.) The patient is at high risk for development of a pressure ulcer and is unable to perform a functional weight shift; or
            b.) The patient utilizes intermittent catheterization for bladder management and is unable to independently transfer from the wheelchair to bed; or
            c.) The power seating system is needed to manage increased tone or spasticity.

II. Group 3 power wheelchairs are considered **not medically necessary** when the above criteria are not met, including but not limited to the following:

A. The patient is capable of ambulation within the home but requires a wheelchair for movement outside the home; or

B. The primary benefit of the wheelchair is to allow the patient to perform leisure or recreational activities; or

C. The patient has been approved for a power operated vehicle (POV); or

D. The accessory is used for the convenience of the patient or caregiver and is not necessary for performance of mobility related activities of daily living (MRADLs); or

E. The patient's functional mobility limitation can be sufficiently resolved with a cane, walker, or manual wheelchair, as described above; or

F. The patient's home does not provide adequate access, maneuvering space, physical layout (e.g., doorway thresholds), or appropriate surfaces to support the requested device; or

G. The underlying condition is reversible, and the length of need is less than 3 months (e.g., following lower extremity surgery which limits ambulation).

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

APPROPRIATE POPULATIONS

Group 3 power wheelchairs are reserved for the severely impaired patient afflicted with diseases such as: Amyotrophic Lateral Sclerosis (ALS), spinal cord injuries resulting in quadriplegia, stroke (CVA) with hemiplegia, late stage Parkinson's, late stage Multiple Sclerosis (MS), cerebral palsy, or Muscular Dystrophy.[1]

A Group 3 power wheelchair would not be appropriate for a beneficiary who has diabetes with peripheral neuropathy. Peripheral neuropathy affects the nerves. It is not a primary neurological condition but rather a symptom of another disease. The Power Mobility Device LCD specifically states that the patient must have a neurological condition; therefore, the beneficiary with peripheral neuropathy does not meet coverage criteria for a group 3 power wheelchair.

DEFINITIONS

Optimally configured wheelchair

An optimally configured wheelchair is one with an appropriate wheelbase, device weight, seating options (seat height and seat tilt/slope), and other appropriate non-powered accessories.

Power operated vehicle (POV)

A POV (scooter) is a chair-like battery powered mobility device for people with difficulty walking due to illness or disability, with integrated seating system, tiller steering, and three or four-wheel non-highway construction.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- Medical records and chart notes pertinent to the PWC request, including history of the present condition(s) and past medical history relevant to mobility needs. Required information includes:
    - Date of face-to-face encounter by the treating practitioner, with signed and dated documentation;
        - Elements of the face-to-face should include:

- Mobility limitation and how it interferes with the performance of ADLs (the physical examination should focus on body systems responsible for ambulatory difficulty or impact on ambulatory ability); (
- Explanation of why a cane, walker, manual wheelchair, or POV (scooter) is unable to meet the mobility needs in the home; and,
- If the member has the physical and mental abilities to operate a power wheelchair safely in the home.

  - The underlying condition, and whether or not it is reversible.
  - Ambulation-limiting symptoms and the diagnoses responsible for them;
  - Medications or other treatment for these symptoms;
  - Progression of ambulation difficulty over time;
  - Other diagnoses that may relate to ambulatory problems;
  - How far the beneficiary can walk without stopping and the pace of ambulation;
  - What ambulatory assistance (e.g., cane, walker, wheelchair, caregiver) currently used. If the prior mobility device is not a POV, provide details regarding the physical and functional changes that now require the use of a power mobility device;
  - Ability to stand up from a seated position without assistance; and,
  - Description of the home setting and the ability to perform activities of daily living in the home.
  - Length of need
- Physical examination relevant to mobility needs;
  - Weight and height;
  - Cardiopulmonary examination;
  - Musculoskeletal examination (i.e., arm and leg strength and range of motion);
  - Neurological examination (i.e., gait, balance and coordination); and,
  - Clearly distinguish the beneficiary's abilities and needs within the home from any additional needs for use outside the home.

BACKGROUND

Wheelchairs can be described in HCPCS coding with one code for the wheelchair base and then additional codes for wheelchair options and accessories. The decision for a particular wheelchair base may be influenced by the chair's intended use, the patient's size or level of disability, or based on specific features that will be incorporated into the chair (for example, a heavy-duty base with additional electronics features may be needed to support a power tilt and/or recline option.)

The following is a list of wheelchair bases and their characteristics:

POWER WHEELCHAIRS (PWCS)

Power wheelchairs are battery powered mobility devices with integrated or modular seating system, electronic steering and four or more-wheel non-highway construction. PWCs are divided into six performance-based groups as listed in Table 1.[2] This policy only addresses Group 3 PWCS:

Table 1. Power Wheelchairs: Six Performance-based Groups

CHAIR/ HCPCS	GROUP 1 K0813-16	GROUP 2 K0820-K0843	GROUP 3 K0848-K0864	GROUP 4 K0868-K0886	GROUP 5 K0890-K0891	GROUP 6 K0898-99
Length	40 inches	48 inches	48 inches	48 inches	48 inches	NA
Width	≤24 inches	≤34 inches	≤34 inches	≤34 inches	≤34 inches	NA
Obstacle Height	20 mm	40 mm	60 mm	75 mm	60 mm	NA
Minimum Top End Speed-Flat	3 MPH	3 MPH	4.5 MPH	6 MPH	4 MPH	NA
Range	5 miles	7 miles	12 miles	16 miles	12 miles	NA
Obstacle height or obstacle climb denotes the vertical height of a solid obstruction that can be climbed.						
Minimum top end speed denotes the minimum speed on a flat hard surface that is acceptable for a given category of devices.						
Range denotes the minimum distance acceptable for a given category of devices on a single charge of the batteries.						
The above six PWC groups are subdivided based on patient weight capacity, seat type, portability and/or power seating system capability.						

There are four weight capacity groups. Those listed in Table 2. represent patient weight handling capacity and are not intended to reflect performance.

Table 2. Weight Capacity Groups

Standard Duty	Heavy Duty	Very Heavy Duty	Extra Heavy Duty
Up to and including 300 pounds	301-450 pounds	451-600 pounds	601 pounds or more

Table 3. Seat Types

Sling Seat/Back-Flexible	Solid Seat/ Back-Rigid	Captains Chair	Stadium Style Seat
Cloth, vinyl, leather or equal material designed to serve as the support for buttocks or back. They may or may not have thin padding but are not intended to provide cushioning or positioning for the user.	Metal or plastic material usually covered with cloth, vinyl, leather or equal material, with or without some padding material designed to serve as the support for the buttocks or back. They may or may not have thin padding but are not intended to provide cushioning or positioning for the user. PWCs with an automotive-style back and a solid seat pan are considered as a solid	A one or two-piece automotive-style seat with rigid frame, cushioning material in both seat and back sections, covered in cloth, vinyl, leather or equal as upholstery, and designed to serve as a complete seating, support, and cushioning system for the user. It may have armrests that can be fixed, swingaway, or detachable. It may or may not have a	A one or two piece stadium-style seat with rigid frame and cushioning material in both seat and back sections, covered in cloth, vinyl, leather or equal as upholstery, and designed to serve as a complete seating, support, and cushioning system for the user. It may have armrests that can be fixed, swingaway, or detachable. It does not have a headrest. Chairs with stadium style seats

Sling Seat/Back-Flexible	Solid Seat/ Back-Rigid	Captains Chair	Stadium Style Seat
	seat/back system, not a Captains Chair.	headrest, either integrated or separate.	are billed using the Captains Chair HCPCS codes.

Portable denotes a PWC that is built of lightweight construction or can be disassembled into lightweight components that allow easy placement into a vehicle for use in a distant location.

Power options that may be added to a PWC to include power tilt, recline, elevating legrests, seat elevators or standing systems. There are three categories of PWCs based on the capability to accept and operate these power options:

- No-power-options PWCs are incapable of accommodating any power options
- Single power option PWCs have the capability to accept and operate only one power accessory at a time on the base.
- Multiple power option PWCs have the capability to accept and operate more than one power accessory at a time on the base.

Pediatric PWCs are uniquely sized for use with very small individuals and have the capability for extensive growth through frame adjustments (not just seating) and special features to address developmental issues (e.g., seat to floor placement, standing capability).

Each power wheelchair base code is intended to include all of the following Basic Equipment Package items on initial issue:

- Lap belt or safety belt (E0978)
- Battery charger single mode (E2366)
- Complete set of tires and casters, any type
- Legrests: Fixed, swingaway, or detachable nonelevating leg rests with or without calf pad (E0995)
- Footrests: Fixed, swingaway, or detachable nonelevating foot rests/plates or foot platform without angle adjustment for any PWC or angle adjustable footplates with Group 1 or 2 PWCs (K0037, K0040, K0041, K0042, K0043, K0044, K0045, K0052)
- Fixed, swingaway, or detachable nonadjustable height armrests (E0994, K0015, K0019) with arm pad (K0019)
- Upholstery for seat and back of proper strength and type for patient weight capacity of the power wheelchair (E0981, E0982)
- Weight specific components per patient weight capacity
- Any seat width and depth or back width except for Group 3 or 4 PWCs with a sling/solid seat/back
- Controller and Input Device.

SUMMARY

Group 3 power wheelchairs may improve overall health outcomes for some people with mobility limitations. According to the U.S. Centers for Medicare & Medicaid Services, Group 3 power wheelchairs are considered reasonable and medically necessary for specific populations when certain situations exist. Therefore, Group 3 power wheelchairs may be considered medically necessary when policy criteria are met. In all other situations, Group 3

power wheelchair use does not change management and does not improve health outcomes. Therefore, Group 3 power wheelchairs are not medically necessary when policy criteria are not met.

Negative Pressure Wound Therapy in the Outpatient Setting

Effective: December 1, 2023

Next Review: December 2024
Last Review: October 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Negative pressure wound therapy (NPWT) involves the use of negative pressure or suction device to aspirate and remove fluids, debris, and infectious materials from the wound bed to promote the formation of granulation tissue and wound healing. This policy addresses NPWT in the outpatient setting.

MEDICAL POLICY CRITERIA

I. A *1-month therapeutic trial* of a powered negative pressure wound therapy (NPWT) system (pump and supplies), may be considered **medically necessary** when both of the following criteria (A. - B.) are met:

   A. Documentation regarding conventional wound care is provided meeting either of the following:

      1. The wound care program meets all of the following (a. – e.):

         a. Documentation in the medical record of evaluation, care, and wound measurements by a licensed medical professional; and

         b. Application of dressings to maintain a moist wound environment; and

         c. Debridement of necrotic tissue if present; and

d. Evaluation of and provision for adequate nutritional status; and

e. Documentation the open wound has not responded to conventional treatment after 30 days OR documentation of the decision-making process supporting less than 30 days of conventional treatment.

2. Documentation is provided indicating that a comprehensive wound care program may not be indicated prior to NPWT for one or more of the following:

a. Open sternal wounds or repeat median sternotomy in high-risk obese patients; or

b. Skin grafts placed on an irregular surface/bed or compromised blood flow, with size >100 cm^2 requiring initial placement of NPWT for graft fixation; or

c. Diabetic foot ulcer with wound classification of Wagner grade II or greater.

B. Any of the following wound-specific criteria are met:

1. For Stage 3 or 4 pressure ulcers all of the following (a. - c.) are met:

a. Appropriate turning and positioning; and

b. Use of group 2 or 3 support surface for pressure ulcers on the posterior trunk or pelvis; and

c. Moisture and incontinence have been appropriately managed; or

2. For neuropathic (for example, diabetic) ulcers all of the following (a. - b.) must be met:

a. A comprehensive diabetic management program; and

b. Reduction in pressure on a foot ulcer with appropriate modalities; or

3. For venous insufficiency ulcers all of the following (a. - b.) must be met:

a. Compression bandages and/or garments applied consistently; and

b. Leg elevation and ambulation have been encouraged; or

4. Chronic (at least 30 days) ulcer of mixed etiology; or

5. Open wounds (including but not limited to post-operative dehiscence, non-healing amputation site in diabetics, high-risk open fracture); or

6. Repeat median sternotomy in high-risk obese patients; or

7. Skin grafts placed on an irregular surface/bed or compromised blood flow, with size >100 cm^2 requiring initial placement of NPWT for graft fixation.

II. Therapeutic trials of powered NPWT systems for the treatment of acute or chronic wounds are considered **not medically necessary** for any of the following:

A. Criterion I. is not met;

B. One or more of the following contraindications are present:

1. The presence in the wound of necrotic tissue with eschar, if debridement is not attempted; or

2. Osteomyelitis within the vicinity of the wound that is not concurrently being treated with intent to cure; or
3. Cancer present in the wound; or
4. The presence of an open fistula to an organ or body cavity within the vicinity of the wound.

III. Associated clinical care and supplies for the effective use of a NPWT system (e.g., wound care services; including for initiation and continuation of care) may be considered **medically necessary** if the primary NPWT system itself was determined to be medically necessary.

IV. Associated clinical care and supplies for the effective use of a NPWT system (e.g., wound care services; including for initiation and continuation of care) are considered **not medically necessary** if the primary NPWT system itself was determined to be not medically necessary or has not been reviewed for medical necessity.

V. *Continuation after a one-month therapeutic trial* of the powered NPWT system, as part of a comprehensive wound care program, may be considered **medically necessary** for up to 3 more months when both of the following criteria are met (A. – B.):
   A. There is documentation that a licensed medical professional has directly assessed the wound(s) being treated with the NPWT system; and
   B. There is continuous documentation of improvement (volume reduction, changes in dimensions and characteristics) which supports objective improvement in the wound.

VI. *Continuation after a one-month therapeutic trial* of the powered NPWT system is considered **not medically necessary** when any of the following occurs:
   A. Criterion III. is not met; or
   B. There is evidence of wound complications contraindicating continued use of NPWT.

VII. *Continuation after four total months* is considered **not medically necessary**.

VIII. Single-use/disposable NPWT systems (powered or nonpowered) and/or associated clinical care, supplies, and accessories are considered **investigational** for the treatment of acute or chronic wounds.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Wagner Grade Classification of Diabetic Foot Ulcers:[1]

Grade	Description
Grade 0	Skin intact but bony deformities lead to “foot at risk”
Grade 1	Superficial ulcer

Grade 2	Deeper; full thickness extension
Grade 3	Deep abscess formation or osteomyelitis
Grade 4	Partial Gangrene of forefoot
Grade 5	Extensive Gangrene

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

For *initial* one-month therapeutic trial:

1. History and physical/chart notes documenting policy criteria; and
2. Documentation, by provider, of indication for NPWT; and
3. Documentation of wound therapy program, including documentation of evaluation, care and wound measurements.

For *continuation* after a one-month therapeutic trial:

1. Documentation that a licensed medical professional has directly assessed the wound(s) being treated with the NPWT system; and
2. There is continuous documentation of improvement (volume reduction, changes in dimensions and characteristics) which supports objective improvement in the wound.

BACKGROUND

CHRONIC WOUNDS

Management

The management and treatment of chronic wounds, including decubitus ulcers, is challenging. Most chronic wounds will heal only if the underlying cause (ie, venous stasis, pressure, infection) is addressed. Also, cleaning the wound to remove nonviable tissue, microorganisms, and foreign bodies is essential to create optimal conditions for either re-epithelialization (ie, healing by secondary intention) or preparation for wound closure with skin grafts or flaps (ie, healing by primary intention). Therefore, debridement, irrigation, whirlpool treatments, and wet-to-dry dressings are common components of chronic wound care.

Negative pressure wound therapy (NPWT) involves the use of a negative pressure therapy or suction device to aspirate and remove fluids, debris, and infectious materials from the wound bed to promote the formation of granulation tissue. The devices may also be used as an adjunct to surgical therapy or as an alternative to surgery in a debilitated patient. Although the exact mechanism has not been elucidated, it is hypothesized that negative pressure

contributes to wound healing by removing excess interstitial fluid, increasing the vascularity of the wound, reducing edema, and/or creating beneficial mechanical forces that lead to cell growth and expansion.

A nonpowered (mechanical) NPWT system has also been developed; the Smart Negative Pressure Wound Care System is portable and lightweight (3 oz) and can be worn underneath clothing. This system consists of a cartridge, dressing, and strap; the cartridge acts as the negative pressure source. The system is reported to generate negative pressure levels similar to other NPWT systems. This system is fully disposable.

The focus of this evidence review is the use of NPWT in the outpatient setting. It is recognized that patients may begin using the device in the inpatient setting as they transition to the outpatient setting.

Regulatory Status

Negative pressure therapy or suction devices cleared by the U.S. Food and Drug Administration (FDA) for treating chronic wounds include, but are not limited to: Vacuum-Assisted Closure® Therapy (V.A.C., also known as negative pressure wound therapy; KCI); Versatile 1™ (V1) Wound Vacuum System (Blue Sky Medical), RENASYS™ EZ PLUS (Smith & Nephew), Foryou NPWT NP32 Device (Foryou Medical Electronics), SVED® (Cardinal Health), and PICO Single Use Negative Pressure Wound Therapy System (Smith & Nephew).

Portable systems include the RENASYS™ GO (Smith & Nephew), XLR8 PLUS (Genadyne Biotechnologies), extriCARE® 2400 NPWT System (Devon Medical), the V.A.C. Via™ (KCI), NPWT PRO to GO (Cardinal Health), and the PICO Single Use Negative Pressure Wound Therapy System (Smith & Nephew). The Prevena™ Incision Management System (KCI) is designed specifically for closed surgical incisions.

A nonpowered NPWT device, the SNaP® Wound Care System (Spiracur, acquired by Acelity in 2015), is a class II device requiring notification to market but not having the FDA premarket approval. In 2009, it was cleared for marketing by the FDA through the 510(k) pathway (K081406) and is designed to remove small amounts of exudate from chronic, traumatic, dehisced, acute, or subacute wounds and diabetic and pressure ulcers.

NPWT devices with instillation include the V.A.C. VERAFLO™ Therapy device (KCI/Acelity). It was cleared for marketing in 2011 by the FDA through the 510(k) pathway (K103156) and is designed to allow for controlled delivery and drainage of topical antiseptic and antimicrobial wound treatment solutions and suspensions. It is to be used with the V.A.C. Ulta unit, which is commercially marketed for use in the hospital setting. Instillation is also available with Simultaneous Irrigation™ Technology tubing sets (Cardinal Health) for use with Cardinal Health SVED® and PRO NPWT devices, however, its use is not indicated for use in a home care setting (K161418).

No NPWT device has been cleared for use in infants and children.

In November 2009, the FDA issued an alert concerning complications and deaths associated with NPWT systems. An updated alert was issued in February 2011.[2]

FDA product code: OMP.

EVIDENCE SUMMARY

Evidence reviews assess the clinical evidence to determine whether the use of technology improves the net health outcome. Broadly defined, health outcomes are the length of life, quality of life (QOL), and ability to function including benefits and harms. Every clinical condition has specific outcomes that are important to patients and managing the course of that condition. Validated outcome measures are necessary to ascertain whether a condition improves or worsens; and whether the magnitude of that change is clinically significant. The net health outcome is a balance of benefits and harms.

To assess whether the evidence is sufficient to draw conclusions about the net health outcome of technology, two domains are examined: the relevance, and quality and credibility. To be relevant, studies must represent one or more intended clinical use of the technology in the intended population and compare an effective and appropriate alternative at a comparable intensity. For some conditions, the alternative will be supportive care or surveillance. The quality and credibility of the evidence depend on study design and conduct, minimizing bias and confounding that can generate incorrect findings. The RCT is preferred to assess efficacy; however, in some circumstances, nonrandomized studies may be adequate. RCTs are rarely large enough or long enough to capture less common adverse events and long-term effects. Other types of studies can be used for these purposes and to assess generalizability to broader clinical populations and settings of clinical practice.

This review was informed by a 2000 TEC Assessment that evaluated negative pressure therapy of pressure ulcers, venous ulcers, and diabetic ulcers.[3] Literature updates for this review have focused on comparative trials with the features described in the 2000 TEC Assessment (e.g., enrollment of patients with wounds refractory to standard treatment, randomization, optimal standard wound care treatment in the control arm, and clinically important endpoints). Also, literature has been sought on the potential benefits of negative pressure wound therapy (NPWT) for the healing of acute wounds.

NPWT devices are classified as either powered (i.e., requiring an electrical power source or batteries) or nonpowered (mechanical). Most evidence found in the literature is for electrically powered devices with large canisters (e.g., the Vacuum-Assisted Closure Therapy device [V.A.C. system]), and so the main discussion of evidence refers to this type of device. A number of portable devices have entered the market and are particularly relevant for use in the outpatient setting. Some portable devices are designed specifically for surgical incisions. Evidence on the newer portable devices is discussed following the review of evidence on the larger electrically powered devices.

The primary endpoints of interest for trials of wound healing are as follows, consistent with guidance from the U.S. Food and Drug Administration (FDA) for the industry in developing products for the treatment of chronic cutaneous ulcer and burn wounds:[4]

- Incidence of complete wound closure
- Time to complete wound closure (reflecting accelerated wound closure)
- Incidence of complete wound closure following surgical wound closure
- Pain control

SYSTEMATIC REVIEWS

The authors of a systematic review for the Agency for Healthcare Research and Quality and the Centers for Medicare & Medicaid Services (2014) reported that due to insufficient evidence, they were unable to draw conclusions about the efficacy or safety of NPWT in the home setting.[5] There were three retrospective cohort studies on diabetic foot ulcers and arterial ulcers, an RCT and two retrospective cohort studies on pressure ulcers, and a retrospective cohort on venous ulcers. Six studies used the V.A.C., and the other used the Smart Negative Pressure (SNaP) Wound Care System device. Reviewers found that interpretation of available data was limited by variability in the types of comparator groups, methodologic limitations, and poor reporting of outcomes.[6]

Another Agency for Healthcare Research and Quality assessment was performed to inform the HCPCS coding decisions for NPWT devices. This 2009 assessment found no studies showing a therapeutic distinction between different NPWT devices.[7]

A 2020 Cochrane review update by Norman evaluated NPWT compared with standard dressings for surgical wound healing by primary closure.[8] Forty-four RCTs were included for analysis (n=7,447). NPWT was associated with a reduced risk of surgical site infection (SSI) (31 studies [n=6,204]; RR 0.66; 95% CI, 0.55 to 0.80; I^2=23%). However, subgroup analysis by surgery type did not maintain a significant benefit for orthopedic, abdominal, or mixed/general surgeries. Treatment benefit for SSI was significant in clean and clean-contaminated procedures only. No significant difference was found for the rates of mortality and wound dehiscence. No significant benefit was seen for rates of reoperations or hospital readmissions. Certainty of evidence was deemed low to moderate per GRADE criteria. Studies were generally limited by imprecision and unclear or high-risk of bias in allocation concealment and blinding of outcome assessors. The analysis was also limited by inclusion of studies with mixed or unclear intervention types and no subgroup analysis for traditional or portable, single-use systems. An update to this above-mentioned systematic review was published by Norman in 2022 to assess the effects of NPWT for preventing SSI in wounds healing through primary closure.[9] In this update to their existing systematic review series, the authors added 18 new randomized controlled trials (RCTs) and one new economic study, resulting in a total of 62 RCTs (13,340 included participants) and six economic studies. Studies evaluated NPWT in a wide range of surgeries, including orthopaedic, obstetric, vascular and general procedures. All studies compared NPWT with standard dressings. This review also confirmed that the use of NPWT could reduce the risk of SSI in wound healing compared to the standard dressing group. But there is probably little or no difference in wound dehiscence between people treated with NPWT and those treated with standard dressing.

A systematic review and meta-analysis by Li (2019) was conducted comparing the effectiveness and safety of NPWT with standard surgical dressing or conventional therapy for prevention of SSI.[10] A total of 45 RCTs assessing 6,624 adult patients were included for analysis. Studies utilized a variety of NPWT devices, including V.A.C., PICO, and Prevena systems. Inclusion criteria did not impose restrictions on SSI grading systems or on surgery types. Surgeries for infected or chronic non-healing wounds including diabetic, venous, and arterial ulcers were excluded. Overall, NPWT was associated with a 40% reduction in SSI risk compared to control, with moderate heterogeneity (RR 0.58; 95% CI, 0.49 to 0.69; I^2=19%; p<0.00001). This significant reduction in risk was particularly maintained in high-risk surgical patients (32 RCTs; RR 0.60; 95% CI, 0.50 to 0.73; I^2=23%; p<0.00001). There was no significant effect of NPWT on wound dehiscence, hematoma occurrence, hospital admission, or length of hospital stay. The certainty of the evidence, based on GRADE criteria was graded

as low to very low due to serious risk of bias stemming from lack of blinding and methodological flaws in SSI assessment and standardization. The authors suggest that further studies are warranted to elucidate the optimal protocol for NPWT utilization.

DIABETIC LOWER-EXTREMITY ULCERS AND AMPUTATION WOUNDS

Clinical Context and Therapy Purpose

The purpose of outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with diabetic lower-extremity ulcers or amputation wounds.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

Systematic Reviews

A systematic review and meta-analysis by Chen (2021) evaluating NPWT for diabetic foot ulcers compared to standard care reported a significant improvement in the wound healing rate with NPWT (odds ratio [OR], 3.60; 95% CI, 2.38 to 5.45; p<.001) based on 6 RCTs representing 536 patients.[11] No significant difference in the incidence of adverse events was reported between groups (OR, 0.49; 95% CI, 0.10 to 2.42; p=.38). The reviewers noted several limitations in the body of evidence, including lack of blinding, unclear follow-up durations, and heterogeneous pressure settings.

A systematic review by Wynn and Freeman (2019) evaluating NPWT for diabetic foot ulcers reported similar benefits in wound healing and the reduction of amputation incidence.[12] However, reviewers emphasized limitations in the present body of evidence, including methodological flaws such as the absence of validated tools for the measurement of wound depth and area, lack of statistical power calculations, and heterogeneity in pressure settings employed during therapy.

A 2013 Cochrane review of NPWT for treating foot wounds in patients with diabetes[13] was updated in 2018 to include 11 RCTs (n=972) with sample sizes ranging from 15 to 341 participants.[14] Two studies addressed post-amputation wounds and all other studies described treatment of diabetic foot ulcers. Only 1 study comparing NPWT and moist dressings for post-amputation wounds reported a follow-up time (n=162), and a statistically

significant improvement in the proportion of wounds healed (RR 1.44, 95% CI, 1.03 to 2.01) was demonstrated after a follow-up duration of 16 weeks. The median time to healing was 21 days shorter for the NPWT group (hazard ratio 1.91, 95% CI, 1.21 to 2.99) compared with moist dressings. Data from 3 studies suggest that people with diabetic foot ulcers allocated to NPWT may be at reduced risk of amputation compared to moist dressings (RR 0.33, 95% CI, 0.15 to 0.70, I2=0%). Reviewers concluded that there was some evidence to suggest that NPWT was more effective than standard care, but the findings were uncertain due to the risk of bias in the unblinded studies. Reviewers recommended further study to reduce uncertainty around decision-making.

Randomized Controlled Trials

Seidel (2020) reported the results of a multicenter, industry-sponsored, blinded RCT that evaluated the superiority of NPWT (n=171) compared to standard moist wound care (n=174) in patients with diabetic foot ulcers.[15] The NPWT devices used included V.I.A. and Renasys systems. Based on intention-to-treat analysis, the primary outcomes of complete, sustained, and confirmed wound closure or time to wound closure, as defined by 100% epithelialization, no drainage, no suture material, and no need for wound dressing or adjuvants within 16 weeks, was not significantly different between NPWT and control groups (p=.53 and p=.100, respectively). The incidence of adverse events was significantly higher in the NPWT arm (56.1%) compared to the control arm (41.4%; p=.007); however, only 16 adverse events were considered related to NPWT. Amputation rates were not significantly different between groups (difference, 0.2%; 95% CI, -19.0% to 18.6%; p=1.00). Limitations include a high number of patients (n=191) with missing data or protocol deviations.

Associated to the study mentioned above, Seidel (2022) published another RCT to compare resource utilization of negative pressure wound therapy (NPWT) and standard moist wound care (SMWC) for diabetic foot wounds after amputation, surgical debridement or wound cleansing.[16] Treatment duration was 16 days shorter with NPWT (mean (SD) 82.8 (31.6), SMWC 98.8 (24.6); U test, p = 0.001) with 14.9 days shorter outpatient treatment (mean (SD) NPWT 68.3 (31.1), SMWC 83.2 (29.7)). The number of dressing changes per study participant was lower with NPWT (mean (SD) 35.1 (18.6), SMWC (42.9 (21.4); U test, p = 0.067). Time per dressing change was significantly lower with SMWC (mean (SD) 19.7 (12.8), NPWT (16.5 (8.2) minutes; U test, p < < 0.0001). Time for surgical debridements per study participant was 23.3 minutes shorter with NPWT (mean (SD) 20.5 (20.5), SMWC (43.8 (46.7); U test, p = 0.395).

The largest study of NPWT for diabetic foot ulcers was a multicenter industry-sponsored RCT by Blume (2008) that compared NPWT with advanced moist wound therapy.[17] Included were 342 patients with Wagner grade 2 or grade 3 foot ulcers of at least 2 cm2; the chronicity of the ulcers was not described. Based on intention-to-treat analysis, a greater proportion of NPWT-treated foot ulcers achieved the primary endpoint of complete ulcer closure (43.2% vs. 28.9%, p=0.007) within the 112-day active treatment phase. For the 240 (72%) patients who completed the active treatment phase, 60.8% of NPWT-treated ulcers closed compared with 40.0% of ulcers treated with advanced moist wound therapy. NPWT patients also experienced significantly fewer secondary amputations (4.1% vs. 10.2%, p=0.035).

Nonrandomized Studies

Borys (2018) conducted a prospective observational study to assess the short-term efficacy, safety, and long-term outcomes of NPWT in treating diabetic foot ulcers. Researchers

assigned 75 patients to NPWT (n=53) or standard care (n=22) based on wound size. Analysis after one-year follow-up showed similar results for both groups, leading researchers to conclude NPWT is a safe alternative to but not necessarily more efficacious than the current standard of care. Limitations include small sample size, the observational design, and nonconsideration of risk factors other than wound size.[18]

Section Summary: Diabetic Lower-Extremity Ulcers and Amputation Wounds

The evidence on NPWT for diabetic lower-extremity ulcers and amputation wounds includes RCTs and systematic reviews of RCTs. Although there is some uncertainty due to the risk of bias in the unblinded studies, there were higher rates of wound healing and fewer amputations with NPWT, supporting its use for diabetic lower-extremity ulcers and amputation wounds.

PORTABLE, SINGLE-USE THERAPY FOR DIABETIC LOWER-EXTREMITY ULCERS AND AMPUTATION WOUNDS

Clinical Context and Therapy Purpose

The purpose of portable, single-use outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with diabetic lower-extremity ulcers or amputation wounds.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

<u>PICO Dressing</u>

PICO is a portable single-use NPWT system that comes with 2 sterile dressings and has a lifespan of 7 to 14 days.

Kirsner (2019) published an RCT that allocated 164 patients with venous leg ulcers (VLU; n=104) or diabetic foot ulcers (DFU; n=60) to treatment with PICO single-use NPWT (s-NPWT; N=80) or traditional, reusable NPWT systems (t-NPWT; N=84).[19] Prior to randomization, patients were excluded if a reduction in target ulcer area ≥30% was achieved with compression or offloading during a two week run-in period as a way to exclude 'quick healers'. Three patients in the t-NPWT arm were excluded from the intention-to-treat (ITT) analysis. For the per protocol (PP) analysis, 16 (20%) and 30 (37%) patients were excluded from the s-

NPWT and t-NPWT arms, respectively. Randomization was stratified by wound type and wound size. The PICO dressing was set to provide -80 mmHg of negative pressure. Choice of traditional, NPWT device manufacturer and pressure setting was at the discretion of the treating physician, with an average pressure of -118.3 mmHg (median, -125 mmHg; SD, 23.4 mmHg) applied.

The study intended to test for noninferiority in the percentage change of target ulcer area with s-NPWT vs t-NPWT over the course of a 12-week treatment period, with a noninferiority margin of 12.5%. The analysis was performed with the PP population to account for dropouts and then repeated on the full analysis set (ITT). Secondary outcomes included wound closure rate, time to wound closure, and quality of life. Participants and investigators were not blinded, and it is unclear if the study utilized blinded assessors. Patients were seen weekly in outpatient wound centers. After adjustment for baseline wound area, pooled study site, wound type, and wound duration at baseline, the mean percentage difference in wound area over 12 weeks was 27% (96.9% vs 69.9%; p=0.003) in the PP analysis and 39.1% (90.24% vs 51%; P<0.001) in the ITT analysis. This treatment effect was also significant in the DFU subgroup (P=0.031). However, confidence intervals were not reported for the primary outcome.

Confirmed wound closure (ITT) was achieved in 54 (33.5%) patients (s-NPWT, 36 [45%]; t-NPWT, 18 [22%]), with an adjusted odds ratio of 0.294 (95% CI, 0.135 to 0.638; p=0.002) for all wound types and 0.161 (95% CI, 0.035 to 0.744; p=0.020) for DFU. However, the subgroup analysis for DFU patients in the PP population was not significant.

The median estimate of the time to achieve confirmed closure was 77 days for s-NPWT (95% CI, 49 to undefined limit) and could not be calculated for t-NPWT due to the low number of patients achieving this endpoint. No significant differences were noted in health-related quality of life between baseline and exit visits. Fifty-seven treatment-related adverse events were reported, 16 related to s-NPWT in 12 patients and 41 related to t-NPWT in 29 patients. Wound-related adverse events included increase in target ulcer size, inability to tolerate NPWT, and periwound skin maceration, resulting in study discontinuation by three treated with s-NPWT and nine treated with t-NPWT. While the PICO dressing met noninferiority, change in wound area is not a primary health outcome of interest due to its inherent heterogeneity. Additionally, the chosen treatment duration may have of insufficient duration to accurately assess effects on wound closure. Required use of fillers, a higher level of negative pressure, and utilization of devices from various t-NPWT manufacturers may have impacted findings. Only 20% of patients in the s-NPWT arm were treated with fillers, mainly in those with DFU.

A subanalysis of this RCT highlighting outcomes in patients with lower-extremity (foot and venous leg) diabetic ulcers was published by Kirsner.[20] The intention-to-treat population included 46 patients in the s-NPWT arm and 49 patients in the t-NPWT arm. The treatment OR for achieving confirmed wound closure at 12 weeks was 0.129 (95% CI, 0.041 to 0.404; p<0.001). In the per protocol population, which included 36 patients in the s-NPWT arm and 25 patients in the t-NPWT arm, the treatment OR for confirmed wound closure at 12 weeks was 0.179 (95% CI, 0.044 to 0.735; p=0.017). Baseline patient characteristics, including distribution of foot and venous leg ulcers in each treatment arm, were not reported. This analysis is also limited by its retrospective, post-hoc nature and insufficient follow-up duration.

SNaP Wound Care System

The portable, nonpowered (mechanical) gauze-based SNaP Wound Care System became available in 2009. The device is designed to remove small amounts of exudate from chronic, traumatic, dehisced, acute, or subacute wounds and diabetic and pressure ulcers.

Armstrong (2011) reported on results of a planned interim analysis of an RCT comparing the SNaP Wound Care System with the V.A.C. Therapy for the treatment of chronic lower-extremity wounds.[21] Final results of this industry-sponsored multicenter noninferiority trial were reported in 2012.[22] The trial enrolled 132 patients with lower-extremity venous or diabetic ulcers with a surface area between 1 cm2 and 100 cm2 and diameter less than 10 cm present for more than 30 days despite appropriate care. Approximately 30% of patients in this study had diabetic ulcers, and no subgroup analyses were conducted. Dressings were changed per the manufacturer's direction: 2 times per week in the SNaP group and 3 times per week in the V.A.C. group. Patients were assessed for up to 16 weeks or until complete wound closure; 83 (63%) patients completed the study. Intention-to-treat analysis with the last observation carried forward showed noninferiority in the primary outcome of wound size reduction at 4, 8, 12, and 16 weeks. When adjusted for differences in wound size at baseline, SNaP-treated subjects showed noninferiority to V.A.C.-treated subjects at 4, 12, and 16 weeks. Kaplan-Meier analysis showed no significant difference in complete wound closure between the 2 groups. At the final follow-up, 65.6% of the V.A.C. group and 63.6% of the SNaP group had wound closure. Survey data indicated that dressing changes required less time with the SNaP device and use of the SNaP device interfered less with mobility and activity than the V.A.C. device.

A 2010 retrospective study with historical controls compared NPWT using the SNaP device (n=28) with wound care protocols using Apligraf, Regranex, and skin grafting (n=42) for the treatment of lower-extremity ulcers.[23] Seven (25%) patients in the SNaP-treated group could not tolerate the treatment and were discontinued from the study because of complications; they were considered treatment failures. Between-group estimates of time-to-wound healing by Kaplan-Meier analysis favored the SNaP treatment group. This study is limited by the use of historical controls, multiple modalities to treat controls, and a large number of dropouts. Subgroup analyses for patients with diabetic (50%) and venous (50%) ulcers were not available. The authors noted that patients in the SNaP-treated group might have benefited from being in an experimental environment, particularly because wounds in this group were seen twice per week compared with variable follow-up in historical controls.

Section Summary: Portable, Single-Use Therapy for Diabetic Lower-Extremity Ulcers and Amputation Wounds

The evidence on portable, single-use NPWT for diabetic ulcers and amputation wounds includes an RCT of the PICO device and an RCT of the nonpowered SNaP System. A 2019 RCT compared the PICO device with standard NPWT in outpatients with diabetic and venous ulcers. In this study, the PICO device demonstrated noninferiority for wound area reduction. A statistically significant benefit in complete wound closure was noted for patients with diabetic ulcers, but was not duplicated in the per protocol population due to a high number of exclusions. Interpretation of this study is limited by variable device settings and short follow-up duration. One study of the SNaP System showed noninferiority to a V.A.C. device for wound size reduction. No significant difference in complete wound closure was reported. Interpretation of this study is limited by a high loss to follow-up. Well-designed comparative studies with larger numbers of patients powered to detect differences in complete wound closure are needed.

CHRONIC PRESSURE ULCERS

Clinical Context and Therapy Purpose

The purpose of outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with chronic pressure ulcers.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

Systematic Reviews

Shi (2023) published an update to the 2015 Cochrane review on treating pressure ulcers in any care setting.[24] The review included eight RCTs with 327 participants total. Six of the eight included studies were deemed to be at a high risk of bias in one or more risk of bias domains, and evidence for all outcomes of interest was deemed to be of very low certainty. Most studies had small sample sizes (range: 12 to 96, median: 37 participants). Five studies compared NPWT to dressings, but only one study reported outcomes that met the review criteria (complete wound healing and adverse events). This study had only 12 participants and there were very few events; only one participant was healed in the study (risk ratio [RR] 3.00, 95% confidence interval [CI] 0.15 to 61.74, very low-certainly evidence). No difference in adverse events was reported, but the evidence for this outcome was also assessed as very low certainty (RR 1.25, 95% CI 0.64 to 2.44). The authors concluded that the efficacy, safety, and acceptability of NPWT in treating pressure ulcers compared to usual care are uncertain due to the lack of key data on complete wound healing, adverse events, time to complete healing, and cost-effectiveness.

A 2015 Cochrane review included 4 RCTs of NPWT (total n=149 patients) for treating pressure ulcers in any care setting, although most of the patients were treated in a hospital setting.[13] Three trials were considered to be at high-risk of bias, and all evidence was considered to be of very low-quality. Only one trial reported on complete wound healing, which occurred in only 1 of the 12 study participants. Reviewers concluded there is high uncertainty about the potential benefits and/or harms for this indication.

Randomized Controlled Trials

One representative trial, from 2003 (noted in the 2015 Cochrane review as “awaiting further information from the authors”), randomized 24 patients with pressure ulcers of the pelvic region to NPWT or standard wound care.[25] All patients with pelvic pressure ulcers were eligible for enrollment and were not required to be refractory to standard treatment. There was no significant group difference for the main outcome measure, time to 50% reduction of wound volume (mean, 27 days in the NPWT group vs. 28 days in the control group). Findings were limited by the small number of patients in the study, the possibility that the control group might not have received optimal wound management, and lack of information on the time to complete wound healing.

Section Summary: Chronic Pressure Ulcers

The evidence on outpatient NPWT for chronic pressure ulcers includes RCTs and systematic reviews. However, all trials were of low-quality and at high-risk of bias. Also, most patients were treated in an inpatient setting.

LOWER-EXTREMITY ULCERS DUE TO VENOUS INSUFFICIENCY

Clinical Context and Therapy Purpose

The purpose of outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with lower-extremity ulcers due to venous insufficiency.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess longer-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

Randomized Controlled Trials

A 2015 Cochrane review of NPWT for venous insufficiency identified a single RCT with 60 patients.[26] This trial, published by Vuerstaek (2006), was performed in an inpatient setting in conjunction with skin grafts and compared the efficacy of NPWT using the V.A.C. system (n=30) with conventional moist wound care (n=30) in patients hospitalized with chronic venous and/or arterial leg ulcers of greater than six months in duration.[27] Full-thickness punch skin grafts from the thigh were applied, followed by four days of NPWT or conventional care to assure complete graft adherence. Each group then received standard care with nonadhesive dressings and compression therapy until complete healing (primary outcome) occurred. The

median time to complete healing was 29 days in the NPWT group and 45 days in the control group (p=0.001). Ninety percent of ulcers treated with NPWT healed within 43 days, compared with 48% in the control group. These results would suggest that NPWT significantly hastened wound healing, although the use of skin autografts makes it difficult to discern the contribution of NPWT to the primary outcome. The 2015 Cochrane review did not identify any RCT evidence on the effectiveness of NPWT as a primary treatment for leg ulcers, nor was there any evidence on the use of NPWT in the home setting.

Section Summary: Lower-Extremity Ulcers due to Venous Insufficiency

A single RCT has been identified on use of NPWT for the treatment of lower-extremity ulcers due to venous insufficiency in the hospital setting. No evidence was identified on treatment in the home setting.

PORTABLE, SINGLE-USE THERAPY FOR LOWER-EXTREMITY ULCERS DUE TO VENOUS INSUFFICIENCY

Clinical Context and Therapy Purpose

The purpose of portable, single-use outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with lower-extremity ulcers due to venous insufficiency.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess longer-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

PICO Dressing

Kirsner (2019) published an RCT that allocated 164 patients with venous leg ulcers (VLU; n=104) or diabetic foot ulcers (DFU; n=60) to treatment with PICO single-use NPWT (s-NPWT; N=80) or traditional, reusable NPWT systems (t-NPWT; N=84).[19] Additional study details and limitations are summarized previously in indication 2.

The primary outcome measure, mean percentage difference in wound area over 12 weeks, was 27% (96.9% vs 69.9%; P=0.003) in the per protocol (PP) analysis and 39.1% (90.24% vs 51%; P<0.001) in the intention-to-treat (ITT) analysis. This treatment effect was also significant in the VLU subgroup (P=0.007). However, confidence intervals were not reported. Confirmed

wound closure (ITT) was achieved in 54 (33.5%) patients (s-NPWT, 36 [45%]; t-NPWT, 18 [22%]), with an adjusted odds ratio of 0.294 (95% CI, 0.135 to 0.638; P=0.002) for all wound types and 0.398 (95% CI, 0.152 to 1.044; P=0.061) for VLU. The subgroup analysis for VLU patients in the PP population was also not significant.

SNaP Wound Care System

Armstrong (2011) reported on results of a planned interim analysis of an RCT comparing the SNaP Wound Care System with the V.A.C. Therapy for the treatment of chronic lower-extremity wounds.[21] Final results of this industry-sponsored multicenter noninferiority trial were reported in 2012.[22] Approximately 70% of the study population had venous leg ulcers. Additional study details and limitations are summarized previously in indication 2.

A subgroup analysis (2015) of 40 patients with venous leg ulcers who completed the study showed a significant improvement in the percentage of those with complete wound closure treated with SNaP (57.9%) compared with the V.A.C. system (38.2%; p=0.008).[28] However, this study had a high loss to follow-up and lacked a comparison with standard treatment protocols.

Section Summary: Portable, Single-Use Therapy for Lower-Extremity Venous Ulcers

The evidence on portable, single-use NPWT for lower-extremity venous ulcers includes an RCT of the PICO device and an RCT of the nonpowered SNaP System. A 2019 RCT compared the PICO device with standard NPWT in outpatients with diabetic and venous ulcers. In this study, the PICO device demonstrated noninferiority for wound area reduction. No significant benefit in complete wound closure was found in patients with venous ulcers. One study of the SNaP System showed noninferiority to a V.A.C. device for wound size reduction. A subgroup analysis of this study found a significant difference in complete wound closure for patients with venous ulcers. However, interpretation of this study is limited by a high loss to follow-up and a lack of a control group treated with standard dressings. Well-designed comparative studies with larger numbers of patients powered to detect differences in complete wound closure are needed.

BURN WOUNDS

Clinical Context and Therapy Purpose

The purpose of outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with burn wounds.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.

- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

Randomized Controlled Trials

A 2014 Cochrane review of NPWT for burn wounds identified an interim report (abstract) of an RCT on NPWT in patients with partial-thickness burns.[29] The abstract did not provide enough evidence to draw any conclusions on the efficacy of NPWT on partial-thickness burn wounds.

Not included in the Cochrane review was a trial by Bloemen (2012) on the effect of NPWT on graft take in full-thickness burn wounds.[30] This multicenter, four-armed RCT enrolled 86 patients and compared a split-skin graft with or without a dermal substitute (MatriDerm), with or without NPWT. Outcome measures included graft take at four to seven days after surgery, the rate of wound epithelialization, and scar parameters at 3 and 12 months postoperatively. Graft take, and wound epithelialization did not differ significantly between groups. Most measures of scar quality also did not differ significantly between groups.

An expert panel convened to develop evidence-based recommendations for the use of NPWT reported that the evidence base in 2011 was strongest for the use of NPWT on skin grafts and weakest as a primary treatment for burns.[31]

Case Series

A retrospective case series by Ehrl (2017) examined outcomes for 51 patients treated for burned hands with topical NPWT at a single-center; of the initial 51 patients, only 30 patients (47 hands) completed follow-up, which was conducted an average of 35 months after injury and included physical examination.[32] Before TNPW therapy, patients received escharotomy or superficial debridement if needed, or split-thickness skin grafts for third-degree burns and the NPWT gloves used allowed caregivers to assess patients' fingertips for perfusion. Ergotherapy was initiated following evidence of epithelialization. Primary endpoints were a dorsal extension of the fingers and capability of complete active fist closure, with the majority of patients achieving one or both outcomes: the first endpoint was reached in 85.1% (n=40) of the cases; the second endpoint was reached in 78.7% of hands (n=37). When evaluated using the Disabilities of the Arm, Shoulder, and Hand questionnaire (scoring range, 0-100; with 0=no disability), patients with injuries resulting in hypertrophic scarring had significantly worse scores (28.8) than patients without similar scarring (11.7; $p<0.05$). Despite a number of limitations, including heterogeneity of burned areas (2.5% to 70% throughout the series), the authors acknowledged NPWT as standard treatment at the institution from which these data were drawn.

Section Summary: Burn Wounds

The evidence on NPWT as a primary treatment of partial-thickness burns is limited. A retrospective case series reported functional outcomes in most patients treated for hand burns with NPWT. One RCT on NPWT for skin grafts showed no benefit for graft take, wound epithelialization, or scar quality.

TRAUMATIC AND SURGICAL WOUNDS

Clinical Context and Therapy Purpose

The purpose of outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with traumatic or surgical wounds.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Identified studies have described various wound types treated over periods ranging from several days to several months. Studies also differed by whether NPWT was used for nonhealing wounds or as a prophylactic treatment for surgical wounds in patients at high-risk for nonhealing.

Review of Evidence

Systematic Reviews

Selected systematic reviews and meta-analyses evaluating the use of NPWT in surgical and/or traumatic wounds are summarized in Table 1.

Table 1. Summary of SR-MAs of NPWT versus Standard Therapy in Surgical Wounds

Review	RCT	Other Studies	Participants[1]	N (Range)	Major Outcomes	Study Quality	Relevance
Cochrane (2014)[33]	9	0	Individuals with wounds expected to heal by primary intention (eg, surgical closure, skin grafts)	785	SSI (NSD) Wound dehiscence (NSD) Reoperation (NSD) Seroma/hematoma (NSD) Skin graft failure (NSD)	Unclear or high risk of bias noted	Unclear; inclusion of "home-made" devices and focus on inpatient therapy
De Vries (2016)[34]	6	15	Individuals treated with prophylactic NPWT in clean and contaminated surgery	RCT: 277 (13-141) Other: 1099 (23-237)	Surgical site infection (RCT: p=0.04; Other: p<0.00001; NSD for	Low quality of evidence due to lack of blinding in outcome assessment	Unclear; focus on inpatient therapy

Review	RCT	Other Studies	Participants[1]	N (Range)	Major Outcomes	Study Quality	Relevance
					trauma/orthopedic surgery)		
Cochrane (2018)[14]	7	0	Individuals with open traumatic wounds (open fractures and other types)	1377 (40-586)	Wound infection (NSD)	Unclear or high risk of bias noted	Limited; focus on inpatient therapy
Ren (2022)[35]	5	1 (retrospect-tive cohort trial)	Individuals who have undergone hepatopan-creatobiliary surgery	657 (345F, 311M)	superficial surgical infection, deep surgical infection, seroma incidence, hematoma incidence, and hospital re-admission		

NPWT: negative pressure wound therapy; NSD: no significant difference; RCT: randomized controlled trial; SR-MA: systematic review and meta-analysis; SSI: surgical site infection.
1 Key eligibility criteria,
2 Assessment according to Cochrane risk of bias criteria.

A 2014 Cochrane review evaluated the evidence on NPWT for skin grafts and surgical wounds expected to heal by primary intention.[33] Healing by primary intention occurs when the wound edges are brought together with sutures, staples, tape, or glue, and contrasts with healing by secondary intention, where the wound is left open to heal from the bottom up (eg, for chronic or infected wounds). Nine randomized trials (total n=785 patients) were included in the review. Three trials involved skin graft patients, four included orthopedic patients, and two included general surgery and trauma surgery patients. All trials had an unclear or high-risk of bias. There were no differences between standard dressing and NPWT for SSIs, wound dehiscence, reoperation (in incisional wounds), seroma/hematoma, or failed skin grafts. Pain intensity was reported to be lower with “home-made” NPWT compared with commercial devices. Most or all studies appeared to have used short-term application of NPWT in an inpatient setting.

A systematic review and meta-analysis by De Vries (2016) included 6 RCTs and 15 observational studies of SSIs after prophylactic NPWT.[34] One study selected used a portable device (PICO, described below), while the others used a V.A.C. Unlike the 2014 Cochrane review, studies on skin grafts were not included. Meta-analysis of the RCTs showed that use of NPWT reduced the rate of SSIs (odds ratio [OR], 0.56; 95% CI, 0.32 to 0.96; p=0.04), and reduced the SSI rate from 140 to 83 per 1000 patients. However, the quality of evidence was rated as low due to high-risk of bias in the nonblinded assessments and imprecision in the estimates. Subgroup meta-analysis of 4 RCTs in orthopedic/trauma surgery did not demonstrate significant benefit in regards to reducing risk of SSI (OR 0.58; 95% CI 0.32 to 1.07).

A 2018 Cochrane review evaluated the effects of NPWT for open traumatic wounds (eg, open fractures or soft tissue wounds) managed in any care setting.[14] Seven RCTs were identified

for the review with sample sizes ranging from 40 to 586 participants. Four studies (n=596) compared NPWT at 125 mmHg with standard care for open fracture wounds. Pooled data revealed no significant difference between groups in the number of participants with healed wounds (RR 0.48, 95% CI 0.81 to 1.27; I2=56%). Pooled data from 2 studies (n=509) utilizing NPWT at 125 mmHg on other open traumatic wounds demonstrated no significant difference in risk of wound infection compared to standard care (RR 0.61, 95% CI 0.31 to 1.18). One study (n=463) assessing NPWT at 75 mmHg against standard care in other open traumatic wounds did not demonstrate a significant difference for wound infection risk (RR 0.44, 95% CI 0.17 to 1.10). One study comparing NPWT at 125 mmHg against 75 mmHg in other open traumatic wounds also failed to demonstrate a significant difference in wound infection risk (RR 1.04, 95% CI 0.31 to 3.51). Evidence was deemed low to very low in certainty and quality due to imprecision and risk of bias.

In contrast, a systematic review and meta-analysis by Liu (2018) highlighted a significantly lower infection rate, shorter wound coverage time, shorter wound healing time, and shorter hospitalization duration for NPWT versus conventional wound dressings in the treatment of open fractures (all p<0.00001).[36] Three of six included RCTs overlapped with the Cochrane review and 1 significantly weighted RCT (n=460) (see Costa [2018][37] in Table 2 below) failing to demonstrate a benefit in infection risk for NPWT was missing in the Liu (2018) analysis, the only RCT identified by Cochrane to conduct blinded outcome assessment of wound healing and infection. However, the risk of bias in the Liu (2018) review was similarly reported as high or unclear. The baseline characteristics of cohort studies included in the analysis suffered from high heterogeneity, with most studies failing to achieve comparable initial injury severity scores based on the Gustilo-Anderson open fracture classification system. Finally, due to the severity of open fracture injuries, the outpatient clinical utility of NPWT for this form of trauma is unclear with most studies focusing on inpatient applications.

Sahebally (2018) performed a systematic review with meta-analysis to evaluate the effects of NPWT on SSIs in closed laparotomy incisions.[38] Researchers searched 4 databases through December 31, 2017, and screened bibliographies of retrieved studies to find further studies; 9 unique studies (three RCTs, two prospective studies, and four retrospective studies) representing 1,266 unique patients were included in the review. The analysis determined that NPWT was associated with a significantly lower rate of SSI compared with standard wound dressing (pooled OR: 0.25; 95% CI 0.12 to 0.52; p<0.001). The review was limited by including mostly non-randomized studies and use of different NPWT devices.

Flynn (2020) published an RCT to determine if PICO dressings reduce surgical site infections or other surgical site complications in primarily closed laparotomy incisions after clean-contaminated surgery in moderate-risk patients.[39] Patients undergoing laparotomy and bowel resection were randomly assigned to PICO or conventional dressings. There were no significant differences in the surgical site infection or development of surgical site complications between the two techniques. The authors conclude that this study does not support the routine use of PICO dressings on uncomplicated laparotomy incisions in moderate-risk patients.

Ren (2022) performed a systematic review to evaluate the comparative influence of NPWT and standard surgical dressing administration on incidence risk for surgical site infections, complications, and hospital re-admission after hepatopancreatobiliary surgery.[35] Six studies were included in this analysis; five RCTs and one retrospective cohort trial. From this study the authors report that NPWT usage slightly reduces the risk of hospital readmission as compared

to standard surgical dressing. Only two studies (featuring small sample sizes) investigated the understanding of the comparative impact of NPWT and standard surgical dressing on hematoma complications.

Randomized Controlled Trials

Selected RCTs of NPWT for surgical or traumatic wounds are summarized in Table 2.

Table 2. Summary of Key RCTs of NPWT versus Standard Therapy in Surgical Wounds

Study; Trial	Surgery Received	No. of Participants	Notes on NPWT effectiveness	P-value
Stannard (2012)[40]	Various, after fractures and other trauma	249	Fewer infections, less discharge than standard closure	0.049
Masden (2012)[41]	Various	81	NSD in infection or healing	NR
Chio and Agrawal (2010)[42]	Radial forearm donor site	43	NSD in wound complications or graft failure	NR
Javed (2018)[43]	Open pacreaticoduodenectomy	123	9.7% of NPWT group developed infections, compared with 31.1% of standard closure group	0.003
Tanaydin (2018)[44]	Bilateral breast reduction mammoplasty	32	Patients used as own control; NPWT associated with significantly lower risk of complication and improved pain and scarring compared with fixation strips	<0.004
Costa (2018); WOLLF[37]	Severe open fracture of the lower limb	460	NSD in self-rated disability, number of deep SSI, or QOL scores	Disability: 0.13 SSI: 0.64 QOL: NR
Seidel (2020); SAWHI[45]	Subcutaneous abdominal wound healing impairment	539 (randomized) 507 (modified ITT) 310 (PP)	Shorter time to wound closure and higher wound closure rate	<0.001

ITT: intention-to-treat; NPWT: negative pressure wound therapy; NR: not reported; NSD: no significant difference; QOL: quality of life; PP: per protocol; RCT: randomized controlled trial; SSI: surgical site infection.

One of the largest studies on prophylactic NPWT for surgical wounds is a report from an investigator-initiated, industry-sponsored multicenter RCT of inpatient NPWT for closed surgical incisions by Stannard (2012).[40] (A preliminary report was published in 2006.)[46] Participants included 249 blunt trauma patients with 263 high-risk fractures (tibial plateau, pilon, calcaneus) requiring surgical stabilization. Patients were randomized to NPWT applied to the closed surgical incision or to standard postoperative dressings. All trial participants were maintained as inpatients until wound drainage was minimal, at which time NPWT was discontinued (mean, 59 hours; range, 21 to 213 hours). Patients in the NPWT group were ready for discharge in 2.5 days compared with 3.0 days for the control group (the difference was not statistically significant). The NPWT group had significantly fewer infections (10% of fractures) than the control group (19% of fractures; p=0.049). Wound dehiscence after discharge was observed less frequently in the NPWT group (8.6%) than in the control group (16.5%). These results would support the efficacy of the short-term use of NPWT when used under highly controlled conditions of inpatient care, but not the effectiveness of NPWT in the outpatient setting. A small 2015 RCT (n=20) of NPWT in an outpatient setting reported that

patients treated with NPWT required significantly fewer dressing changes, reported significantly less pain, and experienced QOL improvements compared with standard wound care.[47]

Other randomized studies have reported no benefit for NPWT for surgical wounds, as reflected in the conclusions of various Cochrane reviews (described above).[14, 33] For example, the RCT by Masden (2012) examined the use of NPWT for surgical closures at high-risk for nonhealing in 81 patients with comorbidities that included diabetes and peripheral vascular disease.[41] At a mean of 113 days follow-up, there were no significant differences in the proportions of patients with wound infection, time to develop infection or dehiscence between NPWT and dry dressing groups. Chio and Agrawal (2010) published results of a randomized trial of 54 patients comparing NPWT with a static pressure dressing for the healing of the radial forearm free flap donor site.[42] There were no statistically significant differences in wound complications or graft failure (percentage of area for graft failure, 7.2% for negative pressure vs 4.5% for standard dressing). Biter (2014) found no significant advantage of two weeks of NPWT in 49 patients who underwent surgical excision for pilonidal sinus disease.[48] Complete wound healing was achieved at a median of 84 days in the NPWT group and 93 days in controls.

Javed (2018) conducted a single-site RCT to evaluate the efficacy of NPWT for SSI after an open pacreaticoduodenectomy. Researchers randomized 123 patients treated from January 2017 through February 2018 to either NPWT (n=62) or standard closure (n=61). In the study, 9.7% of patients who received NPWT developed a postoperative infection at the site, compared with 31.1% of patients who received standard closure, an RR of 0.31 (95% CI 0.13 to 0.73; p=0.003). Limitations of the study included being conducted at a high-volume treatment center and a lack of blinding.[43]

Tanaydin (2018) conducted an RCT to compare NPWT to standard wound care after a bilateral breast reduction mammoplasty.[44] In the study, 32 patients were given NPWT on one breast and fixation strips on the other, simultaneously serving as study group and control group. Sites treated with NPWT showed a significantly lower rate of complications ($p<0.004$) compared to fixation strips, as well as improved pain and scarring. Limitations included the small sample size and lack of blinding.

The Effect of Negative Pressure Wound Therapy vs Standard Wound Management on 12-Month Disability Among Adults With Severe Open Fracture of the Lower Limb (WOLLF) trial by Costa (2018) randomized 460 patients with severe open fracture of the lower limb to NPWT (n=226) or standard wound management (n=234).[37] The primary outcome was the Disability Rating Index score (range, 0 [no disability] to 100 [completely disabled]) at 12 months, with a minimal clinically important difference of 8 points. Secondary outcomes included deep infection and quality of life measures based on the EuroQol 5-dimensions questionnaire. Eighty-eight percent of participants completed the trial. There were no statistically significant differences in disability scores (45.5 vs. 42.4; p=0.13), in the number of deep infections (16 [7.1%] vs. 19 [8.1%]; p=0.64), or in quality of life measures in the NPWT and standard wound management groups, respectively. A 5-year follow-up report found similar patient-reported disability, health-related quality of life, or need for surgery in patients treated with NPWT or standard management.[49] NPWT was used for a limited time frame in the inpatient setting which limits conclusions for the outpatient setting.

The Subcutaneous Abdominal Wound Healing Impairment (SAWHI) multicenter clinical trial by Seidel (2020) randomized adult patients with SAWHI to treatment with NPWT (V.A.C. Therapy) or conventional wound therapy (CWT).[45] The modified ITT population included 256 and 251 patients assigned to NPWT and CWT, respectively. The primary outcome, mean time to wound closure within 42 days, was significantly shorter in the NPWT group (difference, 3.0 d; 95% CI, 1.6 to 4.4; P<0.001) and confirmed via independent, blinded assessors. Additionally, only 35.9% of patients in the NPWT group and 21.5% of patients in the CWT group achieved complete wound closure within 42 days (difference, 14.4%; 95% CI 6.6% to 22.2%; p<0.001). While this met the prespecified non-inferiority margin of 12.5%, the study's statistical model had assumed a complete wound closure rate of 50% in the CWT arm which had not been met within the 42-day treatment period. The benefit of NPWT for these outcomes was sustained in the PP analysis, however, 39% and 31% of patients were excluded from the NPWT and CWT arms, respectively. Primary reasons for exclusion included unauthorized treatment crossovers, insufficient dressing changes, and treatment termination prior to 42 days. More wounds were sutured in the NPWT arm compared to the CWT arm, where more wounds healed by secondary intention. No significant differences were noted for quality of life or pain measures at any time point. The relative risk for adverse events (RR, 1.20; 95% CI, 0.97 to 1.47) and wound-related adverse events (RR, 1.51; 95% CI 0.99 to 2.35) was higher in the NPWT arm. The most frequently documented wound-related adverse events in the NPWT arm included periwound macerations and local infections with signs of inflammation. Overall, it is unclear if a 3-day difference in time to wound closure represents a clinically meaningful benefit. Time to hospital discharge, readmission rates, and duration of outpatient care were not reported.

As an add-on to a multicenter randomized clinical trial, Seidel (2022) published another RCT.[50] The authors compared aspects of hospital discharge, outpatient treatment continuation, and subsequent wound closure outcomes between the treatment arms in patients with subcutaneous abdominal wound healing impairment after surgery without fascia dehiscence in the per protocol population. Time to wound closure was shorter for outpatients in the NPWT arm (outpatient transfer with: NPWT Mean ± standard error 28.8 ± 8.0 days; CWT 28.9 ± 9.5 days) than in the conventional treatment arm (30.4 ± 8.0 days). The authors also report that study site specific avoidance of outpatient NPWT emerges as an additional reason for the prolonged hospitalization time.

Seidel (2022) also published the comparison of resource utilization of NPWT and CWT for SAWHI after surgery.[51] The resource use analysis was primarily based on the per protocol population (NPWT 157; CWT 174). Although treatment length within 42 days was significantly shorter in the NPWT arm (Mean [Standard deviation (SD)] NPWT 22.8 (13.4); CWT 30.6 (13.3); P < 0.001 U-test), hospitalization time was shorter with CWT [Mean (SD) NPWT 13.9 (11.1); CWT 11.8 (10.8); P = 0.047 U-test]. Significantly more study participants were outpatient with CWT [N=167 (96.0%)] than with NPWT [N = 140 (89.2%) (P = 0.017)]. Time for dressing changes per study participant [Mean (SD) (min) NPWT N = 133, 196 (221.1); CWT N = 152, 278 (208.2); P < .001 U-test] and for wound-related procedures [Mean (SD) (min) NPWT 167 (195); CWT 266 (313); P < 0.001 U-test] was significantly lower with NPWT.

Section Summary: Traumatic and Surgical Wounds

The evidence on the use of NPWT for individuals who have traumatic or surgical wounds includes RCTs and systematic reviews. One RCT found no benefit of NPWT on graft take and wound epithelialization in patients with full-thickness burns. Another RCT found a significant decrease in time to wound closure in patients with wound healing impairment following

abdominal surgery; however, it is unclear if this difference is clinically meaningful. An RCT reported significantly shorter treatment length in the NPWT compared to the conventional wound healing. In addition, it also reported shorter hospitalization time, significantly more number of outpatients, and significantly lesser time for dressing. Another RCT also reported shorter time to wound closure and it was noted that study site specific avoidance of outpatient NPWT emerges as an additional reason for the prolonged hospitalization time. A small RCT suggested that prophylactic NPWT might reduce the number of dressing changes and pain when used in an outpatient setting. A small retrospective study reported improved epithelialization in patients free of comorbidities treated with NPWT. In other studies, NPWT showed no benefit for the treatment of patients with surgical wounds or skin grafts healing by primary intention, and a systematic review of NPWT for traumatic and surgical wounds found no differences between standard dressing and NPWT for any wound outcome measure. Another systematic review reported that NPWT was associated with lower rate of surgical site infections. Yet another systematic review reported that NPWT usage slightly reduces the risk of hospital readmission as compared to standard surgical dressing. Additional study in a larger, outpatient sample may be needed to evaluate this outcome measure.

PORTABLE, SINGLE-USE THERAPY FOR TRAUMATIC AND SURGICAL WOUNDS

Clinical Context and Therapy Purpose

The purpose of portable, single-use outpatient NPWT is to provide a treatment option that is an alternative to or an improvement on existing therapies in patients with traumatic and surgical wounds.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with a preference for RCTs.
- In the absence of such trials, comparative observational studies were sought, with a preference for prospective studies.
- To assess long-term outcomes and adverse events, single-arm studies that capture longer periods of follow-up and/or larger populations were sought.
- Studies with duplicative or overlapping populations were excluded.
- Studies conducted exclusively in the inpatient setting were excluded.

Review of Evidence

PICO Dressing

PICO is a portable single-use NPWT system that comes with 2 sterile dressings and has a lifespan of 7 to 14 days. Karlakki (2016) reported on an RCT with 220 patients that evaluated the use of the PICO device in a surgical center immediately after hip and knee arthroplasties.[52] The device was left on for 7 days, including the time after the hospital stay. Strengths of the trial included powered intention-to-treat analysis, but evaluators were not blinded. There were trends toward reductions in hospital length of stay (0.9 days; 95% CI -0.2

to 2.5 days; p=0.07) and postoperative surgical wound complications (8.4% control vs. 2.0% PICO, p=0.06). However, most of the difference in length of stay was due to wound complications in 2 outliers in the control group (up to 61 days). The level of wound exudate was significantly reduced by the PICO device (p=0.007), with 4% of the study group and 16% of the control group having grade 4 (scale grade, 0 to 4) exudate. Blisters were observed in 11% of patients treated with the PICO system, although the blister occurrence was reported to be reduced when the dressing was stretched less.

Peterson (2021) reported on a single-site RCT evaluating the PICO system for incisional NPWT following cesarean delivery in women with class III obesity (body mass index ≥40; n=55) compared to standard dressings (n=55).[53] An unplanned interim analysis was performed due to slow enrollment and publication of larger trials reporting no benefit for NPWT. The interim analysis demonstrated no significant difference in the primary composite outcome of wound complications between groups (risk difference, 9.1%; 95% CI, -8.3% to 25.8%; p=0.38) and the trial was terminated early. In the systematic review by Norman (2022) an RCT by Hyldig (2020) evaluated the cosmetic result of using incisional negative-pressure wound therapy (iNPWT) compared with standard postsurgical dressings in obese women undergoing cesarean delivery.[9] The authors report that this study was not able to detect a difference in the long-term cosmetic result after CD when compared with standard dressings. On the other hand, a few other RCTs in this systematic reviews demonstrated a reduction of surgical site infections by prophylactic incisional negative pressure wound therapy compared with standard postoperative dressings in obese women giving birth by cesarean section. The effect remained statistically significant when adjusted for BMI and other potential risk factors. Another systematic review and meta-analysis by Gillespie (2022) also looked at effect of NPWT (mostly PICO or Prevena) on wound complications in obese women after cesarean birth.[54] Ten RCTs with 5583 patients were included in this study. Meta-analysis results suggested a significant difference favoring the NPWT group [relative risk(RR) 0.79, 95% CI 0.65-0.95, p<0.01], indicating an absolute risk reduction of 1.8% among those receiving NPWT compared to usual care. This study also reports a significant higher risk of blistering in the NPWT group.

Darwisch (2020) published an RCT to evaluate NPWT as a prevention and therapy of superficial infection.[55] In this single-center prospective randomized controlled trial, patients after cardiac surgery performed via median sternotomy (n = 528) were after stratification according to the marker body mass index (BMI ≥35 yes/no) randomized to receive either a disposable PICO dressing (PD) (n = 56/193) or a standard dry dressing (SDD) (n = 66/213) over the incision immediately at the conclusion of surgery. The authors report that use of PICO dressing NPWT compared with SDD did not improve the rate of SSIs in 30 days, but PD treatment reduced the rate of deep type of SSIs; so, there is a shift toward more superficial SSIs.

Prevena System

Pauser (2016) reported on a small RCT (n=21) evaluating Prevena in patients who had hemiarthroplasty for femoral neck fractures.[56] Use of the Prevena System significantly reduced seroma size, days of wound secretion, wound care time, and need for dressing changes.

In 2013, Grauhan published a controlled clinical trial to evaluate negative pressure wound dressing treatment for the prevention of infection.[57] For this study, 150 consecutive obese

patients (body mass index ≥ 30) with cardiac surgery performed via median sternotomy were analyzed. The authors concluded that Negative pressure wound dressing treatment over clean, closed incisions for the first 6 to 7 postoperative days significantly reduces the incidence of wound infection after median sternotomy in a high-risk group of obese patients.

Murphy (2019) published findings from the Negative Pressure Wound Therapy Use to Decrease Surgical Nosocomial Events in Colorectal Resections (NEPTUNE) trial, a single-center, superiority designed prospective randomized open blinded endpoint controlled trial evaluating the use of the Prevena System on closed incisions compared to standard gauze dressings in patients undergoing colorectal resection via laparotomy (n=300).[58] The was no significant difference in the incidence of SSI at 30 days post-surgery between the Prevena and control groups (32% vs. 34%; p=0.68). No significant difference in length of hospital stay was reported.

Hussamy (2019) reported on an open-label RCT evaluating the Prevena System for incisional NPWT following cesarean delivery in women with class III obesity (Body Mass Index ≥ 40; n=222) compared to standard dressings (n=219).[59] The overall composite wound morbidity rate was not significantly different between the Prevena and control cohorts (17% vs. 19%; RR 0.9; 95% CI 0.5 to 1.4).

Tuuli (2020) reported on a large, multicenter RCT evaluating the Prevena System for incisional NPWT following cesarean delivery in women with obesity (body mass index >30; n=806) compared to standard dressings (n=802).[60] The risk of superficial or deep SSI was not significantly different between groups (difference, 0.36%; 95% CI, -1.46% to 2.19%; p=0.70). The trial was terminated following a planned interim analysis which indicated an increased rate of adverse events in the Prevena group (difference, 6.95%; 95% CI, 1.86% to 12.03%; p<0.001) and futility for the primary outcome.

Bertges (2021) conducted a multicenter RCT evaluating the Prevena System for groin incisions in patients undergoing infrainguinal revascularization (n=118) compared to standard dressing (n=124).[61] The primary composite outcome of groin wound complications, SSI, major noninfectious wound complications, or graft infections within 30 days of surgery was not significantly different between Prevena and control groups (31% vs. 28%; p=0.55).

Kim (2020) published a meta-analysis to determine the effective indications of closed-incisional negative-pressure wound therapy (ciNPWT) following total hip or knee arthroplasty.[62] The systematic search was performed on MEDLINE, Embase, and Cochrane Library, and 11 studies were included. The studies comparing between ciNPWT and conventional dressings were categorized into following subgroups based on patient risk and revision procedures: routine vs high-risk patient; primary vs revision arthroplasty. These studies either used the Prevena or PICO system for the ciNPWT. Overall the analysis found that the the wound complication (odds ratio [OR] = 0.38; 95% confidence interval [CI] 0.15-0.93; p = 0.030) and surgical site infection (SSI) (OR = 0.24; 95% CI = 0.09-0.64; p = 0.005) in high-risk patients were significantly lower than the routine patients after ciNPWT. Further, in cases involving revision arthroplasties, the overall rates of wound complication (OR = 0.33; 95% CI = 0.18-0.62; P < .001) and SSI (OR = 0.26; 95% CI = 0.11-0.66; p = o.004) were significantly lower in the ciNPWT.

Cooper (2022) published an RCT to assess whether ciNPWT could decrease SSCs in high-risk patients undergoing direct anterior (DA) approach to total hip arthroplasty (THA).[63] This prospective randomized controlled trial (RCT) enrolled high-risk DA THA patients at 3 centers.

Patients were offered enrollment if they had previously identified risk factors for surgical site complications (SSC): Body mass index (BMI) >30 kg/m2, diabetes, active smoking, or prior hip surgery. Patients were randomized after closure to either an occlusive (control) dressing or ciNPWT (Prevena) dressing for 7 days. One hundred and twenty two patients enrolled; 120 completed data collection. SSCs occurred in 18.3% (11/60) of control patients compared to 8.3% (5/60) of ciNPT patients ($\chi 2 = 2.60$, p = o.107). SSCs included dehiscence to the subcutaneous level and prolonged drainage. Nine control (15.0%) and 2 ciNPWT (3.3%) patients met CDC criteria for superficial surgical site infection (SSI) ($\chi 2 = 4.90$, p = 0.027). Overall, there was a significant reduction in superficial SSIs and a trend toward lower SSCs after ciNPWT.

Section Summary: Portable, Single-Use Therapy for Traumatic and Surgical Wounds

The evidence on portable single-use NPWT includes RCTs of the PICO device and the Prevena Incision Management System. The PICO device was studied in an adequately powered but unblinded RCT of combined in- and outpatient use after total joint arthroplasty. The evidence base for the Prevena System is not sufficiently robust for conclusions on efficacy to be drawn. Well-designed comparative studies with larger numbers of patients treated in an outpatient setting are needed.

SUMMARY OF EVIDENCE

For individuals who have diabetic lower-extremity ulcers or amputation wounds who receive outpatient NPWT, the evidence includes RCTs and systematic reviews of RCTs. Relevant outcomes are symptoms, change in disease status, morbid events, quality of life (QOL), and treatment-related morbidity. There was a higher rate of wound healing and fewer amputations with NPWT, although the studies were at risk of bias due to lack of blinding. The evidence is sufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have diabetic lower-extremity ulcers or amputation wounds who receive portable, single-use outpatient NPWT, the evidence includes RCTs. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. A 2019 RCT compared the PICO device with standard NPWT. In this study, the PICO device demonstrated noninferiority for wound area reduction. A statistically significant benefit in complete wound closure was noted for patients with DFUs, but was not duplicated in the per protocol population due to a high number of exclusions. One study of the Smart Negative Pressure nonpowered Wound Care System (SNaP) showed noninferiority to a V.A.C. device for wound size reduction. No significant difference in complete wound closure was reported. Interpretation of this study is limited by a high loss to follow-up. Well-designed comparative studies with larger numbers of patients powered to detect differences in complete wound closure are needed. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have chronic pressure ulcers who receive outpatient NPWT, the evidence includes RCTs and systematic reviews. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. All trials are of low-quality and at high-risk of bias. Also, most study populations were treated in inpatient settings. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have lower-extremity ulcers due to venous insufficiency who receive outpatient NPWT, the evidence includes an RCT and a systematic review. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. A single RCT in patients with nonhealing leg ulcers who were treated with skin grafts found a faster rate of healing with NPWT when used in the inpatient setting. No studies were identified on the effectiveness of NPWT as a primary treatment for leg ulcers or for the use of NPWT in the outpatient setting. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have lower-extremity ulcers due to venous insufficiency who receive portable, single-use outpatient NPWT, the evidence includes RCTs. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. A 2019 RCT compared the PICO device with standard NPWT. In this study, the PICO device demonstrated noninferiority for wound area reduction. No significant benefit in complete wound closure was found in patients with venous ulcers. One study of the SNaP System showed noninferiority to a V.A.C. device for wound size reduction. A subgroup analysis of this study found a significant difference in complete wound closure for patients with venous ulcers. However, interpretation of this study is limited by a high loss to follow-up and a lack of a control group treated with standard dressings. Well-designed comparative studies with larger numbers of patients powered to detect differences in complete wound closure are needed. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have burn wounds who receive outpatient NPWT, the evidence includes RCTs, systematic reviews, and case series. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. An interim report of an RCT evaluating NPWT in partial-thickness burns, summarized in a Cochrane review, did not permit conclusions on the efficacy of NPWT for this indication. A separate RCT comparing NPWT with split-skin grafts in patients with full-thickness burns did not show differences in graft take and wound epithelialization. A retrospective case series reported functional outcomes for most patients who were treated with NPWT at a single-center. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have traumatic or surgical wounds who receive outpatient NPWT, the evidence includes RCTs and systematic reviews. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. There are limited data on NPWT as a primary treatment of partial-thickness burns. One RCT found no benefit of NPWT on graft take and wound epithelialization in patients with full-thickness burns. Another RCT found a significant decrease in time to wound closure in patients with wound healing impairment following abdominal surgery; however, it is unclear if this difference is clinically meaningful. In other studies, NPWT showed no benefit in the treatment of patients with surgical wounds or skin grafts healing by primary intention, and a systematic review of NPWT for traumatic and surgical wounds found no differences between standard dressing and NPWT for any wound outcome measure. However, a small RCT has suggested that prophylactic NPWT may reduce the number of dressing changes and pain when used in an outpatient setting. A small retrospective study reported improved epithelialization with NPWT in patients free of comorbidities. Additional study in larger, outpatient samples is needed to evaluate this outcome measure. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have traumatic or surgical wounds who receive portable, single-use outpatient NPWT, the evidence includes RCTs. Relevant outcomes are symptoms, change in disease status, morbid events, QOL, and treatment-related morbidity. The PICO device was studied in an adequately powered but unblinded RCT of combined in- and outpatient use after total joint arthroplasty. The evidence base for the Prevena System is not sufficiently robust for conclusions on efficacy to be drawn. Well-designed comparative studies with larger numbers of patients treated in an outpatient setting are needed. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

For obese women undergoing cesarean delivery, there is evidence for NPWT that indicate a significant reduction in surgical site infection. But the contradictory nature of other results of this procedure in obese women undergoing cesarean deliveries suggest that more studies are needed to reach a consensus about use of NPWT in this situation.

PRACTICE GUIDELINE SUMMARY

INTERNATIONAL EXPERT PANEL ON NEGATIVE PRESSURE WOUND THERAPY

In 2011, an international expert panel on NPWT provided evidence-based recommendations for the use of NPWT in chronic wounds.[64] The panel made the following recommendations for the use of NPWT (see Table 3).

Table 3. Recommendations on Use of NPWT in Chronic Wounds

Condition	Recommendation	Grade[a]
Pressure ulcers, grade 3-4	"NPWT may be used until surgical closure is possible/desirable."	C
	"NPWT should be considered to achieve closure by secondary intention…. to reduce wound dimensions…. [and] to improve the quality of the wound bed."	B
Diabetic foot ulcers	"NPWT must be considered as an advanced wound care therapy…. [and] must be considered to achieve healing by secondary intention."	A
	"NPWT should be considered in an attempt to prevent amputation or reamputation."	B
Ischemic lower-limb wounds	"… NPWT … may be considered in specialist hands and never as an alternative for revascularization."	C
	"… NPWT is NOT indicated in acute limb ischemia."	D
Venous leg ulcers	"If first-line therapy (compression) is not efficacious, NPWT should be considered to prepare the wound for surgical closure…."	B

NPWT: negative pressure wound therapy.
[a] Grade A: based on high-quality meta-analyses, systematic reviews of RCTs, or RCTs with very low risk of bias; grade B: based on high-quality systematic reviews of case-control or cohort studies; Grade C: based on well-conducted case-control or cohort studies; Grade D: based on case series or expert opinion.

INTERNATIONAL MULTIDISCIPLINARY CONSENSUS RECOMMENDATIONS

Willy (2017) presented evidence-based consensus guidelines on the use of closed incision negative pressure therapy (ciNPT) following surgery.[65] Among the studies found were 100 randomized controlled studies on ciNPT, most of which found an association between the use of ciNPT and improved outcomes. Based on the evidence, the consensus panel recommended that surgeons evaluate risk in patients before surgery to determine whether patient comorbidities (ie, obesity or diabetes) or the nature of the surgery presents an increased danger of infection. In such cases, the panel recommended the use of ciNPT.

INFECTIOUS DISEASES SOCIETY OF AMERICA AND SURGICAL INFECTION SOCIETY

In 2011, guidelines for the prevention of infections associated with combat-related injuries were endorsed by the Infectious Diseases Society of America and the Surgical Infection Society.[66] The guidelines provided an IB recommendation (strong recommendation, moderate-quality evidence) that NPWT should be used to manage open wounds (excluding central nervous system injuries).

The 2012 guidelines from the Society for the diagnosis and treatment of diabetic foot infections stated that no adjunctive therapy has been proved to improve the resolution of infection, but for select diabetic foot wounds that are slow to heal, clinicians might consider using NPWT (weak recommendation, low-quality evidence).[67]

AMERICAN COLLEGE OF PHYSICIANS

In 2015, the American College of Physicians published guidelines on the treatment of pressure ulcers.[68] The guidelines stated there was low-quality evidence that the overall treatment effect of NPWT did not differ from the standard of care.

ASSOCIATION FOR THE ADVANCEMENT OF WOUND CARE

In 2010, the Association for the Advancement of Wound Care (AAWC) published guidelines on the care of pressure ulcers. NPWT was included as a potential second-line intervention if first-line treatments did not result in wound healing (level B evidence). The guidelines indicated that patients must be selected carefully for this procedure. The guidelines were updated in 2014 with additional validation.[69]

In 2010, the AAWC published guidelines on the care of venous ulcers.[70] The guidelines listed NPWT as a potential adjunctive therapy if conservative therapy does not work in 30 days. The guidelines noted there is limited evidence for NPWT (level B) compared with other adjunctive therapies.

INTERNATIONAL WORKIN GROUP ON THE DIABETIC FOOT

In 2020, the International Working Group on the Diabetic Foot (IWGDF) published updated guidelines on use of interventions to enhance healing of chronic foot ulcers in diabetes.[71] The updated guidelines make the following recommendations:

- “Consider the use of negative pressure wound therapy to reduce wound size, in addition to best standard of care, in patients with diabetes and a post-operative (surgical) wound on the foot. (GRADE strength of recommendation: Weak; Quality of evidence: Low)”
- “We suggest not using negative pressure wound therapy in preference to best standard of care in nonsurgical diabetic foot ulcers. (GRADE strength of recommendation: Weak; Quality of evidence: Low)”

THE AMERICAN ACADEMY OF ORTHOPAEDIC SURGEONS

In 2023, the American Academy of Orthopaedic Surgeons (AAOS) released a clinical practice guideline on the prevention of surgical site infection after major extremity trauma.[72] The guideline is based on a systematic review conducted by the AAOS and the Department of Defense. Each recommendation is rated based on the strength of supporting evidence. The recommendations for the use of NPWT for open and closed fractures was rated as strong (high quality supporting evidence):

- “After closed fracture fixation, negative pressure wound therapy may mitigate the risk of revision surgery or surgery site infections; however, after open fracture fixation, negative pressure wound therapy does not appear to offer an advantage when compared with sealed dressings as it does not decrease wound complications or amputations.”

SUMMARY

One-Month Therapeutic Trial

Overall, the evidence from comparative clinical trials has demonstrated there is a subset of problematic wounds for which the use of powered negative pressure wound therapy (NPWT) may provide a significant clinical benefit. In addition, clinical practice guidelines recommend outpatient NPWT in some situations. Therefore, a one-month therapeutic trial of a NPWT system (pump and supplies) may be considered medically necessary when criteria are met.

The evidence does not show that negative pressure wound therapy (NPWT) improves health outcomes when criteria are not met. Therefore, a one-month therapeutic trial of a NPWT system (pump and supplies) is considered not medically necessary when criteria are not met.

Continuation After One-Month Therapeutic Trial

Overall, the evidence from comparative clinical trials has demonstrated there is a subset of problematic wounds for which the *continuation* of powered negative pressure wound therapy (NPWT) following a one-month trial may provide a significant clinical benefit when there is appropriate supervision and documentation. Therefore, *continuation* of the powered NPWT system may be considered medically necessary when criteria are met.

When there is not documentation of a licensed medical professional assessing the wound and/or the wound is not improving, the *continuation* of powered negative pressure wound therapy at any period of time following a one-month therapeutic trial is therefore considered not medically necessary.

The evidence does not show that negative pressure wound therapy (NPWT) improves health outcomes beyond four months. Therefore, continuation of NPWT after four total months is considered not medically necessary.

Single-Use NPWT Systems

There is not enough evidence to establish the safety and efficacy of single-use NPWT systems. Well-designed comparative studies with larger numbers of patients treated in an outpatient setting are needed. Therefore, single-use NPWT systems (powered or nonpowered) is considered investigational for the treatment of acute or chronic wounds.

CODES

Codes	Number	Description
CPT	97605	Negative pressure wound therapy (e.g., vacuum-assisted drainage collection), utilizing durable medical equipment (DME), including topical application(s),

Codes	Number	Description
		wound assessment, and instruction(s) for ongoing care, per session; total wound(s) surface area less than or equal to 50 square centimeters
	97606	;total wound(s) surface area greater than 50 square centimeters
	97607	Negative pressure wound therapy (eg, vacuum assisted drainage collection), utilizing disposable, non-durable medical equipment including provision of exudate management collection system, topical application(s), wound assessment, and instructions for ongoing care, per session; total wound(s) surface area less than or equal to 50 square centimeters
	97608	;total wound(s) surface area greater than 50 square centimeters
HCPCS	A6550	Wound care set, for negative pressure wound therapy electrical pump, includes all supplies and accessories
	A7000-A7001	Canister for use with suction pump, code range
	A9272	Wound suction, disposable, includes dressing and all accessories and components, any type, each
	E2402	Negative pressure wound therapy electrical pump, stationary or portable
	K0743	Suction pump, home model, portable, for use on wounds
	K0744-K0746	Code range for absorptive wound dressings to be used with home suction pump coded with K0743

Insulin Infusion Pumps, Automated Insulin Delivery and Artificial Pancreas Device Systems

Effective: January 1, 2024

Next Review: October 2024
Last Review: November 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

An external insulin infusion pump is typically used to deliver insulin into patients with diabetes mellitus. Automated insulin delivery systems (including but not limited to artificial pancreas devices) monitor glucose levels and automatically adjust the delivery of insulin to help achieve tight glucose control.

MEDICAL POLICY CRITERIA

Note: This policy is does not address stand-alone continuous glucose monitors (CGM) which may be considered medically necessary.

I. An *automated insulin delivery system* (including artificial pancreas devices) may be considered **medically necessary** for diabetes mellitus when either of the following Criteria are met:

A. The patient has type 1 diabetes mellitus and all of the following Criteria (1. – 3.) are met:

1. The device is approved by the Food and Drug Administration (FDA) and the patient meets the FDA approved age requirements for the device (see Policy

Guidelines); and

2. Glycated hemoglobin level (Hemoglobin A1c or HbA1c) between 5.8% and 10.0%; and
3. Used insulin pump therapy for more than 3 months.

B. The patient has gestational diabetes or preconception/pregnancy related suboptimal glycemic control (e.g., erratic blood sugars, ketoacidosis, or symptomatic hypoglycemia).

II. An *external insulin infusion pump* may be considered **medically necessary** when either of the following Criteria are met:

A. The patient has diabetes mellitus; or

B. The patient has gestational diabetes or preconception/pregnancy related suboptimal glycemic control (e.g., erratic blood sugars, ketoacidosis, or symptomatic hypoglycemia).

III. A replacement for all or part of the *external insulin pump* or FDA-approved *automated insulin delivery system* (including artificial pancreas device systems) may be considered **medically necessary** when both of the following Criteria (A. and B.) are met:

A. The pump is no longer able to perform its basic function due to one or more of the following:

1. Device is out of the warranty period; or
2. Damage or wear; or
3. The device can no longer meet the patient's medical needs due to a significant change in the patient's medical condition (e.g., larger insulin reservoir needed).

B. The current device cannot be repaired or adapted adequately to meet the patient's medical needs.

IV. The use of an *external insulin infusion pump* is considered **not medically necessary** when Criterion II. is not met.

V. A replacement for all or part of the *external insulin pump* or FDA-approved *automated insulin delivery system* (including artificial pancreas device systems) that does not meet Criterion III. is considered **not medically necessary**.

VI. The use of an *automated insulin delivery system* (including artificial pancreas device systems) is considered **investigational** when Criterion I. is not met including but not limited to a device that is not approved by the FDA.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

FDA-Approved Automated Insulin Delivery Systems (Artificial Pancreas Device Systems)

Device	Age Indication	Manufacturer
MiniMed™ 530G System[a] (open-loop, LGS)	≥16 years	Medtronic
MiniMed™ 630G System with SmartGuard™[b] (open-loop, LGS):		Medtronic
o MiniMed™ 630G with Guardian™ Sensor 3	≥14 years	
o MiniMed™ 630G with Enlite™ Sensor	≥16 years	
MiniMed™ 670G System[c] (hybrid closed-loop, LGS or PLGM)	≥7 years	Medtronic
MiniMed™ 770G System[d] (hybrid closed-loop, LGS or PLGM)	≥2 years[e]	Medtronic
MiniMed 780G System (hybrid closed-loop)[f]	≥7 years	Medtronic
t:slim X2 Insulin Pump with Basal-IQ Technology (LGS) t:slim X2 Insulin Pump with Control-IQ Technology (HCL)	≥6 years	Tandem
Omnipod 5 (hybrid closed-loop)	≥2 years	Insulet
iLet Bionic Pancreas (closed loop)	≥6 years	Beta Bionics

[a] MiniMed 530G System consists of the following devices that can be used in combination or individually: MiniMed 530G Insulin Pump, Enlite™ Sensor, Enlite™ Serter, the MiniLink Real-Time System, the Bayer Contour NextLink glucose meter, CareLink® Professional Therapy Management Software for Diabetes, and CareLink® Personal Therapy Management Software for Diabetes (at time of approval).
[b] MiniMed 630G System with SmartGuard™ consists of the following devices: MiniMed 630G Insulin Pump, Enlite® Sensor, One-Press Serter, Guardian® Link Transmitter System, CareLink® USB, Bayer's CONTOUR ® NEXT LINK 2.4 Wireless Meter, and Bayer's CONTOUR® NEXT Test Strips (at time of approval).
[c] MiniMed 670G System consists of the following devices: MiniMed 670G Pump, the Guardian Link (3) Transmitter, the Guardian Sensor (3), One-Press Serter, and the Contour NEXT Link 2.4 Glucose Meter (at time of approval).
[d] MiniMed 770G System consists of the following devices: MiniMed 770G Insulin Pump, the Guardian Link (3) Transmitter, the Guardian Sensor (3), one-press serter, the Accu-Chek Guide Link blood glucose meter, and the Accu-Chek Guide Test Strips. The system requires a prescription.
[e] The 770G System may not be safe for use in patients who require less than a total daily insulin dose of 8 units per day because the device requires a minimum of 8 units per day to operate safely.
[f] MiniMed 780G System consists of the following devices: MiniMed 780G Insulin Pump, the Guardian 4 Transmitter, the Guardian 4 Sensor (3), One-Press Serter, the Accu-Chek Guide™ Link blood glucose meter, and the Accu-Chek Guide™ Test Strips

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- Automated insulin delivery system (artificial pancreas device system)
  - History and physical
  - Age of patient
  - Name and type of device requested
  - Documented use of insulin pump for more than 3 months
  - When applicable, documentation of gestational diabetes or preconception/pregnancy related suboptimal glycemic control (e.g., erratic blood sugars, ketoacidosis, or symptomatic hypoglycemia)
- External insulin infusion pumps
  - Clinical documentation of diabetes mellitus
  - When applicable, documentation of gestational diabetes or preconception/pregnancy related suboptimal glycemic control (e.g., erratic blood sugars, ketoacidosis, or symptomatic hypoglycemia)

- Replacement and upgrades
    - History and physical
    - Name and type of device requested
    - Documentation of specifically why pump is no longer able to perform its basic function
    - Documentation that the current device cannot be repaired or adapted adequately to meet the patient's needs

BACKGROUND

Maintenance of a target blood glucose and target glycated hemoglobin (HgA1c < 7%), a marker which is used as a proxy for average blood glucose, is now considered standard of care for patients with diabetes. Also known as tight diabetes control, this strategy is intended to prevent severe hypoglycemic events and lower the risk of cardiovascular disease mortality associated with uncontrolled glycemia.[1] In order to achieve tight glucose control, several devices may be used individually or in combination which includes but is not limited to continuous glucose monitors, insulin pumps, and more recently artificial pancreas device systems. The Food and Drug Administration (FDA) describes the basic design of an artificial pancreas device system (APDS) as a continuous glucose monitor (CGM) linked to an insulin pump with the capability to automatically stop, reduce, or increase insulin infusion based on specified thresholds of measured interstitial glucose. The APDS components are designed to communicate with each other to automate the process of maintaining blood glucose concentrations at or near a specified range or target and to minimize the incidence and severity of hypoglycemic and hyperglycemic events. An APDS control algorithm is embedded in software in an external processor or controller that receives information from the CGM and performs a series of mathematical calculations. Based on these calculations, the controller sends dosing instructions to the infusion pump.

Different APDS types are currently available for clinical use. Sensor augmented pump therapy (SAPT) with low glucose suspend (LGS) (suspend on low) may reduce the likelihood or severity of a hypoglycemic event by suspending insulin delivery temporarily when the sensor value reaches (reactive) a predetermined lower threshold of measured interstitial glucose. Low glucose suspension (LGS) automatically suspends basal insulin delivery for up to two hours in response to sensor-detected hypoglycemia.

A sensor augmented pump therapy with predictive low glucose management (PLGM) (suspend before low) suspends basal insulin infusion with the prediction of hypoglycemia. Basal insulin infusion is suspended when sensor glucose is at or within 70 mg/dL above the patient-set low limit and is predicted to be 20 mg/dL above this low limit in 30 minutes. In the absence of a patient response, the insulin infusion resumes after a maximum suspend period of two hours. In certain circumstances, auto-resumption parameters may be used.

When a sensor value is above or predicted to remain above the threshold, the infusion pump will not take any action based on CGM readings. Patients using this system still need to monitor their blood glucose concentration, set appropriate basal rates for their insulin pump,

and give premeal bolus insulin to control their glucose levels.

A control-to-range system reduces the likelihood or severity of a hypoglycemic or hyperglycemic event by adjusting insulin dosing only if a person's glucose levels reach or approach predetermined higher and lower thresholds. When a patient's glucose concentration is within the specified range, the infusion pump will not take any action based upon CGM readings. Patients using this system still need to monitor their blood glucose concentration, set appropriate basal rates for their insulin pump, and give premeal bolus insulin to control their glucose levels.

A control-to-target system sets target glucose levels and always tries to maintain these levels. This system is fully automated and requires no interaction from the user (except for calibration of the CGM). There are two subtypes of control-to-target systems: insulin-only and bihormonal (e.g., glucagon). There are no systems administering glucagon marketed in the United States.

An APDS may also be referred to as a “closed-loop” system. A closed-loop system has automated insulin delivery and continuous glucose sensing and insulin delivery without patient intervention. The systems utilize a control algorithm that autonomously and continually increases and decreases the subcutaneous insulin delivery based on real-time sensor glucose levels. There are no completely closed-loop insulin delivery systems marketed in the United States.

A hybrid closed-loop system also uses automated insulin delivery with continuous basal insulin delivery adjustments. However, at mealtime, the patient enters the number of carbohydrates they are eating for the insulin pump to determine the bolus meal dose of insulin. A hybrid system option with the patient administration of a premeal or partial premeal insulin bolus can be used in either control-to-range or control-to-target systems.

REGULATORY STATUS

There are several APDS devices approved by the Food and Drug Administration (FDA). These systems are regulated by the FDA as class III device systems.

The MiniMed® 530G System includes a threshold suspend or LGS feature.[2] The threshold suspend tool temporarily suspends insulin delivery when the sensor glucose level is at or below a preset threshold within the 60- to 90-mg/dL range. When the glucose value reaches this threshold, an alarm sounds. If patients respond to the alarm, they can choose to continue or cancel the insulin suspend feature. If patients fail to respond, the pump automatically suspends action for two hours, and then insulin therapy resumes.

The MiniMed® 630G System with SmartGuard™, which is similar to the 530G, includes updates to the system components including waterproofing.[3] The threshold suspend feature can be programmed to temporarily suspend delivery of insulin for up to two hours when the sensor glucose value falls below a predefined threshold value. The MiniMed 630G System with SmartGuard™ is not intended to be used directly for making therapy adjustments, but rather to provide an indication of when a finger stick may be required. All therapy adjustments should be based on measurements obtained using a home glucose monitor and not on the values provided by the MiniMed 630G system. The device is not intended to be used directly for preventing or treating hypoglycemia but to suspend insulin delivery when the user is unable to respond to the SmartGuard™ Suspend on Low alarm to take measures to prevent or treat hypoglycemia themselves.

The MiniMed® 670G System is a hybrid closed-loop insulin delivery system consisting of an insulin pump, a glucose meter, and a transmitter, linked by a proprietary algorithm and the SmartGuard Hybrid Closed Loop.[4] The system includes an LGS feature that suspends insulin delivery; this feature either suspends delivery on low-glucose levels or suspends delivery before low-glucose levels, and has an optional alarm (manual mode). Additionally, the system allows semiautomatic basal insulin-level adjustment (decrease or increase) to preset targets (automatic mode). As a hybrid system; basal insulin levels are automatically adjusted, but the patient needs to administer premeal insulin boluses. The CGM component of the MiniMed 670G System is not intended to be used directly for making manual insulin therapy adjustments; rather it is to provide an indication of when a glucose measurement should be taken. The MiniMed 670G System was originally approved for marketing in the United States on September 28, 2016 (P160017) and received approval for marketing with a pediatric indication (ages 7-13 years) on June 21, 2018 (P160017/S031).

On August 31, 2020, the MiniMed® 770G System received Premarket Approval from the FDA. The 770G System was approved as a supplement to the previously approved MiniMed 670G System.[5] Approval of the MiniMed 770G System expanded the indications for use to users down to two years old and updated the pump communication protocol to Bluetooth. The 770G System is a hybrid closed loop system that measures glucose levels and automatically adjusts insulin delivery by either administering or withholding insulin. The 770G System consists of the MiniMed 770G Insulin Pump, the Guardian Link (3) Transmitter, the Guardian Sensor (3), one-press serter, the Accu-Chek Guide Link blood glucose meter, and the Accu-Chek Guide Test Strips. The system requires a prescription. The 770G System was approved for the following indications:

> The MiniMed 770G system is intended for continuous delivery of basal insulin (at user selectable rates) and administration of insulin boluses (in user selectable amounts) for the management of type 1 diabetes mellitus in persons two years of age and older requiring insulin as well as for the continuous monitoring and trending of glucose levels in the fluid under the skin. The MiniMed 770G System includes SmartGuard technology, which can be programmed to automatically adjust delivery of basal insulin based on continuous glucose monitoring (CGM) sensor glucose values and can suspend delivery of insulin when the sensor glucose value falls below or is predicted to fall below predefined threshold values.
>
> The Medtronic MiniMed 770G System consists of the following devices: MiniMed 770G Insulin Pump, the Guardian Link (3) Transmitter, the Guardian Sensor (3), one-press serter, the Accu-Chek Guide™ Link blood glucose meter, and the Accu-Chek Guide™ Test Strips. The system requires a prescription.
>
> The Guardian Sensor (3) has not been evaluated and is not intended to be used directly for making therapy adjustments, but rather to provide an indication of when a fingerstick may be required. All therapy adjustments should be based on measurements obtained using a blood glucose meter and not on values provided by the Guardian Sensor (3).

Per the FDA approval, a prominent boxed warning is included in the labeling regarding use of the 770G System in users with a total daily insulin dose of less than 8 units, “Medtronic performed an evaluation of the 770G closed loop system and determined that it may not be safe for use in patients who require less than a total daily insulin dose of 8 units per day because the device requires a minimum of 8 units per day to operate safely.”

On June 21, 2018, the FDA approved the t:slim X2 Insulin Pump with Basal-IQ Technology (PMA P180008) for individuals who are six years of age and older.[6] The System consists of the t:slim X2 Insulin Pump paired with the Dexcom G5 Mobile CGM (Continuous Glucose Monitor), as well as the Basal-IQ Technology. The t:slim X2 Insulin Pump is intended for the subcutaneous delivery of insulin, at set and variable rates, for the management of diabetes mellitus in persons requiring insulin. The t:slim X2 Insulin Pump can be used solely for continuous insulin delivery and as part of the System as the receiver for a therapeutic CGM. The t:slim X2 Insulin Pump running the Basal-IQ Technology can be used to suspend insulin delivery based on CGM sensor readings. Introduction into clinical care is planned for summer 2019.

In December 2019, the FDA approved the t:slim X2 Insulin Pump with Control-IQ Technology through the De Novo process.[7] The device uses the same pump hardware as the insulin pump component of the systems approved in t:slim X2 Insulin Pump with Basal-IQ Technology (P180008) and P140015. A custom disposable cartridge is motor-driven to deliver patient programmed basal rates and boluses through an infusion set into subcutaneous tissue.

In 2022, the FDA approved the Omnipod 5 ACE Pump for the subcutaneous delivery of insulin, at set and variable rates, for the management of diabetes mellitus in persons requiring insulin. In January, approval for the SmartAdjust™ technology was granted for ages six and up, and in September approval was expanded to allow for use in people ages two and older.[8, 9] The Omnipod 5 ACE Pump is able to reliably and securely communicate with compatible, digitally connected devices, including automated insulin dosing software, to receive, execute, and confirm commands from these devices.

In May 2023, the FDA approved the first closed-loop system (iLet Bionic Pancreas) through the 510(k) premarket clearance pathway.[10] The iLet pump is an alternate controller enabled (ACE) pump intended to deliver insulin under the skin based on input from an integrated continuous glucose monitor (iCGM) and an interoperable automated glycemic controller (iAGC), in people 6 years of age or older with diabetes mellitus. The iLet ACE Pump is intended for single-person use; it is not to be shared.[11]

There are many insulin pumps on the market that are approved by the FDA. FDA 510(k) Product Code: LZG.

EVIDENCE SUMMARY

EXTERNAL INSULIN INFUSION PUMP

Randomized controlled trials (RCTs) have evaluated insulin pumps with various functionalities including a low glucose suspend (LGS) feature.[12-17] Results of these studies have demonstrated that insulin infusion pumps may, in carefully selected patient populations, control blood glucose to near-normal levels.

ARTIFICIAL PANCREAS DEVICE SYSTEMS

The key clinical outcomes regarding the clinical utility of artificial pancreas device systems (APDSs) relate to their ability to improve morbidity and mortality associated with clinically significant, severe, and acute hypoglycemia or hyperglycemic events.

Low Glucose Suspend Devices

Systematic Review and Technology Assessments

Alotaibi (2020) published the results of a systematic review (SR) with meta-analysis on the efficacy and safety of insulin pump therapy with predictive low glucose suspend (PLGS) features in children and adolescents with type 1 diabetes (T1D).[18] RCTs evaluating sensor augmented pump (SAP) with a PLGS feature compared to SAP or insulin pump therapy without SAP in decreasing hypoglycemia in children and adolescents with type 1 diabetes were considered. Although all RCTs with patients aged 2 to 18 years with at least two weeks follow-up were evaluated, only five RCTs with total sample size of 493 children aged 6 to 18 years met inclusion criteria. The risk of bias within studies was low for allocation concealment and random sequence generation was low for most studies. Blinding was not always feasible given the nature of the intervention; three of the studies were open-label, whereas in two of the studies, participants were blinded to the intervention, and in one study the outcome assessors also were blinded to the intervention. Risk of publication bias could not be assessed due to the small number of studies evaluated. Intention-to-treat analysis was used in all studies to account for loss of follow-up. Results indicate there is high quality evidence that PLGS is superior to SAP in decreasing percent of time spent in hypoglycemia (sensor glucose [SG] <3.9 mmol/L [<70 mg/dL]/24 h) and nocturnal hypoglycemia (SG <3.9 mmol [<70 mg/dL]/L/night) with an absolute mean difference of 17.4 min/d (95% CI -19.2, -15.5) and 26.3 min/night (95% CI: -35.5, -16.7), respectively. Percent time spent in hyperglycemia or episodes of diabetic ketoacidosis were not found to be different between groups. The only study with a duration long enough to assess health related quality of life showed no significant difference from baseline to study completion. The authors concluded that among children and adolescents with type 1 diabetes treated with insulin pump therapy, the utilization of PLGS is superior to SAP in decreasing mild to moderate daytime and nocturnal hypoglycemia without increasing the risk of hyperglycemia, but note that future studies evaluating long-term safety and cost-effectiveness are warranted.

Randomized Controlled Trials

Collyns (2021) published the results of a randomized crossover study conducted at two sites comparing the MiniMed Advanced Hybrid Closed-Loop (AHCL) 670G system to sensor-augmented pump therapy with predictive low glucose management (SAP + PLGM) in patients with T1D.[19] Of the 60 patients enrolled, 59 completed the study. Patients were naive to automated insulin delivery ranged in age from seven to 80 years (mean age 23.3 ± 14.4 years), The treatment intervention sequence was randomly assigned 1:1 stratified by participants' age. Each study phase was four weeks, preceded by a two- to four-week run-in and separated by a 2-week washout. Time in target range (TIR, 3.9-10 mmol/L) was higher in the AHCL compared to the SAP + PLGM group (70.4 ± 8.1% vs. 57.9 ± 11.7%, $p < 0.001$). Mean sensor glucose (SG) at run-in was 9.3 ± 0.9 mmol/L and improved with AHCL (8.5 ± 0.7 mmol/L, $p < 0.001$) and deteriorated during PLGM (9.5 ± 1.1 mmol/L, $p < 0.001$). There was one episode of mild diabetic ketoacidosis, which occurred during the SAP + PLGM arm, attributed to an infusion set failure in combination with an intercurrent illness.

Beardsall (2020) published the results of a randomized, open-label, parallel controlled trial in 20 pre-term infants receiving CGM alone supported by a paper algorithm compared to CGM with an additional intervention period of closed-loop CGM. The closed-loop system was comprised of (i) an Enlite CGM sensor, (ii) a laptop computer running a model predictive control algorithm and (iii) two Alaris syringe pumps. All 20 babies remained in the study throughout the intervention period from 48 to 72 hours and the mean (SD) length of glucose

data collected in each study arm was 137 (16.4) hours and 136 (8.7) hours for CGM and CGM plus closed loop, respectively. During the intervention period, the median (IQR) time spent in the target range (sensor glucose [SG] 4.0–8.0 mmol/L) was significantly higher in babies in the closed-loop group 91% (78, 99) compared with controls 26% (6-64); p<0.001. In addition, the time spent in the wider target range of 2.6–10.0 mmol/L was higher in the closed-loop group: median 100% compared with control group, median 84%. Lower SG was observed in the closed-loop group median (IQR) 6.2 (6.1-7.1) mmol/L compared with the control group 8.6 (7.4-11.1) mmol/L (p=0.002). Time spent with SG levels <2.6 mmol/L and glucose variability as measured by the SD of SG were similar between groups. In the postintervention period (post-72 hours), there was qualitatively increased time in both glucose target ranges (4.0–8.0 and 2.6–10.0 mmol/L) in the closed-loop group compared with the control group, but these differences did not reach statistical significance. In the closed-loop study group, two babies had documented episodes of hypoglycemia with blood glucose (BG) <2.6 mmol/L, both associated with a change of maintenance fluids. In the control study group, no babies had a documented BG value <2.6 mmol/L. One baby in the control group had an episode lasting 205 min when the SG fell to <2.6 mmol/L (BG was not checked at this time). Limitations to this study include small sample size, lack of blinding, and short study duration. While Medtronic provided the continuous glucose monitoring systems and sensors, the company had no role in study design, data acquisition, preparation of the manuscript, or decision to publish the study.

Breton (2020) published the results of a multi-site RCT comparing a closed-loop system of insulin delivery (closed-loop group, n=78) and a sensor-augmented insulin pump (control group, n=23) in children 6 to 13 years of age who had type 1 diabetes.[20] The primary outcome was the percentage of time that glucose levels were in the target range of 70 to 180 mg per deciliter, as measured by CGM. The mean (±SD) percentage of time that the glucose level was in the target range over the 16 weeks of treatment increased from 53±17% at baseline to 67±10% in the closed-loop group and from 51±16% to 55±13% in the control group (mean adjusted difference, 11 percentage points [equivalent to 2.6 hours per day]; 95% confidence interval, 7 to 14; p<0.001). The median percentage of time that the system was in the closed-loop mode was 93% (interquartile range, 91 to 95) for patients in the closed-loop group. No episodes of diabetic ketoacidosis or severe hypoglycemia were noted in either study group. Improvements were sustained through 28 weeks in an uncontrolled extension study of 100 children who were enrolled in the RCT (Kanapka 2021).[21] Health-related quality of life and patient satisfaction measures from the RCT and the extension phase were reported by Cobry (2021).[22] Neither children nor their parents in the closed-loop system group reported statistically significant changes in these outcomes compared with the sensor-augmented insulin pump group. The authors concluded that children receiving the closed-loop system did not experience increased burden compared with those using sensor-augmented insulin pump.

Outcomes of the Automation to Simulate Pancreatic Insulin Response (ASPIRE) trial were reported by Bergenstal (2013).[16] This industry-sponsored trial used the Paradigm Veo insulin pump. A total of 247 patients were randomized to an experimental group, in which a continuous glucose monitor with the LGS feature was used (n=121), or a control group, which used the continuous glucose monitor but not the LGS feature (n=126). Key eligibility criteria were 16-to-70 years old, T1D, and HbA1c levels between 5.8% and 10.0%. In addition, patients had to have more than six months of experience with insulin pump therapy and at least two nocturnal hypoglycemic events (≤65 mg/dL) lasting more than 20 minutes during a two-week run-in phase. The randomized intervention phase lasted three months. Patients in the LGS group were required to use the feature at least between 10 PM and 8 AM. The threshold value was initially set at 70 mg/dL and could be adjusted to between 70 mg/dL and

90 mg/dL. Seven patients withdrew early from the trial; all 247 were included in the intention-to-treat analysis. The primary efficacy outcome was the area under the curve (AUC) for nocturnal hypoglycemia events. This was calculated by multiplying the magnitude (in milligrams per deciliter) and duration (in minutes) of each qualified hypoglycemic event. The primary safety outcome was change in HbA1c levels.

The primary end point, mean (standard deviation [SD]) AUC for nocturnal hypoglycemic events, was 980 (1200) mg/dL/min in the LGS group and 1568 (1995) mg/dL/min in the control group. The difference between groups was statistically significant ($p<0.001$), favoring the intervention group.

Similarly, the mean AUC for combined daytime and nighttime hypoglycemic events (a secondary outcome) significantly favored the intervention group ($p<0.001$). Mean (SD) AUC values were 798 (965) mg/dL/min in the intervention group and 1164 (1590) mg/dL/min in the control group. Moreover, the intervention group experienced fewer hypoglycemic episodes (mean, 3.3 per patient-week; SD=2.0) than the control group (mean, 4.7 per patient-week; SD=2.7; $p<0.001$). For patients in the LGS group, the mean number of times the feature was triggered per patient was 2.08 per 24-hour period and 0.77 each night (10 PM-8 AM). The median duration of nighttime threshold suspend events was 11.9 minutes; 43% of events lasted for less than five minutes, and 19.6% lasted more than two hours. In both groups, the mean sensor glucose value at the beginning of nocturnal events was 62.6 mg/dL. After four hours, the mean value was 162.3 mg/dL in the LGS group and 140.0 mg/dL in the control group.

Regarding safety outcomes and adverse events, change in HbA1c level was minimal, and there was no statistically significant difference between groups. Mean HbA1c levels decreased from 7.26 to 7.24 mg/dL in the LGS group and from 7.21 to 7.14 mg/dL in the control group. During the study period, there were no severe hypoglycemic events in the LGS group and four events in the control group (range of nadir glucose sensor values in these events, 40-76 mg/dL). There were no deaths or serious device-related adverse events.

Before reporting on in-home findings, the ASPIRE researchers (Garg [2012]) published data from the in-clinic arm of the study.[23] This randomized crossover trial included 50 patients with type 1 diabetes who had at least three months of experience with an insulin pump system. After a two-week run-in period to verify and optimize basal rates, patients underwent two in-clinic exercise sessions to induce hypoglycemia. The LGS feature on the insulin pump was turned on in one session and off in the other session, in random order. When on, the LGS feature was set to suspend insulin delivery for two hours when levels reached 70 mg/dL or less. The goal of the study was to evaluate whether the severity and duration of hypoglycemia were reduced when the LGS feature was used. The study protocol called for patients to start exercise with glucose levels between 100 mg/dL and 140 mg/dL and to use a treadmill or stationary bicycle until their plasma glucose levels were 85 mg/dL or less. The study outcome (duration of hypoglycemia) was defined as the period of time glucose values were lower than 70 mg/dL and above 50 mg/dL, and hypoglycemia severity was defined as the lowest observed glucose value. A successful session was defined as an observation period of 3 to 4 hours and with glucose levels above 50 mg/dL. Patients who did not attain success could repeat the experiment up to three times.

The 50 patients attempted 134 exercise sessions; 98 of them were successful. Duration of hypoglycemia was significantly shorter during the LGS-on sessions (mean, 138.5 minutes;

SD=68) than the LGS-off sessions (mean, 170.7 minutes; SD=91; p=0.006). Hypoglycemia severity was significantly reduced in the LGS-on group. The mean (SD) lowest glucose level was 59.5 (72) mg/dL in the LGS-on group and 57.6 (5.7) mg/dL in the LGS-off group (p=0.015). Potential limitations of the Garg study included evaluation of the LGS feature in a research setting and short assessment period.

A second RCT evaluated the in-home use of the Paradigm Veo System.[12] The trial by Ly (2013) in Australia was excluded from the 2013 TEC Assessment due to the inclusion of children and adults and lack of analyses stratified by age group (the artificial pancreas system approved in the United States at the time of the review was only intended for individuals ≥16 years). The Ly trial included 95 patients with T1D between 4 and 50 years of age (mean age, 18.6 years; >30% of sample <18 years old) who had used an insulin pump for at least 6 months. In addition, participants had to have an HbA1c level of 8.5% or less and have impaired awareness of hypoglycemia (defined as a score of at least four on the modified Clarke questionnaire). Patients were randomized to six months of in-home use of the Paradigm Veo System with automated insulin suspension when the glucose sensor reached a preset threshold of 60 mg/dL or to continued use of an insulin pump without the LGS feature. The primary study outcome was the combined incidence of severe hypoglycemic events (defined as hypoglycemic seizure or coma) and moderate hypoglycemic events (defined as an event requiring assistance from another person). As noted, findings were not reported separately for children and adults.

The baseline rate of severe and moderate hypoglycemia was significantly higher in the LGS group (129.6 events per 100 patient-months) than in the pump-only group (20.7 events per 100 patient-months). After six months of treatment, and controlling for the baseline hypoglycemia rate, the incidence rate per 100 patient-months was 34.2 (95% confidence interval [CI], 22.0 to 53.3) in the pump-only group and 9.6 (95% CI, 5.2 to 17.4) in the LGS group. The incidence rate ratio was 3.6 (95% CI, 1.7 to 7.5), which was statistically significant favoring the LGS group. Although results were not reported separately for children and adults, the trialists conducted a sensitivity analysis in patients younger than 12 years (15 patients in each treatment group). The high baseline hypoglycemia rates could be explained in part by two outliers (children ages nine and 10 years). When both children were excluded from the analysis, the primary outcome was no longer statistically significant. The incidence rate ratio for moderate and severe events excluding the two children was 1.7 (95% CI, 0.7 to 4.3). Mean HbA1c levels (a secondary outcome) did not differ between groups at baseline or at 6 months. Change in HbA1c levels during the treatment period was - 0.06% (95% CI, -0.2% to 0.09%) in the pump-only group and -0.1% (95% CI, -0.3% to 0.03%) in the LGS group; the difference between groups was not statistically significant.

Prospective Studies

Gómez (2017) published the results of a cohort (n = 111) individuals with T1D with documented hypoglycemia and hypoglycemia unawareness who received a sensor-augmented insulin pump with LGS therapy.[24] Participants used a combination system with the Medtronic Paradigm 722 or Paradigm Veo pump connected to the MiniMed CGM device. At a mean follow-up of 47 months (SD=22.7), total daily insulin dose was reduced (mean difference, -0.22 U/kg; 95% CI, -0.18 to -0.26 U/kg; p<0.001). HbA1c levels were reduced from a baseline value of 8.8% (SD=1.9%) to 7.5% (SD=1.0%) at five months (mean difference, -1.3%; 95% CI, -1.09% to -1.50%; p<0.001) and 7.1% (SD=0.8%; mean difference, -1.7%; 95% CI, -1.59% to -1.90%; p<0.001). At baseline, 80% of subjects had had at least one episode of

hypoglycemic awareness compared with 10.8% at last follow-up (p<0.001). Episodes of severe hypoglycemia decreased from 66.6% to 2.7% (p<0.001).

Retrospective Studies

Agrawal (2015) retrospectively analyzed use of the threshold suspend feature associated with the Paradigm Veo System in 20,973 patients, most of whom were treated outside of the United States.[25] This noncontrolled descriptive analysis provided information on the safety of the device when used in a practice setting. The threshold suspend feature was enabled for 100% of the time by 14,673 (70%) patients, 0% of the time by 2249 (11%) patients, and the remainder used it intermittently. The mean (SD) setting used to trigger suspension of insulin was a sensor glucose level of 62.8 (5.8) mg/dL. On days when the threshold suspend feature was enabled, there was a mean of 0.82 suspend events per patient day. Of these, 56% lasted for 0 to 5 minutes, and 10% lasted the full two hours. (Data on the length of the other 34% of events were not reported.) On days when the threshold suspend feature was on, sensor glucose values were 50 mg/dL or less 0.64% of the time compared with 2.1% of sensor glucose values 50 mg/dL or less on days when the feature was off. Reduction in hypoglycemia was greatest at night. Sensor glucose percentages equivalent to 17 minutes per night occurred when the threshold suspend feature was off vs glucose percentages equivalent to five minutes per night when the threshold suspend feature was on. Data on the use of the device has suggested fewer and shorter hypoglycemic episodes. The length and severity of hypoglycemic episodes were not fully discussed in this article.

Section Summary

For individuals who have T1D who receive an artificial pancreas device system with a low glucose suspend feature, the evidence includes three RCTs conducted in patients six years and older. Relevant outcomes are symptoms, change in disease status, morbid events, resource utilization, and treatment-related morbidity. All of these RCTs reported primary outcomes were favorable for the group using an artificial pancreas system; however, findings from one trial were limited by nonstandard reporting of hypoglycemic episodes, and findings from the other trial were no longer statistically significant when two outliers (children) were excluded from analysis. The RCT limited to adults showed an improvement in the primary outcome (AUC for nocturnal hypoglycemic events). AUC is not used for assessment in clinical practice, but the current technology does allow user and provider review of similar trend data with a CGM.

Results from the ASPIRE study suggested that there were increased risks of hyperglycemia and potential DKA in subjects using the threshold suspend feature. This finding may be related to whether or not actions are taken by the user to assess glycemic status, etiology of the low glucose (activity, diet or medication) and to resume insulin infusion. Both retrospective and prospective observational studies have reported reductions in rates and severity of hypoglycemic episodes in automated insulin delivery system users.

In addition, one small study reported favorable outcomes for closed-loop systems in pre-term infants, however, this study is limited by very small sample size, lack of blinding, and short study duration.

The evidence is sufficient that the magnitude of reduction for hypoglycemic events in the population with T1D is likely to be clinically significant. Limitations of the published evidence

preclude determining the effects of the technology on overall glycemic control as assessed by HbA1c and other parameters and thus, net health outcomes.

Hybrid Closed-loop Insulin Delivery Systems

Systematic Review

Michou (2023) published a SR and meta-analysis to evaluate the efficacy of automatic insulin delivery (AID) systems in children and adolescents with T1D.[26] A total of 26 RCTs (n = 915) were included in the meta-analysis. AID systems revealed statistically significant differences in the main outcomes, such as the proportion of time in the target glucose range (3.9-10 mmol/L) ($p < 0.00001$), in hypoglycemia (<3.9 mmol/L) ($p = 0.003$) and mean proportion of HbA1C ($p = 0.0007$) compared to control group. The authors conclude that AID systems are superior to insulin pump therapy, sensor-augmented pumps and multiple daily insulin injections. Most of the included studies have a high risk of bias because of allocation, blinding of patients and blinding of assessment. Sensitivity analyses showed that patients < 21 years of age with T1D can use AID systems, after proper education, following their daily activities.

Peacock (2023) published a systematic review of reported trials and real-world studies for commercial hybrid closed-loop (HCL) automated insulin delivery (AID) systems.[27] Fifty-nine studies were included in the SR (19 for 670G; eight for 780G; 11 for Control-IQ; 14 for CamAPS FX; four for Diabeloop; and three for Omnipod-5). Twenty were real-world studies, and 39 were trials or sub-analyses. These studies highlighted that HCL systems improve time in range (TIR) and arouse minimal concerns around severe hypoglycemia. A meta-analysis was not conducted, and statistical tests were not used due to broad inclusion criteria and heterogeneity of the included papers. Many of the participants in the studies included had optimal baseline TIR and HbA1c and may have been of high socioeconomic status. Furthermore, most of the studies were conducted in the USA. Due to the differences in study designs and trial populations between the various AID systems, it was not possible to conclusively determine differences between them. The authors conclude that HCL systems are an effective and safe option for improving diabetes care. Real-world comparisons between systems and their effects on psychological outcomes require further study.

Karageorgiou (2019) published a systematic review and network meta-analysis evaluating the efficacy of closed-loop systems in glycemic control for non-adults with type 1 diabetes mellitus.[28] The meta-analysis included 25 studies (n = 504). The closed-loop system group spent a significantly higher percentage of time in a target glycemic range and the mean glucose was also decreased in the closed-loop system group (MD: 3.01%, 95% CI 1.68 to 4.34%). Overall, the closed-loop system showed better outcomes compared to standard insulin pumps for non-adults.

Prospective Studies

Edd (2023) published a prospective, multicentre, open-label, RCT in people (n = 75) with T1D, with an HbA1c of at least 8.0% (64 mmol/mol), on MDI+isCGM therapy.[29] To reassess the 6-month efficacy and to assess the 12-month sustained efficacy of the MiniMed™ 780G advanced hybrid closed-loop automated insulin delivery (AID) system compared to multiple daily injections plus intermittently scanned glucose monitoring (MDI+isCGM) in people with type 1 diabetes not meeting glucose targets. After a 6-month study phase, participants randomized at baseline to MDI+isCGM switched to AID (SWITCH) while the others continued AID therapy (SUSTAIN) for an additional 6 months. The primary endpoint of this continuation

phase was the within-group change in mean HbA1c between six and 12 months, with superiority in the SWITCH group and noninferiority in the SUSTAIN group (ClinicalTrials.gov: NCT04235504). A total of 39 SWITCH and 36 SUSTAIN participants entered the continuation phase. In the SWITCH group, HbA1c was significantly decreased by -1.4% (95% confidence interval [CI] -1.7% to -1.1%; p < 0.001) from a mean ± SD of 8.9% ± 0.8% (73.9 ± 8.6 mmol/mol) at six months to 7.5% ± 0.6% (58.5 ± 6.9 mmol/mol) at 12 months. Mean HbA1c increased by 0.1% (95% CI -0.05% to +0.25%), from 7.3% ± 0.6% (56.5 ± 6.7 mmol/mol) to 7.4% ± 0.8% (57.7 ± 9.1 mmol/mol) in the SUSTAIN group, meeting noninferiority criteria. Three severe hypoglycemia events occurred in two SWITCH participants during the continuation phase. The authors concluded that ADAPT study phase glycemic improvements were reproduced and sustained in the continuation phase, supporting the early adoption of AID therapy in people with T1D not meeting glucose targets on MDI therapy.

Brown (2021) reported results of the noncomparative pivotal trial of the Omnipod 5 Automated Insulin Delivery System.[30] The study included 241 participants (112 children ages 6 to 13.9 years and 128 adults ages 14 to 70 years). The mean reduction from baseline in HbA1c was 0.71% for children and 0.38% for adults (both p<0.0001 from baseline). Change in time in range compared to baseline (hours/day) was 3.7 for children and 2.2 for adults (both p<0.0001). Reduction from baseline in time in hypoglycemia <70 mg/dL was 2.0% to 1.09% for adults while no change was reported for children. The adverse events reported were three severe hypoglycemia events not attributed to device malfunction and one diabetic ketoacidosis event from an infusion site failure.

Sherr (2022) reported outcomes in children ages 2 to 5.9 using the Omnipod 5 Automated Insulin Delivery System at 10 U.S. sites.[31] Eighty children were evaluated following use of the device for 13 weeks following 14 days of baseline data collection on their usual therapy. From baseline, HbA1c decreased by 0.55% (6.0 mmol/mol) (p< 0.0001), time with sensor glucose levels in target range (70 to 180 mg/dL) increased by 10.9%, or 2.6 h/day (p< 0.0001), and time with levels <70 mg/dL declined by median 0.27% (p=0.0204).

Bergenstal (2016) published a prospective single-arm study on the safety of the hybrid closed-loop system in patients with type 1 diabetes.[32] It included 124 patients ages 14-to-75 years old who had type 1 diabetes for at least two years, had HbA1c levels less than 10.0%, and who had used an insulin pump for at least six months. There was an initial run-in period at baseline for patients to learn how to use the device followed by a three-month period of device use. The study period included a 6-day hotel stay with a one-day period of frequent sampling of venous blood glucose levels to verify device accuracy. The primary safety end points were the incidence of severe hypoglycemia and diabetic ketoacidosis and the incidence of device-related and serious adverse events.

There were no episodes of severe hypoglycemia or ketoacidosis during the study. A total of 28 device related adverse events occurred, all of which could be resolved at home. There were four serious adverse events, one case each of appendicitis, bacterial arthritis, worsening rheumatoid arthritis, and *Clostridium difficile* diarrhea. There were also a number of predefined descriptive end points (but no statistically powered efficacy end points). The device was in the closed-loop mode for a median of 97% of the study period. Mean (SD) HbA1c levels were 7.4% (0.9%) at baseline and 6.9% (0.6%) at the end of the study, and the percentage of sensor glucose values within the target range was 66.7% at baseline and 72.2% at the end of the study.

A multicenter pivotal trial published by Garg (2017) evaluated the safety of Medtronic's hybrid closed-loop system, using methods similar to those of Bergenstal (NCT02463097) and employing the same device (MiniMed 670G).[33] Of 129 subjects, 124 completed the trial; 30 were adolescents (age range, 14-21 years) and 94 were adults (age range, 22-75 years), all of whom had type 1 diabetes for at least two years before the study, and used insulin pump therapy for six months or more. A three-month study period was preceded by a run-in period for subjects to be more familiar with the equipment, and the sensor glucose values were confirmed by an extended hotel stay (6-day/5-night with daily exercise). In both the adolescent and adult cohorts, the trial found improvements during the study phase over the run-in phase, with an increased percentage of glucose values in the favorable range (for adults, a mean improvement of 68.8% to 73.8%; for adolescents, a mean improvement of 60.4% to 67.2%; p<0.001 for both cohorts). Similarly, the authors reported a decrease in the percentage of values outside of the target range (<70 mg/dL or >180 mg/dL): for adults, time spent below the target range decreased from 6.4% to 3.4% (p<0.001); time above the range decreased from 24.9% to 22.8% (p=0.01). For both cohorts, HbA1c levels showed a significant reduction between baseline and the end of study: for adults, the mean decreased from 7.3% to 6.8% (p<0.001), while for adolescents, the mean decreased from 7.7% to 7.1% (p<0.001). Secondary outcomes, which included a reduction of nocturnal hyperglycemia and hypoglycemia, increase in mean overall body weight, and a reduction of basal insulin, were favorable for the study phase, compared with the run-in phase; measurements from the hotel stay verified the in-home glucose values. However, there were several limitations in the trial, including its nonrandomized design, the exclusion of individuals who had recently experienced diabetic ketoacidosis or severe hypoglycemia, and the interaction between subjects and site personnel. Additionally, most of the adult cohort were already using CGM, and baseline HbA1c levels were lower than average for both cohorts; both baseline characteristics potentially limit the generalizability of the results.

One type of hybrid insulin delivery system employs a predictive algorithm to keep the patient's glucose levels within a specific range or zone, only increasing or decreasing insulin levels if the device detects that glucose levels are going to fall outside the defined zone. Forlenza (2017) published a randomized controlled crossover trial comparing the efficacy of a zone model predictive control algorithm with that of sensor-augmented pump therapy; the trial included 20 subjects (19 completed), all with type 1 diabetes and having at least three months treatment with a subcutaneous insulin infusion pump.[34] The six week, in-home study was divided into 2-week blocks, with two randomized groups alternating treatment between an artificial pancreas system (DiAs web monitoring) or sensor-augmented pump therapy (Dexcom Share); subjects in both arms reported glucose values and, if applicable, sensor failure. For several primary end points, which included percentage of time in the target glucose range (70-180 mg/dL) and reduction in hypoglycemia (<70 mg/dL), the algorithm-controlled artificial pancreas system was found to be superior to the sensor-augmented pump therapy (71.6 vs 65.2%, p=0.008; 1.3 vs 2%, p= 0.001, respectively); however, while the mean glucose value was lower in the artificial pancreas system than in the control group, the difference between them was not significant (p=0.059). Measurements of nocturnal hypoglycemia were consistent with day-to-day findings. For the secondary end point (safety of both systems after extended wear), the study found that the mean glucose did not change between the first and seventh day of wear. A limitation of the trial was its use of remote monitoring of subjects; also, the trialists noted that, given the marked difference in outcomes between responders and nonresponders, an error might have occurred in setting basal rates.

Pinsker (2022) published the results of a randomized crossover trial comparing sensor-augmented pump therapy to an adaptive zone model predictive control device in 35 adults with T1D.[35] The adaptive device ran on a Google Pixel 3 smartphone and wirelessly paired with a Dexcom G6 sensor and a Tandem t:AP insulin pump. The primary outcome was sensor glucose time-in-range 70 to 180 mg/dL at 13 weeks. The automated adaptation settings did not significantly improve time-in-range (66% with sensor augmented pump vs 69% with automated insulin delivery; mean adjusted difference 2%; 95% CI -1% to +6%], p =.22). The investigators concluded that additional study and further refinement of the adaptation system are needed.

The RCT by Tauschman (2018) evaluated individuals with uncontrolled type 1 diabetes as reflected in mean Hb1c <8 %.[36] Approximately, 50% of the subjects were between 6-21 years of age and 25% are 6-12 years old. Both groups achieved a reduction in HbA1c but were statistically greater in the HCL group compared to the control group. The investigators reported that the HbA1c improvements were not different among children, adolescents, and adults (data not shown in tables). No severe hypoglycemic events were reported consistent with decrease in time spent with glucose <70mg/dl.

Abraham (2018) reported the results of a six month, multicenter, RCT in children and adolescents with T1D comparing use of an insulin pump with suspend before low or predictive low-glucose management (PLGM) with sensor-augmented insulin pump therapy (SAPT) alone.[37] At six months, significant reductions were seen in day and night hypoglycemia and number of hypoglycemic events <63mg/dl lasting longer than 20 minutes. There were no differences in HbA1c at six months in either group. A follow-up analysis in 140 participants evaluated the effect of percentage time of sensor use on glycemic control in individuals on SAPT with and without PLGM.[38] The mean ± SD age of the cohort was 13.4 ± 2.8 years, duration of diabetes was 7.1 ± 3.7 years and HbA1c was 7.5 ± 0.8%. The sensor use was calculated as a percentage; the number of sensor glucose recordings was compared to the number of expected total recordings, which was then categorized into four groups <40%, 40 to <60%, 60 to <80% and ≥80%. The frequency of sensor use was 7.86% (n = 11) in <40%, 24.29% (n = 34) in 40 to <60%, 36.43% (n = 51) in 60 to <80% and 31.43% (n = 44) in ≥80%. With every 10% increase in sensor use in participants in the SAPT group, mean reduction of HbA1c was −0.14% [−0.25 to −0.04] (p = 0.007) while in the PLGM group, the mean reduction was −0.04% [−0.15 to 0.06] (p = 0.361). These results indicate that improvement in glycemic control is dependent on frequency of sensor use, with higher sensor uptake corresponding to improved glycemic outcomes.

Forlenza (2019) reported the data and analysis of the supplemental information filed with the FDA to support the expanded indication for the MiniMed 670G system to children 7 to 13 years of age.[39] The nonrandomized, single arm multicenter study reported the day and night use of the automated insulin delivery and PLGM for three months in the home setting. There were no serious adverse events and use of the system was associated with reduction in HbA1c and increased time in target glucose range.

Wood (2018) reported an in-clinic evaluation of a 7 to 13 year-old cohort of the 670G pivotal trial that was designed to evaluate the performance characteristics of the device when activity induced hypoglycemic patterns were used to set individual device parameters for ongoing use by the study participant.[40] The suspend before low prevention capability was confirmed in 97.5% of patients experiencing a sensor glucose of ≤ 55mg/dl.

Messer (2018) reported on a subanalysis of the adolescent and young adult participants in the 670G pivotal trial to better characterize the carbohydrate input and insulin bolus determination features of the device over a three-month period.[41] Participants successfully utilized the device without significant changes in total daily dose of insulin but improved percentage time in range (70 to 180 mg/dl).

Section Summary

For individuals who have T1D who receive an artificial pancreas device system with a hybrid closed-loop insulin delivery system, the evidence includes a multicenter pivotal trial using devices cleared by the Food and Drug Administration, supplemental data and analysis for expanded indications and more recent studies focused on children and adolescents. Three crossover RCTs using a similar first-generation device studied and approved outside the United States have been reported. Relevant outcomes are symptoms, change in disease status, morbid events, resource utilization, and treatment-related morbidity. Of the three crossover RCTs two found significantly better outcomes (ie, time spent in nocturnal hypoglycemia and time spent in preferred glycemic range) with the device than with standard care. The third study had mixed findings (significant difference in time spent in nocturnal hypoglycemia and no significant difference in time spent in preferred glycemic range). Additional evidence from device performance studies and clinical studies all demonstrate reductions in time spent in various levels of hypoglycemia, improved time in range (70 to 180mg/dl), rare diabetic ketoacidosis and few device-related adverse events. The evidence suggests that the magnitude of reduction for hypoglycemic events in the population with T1D population is likely to be clinically significant. The variation in the definition of primary and secondary outcomes in the study design and conduct of the published evidence limit the ability to determine the effects of the technology on net health outcomes. Reduction in the experience of hypoglycemia and inappropriate awareness of hypoglycemia and glycemic excursions were identified as important acute clinical outcomes in children, adolescents and adults and are related to the future risk for end organ complications.

Closed-Loop Insulin Delivery System

Systematic Reviews

Oktavian (2023) published a SR evaluating the use of use of a bionic pancreas in patients with type 1 diabetes (T1D). Nine studies were included in this review. The data from these studies suggested that the use of a bionic pancreas could reduce the HbA1c (mean difference [MD] = −0.40% [95% confidence interval [CI] = −0.59 to −0.21], I2 = 0%, $p < 0.0001$) and mean glucose levels (MD = −21.06 [95% CI = −24.66 to −17.46], I2 = 45%, $p < 0.00001$) and improve the time in range (TIR) (MD = 14.41% [95% CI = 10.99 to 17.83], I2 = 60%, $p < 0.00001$). The most common adverse events reported were nausea and vomiting. Limitations included small sample sizes, lack of long-term follow-up, and heterogeneity of study methods. The authors conclude that the use of a bionic pancreas shows potential in preventing complications of T1D by improving the TIR and decreasing the HbA1c and mean glucose levels. Furthermore, serious adverse events with the use of a bionic pancreas and standard of care show insignificant results, suggesting a good safety profile.

Randomized Controlled Trials

Castellanos (2023) evaluated the performance of the iLet bionic pancreas (BP) in non-Hispanic White individuals (here referred to as "Whites") and in Black, Hispanic, and other individuals

(here collectively referred to as "Minorities").[42] This multicenter, RCT evaluated glycemic management with the BP versus standard of care (SC) in 161 adult and 165 pediatric participants with T1D over 13 weeks. In Whites (n = 240), the mean baseline-adjusted difference in 13-week HbA1c between the BP and SC groups was -0.45% (95% CI -0.61 to -0.29 [-4.9 mmol/mol; -6.6 to -3.1]; P < 0.001), while this difference among Minorities (n = 84) was -0.53% (-0.83 to -0.24 [-6.0 mmol/mol; -9.2 to -2.8]; p < 0.001). In Whites, the mean baseline-adjusted difference in time in range between the BP and SC groups was 10% (95% CI 7-12; p < 0.001) and in Minorities was 14% (10-18; p < 0.001). The authors conclude that the BP improves glycemic control in both Whites and Minorities and offers promise in decreasing health care disparities.

Ekhlaspour (2023) published the results of a six-month, multicenter RCT evaluating the benefits of automated insulin delivery (AID) among individuals with T1D in sub-populations of baseline device use determined by continuous glucose monitor (CGM) use status and insulin delivery via multiple daily injections (MDI) or insulin pump.[43] Participants (n = 168) were assigned to closed-loop control (CLC, Control-IQ, Tandem Diabetes Care), or sensor-augmented pump (SAP) therapy. The trial included a two- to eight-week run-in phase to train participants on study devices. The participants were stratified into four subgroups: insulin pump and CGM (pump+CGM), pump-only, MDI and CGM (MDI+CGM), and MDI users without CGM (MDI-only) users. We compared glycemic outcomes among four subgroups. At baseline, 61% were pump+CGM users, 18% pump-only users, 10% MDI+CGM users, and 11% MDI-only users. Mean time in range 70-180 mg/dL (TIR) improved from baseline in the four subgroups using CLC: pump+CGM, 62% to 73%; pump-only, 61% to 70%; MDI+CGM, 54% to 68%; and MDI-only, 61% to 69%. The reduction in time below 70 mg/dL from baseline was comparable among the four subgroups. No interaction effect was detected with baseline device use for TIR (P = .67) or time below (p = 0.77). On the System Usability Questionnaire, scores were high at 26 weeks for all subgroups: pump+CGM: 87.2 ± 12.1, pump-only: 89.4 ± 8.2, MDI+CGM 87.2 ± 9.3, MDI: 78.1 ± 15. The authors conclude that there was a consistent benefit in patients with T1D when using CLC, regardless of baseline insulin delivery modality or CGM use. Suggesting that this CLC system can be considered across a wide range of patients.

Mauras (2023) published the results of a RCT evaluating the bionic pancreas (BP) generated backup insulin dose for injection for pump users (including long-acting insulin dose, a four period basal insulin profile, short acting meal doses and a glucose correction factor) provided in case of device malfunction.[44] Following a 13-week trial in T1D, participants using the BP (6-83 years) completed 2-4 days, in which they were randomly assigned to their prestudy insulin regimen (n = 147) or to follow BP-provided guidance (n = 148). Glycemic outcomes with BP guidance were similar to those reinstituting their prestudy insulin regimen, with both groups having higher mean glucose and lower time-in-range than while using the BP during the 13-week trial. In conclusion, a backup insulin regimen automatically generated by the BP can be safely implemented if need arises to discontinue use of the BP. Clinical Trial Registry: clinicaltrials.gov; NCT04200313.

The iLet Bionic Pancreas System was compared to standard care in a multicenter RCT (NCT04200313) enrolling 219 individuals ages 6 to 79 years with type 1 diabetes.[45] Comparator group participants continued their pre-study subcutaneous insulin delivery (either multiple daily injections, an insulin pump without automation of insulin delivery, an insulin pump with predictive low glucose suspend feature, or an insulin pump as part of an HCL system)

plus real-time CGM. The primary outcome was glycated hemoglobin level at 13 weeks and the key secondary outcome was the percent time A1c was below < 54 mg/dL at 13 weeks.

The main results for the full group (n = 326) were reported by Russell (2022).[45] Mean glycated hemoglobin decreased from 7.9% to 7.3% in the closed-loop insulin delivery system group while it did not change (7.7% at both time points) in the standard-care group (mean adjusted difference at 13 weeks, −0.5%; 95% CI −0.6% to −0.3%; p <0.001). The rate of severe hypoglycemia was 17.7 events per 100 participant-years in the closed-loop insulin delivery system group and 10.8 events per 100 participant-years in the standard-care group (p = 0.39). No episodes of diabetic ketoacidosis occurred in either group.

The trial results for the subgroups of adults (ages 18 and older) and youth (ages 6 to 17 years) have additionally been reported and were similar to the main results for the full cohort (see Table 6). Kruger (2022) reported results for adults ages 18 and over (n= 161).[46] In this subgroup, mean glycated hemoglobin decreased from 7.6% (± 1.2%) at baseline to 7.1% (± 0.6%) at 13 weeks in the intervention group versus 7.6% (± 1.2%) to 7.5% (± 0.9%) with standard care (adjusted difference -0.5%, 95% confidence interval [CI] -0.6% - -0.3%, p <.001). Time below 54 mg/dL was low at baseline (median 0.2%) and not significantly different between groups over 13 weeks (p = 0.24). The incidence of severe hypoglycemia did not differ between groups. Messer (2022) reported results for children and youth ages 6 to 17 years (n = 165).[47] Mean glycated hemoglobin decreased from 8.1% (± 1.2%) at baseline to 7.5% (± 0.7%) at 13 weeks in the intervention group versus 7.8% (± 1.1%) at both baseline and 13 weeks with standard care (adjusted difference -0.5%; 95% CI -0.7% - -0.2%).

Following the 13-week randomized portion of the trial, comparator group participants (n = 90 of 107) crossed over and received the closed-loop insulin delivery system for 13 weeks.[48] In this extension phase, improvement in glycemic control was of a similar magnitude to that observed during the randomized trial. Results were similar in the adult (n = 42) and pediatric (n = 48) cohort

Section Summary: Closed-Loop Insulin Delivery System

The evidence includes a SR (nine studies), including a 13-week multicenter RCT of the iLet Bionic Pancreas System compared to usual care in 219 individuals ages 6 to 79 years with type 1 diabetes. Comparator group participants continued their pre-study subcutaneous insulin delivery (either multiple daily injections, an insulin pump without automation of insulin delivery, an insulin pump with predictive low glucose suspend feature, or an insulin pump as part of an HCL system) plus real-time CGM. The glycated hemoglobin level decreased from 7.9% to 7.3% in the closed-loop insulin delivery system group and did not change (7.7% at both time points) in the standard-care group (mean adjusted difference at 13 weeks, −0.5%; 95%CI −0.6 to −0.3; p <0.001). The rate of severe hypoglycemia was 17.7 events per 100 participant-years in the closed-loop insulin delivery system group and 10.8 events per 100 participant-years in the standard-care group (p = 0.39). No episodes of diabetic ketoacidosis occurred in either group. The trial's results for the subgroups of adults (ages 18 and older) and youth (ages 6 to 17 years) have additionally been reported and were similar to the main results for the full cohort. The evidence supports the bionic pancreas may improve health outcomes by preventing complications of T1D by improving the TIR and decreasing the HbA1c and mean glucose levels. Furthermore, serious adverse events with the use of a bionic pancreas and standard of care show insignificant results, suggesting a good safety profile.

PRACTICE GUIDELINE SUMMARY

AMERICAN DIABETES ASSOCIATION

The 2023 American Diabetes Association Standards of Medical Care in Diabetes provides the following recommendations on controlling diabetes:[49]

> Insulin pump therapy alone with or without sensor-augmented pump low glucose suspend feature and/or automated insulin delivery systems should be offered for diabetes management to youth and adults on multiple daily injections with type 1 diabetes (Level of Evidence A) or other types of insulin-deficient diabetes (Level of Evidence E) who are capable of using the device safely (either by themselves or with a caregiver) and are not able to use or do not choose an automated insulin delivery system. The choice of device should be made based on the individual's circumstances, preferences, and needs. (Level of Evidence A)
>
> Individuals with diabetes may be using systems not approved by the U.S. Food and Drug Administration, such as do-it yourself closed-loop systems and others; health care professionals cannot prescribe these systems but should assist in diabetes management to ensure the safety of people with diabetes. (Level of Evidence E)

AMERICAN ASSOCIATION OF CLINICAL ENDOCRINOLOGISTS AND THE AMERICAN COLLEGE OF ENDOCRINOLOGY

The American Association of Clinical Endocrinologists published a 2022 update of their Clinical Practice Guideline: Developing a Diabetes Mellitus (DM)Comprehensive Care Plan.[50] The guideline includes the following recommendations:

> Insulin pump therapy (CSII) provides constant/continuous infusion of fast-acting insulin driven by mechanical force and delivered via a cannula inserted under the skin. CSII can improve (or enhance) glycemic control and should be an option for insulin delivery for appropriate persons with DM. Ideally, these individuals should also use CGM. (Grade B, Best Evidence Level 1)
>
> Automated insulin delivery systems (AIDs), which include an insulin pump, an integrated CGM, and computer software algorithm, aim to better emulate physiological insulin replacement and achieve glycemic targets. This technology is recommended for many persons with T1D since its use has been shown to increase TIR while often reducing hypoglycemia or at least without causing increased hypoglycemia. (Grade A, Best Evidence Level 1)

The American Association of Clinical Endocrinologists and American College of Endocrinology (2018) published a joint position statement on the integration of insulin pumps and continuous glucose monitoring in patients with diabetes.**[51]** The statement emphasized the use of continuous glucose monitoring and insulin pump therapy for T1D patients who are not in glycemic target ranges despite intensive attempts at self-blood glucose monitoring and multiple insulin injection therapy.

AMERICAN ASSOCIATION OF CLINICAL ENDOCRINOLOGISTS

In 2021, the American Association of Clinical Endocrinologists published a clinical practice guideline for the use of advanced technology in the management of individuals with diabetes.[52] The guideline included the following statements:

"Low-glucose suspend (LGS) is strongly recommended for all persons with T1D to reduce the severity and duration of hypoglycemia, whereas predictive low glucose suspend (PLGS) is strongly recommended for all persons with T1D to mitigate hypoglycemia. Both systems do not lead to a rise in mean glucose, and lead to increased confidence and trust in the technology, more flexibility around mealtimes, and reduced diabetes distress for both persons with diabetes and caregivers. Therefore, anyone with frequent hypoglycemia, impaired hypoglycemia awareness, and those who fear hypoglycemia leading to permissive hyperglycemia should be considered for this method of insulin delivery. "Grade A; High Strength of Evidence

"Automated insulin delivery (AID) systems are strongly recommended for all persons with T1D, since their use has been shown to increase TIR, especially in the overnight period, without causing an increased risk of hypoglycemia. Given the improvement in TIR and the reduction in hyperglycemia with AID, this method of insulin delivery is preferred above other modalities. For persons with diabetes with suboptimal glycemia, significant glycemic variability, impaired hypoglycemia awareness, or who allow for permissive hyperglycemia due to the fear of hypoglycemia, such AID systems should be considered." Grade A; High Strength of Evidence

SUMMARY

There is enough research to show that the use of an external insulin infusion pump or FDA-approved automated insulin delivery system (artificial pancreas device) improves health outcomes for select patients with diabetes mellitus or preconception/pregnancy related suboptimal glycemic control. Clinical practice guidelines based on research recommend these devices in certain populations and clinical scenarios. Therefore, the use of an external insulin infusion pump or an FDA-approved automated insulin delivery system (artificial pancreas device) may be considered medically necessary when policy criteria are met.

There is not enough research to show that an insulin pump or FDA-approved automated insulin delivery system (artificial pancreas device) improve health outcomes in all other situations. No clinical practice guidelines based on research recommend these devices for patients not addressed in the policy criteria. Therefore, the use of an external insulin infusion pump or FDA-approved automated insulin delivery system (artificial pancreas device) is investigational when the policy criteria are not met.

All or part of an insulin pump or automated insulin delivery system (artificial pancreas device) may warrant replacement or upgrade when the current device is no longer able to perform its basic function and cannot be repaired or adapted adequately to meet the patient's medical needs. Therefore, a replacement or upgrade may be considered medically necessary when policy criteria are met. A replacement or upgrade is considered not medically necessary when the device is adequately functioning and can meet the patient's medical needs.

Myoelectric Prosthetic and Orthotic Components for the Upper Limb

Effective: August 1, 2023

Next Review: June 2024
Last Review: June 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Myoelectric prostheses and orthotics are powered by electric motors with an external power source. The joint movement of upper limb prostheses or orthoses (e.g., hand, wrist, and/or elbow) is driven by microchip-processed electrical activity in the muscles of the remaining limb or limb stump.

MEDICAL POLICY CRITERIA

I. Myoelectric upper limb prostheses may be **medically necessary** when all of the following criteria are met (A. – F.):

A. The patient has an amputation or missing limb at the wrist or above (forearm, elbow, etc.); and

B. Standard body-powered prosthetic devices cannot be used or are insufficient to meet the functional needs of the individual in performing activities of daily living; and

C. The remaining musculature of the arm(s) contains the minimum microvolt threshold to allow operation of a myoelectric prosthetic device, as demonstrated by functional testing using a physical or computer model prosthesis; and

D. The patient has demonstrated sufficient neurological and cognitive function to operate the prosthesis effectively; and

E. The patient is free of comorbidities that could interfere with function of the prosthesis (neuromuscular disease, etc.); and

F. Functional evaluation by a qualified professional (e.g., prosthetist) indicates that with training, use of a myoelectric prosthesis and associated components is necessary to meet the functional needs of the individual (e.g., automatic grasp features, microprocessor control features, or other components to aid gripping, releasing, holding, and coordinating movement of the prosthesis) when performing activities of daily living. This evaluation should consider the patient's needs for control, durability (maintenance), function (speed, work capability), and usability. Both of the following criteria must be met (1. and 2.):

1. The device is necessary for the patient to perform instrumental activities of daily living including job functioning; and

2. The device is *not* primarily for the purpose of allowing the patient to perform leisure or recreational activities.

II. The replacement of all or part of an existing myoelectric upper limb prosthesis is considered **medically necessary** when the existing myoelectric upper limb prosthesis is malfunctioning, cannot be repaired, and is no longer under warranty OR when the current prosthetic can no longer meet the patient's medical needs due to a significant change in the patient's physiological condition.

III. Replacement of all or part of an existing myoelectric upper limb prosthesis is considered **not medically necessary** when Criterion II. is not met.

IV. Myoelectric upper limb prosthetic components are considered **not medically necessary** under all other conditions.

V. Upper-limb prosthetic components with both sensor and myoelectric control are considered **investigational**.

VI. Myoelectric controlled upper-limb orthoses are considered **investigational**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- Documentation of amputation or missing limb at the wrist or above
- Documentation that standard body-powered devices can't be used or are not efficient including the ADLs that cannot be accomplished currently
- Documentation that the remaining musculature in the limb contains the minimum microvolt threshold to allow operation of the device including a functional test using a physical or computer model prosthesis

- Documentation the patient is cognitively and neurologically able to operate the prosthetic
- Documentation the patient doesn't have any comorbidities that might interfere with the use of the prosthetic
- An evaluation by a qualified professional such as a prosthetist that show the patient will be able to use the prosthetic for ADLs including the patient's ability to control, maintain, function, and use the prosthetic including why it is necessary for the patient to perform ADLs or job functions and evidence it is not being requested only for leisure or recreational activities
- Documentation that the prosthetic is not being requested to replace a functioning prosthetic

BACKGROUND

Upper limb prostheses are used following amputation at any level from the hand to the shoulder. The need for a prosthesis can occur for a number of reasons, including trauma, surgery, or congenital anomalies. The primary goals of the upper limb prosthesis are to restore natural appearance and function. Achieving these goals also requires sufficient comfort and ease of use for continued acceptance by the wearer. The difficulty of achieving these diverse goals with an upper limb prosthesis increases as the level of amputation (digits, hand, wrist, elbow, and shoulder), and thus the complexity of joint movement, increases.

Upper limb prostheses are classified based on the means of generating movement at the joints as follows:

PASSIVE PROSTHESIS:

- The lightest weight upper extremity prosthesis
- Patients generally describe this as the most comfortable of the three types
- Must be repositioned manually, typically by moving it with the opposite arm
- Cannot restore function.

BODY-POWERED PROSTHESIS

- Uses a body harness and cable system to provide functional manipulation of the elbow and hand. Voluntary movement of the shoulder and/or limb stump extends the cable and transmits the force to the terminal device.
- Prosthetic hand attachments, which may be claw-like devices that allow good grip strength and visual control of objects or latex-gloved devices that provide a more natural appearance at the expense of control, can be opened and closed by the cable system.
- Patient complaints with body-powered prostheses include harness discomfort, particularly the wear temperature, wire failure, and the unattractive appearance.

MYOELECTRIC PROSTHESIS

Uses muscle activity from the remaining limb for the control of joint movement.

- Electromyographic (EMG) signals from the limb stump are detected by surface electrodes, amplified, and then processed by a controller to drive battery-powered motors that move the hand, wrist, or elbow.
- Implantable EMG sensors with wireless signal transmission (e.g., Implantable Myoelectric Sensors [IMES®]) are being studied as alternatives to surface electrodes to improve prosthetic hand function. These implantable sensors may eliminate the limitations inherent in surface electrodes such as issues related to poor skin contact (e.g., skin sweating) and the ability to detect signals only from superficial muscles.
- Although upper arm movement may be slow and limited to one joint at a time, myoelectric control of movement may be considered the most physiologically natural.
- Myoelectric hand attachments are similar in form to those offered with the body-powered prosthesis, but are battery powered.
- Patient dissatisfaction with myoelectric prostheses includes the increased cost, maintenance (particularly for the glove), and weight.
- Examples of available technologies:
    - The SensorHand™ by Advanced Arm Dynamics, which is described as having an AutoGrasp feature, an opening/closing speed of up to 300 mm/second, and advanced EMG signal processing.
    - The Utah Arm 3 by Motion Control has a microprocessor interface that allows individualized adjustments to achieve maximum performance.
    - The i-LIMB™ hand (Touch Bionics), sometimes referred to as the bionic hand, is the first commercially available myoelectric hand prosthesis with individually powered digits.
    - ProDigits™, also from Touch Bionics, are prosthetic digits for one or more fingers in patients with amputation at a transmetacarpal level or higher.
    - Otto Bock has a number of myoelectric hand and elbow prostheses including the AutoGrasp feature, the Michelangelo® Hand, and the Electrohand 2000 designed for children.
    - LTI Boston Digital Arm™ System by Liberating Technologies Inc. is marketed as having greater torque than any other powered prosthetic elbows
    - These devices may be covered by LIVINGSKIN™, a high-definition silicone prosthesis created to resemble a patient's natural skin.

SENSOR AND MYOELECTRIC PROSTHESIS

The LUKE Arm (previously known as the DEKA Arm System) can perform complex tasks with multiple simultaneous powered movements (e.g., movement of the elbow, wrist, and hand at the same time). In addition to the EMG electrodes, the LUKE Arm contains a combination of mechanisms including switches, movement sensors, and force sensors. The Luke Arm is the same shape and weight as an adult arm.

HYBRID SYSTEM, A COMBINATION OF BODY-POWERED AND MYOELECTRIC COMPONENTS

- May be used for high-level amputations (at or above the elbow).
- Allows control of two joints at once (i.e., one body-powered and one myoelectric)
- Generally lighter weight and less expensive than a prosthesis composed entirely of myoelectric components.

- An example of a hybrid system is the ErgoArm by Otto Bock which has a myoelectric hand and a cable-controlled elbow joint

Technology in this area is rapidly changing, driven by advances in biomedical engineering and by the U.S. Department of Defense Advanced Research Projects Agency (DARPA), which is funding a public and private collaborative effort on prosthetic research and development. Areas of development include the use of skin-like silicone elastomer gloves, “artificial muscles,” and sensory feedback. Smaller motors, microcontrollers, implantable myoelectric sensors, and re-innervation of remaining muscle fibers are being developed to allow fine movement control. Lighter batteries and newer materials are being incorporated into myoelectric prostheses to improve comfort.

MYOELECTRIC ORTHOSES

The MyoPro (Myomo) is a myoelectric powered upper-extremity orthotic. This orthotic device weighs about 1.8 kilograms (4 pounds), has manual wrist articulation, and myoelectric initiated bi-directional elbow movement. The MyoPro detects weak muscle activity from the affected muscle groups. A therapist or prosthetist/orthoptist can adjust the gain (amount of assistance), signal boost, thresholds, and range of motion. Potential users include patients with traumatic brain injury, spinal cord injury, brachial plexus injury, amyotrophic lateral sclerosis, and multiple sclerosis. Use of robotic devices for therapy has been reported. The MyoPro is the first myoelectric orthotic available for home use.

Regulatory Status

Prostheses are class I devices that are exempt from U.S. Food and Drug Administration (FDA) marketing clearance, but manufacturers must register prostheses with the restorative devices branch of the FDA and keep a record of any complaints.

Examples of available myoelectric devices are listed above.

The MyoPro® (Myomo) is registered with the FDA as a class 1 limb orthosis.

EVIDENCE SUMMARY

In evaluating the effects of the increased sophistication of myoelectric upper limb prostheses compared with body-powered prostheses, passive prostheses, or no prosthesis, the most informative data are from prospective comparative studies with objective and subjective measures that directly address function and health-related quality of life.

In light of the magnitude of functional loss in upper extremity amputation, evaluation of the evidence is based on two assumptions:

1. Use of any prosthesis confers clinical benefit, and

2. Self-selected use is an acceptable measure of the perceived benefit (combination of utility, comfort, and appearance) of a prosthesis for that individual.

It should be considered that the upper limb amputee’s needs may depend on their situation. For example, increased functional capability may be needed with heavy work or domestic duties, while a more natural appearing prosthesis with reduced functional capability may be acceptable for an office, school, or another social environment.

MYOELECTRIC UPPER LIMB PROSTHESIS

Systematic Reviews

A 2015 systematic review (SR) by Carey evaluated differences between myoelectric and body-powered prostheses. The SR included 31 studies.[1] The evidence was conflicting for functional performance between the two prostheses. The authors concluded that there is insufficient evidence to show that one system provides a significant advantage over the other and that prosthetic selection should be based on patient preference and functional needs.

A 2007 SR by Biddis of 40 articles published over the previous 25 years assessed upper limb prosthesis acceptance and abandonment.[2] For pediatric patients the mean rejection rate was 38% for passive prostheses (one study), 45% for body-powered prostheses (three studies), and 32% for myoelectric prostheses (12 studies). For adults there was considerable variation between studies, with mean rejection rates of 39% (six studies), 26% (eight studies), and 23% (10 studies) for passive, body-powered and myoelectric prostheses, respectively. The authors found no evidence that the acceptability of passive prostheses had declined over the period from 1983 to 2004, “despite the advent of myoelectric devices with functional as well as cosmetic appeal.” Body-powered prostheses were also found to have remained a popular choice, with the type of hand-attachment being the major factor in acceptance. Body-powered hooks were considered acceptable by many users, but body-powered hands were frequently rejected (80% to 87% rejection rates) due to slowness in movement, awkward use, maintenance issues, excessive weight, insufficient grip strength, and the energy needed to operate. Rejection rates of myoelectric prostheses tended to increase with longer follow-up. There was no evidence of a change in rejection rates over the 25 years of study, but the results are limited by sampling bias from isolated populations and the generally poor quality of the studies included.

Randomized Controlled Trials

Touillett (2023) published the results of a monocentric, randomized, controlled, cross-over trial evaluating shoulder abduction and manual dexterity in transradial amputees (N = 8) fitted with two prosthetic myoelectric hooks, the Greifer and the Axon-Hook.[3] They also made comparisons with the non-affected (NA) side. Shoulder abduction was significantly higher with the Greifer (60.9 ± 20.3, $p = 0.03$) than with the Axon-Hook (39.8 ± 16.9) and also than with the NA side (37.6 ± 19.4, $p = 0.02$). Shoulder abduction on the NA side (37.6 ± 19.4) was close to that of the Axon-Hook (39.8 ± 16.9). There was no difference between devices or with the NA side in the percentage of time spent with shoulder abduction > 60 during the Box Block Test (BBT). A significant strong negative correlation was found between shoulder abduction and wrist position with the Axon-Hook ($r = -0.86$; $p < 0.01$), but not with the Greifer. Manual dexterity and satisfaction did not differ significantly between the two devices.

In comparative studies of prostheses, subjects served as their own control. Since these studies included use by all subjects of both a myoelectric and a body-powered prosthesis, randomization was directed at the order in which each amputee used the prostheses. Two trials were found in which a total of 196 children used both a myoelectric and a body-powered hand prosthesis, in randomized order, for a period of three months each.[4, 5] No clinically relevant objective or subjective difference was found between the two types of prostheses.

Nonrandomized Studies

A number of small (n<50) non-randomized case series[6-8] and online, telephone, or mailed surveys[9-13] were found, but few studies directly addressed whether myoelectric prostheses improved function and health-related quality of life. Most of the studies identified described amputees' self-selected use or rejection rates. The results were usually presented as hours worn at work or school, hours worn at home, and hours worn in social situations. Amputees' self-reported reasons for use and abandonment were also frequently reported. The limited evidence available suggests that, in comparison with body-powered prostheses, myoelectric components may improve range of motion to some extent, have similar capability for light work, but may have reduced performance under heavy working conditions. The literature also indicated that the percentage of amputees who accepted use of a myoelectric prosthesis was about the same as those who prefer to use a body-powered prosthesis, and that self-selected use depended at least in part on the individual's activities of daily living. Appearance was most frequently cited as an advantage of myoelectric prostheses. Nonuse of any prosthesis was associated with lack of functional need, discomfort (excessive weight and heat), and impediment to sensory feedback.

Section Summary: Myoelectric Upper-Limb Prosthesis

The identified literature focuses primarily on patient acceptance and rejection; data are limited or lacking in the areas of function and functional status. The limited evidence suggests that the percentage of amputees who accept a myoelectric prosthesis is approximately the same as those who prefer to use a body-powered prosthesis, and that self-selected use depends partly on the individual's activities of daily living. When compared with body-powered prostheses, myoelectric components possess similar capability to perform light work, and myoelectric components may improve range of motion. The literature has also indicated that appearance is most frequently cited as an advantage of myoelectric prostheses, and for patients who desire a restorative appearance, the myoelectric prosthesis can provide greater function than a passive prosthesis with equivalent function to a body-powered prosthesis for light work.

SENSOR AND MYOELECTRIC UPPER LIMB COMPONENTS

Investigators from three Veterans Administration medical centers and the Center for the Intrepid at Brooke Army Medical Center published a series of reports on home use of the LUKE prototype (DEKA Gen 2 and DEKA Gen 3) in 2017 and 2018.[14-18] Participants were included in the in-laboratory training if they met criteria and had sufficient control options (e.g., myoelectric and/or active control over one or both feet) to operate the device. In-lab training included a virtual reality training component. At the completion of the in-lab training, the investigators determined, using a priori criteria, which participants were eligible to continue to the 12-week home trial. The criteria included the independent use of the prosthesis in the laboratory and community setting, fair, functional performance, and sound judgment when operating or troubleshooting minor technical issues.

One of the publications (Resnick, 2017) reported on the acceptance of the LUKE prototype before and after a 12-week trial of home use.[16] Of 42 participants enrolled at the time, 32 (76%) participants completed the in-laboratory training, 22 (52%) wanted to receive a LUKE Arm and proceeded to the home trial, 18 (43%) completed the home trial, and 14 (33%) expressed a desire to receive the prototype at the end of the home trial. Over 80% of those who completed the home trial preferred the prototype arm for hand and wrist function, but as many preferred the weight and look of their own prosthesis. One-third of those who completed the home training thought that the arm was not ready for commercialization. Participants who

completed the trial were more likely to be prosthesis users at study onset (p=0.03), and less likely to have musculoskeletal problems (p=0.047).[14] Reasons for attrition during the in-laboratory training were reported in a separate publication by Resnik and Klinger (2017).[17] Attrition was related to the prosthesis entirely or in part by 67% of the participants, leading to a recommendation to provide patients with an opportunity to train with the prosthesis before a final decision about the appropriateness of the device.

Functional outcomes of the Gen 2 and Gen 3 arms, as compared with participants' prostheses, were reported by Resnick et al (2018).[15] At the time of the report, 23 regular prosthesis users had completed the in-lab training, and 15 had gone on to complete the home use portion of the study. Outcomes were both performance-based and self-reported measures. At the end of the lab training, dexterity was similar, but performance was slower with the LUKE prototype than with their conventional prosthesis. At the end of the home study, activity speed was similar to the conventional prostheses, and one of the performance measures (Activities Measure for Upper-Limb Amputees) was improved. Participants also reported that they were able to perform more activities, had less perceived disability, and less difficulty in activities, but there were no differences between the two prostheses on many of the outcome measures including dexterity, prosthetic skill, spontaneity, pain, community integration, or quality of life. Post hoc power analysis suggested that evaluation of some outcomes might not have been sufficiently powered to detect a difference.

In a separate publication, Resnick (2017) reported that participants continued to use their prosthesis (average, 2.7 h/d) in addition to the LUKE prototype, concluding that availability of both prostheses would have the greatest utility.[18] This conclusion is similar to those from earlier prosthesis surveys, which found that the selection of a specific prosthesis type (myoelectric, powered, or passive) could differ depending on the specific activity during the day. In the DEKA Gen 2 and Gen 3 study reported here, 29% of participants had a body-powered device, and 71% had a conventional myoelectric prosthesis.

Section Summary: Sensor and Myoelectric Upper-Limb Components

The LUKE Arm was cleared for marketing in 2014 and is now commercially available. The prototypes for the LUKE Arm, the DEKA Gen 2 and Gen 3, were evaluated by the U.S. military and Veteran's Administration in a 12-week home study, with study results reported in a series of publications. Acceptance of the advanced prosthesis in this trial was mixed, with one-third of enrolled participants desiring to receive the prototype at the end of the trial. Demonstration of improvement in function has also been mixed. After several months of home use, activity speed was shown to be similar to the conventional prosthesis. There was an improvement in the performance of some, but not all, activities. Participants continued to use their prosthesis for part of the day, and some commented that the prosthesis was not ready for commercialization. There were no differences between the LUKE Arm prototype and the participants' prostheses for many outcome measures. Study of the current generation of the LUKE Arm is needed to determine whether the newer models of this advanced prosthesis lead to consistent improvements in function and quality of life.

MYOELECTRIC ORTHOTIC

Page (2020) compared the efficacy of a myoelectric orthosis combined with repetitive task-specific practice to repetitive task-specific practice alone in improving performance for subjects with post-stroke upper extremity hemiparesis.[19] A total of 34 patients with chronic, moderate, stable, post-stroke, upper extremity hemiparesis were randomly assigned to Myomo +

repetitive, task-specific practice; repetitive, task-specific practice only; or Myomo only. The primary outcome was the upper extremity section of the Fugl-Meyer Impairment Scale and the secondary outcome was the Arm Motor Activity Test. The groups all increased on the Fugl-Meyer Impairment Scale and the Arm Motor Activity Test, with no significant differences between groups.

Peters (2017) evaluated the immediate effect (no training) of a myoelectric elbow-wrist-hand orthosis on paretic upper-extremity impairment.[20] Participants (n=18) were stable and moderately impaired with a single stroke 12 months or later before study enrollment. They were tested using a battery of measures without, and then with the device; the order of testing was not counterbalanced. The primary measure was the upper-extremity section of the Fugl-Meyer Assessment, a validated scale that determines active movement. Upper-extremity movement on the Fugl-Meyer Assessment was significantly improved while wearing the orthotic (a clinically significant increase of 8.71 points, $p<0.001$). The most commonly observed gains were in elbow extension, finger extension, grasping a tennis ball, and grasping a pencil. The Box and Block test (moving blocks from one side of a box to another) also improved ($p<0.001$). Clinically significant improvements were observed for raising a spoon and cup, and there were significant decreases in the time taken to grasp a cup and gross manual dexterity. Performance on these tests changed from unable to able to complete. The functional outcome measures (raising a spoon and cup, turning on a light switch, and picking up a laundry basket with two hands) were developed by the investigators to assess these moderately impaired participants. The authors noted that performance on these tasks was inconsistent, and proposed a future study that would include training with the myoelectric orthosis before testing.

Page (2013) compared the efficacy of a myoelectric orthosis combined with repetitive task-specific practice to repetitive task-specific practice alone in improving performance following stroke.[21] Sixteen subjects at a mean of 75 months post-stroke were divided into two groups. Both groups received therapist-supervised repetitive task-specific practice for three days a week for eight weeks. One group used the orthotic during practice. After intervention, there was no significant difference between groups in Fugl-Meyer score increases, six measures of the Stroke Impact Scale, or Canadian Occupational Performance Measure Performance. There was a significant difference in the Stroke Impact Scale Total ($p=0.027$).

Section Summary: Myoelectric Orthotic

The largest study identified tested participants with and without the orthosis. This study evaluated the function with and without the orthotic in stable poststroke participants who had no prior experience with the device. Outcomes were inconsistent. Studies are needed that show consistent improvements in relevant outcome measures. Results should also be replicated in a larger number of patients.

PRACTICE GUIDELINE SUMMARY

No practice guidelines identified.

SUMMARY

There is enough research to show that myoelectric upper limb prostheses improve health outcomes for people with an amputation or missing limb at the wrist or above when the

medical policy criteria are met. Therefore, myoelectric upper limb prostheses may be considered medically necessary when policy criteria are met.

In certain situations, a myoelectric upper limb prosthesis may no longer be able to perform its basic function due to damage or wear. When it is out of its warranty period and cannot be repaired adequately to meet the patient's medical needs, replacement of the device may be medically appropriate. Therefore, replacement of all or part of a myoelectric upper limb prosthesis may be considered medically necessary when device replacement Criteria are met.

When a myoelectric upper limb prosthesis is in its warranty period or can be repaired or adapted adequately to meet the patient's medical needs, replacement of the device is not medically appropriate. Therefore, replacement of all or part of a myoelectric upper limb prosthesis is considered not medically necessary when device replacement Criteria are not met.

There is enough research to show that myoelectric upper limb prostheses do not improve health outcomes when policy criteria are not met. Therefore, myoelectric upper limb prostheses, under all other conditions including but not limited to replacement of an existing functioning prostheses are considered not medically necessary when policy criteria are not met.

There is not enough research to show that upper-limb prosthetic components with both sensor and myoelectric control improve health outcomes compared with conventional prostheses. Therefore, upper-limb prosthetic components with both sensor and myoelectric control are considered investigational.

There is not enough research to show that myoelectric controlled upper-limb orthoses improve health outcomes for people with upper limb weakness or paresis. Only two comparative studies have been published examining myoelectric orthoses. They had small sample sizes and demonstrated inconsistent performance. Therefore, myoelectric controlled upper-limb orthoses are considered investigational.

Powered and Microprocessor-Controlled Knee and Ankle-Foot Prostheses and Microprocessor-Controlled Knee-Ankle-Foot Orthoses

Effective: January 1, 2024

Next Review: September 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Microprocessor-controlled prostheses and orthoses use feedback from sensors to adjust joint movement on a real-time as-needed basis and powered prostheses are designed to replace muscle activity in the affected limb.

MEDICAL POLICY CRITERIA

I. Microprocessor-controlled knee may be considered **medically necessary** in amputees when all of the following criteria are met (A. – E.):

   A. At least one of the following criteria are met:

      1. Demonstrated need for ambulation at variable rates or for long distances such that the patient would benefit from a device that may reduce energy consumption. (Use of the limb only in the home and/or for basic community ambulation does not establish medical necessity of the computerized limb over standard limb applications); or

      2. Demonstrated daily activities or job tasks that do not permit full focus of concentration on knee control and stability, including but not limited to

ambulation on uneven terrain, curbs, ramps, regular use on stairs or repetitive lifting and/or carrying. (Use of the limb for limited stair climbing in the home or employment environment does not establish medical necessity of the computerized limb over standard prosthetic application).

B. All of the following criteria must be met to demonstrate adequate physical ability:
    1. Adequate cardiovascular and pulmonary reserve for ambulation at faster than normal walking speed; and
    2. Adequate stride strength and balance to activate the knee unit; and
    3. Classified as one of the following Medicare Functional Levels:
        a. Select Level K2—Patients capable of limited community ambulation, but only if improved stability in stance permits increased independence, decreased risk of falls, and potential to advance to a less restrictive walking device. The microprocessor is required to enable fine-tuning and adjustment of the hydraulic mechanism to accommodate the unique motor skills and demands of the functional level K2 ambulator; or
        b. Level K3—Patients who have the ability or potential for ambulation with variable cadence. Typical of the community ambulator who has the ability to traverse most environmental barriers and may have vocational, therapeutic, or exercise activity that demands prosthetic utilization beyond simple locomotion; or
        c. Level K4—Patients who have the ability or potential for prosthetic ambulation that exceeds basic ambulation skills, exhibiting high impact, stress, or energy levels. Typical of the prosthetic demands of the child, active adult, or athlete.

C. Adequate cognitive ability to master use and care requirements for the technology; and

D. Patients with amputation from hemi-pelvectomy through knee-disarticulation level including bilateral lower extremity; and

E. All of the following criteria must also be met:
    1. Stable or absent wound; and
    2. The request is for either a microprocessor-controlled knee or a non-microprocessor-controlled mechanical prosthesis but not both for a single knee; and
    3. Adequate socket fitting with the potential to return to active lifestyle.

II. The replacement of all or part of an existing microprocessor-controlled knee is considered **medically necessary** when either of the following are met:

A. The existing microprocessor-controlled knee is malfunctioning, cannot be repaired, and is no longer under warranty; or

B. The current prosthetic can no longer meet the patient's medical needs due to a significant change in the patient's physiological condition.

III. Replacement of all or part of an existing microprocessor-controlled knee is considered **not medically necessary** when Criterion II. is not met.

IV. A microprocessor-controlled knee is considered **not medically necessary** when Criterion I. is not met or when any of the following apply:

   A. Medicare Functional Levels K0, K1, and the subset of K2 patients capable of limited community ambulation who do not have the cardiovascular reserve, strength, and balance to improve stability in stance to permit increased independence, decreased risk of falls and potential to advance to a less restrictive walking device

   B. When the primary benefit is to allow the patient to perform leisure or recreational activities

   C. Inability to tolerate the weight of the prosthesis

   D. Significant hip flexion contracture (over 20 degrees)

   E. Patient falls outside of recommended weight or height guidelines of manufacturer

V. A powered knee or ankle-foot is considered **investigational**.

VI. A microprocessor-controlled ankle-foot *prosthesis* or knee-ankle-foot *orthosis* is considered **investigational**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- Documentation of need at variable rates or for long distance ambulation from a device that reduces energy consumption
- Documentation of specific ADLS including job tasks that call do not permit full focus of concentration on knee control and stability
- Documentation of adequate ability to ambulate faster than normal walking speed including cardiovascular/pulmonary reserve, stride length, balance, Medicare Functional Level, and cognitive ability
- Type of amputation
- Wound status if applicable
- If a replacement is requested, documentation that the device is malfunctioning, cannot be repaired, and is no longer under warranty OR documentation of a significant change in the patient's physiological condition that makes the current prosthetic no longer able to meet the patient's medical needs

BACKGROUND

MICROPROCESSOR-CONTROLLED PROSTHETIC KNEES

Microprocessor-controlled prosthetic knees have been developed, including the Intelligent Prosthesis (IP) (Blatchford, England), the Adaptive (Endolite, England), the Rheo Knee® (Össur, Iceland), the C-Leg®, Genium™ Bionic Prosthetic System, and the X2 and X3 prostheses (Otto Bock Orthopedic Industry, Minneapolis, MN), and Seattle Power Knees (3 models include Single Axis, 4-bar and Fusion, from Seattle Systems). These devices are equipped with a sensor that detects when the knee is in full extension and adjusts the swing phase automatically, permitting a more natural walking pattern of varying speeds. For example, the prosthetist can specify several different optimal adjustments that the computer later selects and applies according to the pace of ambulation. In addition, these devices (with the exception of the IP) use microprocessor control in both the swing and stance phases of gait. (The C-Leg Compact provides only stance control). By improving stance control, they may provide increased safety, stability, and function. For example, the sensors are designed to recognize a stumble and stiffen the knee, thus avoiding a fall. Other potential benefits of microprocessor-controlled knee prostheses are improved ability to navigate stairs, slopes, and uneven terrain and reduction in energy expenditure and concentration required for ambulation. The C-Leg was cleared for marketing in 1999 through the 510(k) process of the U.S. Food and Drug Administration (FDA; K991590). Next-generation devices such as the Genium Bionic Prosthetic system and the X2 and X3 prostheses utilize additional environmental input (e.g., gyroscope and accelerometer) and more sophisticated processing that is intended to create more natural movement. One improvement in function is step-over-step stair and ramp ascent. They also allow the user to walk and run forward and backward. The X3 is a more rugged version of the X2 that can be used, for example, in water, sand, and mud. The X2 and X3 were developed by Otto Bock as part of the Military Amputee Research Program.

MICROPROCESSOR-CONTROLLED ANKLE-FOOT PROSTHESES

Microprocessor-controlled ankle-foot prostheses are being developed for transtibial amputees. These include the Proprio Foot® (Össur), the iPED (developed by Martin Bionics and licensed to College Park Industries), and the Elan Foot (Endolite). With sensors in the feet that determine the direction and speed of the foot's movement, a microprocessor controls the flexion angle of the ankle, allowing the foot to lift during the swing phase and potentially adjust to changes in force, speed, and terrain during the step phase. The intent of the technology is to make ambulation more efficient and prevent falls in patients ranging from the young active amputee to the elderly diabetic patient. The Proprio Foot™ and Elan Foot are microprocessor-controlled foot prostheses that are commercially available and considered class I devices that are exempt from 510(k) marketing clearance. Information on the Össur website indicates use of the Proprio Foot™ for low- to moderate-impact for transtibial amputees who are classified as level K3 (i.e., community ambulatory, with the ability or potential for ambulation with variable cadence). The Meridium and Empower are microprocessor ankle-feet available from Otto Bock, and the Kinnex is a microprocessor ankle-foot available from Freedom Innovations.

POWERED PROSTHESES

In development are lower-limb prostheses that also replace muscle activity in order to bend and straighten the prosthetic joint. For example, the PowerFoot BiOM® (developed at the Massachusetts Institute of Technology and licensed to iWalk) is a myoelectric prosthesis for transtibial amputees that uses muscle activity from the remaining limb for the control of ankle

movement. This prosthesis is designed to propel the foot forward as it pushes off the ground during the gait cycle, which in addition to improving efficiency, has the potential to reduce hip and back problems arising from an unnatural gait with use of a passive prosthesis. This technology is limited by the size and the weight required for a motor and batteries in the prosthesis. The Power Knee™ (Össur), which is designed to replace muscle activity of the quadriceps, uses artificial proprioception with sensors similar to the Proprio Foot in order to anticipate and respond with the appropriate movement required for the next step.

REGULATORY STATUS

Microprocessor-controlled prostheses are categorized as class I, exempt devices. Manufacturers must register prostheses with the restorative devices branch of FDA and keep a record of any complaints but do not have to undergo a full FDA review. FDA product codes include ISW and KFX.

EVIDENCE SUMMARY

Evaluating the effects of the increased sophistication of powered knee, powered ankle-foot, and microprocessor-controlled ankle-foot prostheses requires comparison with body-powered prostheses, passive prostheses, or no prosthesis. The most informative data are prospective comparative studies with objective measures that directly address function, safety, and health-related quality of life.

The evidence review below does not address microprocessor-controlled knees, which have been shown to improve function measures and decrease the cognitive burden associated with monitoring the prosthesis.

MICROPROCESSOR-CONTROLLED ANKLE-FOOT PROSTHESES

Systematic Reviews

A 2004 Cochrane review of ankle-foot prostheses (updated in 2008 with search dates through June 2006) concluded that there is insufficient evidence from high quality comparative studies to determine the overall superiority of any individual type of prosthetic ankle-foot mechanism.[1] The review included 26 cross-over studies with 3 to 16 participants in each study (n=245). Only one study was considered to be of high methodological quality while the remainders were considered of moderate quality. The vast majority of clinical studies on human walking have used standardized gait assessment protocols (e.g., treadmills) with limited “ecological validity”. The authors recommended that for future research, functional outcomes should be assessed for various aspects of mobility such as making transfers, maintaining balance, level walking, stair climbing, negotiating ramps and obstacles, and changes in walking speed.

Randomized Controlled Trials

Colas-Ribas (2022) conducted a cross-over study in 45 patients with ankle prosthesis at two centers in France.[2] Participants had a prosthetic foot for more than three months and were able to walk outdoors. After randomization, each foot (Proprio Foot or non-microprocessor) was worn for a total of 34 days which included two weeks of adaptation and adaptation confirmation and 20 days in everyday life. Energy expenditure was similar between prostheses (19.4 mL/kg/min with Proprio Foot and 19.1 mL/kg/min with other prostheses). Mean Short Form 36 (SF-36) physical scores with Proprio Foot were significantly better than with other prostheses (68.5 vs. 62.1; p=0.005) as were mental scores (72.0 vs. 66.2; p=0.006).

Gailey (2012) published a randomized, within-subject crossover study that compared self-reported and objective performance outcomes for four types of prosthetic feet, including the SACH (solid ankle cushion heel), SAFE (stationary attachment flexible endoskeletal), Talux mechanical foot, and the Proprio Foot microprocessor-controlled ankle prosthesis.[3] Ten patients with transtibial amputation were tested with their own prosthesis and then, in random order, each of the other prostheses after training and a two week acclimation period. No differences between prostheses were detected for the following measures:

- Prosthesis Evaluation Questionnaire (PEQ) (self-reported subjective rating of ease of use, social and emotional issues, and function over different surfaces)
- Locomotor Capabilities Index (self-reported subjective rating of capability to perform certain activities such as walking in various environments on various surfaces, sitting, standing, bending)
- Six-minute walk test (objective distance measurement)
- Steps per day
- Hours of daily activity

In 2014, the same investigators reported the effects of these prosthetic feet on ramp ambulation in 10 unilateral transtibial amputees.[4] Higher symmetry was reported with the Talux mechanical foot and the Proprio Foot during ramp descent, while no significant difference was found between the prostheses during ramp ascent.

Due to the limited sample sizes in these studies, conclusions cannot be reached about the comparisons between the various types of foot prostheses.

Nonrandomized Comparative Studies

Riveras (2020) reported on minimum toe clearance and tripping probability in 13 transtibial amputees using three prosthetic ankle-foot designs.[5] The participants tested a non-articulating ankle (NAA), an articulating hydraulic ankle (AHA), and an articulating hydraulic ankle with microprocessor (AHA-MP). Statistically significant differences were found for minimum toe clearance for ramp ascending ($p \leq 0.001$) and descending ($p=0.003$), with larger median values in the prosthetic limb when using the AHA-MP. The coefficient of variation was also significantly lower on the prosthetic limb for both types of articulating hydraulic ankle compared to the non-articulating ankle during ramp descent ($p=0.014$). The lowest tripping probability was reported for the AHA-MP.

Two comparative trials of the microprocessor-controlled ankle from the same investigators investigated the Proprio Foot. Its use was evaluated in 16 transtibial amputees during stair ascent and descent[6] or while walking up and down a ramp[7]. These studies were limited to the effect of flexion angles (flexion versus neutral angle). Healthy controls were also used for comparison. The outcomes of these studies were mixed. For example, the adapted mode (ankle flexion) resulted in more normal gait analysis results during ramp ascent but not during descent; however, some patients reported feeling safer with the adaptive mode ankle than with the Proprio Foot.

Thomas-Pohl (2021) compared three different types of ankle-foot prostheses, including the Proprio Foot, in a within-subject crossover study.[8] The primary outcome was to evaluate the ability of these prostheses to adapt to ground inclination. Six patients tested each of the three devices; each data acquisition was preceded with a two-week acclimation period and was

followed by a three-week wash-out period with the patient's energy storing and returning foot. Overall, the study found that microprocessor prostheses allowed for better posture and a reduction of residual knee moment on positive and/or negative slope when compared to the patients' energy storing and returning feet. Patients exhibited the most symmetric balance when they wore the Proprio Foot compared to the other microprocessor feet, but clinical functional tests between microprocessor prostheses and other feet did not differ greatly.

Other small studies have reported on these devices, including a study on ankle flexion using individuals as their own comparison group.[9] A within-subject study of six patients reported no benefit of an active Proprio Foot compared with the same prosthesis turned off with level walking or with slope ascent or descent.[10] An additional study reported a lower energy cost of floor walking with the Proprio Foot compared with a dynamic carbon fiber foot in 10 transtibial amputees.[11]

Section Summary

These studies do not permit conclusions about the clinical benefits and risks of the microprocessor-controlled foot compared with mechanical prostheses due to methodological limitations. These limitations included, among others, the small sample size, which limits the ability to rule out chance as an explanation of the study findings.

POWERED KNEE AND/OR ANKLE-FOOT PROSTHESES

Cacciola (2022) conducted a survey of 57 individuals who were current or (n=41) or former (n=16) users of a powered ankle-foot. All survey respondents were male with an average age of 53.5 years and an average of 13.1 years since amputation.[12] Among the current users, numeric rating scale pain scores were significantly improved with Empower compared with a passive foot in terms of sound knee pain (one vs. two; p=0.001), amputated side knee pain (one vs. two; p=0.001), and low-back pain (one vs. three; p<0.001). Limitations of this study include the use of recall data for pain and pain-related function since individuals tend to overestimate past pain, and other factors that may impact musculoskeletal pain, such as prosthetic alignment or concurrent medical treatments, were not accounted for in the study comparisons.

Kim (2021) reported results of a randomized trial of twelve participants that compared the BiOM powered ankle prosthesis with the participants' prescribed, unpowered prostheses.[13] Seven participants were randomly allocated to the powered prosthesis first group and five to the unpowered prosthesis first. Ten participants completed the study. No significant differences were identified in metabolic costs (p=0.585), daily step count (p=0.995), walking speed in-lab (p=0.145) and in daily life (p=0.226), or perception of mobility between prostheses (p≥0.058).

Ferris compared the BiOM powered ankle-foot prosthesis with an energy-storing and –returning (ESR) foot in 11 transtibial amputees. These results were also compared with 11 matched controls with intact limbs.[14] Compared with the ESR foot, the powered ankle-foot increased walking speed, but there were no significant differences in physical performance measure or conditions on the PEQ. Compared with the intact limb, the powered ankle-foot had increased step length and greater ankle peak power but had reduced range of motion. There appeared to be an increase in compensatory strategies at proximal joints with the powered prosthesis; the authors noted that normalization of gait kinematics and kinetics may not be

possible with a uniarticular device. Seven patients preferred the PowerFoot BiOM and four preferred the ESR prosthesis.

In another small study of seven amputees and seven intact controls, Herr (2012) reported gross metabolic cost and preferred walking speed to be more similar to non-amputee controls with the powered foot than with the ESR prosthesis.[15]

Mancinelli (2011) compared the PowerFoot BiOM with a passive-elastic foot in five transtibial amputees.[16] At the time of this study the powered prosthesis was a prototype and subjects' exposure to the prosthesis was limited to the laboratory. Laboratory assessment of gait biomechanics showed an average increase of 54% in the peak ankle power generation during late stance. Metabolic cost measured by oxygen consumption while walking on an indoor track was reduced by an average of 8.4% (p=0.06). This study did not report the impact of these measurements on patient function.

Section Summary

The current evidence is insufficient to permit conclusions about the benefits of powered lower extremity prostheses compared with other prostheses. These small studies mainly report on the feasibility of various prototypes. Larger, higher quality studies are needed to determine the impact of these devices on functional outcomes with greater certainty.

MICROPROCESSOR-CONTROLLED ORTHOSES

Randomized Controlled Trials

A randomized crossover trial of a microprocessor swing- and stance-controlled knee-ankle-foot orthosis was reported by Deems-Dluhy in 2021.[17] A total of 18 community-dwelling adults were assigned to receive a C-brace orthosis and a stance-control-orthosis in a randomized order. The C-brace controls with a microprocessor-controlled knee throughout stance and swing phases of gait. All participants received six sessions of training over a one-month period. Statistically significant differences were reported between post-microprocessor orthosis and post-stance-control orthosis in the six-minute walk test, with longer times post-microprocessor orthosis. Higher quality of life scores were reported in the Modified Falls Efficacy Scale, Orthotic and Prosthetic User's Survey (OPUS) (p=0.02) and physical health domain of the World Health Organization Quality of Life (WHOQOL-BREF) (p=0.037) after using the microprocessor-controlled orthosis. There were also fewer participant-reported falls when wearing the microprocessor-controlled orthosis versus a stance-control-orthosis or locked knee-ankle-foot orthosis.

Nonrandomized Comparative Studies

Pröbsting (2017) reported results of a questionnaire filled out by 13 patients at baseline (regarding their current locked knee ankle foot orthosis or stance control orthosis) and following use of a microprocessor stance and swing control orthosis.[18] The patients completed the Orthosis Evaluation Questionnaire, a new self-reported outcome measure created by modifying the Prosthesis Evaluation Questionnaire for use in lower limb orthotics and the Activities of Daily Living Questionnaire. There were statistically significant differences in the total score and the domains of ambulation (p=0.001), paretic limb health (p=0.04), sounds (p =0.02), and well-being (p=0.01), with superior results reported for the microprocessor orthosis.

Section Summary

The current evidence is insufficient to permit conclusions about the benefits of microprocessor-controlled lower extremity orthoses compared with other orthoses. These limitations include, among others, the small sample size. Larger, higher quality studies are needed to determine the impact of these devices on functional outcomes with greater certainty.

PRACTICE GUIDELINE SUMMARY

A 2019 clinical practice guideline from the Department of Veterans Affairs and the Department of Defense (VA/DoD) included the following recommendation with a weak strength of evidence:[19]

> We suggest offering microprocessor knee units over non-microprocessor knee units for ambulation to reduce risk of falls and maximize patient satisfaction. There is insufficient evidence to recommend for or against any particular socket design, prosthetic foot categories, and suspensions and interfaces.

The VAs' Prosthetic and Sensory Aids Strategic Healthcare Group was directed by the Under Secretary for Health to establish a Prosthetic Clinical Management Program to coordinate the development of clinical practice recommendations for prosthetic prescriptive practices. The following are guidelines from the Veterans Health Administration Prosthetic Clinical Management program:[20]

A. Contraindications for use of the microprocessor knee should include:
   - Any condition that prevents socket fitting, such as a complicated wound or intractable pain which precludes socket wear.
   - Inability to tolerate the weight of the prosthesis.
   - Medicare Level K 0—no ability or potential to ambulate or transfer.
   - Medicare Level K 1—limited ability to transfer or ambulate on level ground at fixed cadence.
   - Medicare Level K 2—limited community ambulator that does not have the cardiovascular reserve, strength, and balance to improve stability in stance to permit increased independence, less risk of falls, and potential to advance to a less-restrictive walking device.
   - Inability to use swing and stance features of the knee unit.
   - Poor balance or ataxia that limits ambulation.
   - Significant hip flexion contracture (over 20 degrees).
   - Significant deformity of remaining limb that would impair ability to stride.
   - Limited cardiovascular and/or pulmonary reserve or profound weakness.
   - Limited cognitive ability to understand gait sequencing or care requirements.
   - Long distance or competitive running.
   - Falls outside of recommended weight or height guidelines of manufacturer.
   - Specific environmental factors—such as excessive moisture or dust, or inability to charge the prosthesis.
   - Extremely rural conditions where maintenance ability is limited.

B. Indications for use of the microprocessor knee should include:
   - Adequate cardiovascular and pulmonary reserve to ambulate at variable cadence.
   - Adequate strength and balance in stride to activate the knee unit.

- Should not exceed the weight or height restrictions of the device.
- Adequate cognitive ability to master technology and gait requirements of device.
- Hemi-pelvectomy through knee-disarticulation level of amputation, including bilateral; lower extremity amputees are candidates if they meet functional criteria as listed
- Patient is an active walker and requires a device that reduces energy consumption to permit longer distances with less fatigue.
- Daily activities or job tasks that do not permit full focus of concentration on knee control and stability—such as uneven terrain, ramps, curbs, stairs, repetitive lifting, and/or carrying.
- Medicare Level K 2—limited community ambulator, but only if improved stability in stance permits increased independence, less risk of falls, and potential to advance to a less restrictive walking device, and patient has cardiovascular reserve, strength, and balance to use the prosthesis. The microprocessor enables fine-tuning and adjustment of the hydraulic mechanism to accommodate the unique motor skills and demands of the functional level K2 ambulator.
- Medicare Level K 3—unlimited community ambulator.
- Medicare Level K 4—active adult, athlete who has the need to function as a K 3 level in daily activities.
- Potential to lessen back pain by providing more secure stance control, using less muscle control to keep knee stable.
- Potential to unload and decrease stress on remaining limb.
- Potential to return to an active lifestyle.

C. Physical and Functional Fitting Criteria for New Amputees:
- New amputees may be considered if they meet certain criteria as outlined above.
- Premorbid and current functional assessment important determinant.
- Requires stable wound and ability to fit socket.
- Immediate postoperative fit is possible.
- Must have potential to return to active lifestyle.

SUMMARY

Research has shown that microprocessor-controlled knees improve function for some amputees and decrease the cognitive burden associated with monitoring the prosthesis. Those considered most likely to benefit from these prostheses have both the potential and need for frequent movement at a variable pace, uneven ground, or on stairs. Therefore, a microprocessor-controlled knee may be considered medically necessary when policy criteria are met.

In certain situations, a microprocessor-controlled knee may no longer be able to perform its basic function due to damage or wear or because of a change in the patient's physiological condition. When this occurs, replacement of the device may be medically appropriate. Therefore, replacement of all or part of a microprocessor-controlled knee may be considered medically necessary when device replacement Criteria are met.

When a microprocessor-controlled knee is in its warranty period or can be repaired or adapted adequately to meet the patient's medical needs, replacement of the device is not

medically appropriate. Therefore, replacement of all or part of a microprocessor-controlled knee is considered not medically necessary when device replacement Criteria are not met.

There is not enough research to show if or how well microprocessor-controlled knees improve health outcomes when criteria are not met. Therefore, microprocessor-controlled knees are not medically necessary when policy criteria are not met.

There is not enough research to show that there are improved health outcomes for microprocessor-controlled ankle-foot prostheses compared with conventional prostheses. Therefore, microprocessor-controlled ankle-foot prostheses are considered investigational.

There is not enough research to evaluate the health benefits and risks of powered lower limb prostheses. Therefore, powered knee and/or powered ankle-foot prostheses are considered investigational.

There is not enough research to show that microprocessor-controlled knee-ankle-foot orthoses improve health outcomes compared with conventional orthoses. Therefore, microprocessor-controlled knee-ankle-foot orthoses are considered investigational.

Noninvasive Ventilators in the Home Setting

Effective: September 1, 2023

Next Review: July 2024
Last Review: July 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Noninvasive ventilation (NIV) assistance or noninvasive positive pressure ventilation (NPPV) uses a nasal mask, face mask, or mouthpiece, connected to a ventilator to provide ventilation support during sleep or intermittently throughout the day.

MEDICAL POLICY CRITERIA

Notes: This policy only addresses home ventilators with a *noninvasive* interface (HCPCS code E0466). It does not address the use of other types of home ventilators, including those with an *invasive* interface (HCPCS E0465) or a multi-function home ventilator (HCPCS E0467).

I. Use of a noninvasive ventilator in the home setting may be considered **medically necessary** when both of the following criteria are met (A. and B.):

A. The device is being requested to treat any of the following indications:

1. Neuromuscular disease, or
2. Thoracic restrictive disease, or

3. Chronic respiratory failure consequent to chronic obstructive pulmonary disease.

B. There is sufficient documentation in the medical record to support the condition is life-threatening where interruption of respiratory support would quickly lead to serious harm or death.

II. Use of a noninvasive ventilator in the home setting is considered **not medically necessary** when Criterion I. is not met, including but not limited to the following situations:

A. The patient's condition is such that treatment may be adequately provided by a bilevel positive airway pressure device; or

B. Severity of the patient's condition is not severe and life-threatening.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

VENTILATOR WITH NOINVASIVE INTERFACES

The Centers for Medicare & Medicaid Services (CMS) National Coverage Determinations Manual (Internet-Only Manual, Publ. 100-03) in Chapter 1, Part 4, Section 280.1 stipulates that ventilators (E0465, E0466) are covered for the following conditions:[1]

"[N]euromuscular diseases, thoracic restrictive diseases, and chronic respiratory failure consequent to chronic obstructive pulmonary disease."

Each of these disease categories are comprised of conditions that can vary from severe and life-threatening to less serious forms. These ventilator-related disease groups overlap conditions described in this Respiratory Assist Devices LCD used to determine coverage for bi-level PAP devices. Each of these disease categories are conditions where the specific presentation of the disease can vary from patient to patient. For conditions such as these, the specific treatment plan for any individual patient will vary as well. Choice of an appropriate treatment plan, including the determination to use a ventilator vs. a bi-level PAP device, is made based upon the specifics of each individual beneficiary's medical condition. In the event of a claim review, there must be sufficient detailed information in the medical record to justify the treatment selected.

Ventilators fall under the Frequent and Substantial Servicing (FSS) payment category, and payment policy requirements preclude FSS payment for devices used to deliver continuous and/or intermittent positive airway pressure, regardless of the illness treated by the device. (Social Security Act 1834(a)(3)(A)) This means that products currently classified as HCPCS code E0465 or E0466 when used to provide CPAP or bi-level PAP (with or without backup rate) therapy, regardless of the underlying medical condition, shall not be paid in the FSS payment category. A ventilator is not eligible for reimbursement for any of the conditions described in this RAD LCD even though the ventilator equipment may have the capability of operating in a bi-level PAP (E0470, E0471) mode. Claims for ventilators used to provide CPAP or bi-level CPAP therapy for conditions described in this RAD policy will be denied as not reasonable and necessary.

General principles of correct coding require that products assigned to a specific HCPCS code only be billed using the assigned code. Thus, using the HCPCS codes for CPAP (E0601) or bi-level PAP (E0470, E0471) devices for a ventilator (E0465, E0466) used to provide CPAP or bi-level PAP therapy is incorrect coding. Claims for ventilators billed using the CPAP or bi-level PAP device HCPCS codes will be denied as incorrect coding.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- All chart notes and medical records pertinent to the request (e.g., supporting documentation of neuromuscular disease, thoracic restrictive disease, and/or chronic respiratory failure consequent to COPD).
- Documentation must demonstrate that the condition is life-threatening where interruption of respiratory support would quickly lead to serious harm or death.

CROSS REFERENCES

1. Phrenic Nerve Stimulation for Central Sleep Apnea, Surgery, Policy No. 212

BACKGROUND

This policy is based on the Centers for Medicare & Medicaid Services (CMS) National Coverage Determinations Manual (Internet-Only Manual, Publ. 100-03) in Chapter 1, Part 4, Section 280.1; and Local Coverage Determination (LCD): Respiratory Assist Devices (L33800).[1, 2]

NONINVASIVE VENTILATORS

Ventilators, also known as respirators, are medical devices used to mechanically assist with a patients' breathing. Mechanical ventilation is often categorized by the interface used, such as a tracheostomy tube for invasive ventilation, or a mask for non-invasive ventilation. Non-invasive ventilation (NIV) assistance or non-invasive positive pressure ventilation (NPPV) uses a nasal mask, face mask, or mouthpiece, connected to a ventilator to provide ventilation support during sleep or intermittently throughout the day. In the hospital setting, a trial of NPPV may be attempted prior to invasive treatment. Ventilation support rests the lung muscles and improves breathing performance during the day. At night, ventilation may be used to treat sleep-associated hypoventilation. If use is at night only, this is referred to as nocturnal NPPV. If use is intermittent, this may be referred to as "Mouthpiece" or "Sip and Puff" ventilation. Supplemental oxygen may also be added to this type of system.

In recent decades, NPPV has been used for treatment in the home setting. BPAP are portable pressure-limited ventilators, which are more commonly used than portable volume-limited ventilators. In some populations, efficacy is similar with both types of devices according to comparative studies, thus the portable pressure-limited ventilators are usually preferred over portable volume-limited ventilators, because of lower cost, better portability, and often greater comfort.[3]

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) has approved numerous portable home ventilators through the 510(k) process. A non-exhaustive list of examples includes the following:

- Servo-u Ventilator system 4.1 (Rontgenvagen)
- Trilogy™ (Philips Respironics)
- Newport® (Newport Medical Instruments)
- IVent (GE Healthcare)
- Puritan™ (Covidien)
- LTV® (Carefusion)

FDA Product Code: CBK.

SUMMARY

There is enough research to show that use of a noninvasive ventilator in the home setting improves health outcomes for patients with neuromuscular disease, thoracic restrictive disease, or chronic respiratory failure consequent to chronic obstructive pulmonary disease. Clinical guidelines based on research recommend noninvasive ventilators for use in the home setting for these populations. Therefore, the use of a noninvasive ventilator in the home setting may be considered medically necessary when policy criteria are met.

In all other situations, the use of a noninvasive ventilator in the home setting is not associated with improvements in health outcomes. Therefore, the use of a noninvasive ventilator in the home setting is considered not medically necessary when policy criteria are not met.

HTCC Decision: Negative Pressure Wound Therapy

Implementation 1/1/18

Definition of "Complete Wound Therapy Program"

A minimum of the following measures must be addressed and documented:
a. Evaluation, care and wound measurements by a licensed medical professional, and
b. Application of dressings to maintain a moist wound environment, and
c. Debridement of necrotic tissue if present, and
d. Evaluation of and provision for adequate nutritional status, and
e. Standard forms of treatment specific to the type of wound.

Endometrial Ablation

Effective: May 1, 2024

Next Review: October 2024
Last Review: March 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Endometrial ablation involves ablation or destruction of the endometrium using a variety of techniques to treat people with menorrhagia when standard therapy is ineffective.

MEDICAL POLICY CRITERIA

I. Endometrial ablation, with or without hysteroscopic guidance, may be considered **medically necessary** when the clinical records document all of the following criteria (I.A. - D.) are met:

A. There is a diagnosis of abnormally heavy uterine bleeding in a patient who is not post-menopausal; *and*

B. Hysteroscopy, sonohysterography (SIS), pelvic ultrasound, or other pelvic imaging (e.g. pelvic MRI, pelvic CT) has been performed and clinical documentation of the results is provided; *and*

C. Clinical documentation confirms counseling regarding hormonal treatment options has been addressed (see Policy Guidelines); *and*

D. Endometrial sampling or dilation and curettage (D&C) has been performed or is planned according to either of the following:

1. Endometrial sampling or D&C has been performed to evaluate the current

abnormal bleeding episode and clinical documentation of the results is provided, either showing absence of endometrial hyperplasia or uterine cancer OR inadequate tissue was obtained for diagnosis; *or*

2. Cervical stenosis documented in the clinical record precludes endometrial sampling, and D&C is planned concomitantly with ablation procedure.

II. Repeat endometrial ablation may be considered **medically necessary** when all of the following (A. - C.) criteria are met:

A. There is a recurrent diagnosis of abnormally heavy uterine bleeding in a patient who is not post-menopausal; *and*

B. The initial endometrial ablation procedure was performed at least six months prior; *and*

C. Endometrial sampling or D&C has been performed or is planned according to either of the following:

1. Endometrial sampling or D&C has been performed to evaluate the current abnormal bleeding episode since the previous ablation procedure, and the clinical documentation of the results is provided, either showing absence of endometrial hyperplasia or uterine cancer OR inadequate tissue was obtained for diagnosis; *or*

2. Cervical stenosis documented in the clinical record precludes endometrial sampling, and D&C is planned concomitantly with ablation procedure.

III. Endometrial ablation using *any* technique is considered **not medically necessary** for all other indications not meeting the criteria in I.A.-D., or II.A.-C.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

HORMONAL THERAPY OPTIONS

Counseling regarding hormonal treatment options has occurred, or uterine intracavitary abnormality (i.e., endometrial polyps, submucosal fibroids) is found on hysteroscopy, sonohysterography, pelvic ultrasound, or endometrial biopsy/curettings and endometrial ablation is to be performed concomitantly with surgical treatment of the uterine intracavitary abnormality.

LIST OF INFORMATION NEEDED FOR REVIEW

SUBMISSION OF DOCUMENTATION

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and physical chart notes
- Clinical documentation that affirms:

    - Endometrial sampling or D&C was completed with date performed, and description of the results, OR
    - Cervical stenosis; AND
- Clinical documentation that affirms:
    - Hysteroscopy, sonohysterography (SIS), pelvic ultrasound, or other pelvic imaging (e.g. pelvic MRI, pelvic CT) was completed with date performed, and description of the results, OR
    - Repeat endometrial ablation is planned at least six months after the initial procedure
- When relevant, clinical documentation of counseling regarding hormonal treatment options

5. Hysterectomy, Surgery, Policy No. 218

BACKGROUND

Ablation or destruction of the endometrium is used to treat abnormal uterine bleeding in premenopausal women when standard medical therapy is ineffective. Standard medical management typically includes a trial of nonhormonal therapy with adequate doses of nonsteroidal anti-inflammatory medication and oral tranexamic acid. If this fails, management with hormonal treatment to thin the endometrium may be tried. Hormonal treatment may include oral contraceptive pills, patch, vaginal ring, or progestin-only hormonal therapy (oral, IUD, implant, or injection). Ablation is considered a less invasive alternative to hysterectomy; however, as with hysterectomy, the procedure is not recommended for women who wish to preserve their fertility.

Techniques for endometrial ablation are generally divided into two categories:

HYSTEROSCOPIC TECHNIQUES

Hysteroscopic techniques require skilled surgeons and, due to the requirement for cervical dilation, use of general or regional anesthesia. In addition, the need for the instillation of hypotonic distension media creates a risk of pulmonary edema and hyponatremia such that very accurate monitoring of fluids is required.

The initial hysteroscopic technique involved photovaporization of the endometrium using an Nd-YAG laser. This was followed by electrosurgical ablation using an electrical rollerball or electrical wire loop. The latter technique is also known as transcervical resection of the endometrium, or TCRE. Hydrothermal ablation is another technique involving hysteroscopy.

NON-HYSTEROSCOPIC TECHNIQUES

Non-hysteroscopic techniques can be performed without general anesthesia and do not involve use of a fluid distention medium. Techniques include thermal fluid-filled balloon, cryosurgical endometrial ablation, instillation of heated saline, and radio frequency (RF) ablation.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) indicated that endometrial devices are for use in premenopausal women with menorrhagia due to benign causes for whom childbearing is complete. FDA-approved devices for endometrial ablation include, but may not be limited to, laser therapy, electrical wire loop, rollerball using electric current, and thermal ablation using a liquid-filled balloon, microwave, electrode array, or a cryosurgical device. Examples of devices for endometrial ablation are listed below. FDA product code: MNB.

- The Genesys HTA™ system (Boston Scientific), This system involves the instillation and circulation of heated saline into the uterus using hysteroscopic guidance and includes features such as a smaller console and simplified set-up requirements, was approved by the FDA in May 2010.
- The Microwave Endometrial Ablation (MEA) system (Microsulis Medical): This delivers fixed-frequency microwave energy and may be performed in a physician's office but does require use of the hysteroscope.
- The ThermaChoice® device (J&J Ethicon Gynecare): This device ablates endometrial tissue by thermal energy heating of sterile injectable fluid within a silicone balloon. Endometrial ablation will only work when there is direct contact between the endometrial wall and the fluid-filled balloon. Therefore, patients with uteri of abnormal shape, resulting from tumors such as myomas or polyps, or large size, due to fibroids, are generally not considered candidates for this procedure.
- The NovaSure® impedance-controlled endometrial ablation system (Hologic®): The system delivers RF energy to the endometrial surface. The device consists of an electrode array on a stretchable porous fabric that conforms to the endometrial surface.
- Her Option™ Uterine Cryoablation Therapy™ system (American Medical Systems): The system consists of, in part, a cryoprobe that is inserted through the cervix into the endometrial cavity. When cooled, an ice ball forms around the probe, which permanently destroys the endometrial tissue. Cryoablation is typically monitored by abdominal ultrasound.

EVIDENCE SUMMARY

SYSTEMATIC REVIEWS

Several published systematic reviews have evaluated the accumulated evidence for endometrial ablation. These reviews address both first- generation techniques (laser ablation, electrical wire loop, rollerball, or vaporizing electrode procedure) and second-generation techniques (newer techniques that generally do not require hysteroscopy such as balloon ablation, microwave ablation, and electrode ablation).

Oderkerk (2022) published a systematic review to assess whether previous endometrial ablation affects future endometrial cancer (EC) risk.[1] The review involved 29,102 patients from 11 studies and found that previous endometrial ablation is associated with a reduced risk for EC (0.0% - 1.6% vs.3.1% average lifetime risk of EC). The review is limited by follow-up times of fewer than 15 years in nine of the studies.

Vitale (2022) published a systematic review and meta-analysis of randomized controlled trials (RCTs) to compare quality of life after endometrial ablation or hysteroscopic endometrial resection (ER/GEA) to hysterectomy.[2] Twelve RCTs involving 2773 premenopausal women

were included. Outcomes were post-operative scores on the 36-Item Short Form Health Survey (SF-36), post-operative anxiety and depression, and the rate of surgical complications. The overall risk of bias was intermediate. SF-36 scores for general health perception ($p<0.00001$), social function ($p=0.02$), emotional role limitation ($p=0.02$), and vitality ($p=0.02$) were lower in the ER/GEA group, but the groups were similar in perception of physical functioning ($p=0.19$), pain ($p=0.08$), and mental health ($p=0.06$). Anxiety and depression, measured with the Hospital Anxiety and Depression Scale (HADS) were not different ($p=0.26$, $p=0.85$). The rate of post-operative complications was also not significantly different ($p=0.13$). Limitations include the studies were not blinded and the use of outdated ablation techniques.

Oderkerk (2023) conducted a systematic review and meta-analysis assessing the risk of hysterectomy at least one year after non-rectoscopic endometrial ablation.[3] The analysis involved 48,071 patients from 53 studies. Hysterectomy rates increased with time, and the study found a 12% risk of hysterectomy five years after endometrial ablation, but study design and ablation technique did not significantly affect hysterectomy rates.

Bergeron (2020) performed a systematic review and meta-analysis of the efficacy and safety of endometrial ablation or resection compared with the levonorgestrel intra-uterine system (LNG-IUS) in the treatment of premenopausal women with heavy menstrual bleeding.[4] A total of 13 randomized controlled trials met inclusion criteria. The meta-analysis identified no significant differences between groups for subsequent hysterectomy, satisfaction, quality of life, amenorrhea and treatment failure. Based on data from 10 studies, there was a statistically significant difference between groups for side effects, which were less common in the endometrial ablation/resection group (RR = 0.52, 95% CI 0.37 to 0.71, $p<0.001$, $I^2=0\%$). There was significant heterogeneity between studies for mean age of the included population ($p=0.01$). When age was limited to 42 years or younger, there was higher risk of subsequent hysterectomy for the endometrial ablation/resection group compared to the LNG-IUS group (RR=5.26, 95% CI 1.21 to 22.91, $p=0.03$, $I^2=0\%$).

In 2018, an updated Cochrane systematic review and meta-analysis compared the efficacy and safety of different endometrial ablation techniques.[5-7] The review included RCTs that compared ablation techniques and assessed amenorrhea and patient satisfaction.

A total of 28 studies with 4,287 premenopausal women were eligible for the review. Five of the trials compared two “first generation” ablation methods (laser ablation, electrical wire loop, rollerball, or vaporizing electrode procedure) to one another and five trials compared “second generation” techniques to one another. Fifteen trials compared first- to second-generation procedures. Eighteen trials had adequate randomization methods, but in most trials blinding was not performed or was not reported. Of the studies that compared among second generation techniques, three described triple blinding and two described double blinding.

The investigators also conducted a meta-analysis that combined studies comparing first- and second-generation techniques. A pooled analysis of 12 studies (total n=2,085) did not find a significant difference in the rate of amenorrhea at one year (OR 0.94; 95% CI 0.74 to 1.20). Eleven studies (total n=1,690) reported satisfaction rates at one year, and there was not a significant difference between first-and second-generation techniques (OR 1.00; 95% CI, 0.97 to 1.02). Pooled analysis of adverse effects did not find any significant differences in the rate of perforation (eight studies), endometritis (four studies), or hemorrhage (four studies) using first- versus second-generation ablation techniques. Rates of fluid overload (three studies) and

cervical lacerations (seven studies) and hematometra (five studies) were significantly higher with first-generation techniques than with second-generation techniques.

The authors of the Cochrane review concluded that, overall, the existing evidence suggests that success rates and complications profiles of second-generation techniques compare favorably with the first generation hysteroscopic techniques.

In 2011, the Health Technology Assessment (HTA) program in the U.K. conducted a meta-analysis of individual patient data from RCTs evaluating second-line treatments for menorrhagia.[8] They identified data on 2,448 women from 14 trials comparing first- and second-generation endometrial ablation devices and data on 1,127 women from seven trials comparing first-generation devices to hysterectomy. A limitation of the review is that individual patient data were not available for approximately 35% of women randomized in the trials. The most frequently measured outcome in the studies was patient satisfaction/dissatisfaction and this was used as the primary outcome of the meta-analysis. After 12 months of follow-up, 7.3% (57/454) of women treated with first-generation endometrial ablation devices and 5.3% (23/432) of women who had a hysterectomy were dissatisfied with their treatment outcome. This difference was statistically significant, favoring hysterectomy (OR 2.46, 95% CI 1.54 to 3.93, p=0.0002). Rates of dissatisfaction were similar among women treated with first-generation endometrial ablation devices (123/1,006 [12.2%]) and second-generation devices (110/1,034 [10.6%], p=0.20). The authors noted that rates of dissatisfaction were low for all treatments.

The HTA also conducted meta-analyses on several clinical outcomes. For example, when first- and second-generation endometrial ablation devices were compared, there was not a significant difference between groups in the rate of amenorrhea after 12 months. When findings from 13 studies were pooled, rates of amenorrhea were 326/899 (36%) with first-generation devices and 464/1,261 (37%) with second-generation devices (OR 1.12; 95% CI 0.93 to 1.35). There were insufficient data to conduct meta-analyses of longer-term amenorrhea rates. Similarly, the rates of menorrhagia after 12 months did not differ between groups. In a pooled analysis of 12 studies, rates were 111/899 (12.3%) with first-generation devices and 151/1,281 (11.8%) after second-generation devices (pooled OR 0.97, 95% CI 0.74 to 1.28). In addition, a pooled analysis of 6 studies did not find a significant difference in repeat endometrial ablations over 12 months after initial treatment with first-generation devices (4/589, 0.7%) or second-generation devices (4/880, 0.5%) (OR 0.71, 95% CI 0.17 to 2.94). The proportion of women requiring hysterectomy within 12 months after endometrial ablation did not differ significantly when first-generation devices (39/933 [4.2%]) or second-generation devices (35/1,343 [2.6%]) were used (OR 0.77; 95% CI 0.47 to 1.24 [11 studies]).

In addition to the meta-analyses of data from published studies, the HTA included an analysis of individual patient data from national databases in Scotland to evaluate long-term outcomes after hysterectomy or endometrial ablation. The investigators identified a total of 37,120 women who underwent hysterectomy and 11,299 women who underwent endometrial ablation for dysfunctional uterine bleeding between 1989 and 2006. Women who received endometrial ablation were significantly older (mean of 42.5 years) compared to those receiving hysterectomy (mean of 41.0 years). The type of endometrial ablation device could not be determined. The median duration of follow-up was 6.2 years in the endometrial ablation group and 11.6 years in the hysterectomy group. During follow-up, 962 (8.5%) women who received endometrial ablation had additional gynecologic surgery compared to 1,446 (3.9%) women who had hysterectomy; this difference was statistically significant (adjusted hazard ratio [HR]:

3.56, 95% CI 3.26 to 3.89). The most common types of additional surgery after endometrial ablation were intrauterine procedures (n=577, 5.1%) and repeat endometrial ablation (n=278, 2.5%). However, women who had initial endometrial ablation procedures were significantly less likely than those with initial hysterectomies to have surgery for pelvic floor repair (0.9% vs. 2.2%, respectively, adjusted HR 0.50 to 0.77). Women were also less likely to have tension-free vaginal tape surgery for stress urinary incontinence after endometrial ablation than after hysterectomy (0.5% vs. 1.1%, respectively, adjusted HR 0.55, 95% CI 0.41 to 0.74).

In 2012, Daniels compared first- and second-generation methods using 14 trials previously addressed in the HTA assessment.[9] A pooled analysis of these studies yielded conclusions that were similar to the HTA group, in that no significant difference in amenorrhea rates was observed with the two types of techniques (OR 0.72, 95% CI 0.52 to 1.101). In addition, three studies compared the second-generation techniques, thermal balloon ablation and bipolar radiofrequency (RF) (total n=264). A pooled analysis showed a higher rate of amenorrhea with bipolar RF (OR 4.56; 95% CI 2.24 to 9.26).

In 2013, Kroft also reported no difference in amenorrhea rates when comparing first- and second-generation methods as a treatment for menorrhagia in premenopausal women (11 randomized controlled trials[10] were included in the review). However, authors did note a decrease in complication rates (seven studies with 1272 patients, rate ratio 0.52, 95% CI 0.35 to 0.76; p<0.001), operating time (16.6 minutes three studies with 486 patients, 95% CI 12.1 to 21.2 minutes; p<0.001) and improved compatibility with anaesthesia (three studies with 558 patients, rate ratio 1.87, 95% CI 1.04 to 3.37; p=0.04) in second-generation devices compared to first-generation methods. In addition, authors reported higher rates of amenorrhea in patients treated with Novasure compared to other second-generation devices (four studies with 407 patients, rate ratio 2.60, 95% CI 1.63 to 4.14; p<0.001).

Several medium and large nonrandomized studies have reported time to surgical reoperation rates, including repeat endometrial ablation, in women who fail initial procedure.[11-13] The majority of surgical reoperations occurred at least one year after the initial procedure.

Section Summary

Evidence from these large systematic reviews do not demonstrate that one ablation technique is superior to another. Overall, these studies continue to report similar amenorrhea rates in first-generation and second-generation techniques.

SAFETY

In 2012, Brown published an analysis of adverse events associated with endometrial ablation procedures that were reported in the U.S. Food and Drug Administration (FDA's) Manufacturer and User Facility Device Experience (MAUDE) database.[14] There were a total of 829 reported adverse events between 2005 and 2011. Nearly two-thirds of the adverse events (540 of 829, 65%) were genital tract or skin burns and 529 of these events (98%) were associated with hydrothermal endometrial ablation. The next two most frequent types of adverse events were thermal bowel injury (93 of 820, 11%) and transmural uterine thermal activity (89 of 820, 11%). Of the 182 thermal injuries, 140 (77%) were associated with radiofrequency endometrial ablation. In addition, 47 instances of sepsis or bacteremia were reported, and 43 of these cases (91%) were associated with radiofrequency endometrial ablation. There were four reported deaths, two associated with radiofrequency ablation and one each associated with thermal balloon ablation and cryoablation. Sixty-six of the 829 events (8%) occurred when

endometrial ablation was performed outside of the labeled instructions for use of the procedure. The authors did not report the total number of endometrial ablations performed during this time period, therefore the proportion of procedures with adverse events cannot be determined from these data.

A 2014 study by Dood examined whether women who undergo endometrial ablation are at increased risk of endometrial cancer compared with those with abnormal uterine bleeding that is managed with medication.[15] The data were collected from a population-based cohort in the U.S. and included a total of 234,721 women with abnormal bleeding, 4776 of whom underwent endometrial ablation. During a median follow-up period of 4.1 years, three women with a history of endometrial ablation and 601 women who were treated medically developed endometrial cancer. There was not a statistically significant difference in endometrial cancer rates between groups (age-adjusted HR=0.61, 95% CI, 0.20 to 1.89, p=0.17). Moreover, the median time to endometrial cancer diagnosis, 237 days after ablation and 299 days with medical management, did not differ significantly between groups.

Section Summary

Adverse events have been associated with endometrial ablation procedures. Certain types of adverse events are more likely to occur with specific approaches to endometrial ablation. Due to lack of information about the total number of procedures and the number of each type of endometrial ablation procedure performed, conclusions cannot be drawn from these data about the relative safety of different types of endometrial ablation procedures.

PRACTICE GUIDELINE SUMMARY

PRACTICE COMMITTEE OF THE AMERICAN SOCIETY FOR REPRODUCTIVE MEDICINE

In 2008, the American Society for Reproductive Medicine (ASRM) reviewed their 2006 Practice Committee report and reissued their statement on indications and options for endometrial ablation.[16] Conclusions were:

- “Endometrial ablation is an effective therapeutic option for the management of menorrhagia.
- Hysteroscopic and nonhysteroscopic techniques for endometrial ablation offer similar rates of symptom relief and patient satisfaction.
- Later definitive surgery may be required in 6% to 20% of women after endometrial ablation.
- Women who undergo hysterectomy after a failed endometrial ablation report significantly more satisfaction after 2 years of follow-up.
- Endometrial ablation generally is more effective when the endometrium is relatively thin.
- Ideally, hysteroscopic methods for endometrial ablation should be performed using a fluid monitoring system to reduce the risks and complications relating to fluid overload and electrolyte imbalance.
- Nonhysteroscopic methods for endometrial ablation require less skill and operating time.”

A 2015 patient fact sheet from the ASRM states that women who meet the following criteria should not have endometrial ablation:

> "Women who are pregnant, who would like to have children in the future, or have gone through menopause should not have this procedure."[17]

AMERICAN CONGRESS OF OBSTETRICIANS AND GYNECOLOGISTS

The American Congress of Obstetricians and Gynecologists (ACOG) published a practice bulletin on endometrial ablation in 2007, which was later reaffirmed in 2013, 2015, and 2018.[18] ACOG made the following recommendations, as being based on good and consistent evidence:

> "For women with normal endometrial cavities, resectoscopic endometrial ablation and nonresectoscopic endometrial ablation systems appear to be equivalent with respect to successful reduction in menstrual flow and patient satisfaction at 1 year following index surgery."

> "Resectoscopic endometrial ablation is associated with a high degree of patient satisfaction but not as high as hysterectomy."

In addition, the ACOG practice bulletin regarding endometrial ablation included the following statement regarding preoperative evaluation:

> "The structure and histology of the endometrial cavity should be thoroughly evaluated, both to assess for malignancy or endometrial hyperplasia and to ensure that the length and configuration is suitable for endometrial ablation. These parameters will vary depending on the technique or system used. Endometrial sampling, typically with an outpatient technique, can be used to evaluate all women for hyperplasia or malignancy, and results should be reviewed before ablation is scheduled. Women with endometrial hyperplasia or uterine cancer should not undergo endometrial ablation."

In 2013, ACOG published committee opinion number 557 (reaffirmed in 2020) regarding the management of acute abnormal uterine bleeding (AUB) in nonpregnant reproductive-aged women.[19] Recommendations regarding laboratory testing and imaging of these patients are as follows:

> "Endometrial tissue sampling should be performed in patients with AUB who are older than 45 years as a first-line test. Endometrial sampling also should be performed in patients younger than 45 years with a history of unopposed estrogen exposure (such as seen in patients with obesity or polycystic ovary syndrome), failed medical management, and persistent AUB."

Recommendations regarding surgical management of women who do not respond to medical management of symptoms are as follows:

> "Surgical options include dilation and curettage (D&C), endometrial ablation, uterine artery embolization, and hysterectomy."

> "Endometrial ablation, although readily available in most centers, should be considered only if other treatments have been ineffective or are contraindicated, and it should be performed only when a woman does not have plans for future childbearing and when the possibility of endometrial or uterine cancer has been reliably ruled out as the cause of the acute AUB."

The 2013, ACOG practice bulletin regarding the management of abnormal uterine bleeding associated with ovulatory dysfunction (AUB-O) was reaffirmed in 2018.[20] The following recommendation is made primarily based upon consensus and expert opinion:

> "Endometrial ablation is not recommended as a first-line therapy for AUB-O. Physicians must provide thorough informed consent and adequate counseling to women with AUB-O who desire endometrial ablation."

Furthermore, the practice bulletin recommends combined hormonal contraceptive therapy or progestin therapy, and other medical management depending upon age group and menopause status. The bulletin stresses that contraindications to combined hormonal contraceptive therapy should be excluded.

SOCIETY FOR GYNECOLOGIC SURGEONS

In 2012, the Society for Gynecologic Surgeons (SGS) published a clinical practice guideline on treatment of abnormal uterine bleeding.[21] The guideline recommends that, in women with bleeding caused mainly by ovulatory disorders or endometrial hemostatic disorders, any of the following treatments may be chosen depending on patient values and preferences: hysterectomy, endometrial ablation, systemic medical therapies or levonorgestrel-releasing intrauterine systems. In choosing between endometrial ablation and hysterectomy, if the patient's preference is for amenorrhea, less pain or avoiding additional therapy, hysterectomy is suggested. If the patient's preference is for lower operative and postoperative procedural risk, and a shorter hospital stay, endometrial ablation is recommended.

SUMMARY

There is enough research to show that endometrial ablation improves overall health outcomes in women with abnormally heavy uterine bleeding who are not post-menopausal. Clinical guidelines recommend endometrial ablation for clinical scenarios that generally align with the policy criteria. Therefore, endometrial ablation may be considered medically necessary when criteria are met.

Evidence and guidelines do not support the use of endometrial ablation when policy criteria are not met. Therefore, endometrial ablation for indications or using techniques other than those specified in policy criteria are considered not medically necessary.

Medical Policy Manual Surgery, Policy No. 08

Cochlear Implant

Effective: May 1, 2024

Next Review: March 2025
Last Review: March 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

A cochlear implant is a device for the treatment of severe-to-profound hearing loss in individuals who only receive limited benefit from amplification with hearing aids. A cochlear implant provides direct electrical stimulation to the auditory nerve, bypassing the usual transducer cells that are absent or nonfunctional in deaf cochlea.

MEDICAL POLICY CRITERIA

Notes:

- This policy does not apply to surgically anchored bone-conduction hearing aids or externally worn air-conduction hearing aids. Cochlear implants are not hearing aids. While hearing aids function by amplifying sound, cochlear implants replace the functions of an absent or nonfunctioning cochlea.
- This policy does not address the use of the Nucleus® 24 Auditory Brain Stem Implant, which is designed to restore hearing in patients with neurofibromatosis who are deaf secondary to removal of bilateral acoustic neuromas.
- Hybrid cochlear implant/hearing aid systems are devices that include a hearing aid integrated into the external sound processor of the cochlear implant. If hearing aid components of such systems are billed separately, there may be specific member

benefit language addressing coverage of hearing aids that would be applicable. Contract language takes precedence over medical policy.

- Repeat hearing tests or trials of hearing aids are not necessary for patients who have previously met Criteria I. and II. as it is unlikely that natural hearing or the benefit from hearing aids will improve significantly over time.

I. **For individuals with bilateral hearing loss, implantation of cochlear implants (unilateral or bilateral)**, ***other than*** cochlear implant/hearing aid ***hybrid*** devices, and associated aural rehabilitation may be considered **medically necessary** when all of the following criteria (A. – D.) are met:

A. Meets one of the following age requirements:

1. Age 9 months or older for the Nucleus 24 cochlear implant system (with any of the Cochlear® sound processors); or
2. Age 12 months or older.

B. Meets one or more of the following:

1. Patients diagnosed with enlarged vestibular aqueduct (EVA) (greater than 1mm at the midpoint), as evidenced by MRI or CT imaging; or
2. Patients with both of the following (a. and b.):
   a. Patients meeting criterion (i. or ii.):
      i. Bilateral severe to profound pre- or postlingual (sensorineural) hearing loss, defined as a pure-tone average of 70 decibels (dB) hearing threshold or greater at 500 Hz (hertz), 1000 Hz and 2000 Hz; or
      ii. Severe to profound pre- or postlingual (sensorineural) hearing loss, defined as a pure-tone average of 70 dB hearing threshold or greater at 500 Hz (hertz), 1000 Hz and 2000 Hz in one ear with documented progressive hearing loss (i.e., documentation of multiple audiograms demonstrating progressive hearing loss with expectation of continued progressive hearing loss) in the contralateral ear; and
   b. Limited or no benefit from hearing aids (defined below) unless hearing aids are unreasonable.
      i. **Adults:** Scores less than or equal to 50 percent correct on tape recorded sets of open-set sentence recognition in the ear to be implanted.
      ii. **Children:** Failure to develop basic auditory skills, and in older children, less than or equal to 30 percent correct on open-set tests.

C. Implanted device is FDA approved PMA or 510(k) only.

D. Patients do not have any of the following contraindications:

1. Deafness due to lesions of the acoustic nerve (eighth cranial nerve), central auditory pathways, or brain stem in the implanted ear.

2. Active or chronic infections of the external or middle ear and mastoid cavity in the implanted ear, including but not limited to otitis media.
3. Tympanic membrane perforation.
4. Radiographic evidence of absent cochlear development in the implanted ear.
5. Inability or lack of willingness to participate in post-implantation aural rehabilitation.

II. **For individuals with bilateral hearing loss, unilateral implantation of *hybrid* cochlear implant/hearing aid systems** that include the hearing aid integrated into the external sound processor of the cochlear implant may be considered **medically necessary** when all of the following criteria are met (A. – F.):

A. Age 18 years or older.

B. Bilateral severe to profound pre- or postlingual (sensorineural) hearing loss, defined as a pure-tone average of 70 decibels (dB) hearing threshold or greater at 500 Hz (hertz), 1000 Hz and 2000 Hz.

C. Limited or no benefit from hearing aids unless hearing aids are unreasonable, defined as scores less than 50 percent correct on tape recorded sets of open-set sentence recognition in the ear selected for implantation.

D. Meets all of the following (1. and 2.):

1. All of the following in the ear selected for implantation (a. – c.):
    a. Low frequency hearing thresholds no poorer than 60 dB hearing level up to and including 500 Hz (averaged over 125, 250, and 500 Hz; i.e., threshold average of 125, 250, and 500 Hz less than or equal to 60 dB hearing level); and
    b. Severe to profound mid-to-high frequency hearing loss (threshold average of 2000, 3000, and 4000 Hz greater than or equal to 75 dB hearing level); and
    c. Aided consonant-nucleus-consonant word recognition score from 10 percent to 60 percent in the preoperative aided condition.
2. All of the following for the contralateral ear (a and b):
    a. Moderately severe to profound mid-to-high frequency hearing loss (threshold average of 2000, 3000, and 4000 Hz greater than or equal to 60 dB hearing level); and
    b. Aided consonant-nucleus-consonant word recognition score equal to or better than that of the ear selected for implantation but not more than 80 percent correct.

E. Implanted device is FDA approved PMA or 510(k) only.

F. Does not have any of the following contraindications:

1. Deafness due to lesions of the acoustic nerve (eighth cranial nerve), central auditory pathways, or brain stem in the implanted ear
2. Active or chronic infections of the external or middle ear and mastoid cavity in

the implanted ear, including but not limited to otitis media

3. Tympanic membrane perforation
4. Radiographic evidence of absent cochlear development in the implanted ear
5. Inability or lack of willingness to participate in post-implantation aural rehabilitation
6. A duration of severe to profound hearing loss of 30 years or greater.

III. **For individuals with unilateral hearing loss (single sided deafness), unilateral implantation of cochlear implant, *other than*** cochlear implant/hearing aid ***hybrid*** devices, and associated rehabilitation may be considered **medically necessary** when all of the following criteria (A. - F.) are met:

A. Five years of age or older.

B. Profound sensorineural hearing loss in one ear (defined as having a pure-tone average of 90dB hearing loss or greater at 500 Hz, 1000 Hz, 2000 Hz and 4000 Hz.)

C. One of the following in the contralateral ear (1. or 2.):

1. Normal hearing or mild sensorineural hearing loss in the contralateral ear. Normal hearing is defined as having a PTA of up to 15 dB Hearing Loss at 500 Hz, 1000 Hz, 2000 Hz and 4000 Hz. (i.e., single sided deafness); or
2. Mild to moderately severe sensorineural hearing loss in the contralateral ear, with a difference of at least 15 dB in pure tone averages (PTAs) between ears (i.e., asymmetric hearing loss).

D. Documented limited benefit from an appropriately fitted unilateral hearing aid in the ear to be implanted.

E. Implanted device is FDA approved - PMA or 510(k) only.

F. Does not have any of the following contraindications:

1. Deafness due to lesions of the acoustic nerve (eighth cranial nerve), central auditory pathways, or brain stem in the implanted ear.
2. Active or chronic infections of the external or middle ear and mastoid cavity in the implanted ear, including but not limited to otitis media.
3. Tympanic membrane perforation.
4. Radiographic evidence of absent cochlear development in the implanted ear.
5. Inability or lack of willingness to participate in post-implantation aural rehabilitation.

IV. Implantation of cochlear implants is considered **not medically necessary** when one of Criterion I. II. or III. above is not met.

V. **Implant replacement, including replacement parts or upgrades** to existing cochlear implants and/or components, may be considered **medically necessary** when components are no longer functional, or for functional devices only in the small subset of patients whose response to existing components is inadequate to the point of interfering with activities of daily living, which would include school and work.

VI. **Implant replacement, including replacement parts or upgrades** to existing cochlear implants and/or components, are considered **not medically necessary** when Criterion V. is not met, including but not limited to upgrades of existing, functioning external systems to achieve aesthetic improvement, such as smaller profile components, or a switch from a body-worn external sound processor to a behind-the-ear (BTE) model.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

A Pure Tone Average (PTA) is determined by averaging the hearing threshold levels at a set of specified frequencies: for example, 500, 1000, and 2000 Hz (PTA = 500 Hz (T)+ 1000 Hz (T) + 2000Hz (T) ÷ 3).

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- Manufacturer and Model Name of Cochlear Implant being requested
- Audiology test results

BACKGROUND

Hearing loss is rated on a scale based on the threshold of hearing sounds, measured in decibels (dB). The generally accepted range for human hearing is 0 -120 dB (where 0 dB is no sound, 120 dB is very loud). Severe hearing loss is defined as a hearing threshold of 70-90 decibels (dB) and profound hearing loss is defined as a hearing threshold of 90 dB and above. Profound unilateral sensorineural hearing loss (UHL) or single-sided deafness (SSD), is clinically unaidable hearing defined by severe-to-profound hearing thresholds with a poor word recognition ability.

A cochlear implant provides direct electrical stimulation to the auditory nerve, bypassing the usual transducer cells that are absent or nonfunctional in deaf cochlea. The basic components of a cochlear implant include both external and internal components. The external components include a microphone, an external sound processor, and an external transmitter. The internal components are implanted surgically and include an internal receiver implanted within the temporal bone, and an electrode array that extends from the receiver into the cochlea through a surgically created opening in the round window of the middle ear.

Sounds that are picked up by the microphone are carried to the external signal processor, which transforms sound into coded signals that are then transmitted transcutaneously to the

implanted internal receiver. The receiver converts the incoming signals to electrical impulses that are then conveyed to the electrode array, ultimately resulting in stimulation of the auditory nerve.

Cochlear implants may be implanted in one or both ears. Implantation in both ears can be done sequentially or simultaneously. A post-cochlear implant rehabilitation program is necessary to achieve benefit from the cochlear implant. The rehabilitation program includes development of skills in understanding running speech, recognition of consonants and vowels, and tests of speech perception ability.

REGULATORY STATUS

Note: Full FDA approval includes only Premarket Approval (PMA) and 510k approval. Devices with Investigational Device Exemption (IDE) or Humanitarian Device Exemption (HDE) are not considered fully FDA approved.

Several cochlear implants are commercially available in the United States. The FDA-labeled indications for currently marketed electrode arrays are summarized in the table below. Over the years, subsequent generations of the various components of the devices have been FDA approved, focusing on improved electrode design and speech-processing capabilities. Furthermore, smaller devices and the accumulating experience in children have resulted in broadening of the selection criteria to include children as young as 9 months.

Med El® • Maestro system • Synchrony Implant • Synchrony 2 Implant • Concerto Implant	<u>Bilateral Hearing Loss</u> <u>Adults</u>: • ≥ 18 years old • Severe to profound bilateral sensorineural hearing loss (≥70dB) • ≤40% correct Hearing in Noise test (HINT) sentences with best-sided listening condition

Manufacturer and FDA approved Cochlear Implants	Indications for Adults or Children
Sound Processors: • Sonnet • Sonnet 2 • Concerto implant • Opus • Opus 2 • Rondo 2 Predecessors: • Combi 40+ • Sonata • Pulsar	<u>Children:</u> • 12 months to 18 years with profound sensorineural hearing loss (≥90dB) • In younger children, little or no benefit is defined by lack of progress in the development of simple auditory skills with hearing aids over a 3-6 month period • In older children, lack of aided benefit is defined as <20% correct on the MLNT or LNT depending upon the child's cognitive ability and linguistic skills • A 3-6 month trial with hearing aids is required if not previously experienced <u>Single-Sided Deafness and Asymmetric Hearing Loss</u> • ≥ 5 years old • Single-sided deafness (SSD) or asymmetric hearing loss (AHL), where: o SSD is defined as profound sensorineural hearing loss in one ear and normal hearing or mild sensorineural hearing loss in the other ear. o AHL is defined as a profound sensorineural hearing loss in one ear and mild to moderately severe sensorineural hearing loss in the other ear, with a difference of at least 15 dB in pure tone averages (PTAs) between ears. • Limited benefit from an appropriately fitted unilateral hearing aid in the ear to be implanted. • For ages 18 years-old and above, limited benefit from unilateral amplification is defined by test scores of 5% correct or less on monosyllabic consonant-nucleus-consonant (CNC) words in quiet when tested in the ear to be implanted alone. • For ages between 5 and 18 years-old, insufficient functional access to sound in the ear to be implanted must be determined by aided speech perception test scores of 5% or less on developmentally appropriate monosyllabic word lists when tested in the ear to be implanted alone • At least 1 month experience wearing a Contra Lateral Routing of Signal (CROS) hearing aid or other relevant device and not show any subjective benefit
Oticon Medical Neuro Cochlear Implant System (Neuro 2 sound processor and Neuro Zti implant)	<u>Adults:</u> • Severe-to-profound bilateral SNHL (≥70 dB at 500, 1000, and 2000 Hz) • Limited benefit from appropriately fit hearing aids, defined as scoring ≤50% correct HINT sentences in quiet or noise with best-sided listening condition
HYBRID COCHLEAR IMPLANTS	
Cochlear®	<u>Adults:</u> • ≥ 18 years old • Residual low-frequency hearing sensitivity

Manufacturer and FDA approved Cochlear Implants	Indications for Adults or Children
• Nucleus® Hybrid™ L24 Cochlear Implant (Nucleus 6)	• Severe to profound high-frequency sensorineural hearing loss • Limited benefit from appropriately fit bilateral hearing aids
Med El® • Med EL EAS™	Adults: • ≥ 18 years old • Residual low-frequency hearing sensitivity • Severe to profound high-frequency sensorineural hearing loss • Candidates should go through a suitable hearing aid trial, unless already appropriately fit with hearing aids
RECENTLY FDA-APPROVED DEVICES	
• New devices that come onto the market are added to the policy at policy updates. In the interim, new devices may be approved for coverage for FDA-approved indications when applicable criteria are met.**	

*Note: Cochlear, Ltd. voluntarily recalled the Nucleus CI500 range in September 2011 for device malfunction in the CI512 implant. The external Nucleus 5 sound processor is not a part of the recall. Advanced Bionics HiRes90K was voluntarily recalled in November 2010 and given FDA-approval for re-entry to market the device in September 2011.
** FDA-approved indications can be found by searching by device name in the FDA 510(k) Premarket Notification Database or the De Novo Database and viewing the Summary.

While cochlear implants have typically been used mono laterally, in recent years, interest in bilateral cochlear implantation has arisen. The proposed benefits of bilateral cochlear implants are to improve understanding of speech in noise and localization of sounds. Improvements in speech intelligibility may occur with bilateral cochlear implants through binaural summation; i.e., signal processing of sound input from two sides may provide a better representation of sound and allow one to separate out noise from speech. Speech intelligibility and localization of sound or spatial hearing may also be improved with head shadow and squelch effects, i.e., the ear that is closest to the noise will be received at a different frequency and with different intensity, allowing one to sort out noise and identify the direction of sound. Bilateral cochlear implantation may be performed independently with separate implants and speech processors in each ear or with a single processor. However, no single processor for bilateral cochlear implantation has been FDA approved for use in the United States. In addition, single processors do not provide binaural benefit and may impair localization and increase the signal to noise ratio received by the cochlear implant.

In March 2014, FDA approved the Nucleus® Hybrid™ L24 Cochlear Implant System (Cochlear Corporation) through the premarket approval process.[1] This system is a hybrid cochlear implant and hearing aid, with the hearing aid integrated into the external sound processor of the cochlear implant. It is indicated for unilateral use in patients aged 18 years and older who have residual low-frequency hearing sensitivity and severe to profound high-frequency sensorineural hearing loss, and who obtain limited benefit from appropriately fit bilateral hearing aid. The electrode array inserted into the cochlea is shorter than conventional cochlear implants. According to the FDA's premarket approval notification, labeled indications for the device include:

- Preoperative hearing in the range from normal to moderate hearing loss (HL) in the low frequencies (thresholds no poorer than 60 dB HL up to and including 500 Hz).

- Preoperative hearing with severe to profound mid- to high-frequency hearing loss (threshold average of 2000, 3000, and 4000 Hz ≥75 dB HL) in the ear to be implanted.
- Preoperative hearing with moderately severe to profound mid- to high-frequency hearing loss (threshold average of 2000, 3000, and 4000 Hz ≥60 dB HL) in the contralateral ear.
- Consonant-Nucleus-Consonant (CNC) word recognition score between 10% to 60% (inclusively) in the ear to be implanted in the preoperative aided condition and in the contralateral ear equal to or better than that of the ear to be implanted but not more than 80% correct.

In January 2022, the FDA approved to expand the indication for the Nucleus 24 Cochlear Implant System to individuals aged 5 years and older with single-sided deafness (SSD) or asymmetrical hearing loss (AHL).[2]

> According to the FDA's summary of safety and effectiveness data, approval was based on unpublished data in 42 adults from a feasibility study (n=10) and real-world data from two cochlear implantation centers (n=32). Study interpretation is limited by small sample size in adult subjects only, unclear rationale for the efficacy threshold, and missing data. The FDA has required Cochlear Americas to conduct a postmarketing study to continue to assess the safety and efficacy of the implant in a new enrollment cohort of adults and children. (P970051/S205).

In September 2016, FDA approved the Med EL EAS™ (Electric Acoustic Stimulation) Hearing Implant System (Med EL Corp.).[3] This system is a hybrid cochlear implant and hearing aid, with the hearing aid integrated into the external sound processor of the cochlear implant. It is the combination of the SYNCHRONY cochlear implant and the SONNET EAS audio processor. According to the FDA's premarket approval notification:[4]

> The MED-EL EAS System is indicated for partially deaf individuals aged 18 years and older who have residual hearing sensitivity in the low frequencies sloping to a severe/profound sensorineural hearing loss in the mid to high frequencies, and who obtain minimal benefit from conventional acoustic amplification. Typical preoperative hearing of candidates ranges from normal hearing to moderate sensorineural hearing loss in the low frequencies (thresholds no poorer than 65 dB HL up to and including 500 Hz) with severe to profound mid- to high-frequency hearing loss (no better than 70 dB HL at 2000 Hz and above) in the ear to be implanted. For the non-implanted ear, thresholds may be worse than the criteria for the implanted ear, but may not be better. The CNC word recognition score in quiet in the best-aided condition will be 60% or less, in the ear to be implanted and in the contralateral ear. Prospective candidates should go through a suitable hearing aid trial, unless already appropriately fit with hearing aids.

In July 2019, the FDA expanded indications for the MED-EL Cochlear Implant System to include SSD and AHL.[5]

> The indications for use are as follows: The MED-EL Cochlear Implant System is indicated for evoking auditory sensations via electrical stimulation of the auditory pathways for individuals ages 5 years and above with single-sided deafness (SSD) or asymmetric hearing loss (AHL), where: SSD is defined as profound sensorineural hearing loss in one ear and normal hearing or mild sensorineural hearing loss in the other ear. AHL is defined as a profound sensorineural hearing loss in one ear and mild to moderately severe sensorineural hearing loss in the other ear, with a difference of at least 15 dB in pure tone averages (PTAs) between ears. Profound hearing loss is

defined as having a PTA of 90 dB HL or greater at 500 Hz, 1000 Hz, 2000 Hz and 4000 Hz. Normal hearing is defined as having a PTA of up to 15 dB HL at 500 Hz, 1000 Hz, 2000 Hz and 4000 Hz. Mild hearing loss is defined as having a PTA of up to 30 dB HL at 500 Hz, 1000 Hz, 2000 Hz and 4000 Hz. Mild to moderately severe hearing loss is defined as having a PTA ranging from 31 to up to 55 dB HL at 500 Hz, 1000 Hz, 2000 Hz and 4000 Hz. Individuals with SSD or AHL must obtain limited benefit from an appropriately fitted unilateral hearing aid in the ear to be implanted. For individuals ages 18 years-old and above, limited benefit from unilateral amplification is defined by test scores of five (5) percent correct or less on monosyllabic consonant-nucleus-consonant (CNC) words in quiet when tested in the ear to be implanted alone. For individuals between 5 and 18 years-old, insufficient functional access to sound in the ear to be implanted.

EVIDENCE SUMMARY

Cochlear implants (CI) are recognized effective treatment of sensorineural deafness in select patient, as noted in a 1995 National Institutes of Health Consensus Development conference, which offered the following conclusions:[6]

- Cochlear implantation has a profound impact on hearing and speech reception in postlingually deafened adults with positive impacts on psychological and social functioning.
- The results are more variable in children. Benefits are not realized immediately but rather are manifested over time, with some children continuing to show improvement over several years.
- Prelingually deafened adults may also benefit, although to a lesser extent than postlingually deafened adults. These individuals achieve minimal improvement in speech recognition skills. However, other basic benefits, such as improved sound awareness, may meet safety needs.
- Training and educational intervention are fundamental for optimal post implant benefit.
- Cochlear implants in children under two years old are complicated by the inability to perform detailed assessment of hearing and functional communication. However, a younger age of implantation may limit the negative consequences of auditory deprivation and may allow more efficient acquisition of speech and language. Some children with post-meningitis hearing loss have been implanted under the age of two years due to the risk of new bone formation associated with meningitis, which may preclude a cochlear implant at a later date.

ENLARGED VESTIBULAR AQUEDUCTS (EVA)

Enlarged vestibular aqueduct (also known as enlarged vestibular aqueduct syndrome (EVAS), large vestibular aqueduct, large vestibular aqueduct syndrome (LVAS), or dilated vestibular aqueduct) is a condition which is associated with childhood hearing loss. According to the NIH National Institute on Deafness and other Communication Disorders (NIDCD):[7] most children with enlarged vestibular aqueducts (EVA) will develop some amount of hearing loss, and approximately 5 to 15% of children with sensorineural hearing loss (hearing loss caused by damage to sensory cells inside the cochlea) have EVA.

Systematic Reviews

Alahmadi (2022) published a systematic review (SR) evaluating the surgical and clinical outcomes of cochlear implant among patients with EVA.[8] Of the 4035 subjects (34 studies)

included, 853 (21.14%) underwent cochlear implantation. Unilateral implantation was performed in 258 cases while bilateral in 119 subjects. Postoperative complications included CSF/perilymph gusher (n = 112), CSF oozing (n = 18), and partial electrode insertion (n = 6). Closing the cochleostomy with temporalis fascia, muscle, connective tissue, or fibrin glue was the most frequently reported approach to manage CSF/perilymph gusher (n = 67, 56.7%) while packing was performed in six patients. The authors conclude that patients with EVA demonstrated audiometric and speech performance improvement after CI. However, many patients had intra- or postoperative complications.

Hansen (2022) published a SR to evaluate the age at implantation, improvement in hearing and speech perception outcomes, as well as surgical complications in pediatric cochlear implant recipients with Pendred Syndrome (PS) or non-syndromic enlarged vestibular aqueduct (NSEVA). A total of 55 studies were included in the analysis. The authors reported that the four-frequency pure-tone audiogram average improved by 60 to 78 dB HL due to cochlear implantation (in 46 studies with audiogram results). Auditory performance and speech intelligibility scores increased by 44%. The overall average implantation age was 60 months. Perilymph gusher/oozing was the most common surgical incident reported, occurring in 187 of 1572 implantations. The authors conclude that in children with PS/NSEVA, cochlear implantation improves pure-tone average by 60 to 78 dB HL and capacity of auditory performance/speech intelligibility by 44%. The implantation age for these children has decreased during the last two decades but is still somewhat higher than reported for unselected pediatric cochlear implantation.

Pan (2022) reported a SR and meta-analysis of the safety and effectiveness of cochlear implantation for patients with large vestibular aqueduct deformity.[9] A total of five randomized controlled trials met inclusion criteria. There was low to high risk of bias for blinding of participants and personnel and low or unclear risk of bias for the other evaluated biases. Meta-analysis evaluated postoperative hearing ability and speech intelligibility rate between EVA patients and those with normal inner ear structure. No significant differences between groups were identified.

In 2014, Xu conducted a SR in Chinese to assess the efficacy and safety of cochlear implantation in deaf patients with inner ear malformations compared to deaf patients with normal inner ear structure, including 11 RTCs (n=655 patients).[10] In terms of postoperative complications, electrode impedance, behavior T-level, hearing abilities and speech discrimination; patients with mixed inner ear malformations, Mondini syndrome or EVA were not significantly different than controls. However, the reviewers concluded that additional larger controlled studies with longer follow-up may help to evaluate the efficacy of cochlear implantation for deaf patients with inner ear malformation more reliably.

Pakdaman (2012) conducted a SR to determine if abnormal cochleovestibular anatomy influences surgical and audiologic outcomes following cochlear implant (CI) surgery in children, including 22 studies.[11] Out of the 311 children included, 89 (29%) were diagnosed with EVA, considered to be a mild/moderate anomaly. Outcomes of CI surgery were analyzed based on the severity of the ear malformation (mild/moderate anomaly versus severe), and subgroup analyses were not performed based on the different malformations observed. The reviewers reported that severe inner ear dysplasia was associated with increased surgical difficulty and lower speech perception.

Nonrandomized Studies

There have been a number of case series and retrospective analyses published on the efficacy of cochlear implants in patients with EVA, all generally reporting an improvement of outcomes including various clinical scores for hearing improvement and scores measuring quality of life. These studies range in size from three to 47 cases.[12-22] Some of these studies have focused on pediatric patients, while others have included mixed patient populations and have not analyzed pediatric patients from adults in terms of outcomes. Overall, these studies report that outcomes in EVA patients are comparable to cochlear implant patients with no malformations, including similar risk of cerebrospinal fluid (CSF) gusher during cochlear implantation.

There is research indicating that the age of cochlear implantation for patients with EVA affects health outcomes. In 2013, Ko conducted a study (1) to assess health outcomes of Mandarin-speaking patients with EVA after cochlear implantation (CI); (2) to compare their performance with a group of CI users without EVA; (3) to understand the effects of age at implantation and duration of implant use on the CI outcomes.[23] Forty-two patients with EVA participating in this study were divided into two groups: the early group received CI before five years of age and the late group after five years of age. The patients with EVA with more than five years of implant use (18 cases) achieved a mean score higher than 80% on the most recent speech perception tests and reached the highest level on the CAP/SIR scales. The early group developed speech perception and intelligibility steadily over time, while the late group had a rapid improvement during the first year after implantation. The two groups, regardless of their age at implantation, reached a similar performance level. These patients do not necessarily need to wait until their hearing thresholds are higher than 90 dB HL or PB word score lower than 40% to receive CI. Similar results have been reported in small pediatric case series, indicating that if patients receive cochlear implants prior to becoming severely to profoundly deaf, that residual hearing is preserved.[12, 24]

In contrast to studies reporting favorable outcomes, one small retrospective study performed by Bichy in 2002 that reported better hearing outcomes in patients with EVA using hearing aid than those who had undergone cochlear implantation.[25] The analysis in this study included 16 children and adults with EVA that had undergone cochlear implantation and 10 children and adults undergoing treatment of progressive or fluctuant sensorineural hearing loss with the use of a hearing aid alone. Although the hearing aid group had a better mean pure-tone average (70.8 dB; SD 24.4) versus (107.0 dB; SD 21.7) for the cochlear implant group, the use of health utility indexes determined that greater net health benefit (including quality of life) was derived from cochlear implantation over hearing aids.

INFANTS UNDER AGE 12 MONTHS

The literature review focused on studies comparing the impact on hearing, speech development and recognition, and complication rates of implantation in infants younger than 12 months with those of older age groups. This includes the question of whether any early benefits that may occur in these very young patients later converge with those in older patients.

Systematic Reviews

Sbeih (2022) reported a SR that assessed the safety of cochlear implantation in children 12 months and younger.[26] A total of 18 studies met inclusion criteria. Major and minor complications were reported in 3.1% and 2.4% of patients, respectively. The authors noted that this is similar to rates of complications in older cohorts.

Two older SRs were identified that addressed CI in children under 12 months of age. The reviews, summarized below, reported few studies of CI in this age group compared with CI in children over one year of age. Both systematic reviews ranked the available studies as poor to fair due to heterogeneity in study participants and study designs, and high risk for potential bias. In addition, differences in outcomes between the age groups did not reach statistical significance.

In 2011 Forli reported similar findings in seven studies comparing CI implanted prior to one year of age with implantations performed after one year of age.[27] The studies precluded meta-analysis due to heterogeneity of age ranges analyzed and outcomes evaluated. While studies suggested improvements in hearing and communicative outcomes in children receiving implants prior to one year of age, between-group differences did not reach statistical significance. In addition, it is not certain whether any improvements were related to duration of cochlear implant usage rather than age of implantation. Nor is it clear whether any advantages of early implantation are retained over time.

In 2010, Vlastarakos conducted a SR of studies on bilateral cochlear implants in a total of 125 children implanted before one year of age.[28] The authors noted that follow-up times ranged from a median duration of 6 to 12 months and, while results seemed to indicate accelerated rates of improvement in implanted infants, the evidence available was limited and of lower quality. Additionally, the lack of reliable outcome measures for infants demonstrated the need for further research before cochlear implantation prior to one year of age becomes widespread.

Nonrandomized Studies

In March 2020, the FDA approved an expansion of the indications for Cochlear Americas' Nucleus 24 cochlear implant system for infants aged 9 to 12 months of age with bilateral profound sensorineural deafness who demonstrate limited benefit from appropriate binaural hearing aids. Previously, this device was approved for ages 12 months and older. According to the FDA's summary of safety and effectiveness data, approval was based on supporting evidence from a comprehensive literature review and a clinical feasibility study. The clinical feasibility study was a retrospective clinical analysis of 84 subjects implanted with cochlear implants between the ages of 9 and 12 months. Descriptive statistics were reported for time under anesthesia (unilateral: 2hrs 34min, bilateral: 4hrs 15min), estimated blood loss (unilateral: 10.75 cc, bilateral: 19.88 cc), time in recovery (unilateral: 2hr 18min, bilateral: 1hr 59min), and adverse events (Percent of subjects: 2.4% cerebral spinal fluid leak; 2.4% facial weakness; 2.4% infection; 7.1% minor post-op complication; 3.6% minor skin irritation; 3.6% otitis media; 2.4% seroma; 7.1% temperature regulation during procedure).

The supporting literature review identified 49 articles including 750 total (not necessarily unique) patients implanted with cochlear implants prior to 12 months of age. Safety results were reported on a per-study basis with no meta-analysis. Complication rates were reported between 1.5% and 10% except for two studies. One reported a rate of 29%, and the other reported on two techniques, one of which had a rate of 20.6% and the other 61.5%. Two studies compared complications across different age ranges. One reported similar complication rates across ages and the other reported higher rates for younger ages. The summary section states that the study findings support that the safety profile for cochlear implantation in pediatric patients who are implanted between 9 and 12 months of age is comparable to that of the currently approved population of age 12 months and older. Effectiveness results were reported on a per-study basis with no meta-analysis. No study

reported worse hearing outcomes for the early-implanted group and many reported significantly better outcomes for this group.

A 2017 retrospective study by Kalejaiye assessed surgical complications, operative times, and reoperation rates in 73 patients under one year of age.[30] They compared these patients, identified from the American College of Surgeons National Surgical Quality Improvement Program Pediatric database (2012-2013), with pediatric patients in the database above the age of one. They found that the patients under one year had higher readmission rates (6.9% vs. 2.7%) and longer mean operative times (191 minutes vs. 160 minutes), but no significant differences were noted in complication rate, postoperative length of stay, or reoperation rate.

In 2015, Guerzoni conducted a prospective study of 28 children with profound sensorineural hearing loss who were implanted early with cochlear implants (mean age at device activation: 13.3 months).[31] The investigators reported that at one-year follow-up, assertiveness and responsiveness scores were within the normal range of normal-hearing age-matched peers. Age at cochlear implant activation exerted a significant impact, with the highest scores associated to the youngest patients.

In 2011, Colletti reported on the 10-year results comparing 19 children with cochlear implants received between the ages of 2 to 11 months to 21 children implanted between 12-23 months and 33 children implanted between 24 to 35 months.[32] Within the first six months post-implantation, there was no significant difference among groups in Category of Auditory Performance testing but differences became significantly better in the infant group (early implantation) at the 12 and 36 month testing. Previously, Colletti reported on findings from 13 infants who had implants placed before 12 months.[33] The procedures were performed between 1998 and 2004. In this small study, the rate of receptive language growth for these early implant infants overlapped scores of normal-hearing children. This overlap was not detected for those implanted at 12 to 23 or 24 to 36 months.

In 2009 Ching published an interim report on early language outcomes of children with cochlear implants.[34] This study evaluated 16 children who had implants before 12 months of age compared to 23 who had implants after 12 months (specific time of implantation was not provided). The preliminary results demonstrated that children who received an implant before 12 months of age developed normal language skills at a rate comparable to normal-hearing children, while those with later implants performed at two standard deviations below normal. The authors noted that these results are preliminary, as there is a need to examine the effect of multiple factors on language outcomes and the rate of language development.

Johr (2008) highlighted the surgical and anesthetic considerations when performing cochlear implant surgery in very young infants.[35] This was an observational study and literature review by pediatricians at a tertiary children’s hospital in Switzerland. Surgical techniques and anesthetic management aspects of elective surgeries in small infants were analyzed in patients younger than one year of age undergoing cochlear implant surgeries. The results demonstrated that the age of the patient and the pediatric experience of the anesthesiologist, but not the duration of the surgery, are relevant risk factors. The authors concluded, “Further research is needed to provide more conclusive evidence that the performance outcome for children implanted before 12 months of age does not converge with the results of children implanted between 12 and 18 months.”

ADULTS AND CHILDREN OVER AGE 12 MONTHS; BILATERAL HEARING LOSS

Since there is sufficient evidence that bilateral and unilateral cochlear implants are safe and lead to improvements in health outcomes in adults and children over the age of twelve months with bilateral severe to profound pre- or postlingual (sensorineural) hearing loss, the evidence reviewed below will be focused on systematic reviews and randomized studies. Nonrandomized studies will not be described in detail.

Systematic Reviews

The following is a summary of the most recent SRs related to CI. These reviews included a critical analysis of the quality of the included studies. While noting the heterogeneity of the studies, and the potential for bias, these reviews found that the studies consistently reported beneficial outcomes for both bilateral and unilateral CI in select children and adults compared with no hearing devices or with conventional hearing aids.

Adults

A technology assessment published by Health Quality Ontario in 2018 evaluated bilateral cochlear implantation in adults and children in separate analyses.[36] The literature search conducted through March 2017 identified 10 studies on bilateral cochlear implantation in adults: three RCTs and seven prospective observational studies. Two of the three RCTs included data from a single RCT and compared simultaneous bilateral with unilateral cochlear implantation for severe bilateral sensorineural hearing loss. The third RCT randomized 24 adult patients with severe bilateral sensorineural hearing loss to receive bilateral implantation immediately or after a six-month waiting period. The observational studies performed within- or between-patient comparisons of bilateral cochlear implantation with unilateral cochlear implantation with or without hearing aids in the nonimplanted ear. Study quality was evaluated using the GRADE system. The quality of the RCTs was high, medium, and low and the quality of the prospective observational studies ranged from very low to low. The GRADE of evidence for adults overall was rated moderate to high. Overall, the authors concluded that bilateral cochlear implantation improved sound localization, speech perception in noise, and subjective benefits of hearing and that the safety profile was acceptable.

In a meta-analysis, McRackan (2018) examined the impact of cochlear implantation on quality of life (QOL).[37] From 14 articles with 679 CI patients who met the inclusion criteria, pooled analyses of all hearing-specific QOL measures revealed a very strong improvement in QOL after cochlear implantation (standardized mean difference [SMD]=51.77). Subset analysis of CI-specific QOL measures also showed very strong improvement (SMD=51.69). Thirteen articles with 715 patients met the criteria to evaluate associations between QOL and speech recognition. Pooled analyses showed a low positive correlation between hearing-specific QOL and word recognition in quiet (r=50.213), sentence recognition in quiet (r=50.241), and sentence recognition in noise (r=50.238). A subset analysis of CI-specific QOL showed similarly low positive correlations with word recognition in quiet (r=50.213), word recognition in noise (r=50.241), and sentence recognition in noise (r=50.255) between QOL and speech recognition ability. Using hearing-specific and CI-specific measures of QOL, patients report significantly improved QOL after cochlear implantation. This study is limited in that widely used clinical measures of speech recognition are poor predictors of patient-reported QOL with CIs.

In a meta-analysis, McRackan (2018) aimed to determine the change in general health-related quality of life (HRQOL) after cochlear implantation and association with speech recognition.[38] Twenty-two articles met criteria for meta-analysis of HRQOL improvement, but 15 (65%) were

excluded due to incomplete statistical reporting. From the seven articles with 274 CI patients that met inclusion criteria, pooled analyses showed a medium positive effect of cochlear implantation on HRQOL (SMD=0.79). Subset analysis of the HUI-3 measure showed a large effect (SMD=0.84). Nine articles with 550 CI patients met inclusion criteria for meta-analysis of correlations between non-disease specific PROMs and speech recognition after cochlear implantation (word recognition in quiet [r=0.35], sentence recognition in quiet [r=0.40], and sentence recognition in noise [r=0.32]). Some limitations are, though regularly used, HRQOL measures are not intended to measure nor do they accurately reflect the complex difficulties facing CI patients. Only a medium positive effect of cochlear implantation on HRQOL was observed along with a low correlation between non-disease specific PROMs and speech recognition. The use of such instruments in this population may underestimate the benefit of cochlear implantation.

In 2013, the authors of the 2011 AHRQ technology assessment reported the following findings of an updated systematic review of studies published through May 2012:[39]

- Unilateral cochlear implants

  Sixteen (of 42) studies were of unilateral cochlear implants. Most unilateral implant studies showed a statistically significant improvement in mean speech scores as measured by open-set sentence or multi-syllable word tests. A meta-analysis of four studies revealed a significant improvement in cochlear-implant relevant quality of life (QOL) after unilateral implantation. However, these studies varied in design and there was considerable heterogeneity observed across studies, making it difficult to compare outcomes across studies.

- Bilateral cochlear implants

  Thirteen studies reported improvement in communication-related outcomes with bilateral implantation compared with unilateral implantation and additional improvements in sound localization compared with unilateral device use or implantation only. The risk of bias varied from medium to high across studies. Based on results from at least two studies, the QOL outcomes varied across tests after bilateral implantation. A meta-analysis was not performed because of heterogeneity in design between the studies.

In 2012 and 2013 Crathorne and van Schoonhoven, respectively, published updated SRs for the National Institute for Health and Care Excellence (NICE). Included studies were from the U.S. and Europe and compared bilateral with unilateral cochlear implants. In two studies the unilateral implant group also had an acoustic hearing aid for the contralateral ear. Neither systematic review was able to conduct a meta-analysis due to the heterogeneity of the studies and the level of evidence of the studies which was rated as moderate-to-poor.

In October 2011, Berrettini published results of a systematic review of unilateral and bilateral cochlear implant effectiveness in adults.[40]

- Unilateral cochlear implants

  Eight articles on unilateral cochlear implants in advanced age patients were included. All of the studies reported benefits with cochlear implantation despite advanced age at time of implant (age 70 years or older). In six studies, results were not significantly different between younger and older patients. However, two studies reported statistically significant

inferior perceptive results (e.g., hearing in noise test and consonant nucleus consonant test) in older patients. This systematic review also examined three studies totaling 56 adults with pre-lingual deafness who received unilateral cochlear implants. The authors concluded unilateral cochlear implants provided hearing and quality-of-life benefits in prelingually deaf patients, but results were variable.

- Bilateral cochlear implants

  Thirteen articles on bilateral cochlear implants were reviewed. Sound localization improved with bilateral cochlear implants compared with monaural hearing in six studies. Significant improvements in hearing in noise and in quiet environments with bilateral implants compared with unilateral implants were reported in ten studies and seven studies, respectively. Five of the studies reviewed addressed simultaneous implantation, five studies reviewed sequential implantation, and three studies included a mix of simultaneous and sequential implantation. However, no studies compared simultaneous to sequential bilateral implantation results, and no conclusions could be made on the timing of bilateral cochlear implantation.

In June 2011 the most recent technology assessment, by the Tufts Evidence-based Practice Center for the Agency for Health Care Research and Quality (AHRQ), reported the following findings on the effectiveness of unilateral and bilateral cochlear implants (CIs) in adults:[41]

- Unilateral cochlear implants

  The assessment examined 22 studies with 30 or more patients and concluded that, while the studies reviewed were rated as poor to fair quality, unilateral cochlear implants are effective in adults with sensorineural hearing loss. Pre- and post-cochlear implant scores on multi-syllable tests and open-set sentence tests demonstrated significant gains in speech perception regardless of whether a contralateral hearing aid was used along with the cochlear implant. Additionally, the assessment found generic and disease-specific health-related quality of life improved with unilateral cochlear implants. However, the available evidence was insufficient to draw conclusions on improvements in open-set sentence test scores (i.e., >40% and ≤50% or >50% and ≤60%), and any relationship between pre-implantation patient characteristics and outcomes [e.g., age, duration of hearing impairment, Hearing in Noise Test (HINT) scores and pre- or post-linguistic deafness.]

- Bilateral cochlear implants

  The technology assessment examined 16 studies published since 2004 which were determined to be of fair to moderate quality. The assessment concluded that bilateral cochlear implants provided greater benefits in speech perception test scores, especially in noise, when compared with unilateral cochlear implants with or without contralateral hearing aids. Significant binaural head shadow benefits were noted along with some benefit in binaural summation, binaural squelch effects, and sound localization with bilateral cochlear implants. However, it was unclear if these benefits were experienced under quiet conditions, although benefits increased with longer bilateral cochlear implant usage indicating a need for longer term studies. Hearing-specific quality of life could not be assessed because only one study evaluated this outcome. Additionally, although gains were experienced in speech perception using open-set sentences or multi-syllable tests

compared with unilateral cochlear implants or unilateral listening conditions, the evidence available on simultaneous bilateral implantation was found to be insufficient. The assessment noted longer term studies are needed to further understand the benefits with bilateral cochlear implantation and identify candidacy criteria given the risks of a second surgery and the destruction of the cochlea preventing future medical intervention.

Children

Vanstrum (2023) published a SR to characterize cochlear implant (CI) outcomes in patients with a confirmed clinical diagnosis of Waardenburg Syndrome (WS) which is a genetic condition associated with moderate to profound sensorineural hearing loss.[42] Twenty articles meeting inclusion criteria provided data on 192 WS patients and 210 CIs. The mean age at CI was 3.8 years (95% confidence interval [95%CI]; 3.1-4.5 years), and the mean duration of follow up was 5.2 years (95% CI; 3.4-7.0 years). Surgical complications were rare (11/210 implants, 5.2%) where gusher was the most common complication. Cochlear Implants yielded favorable hearing outcomes in 90% (95% CI; 84-94%) of cases and appear successful for those with temporal bone anomalies ($p = 0.04$). The authors concluded that CI had favorable hearing outcomes and low rates of surgical complications and had clinical benefits in patients with WS.

Bo (2023) evaluated 15 studies to assess the effect of cochlear implantation on auditory and speech performance outcomes of children with Auditory Neuropathy Spectrum Disorder (ANSD).[43] The evidence suggested that children with ANSD who received cochlear implants appeared to achieve similar improvements in their auditory and speaking abilities as children with non-ANSD sensorineural hearing loss. According to pooled data, the categories of auditory performance, speech recognition score, speech intelligence rating score, and open-set speech perception did not significantly differ between the ANSD and sensorineural hearing loss groups.

The technology assessment published by Health Quality Ontario in 2018 discussed above regarding its findings on adult implantation identified 14 studies (all prospective observational studies) on bilateral cochlear implantation in children.[36] Two studies included both sequential and simultaneous bilateral implantation while the rest evaluated sequential only. As for adults, overall, the authors concluded that bilateral cochlear implantation improved sound localization, speech perception in noise, and subjective benefits of hearing and that the safety profile was acceptable (GRADE of evidence: moderate to high). The authors additionally concluded that bilateral cochlear implantation allowed for better language development and more vocalization in preverbal communication in children (GRADE of evidence: moderate).

In a 2015 systematic review, Fernandes evaluated 18 published studies and two dissertations that reported hearing performance outcomes for children with ANSD and cochlear implants.[44] Studies included four nonrandomized controlled studies considered high quality, five RCTs considered low quality, and 10 clinical outcome studies. Most studies (n=14) compared the speech perception in children with ANSD and cochlear implants with the speech perception in children with sensorineural hearing loss and cochlear implants. Most of these studies concluded that children with ANSD and cochlear implants developed hearing skills similar to those with sensorineural hearing loss and cochlear implants; however, these types of studies do not allow comparisons of outcomes between ANSD patients treated with cochlear implants and those treated with usual care.

In a 2014 systematic review, Lammers summarized the evidence on the effectiveness of bilateral cochlear implantation compared with unilateral implantation among children with sensorineural hearing loss.[45] The authors identified 21 studies that evaluated bilateral cochlear implantation in children, with no RCTs identified. Due to the limited number of studies, heterogeneity in outcomes and comparison groups, and high risk for bias in the studies, the authors were unable to perform pooled statistical analyses, so a best-evidence synthesis was performed. The best-evidence synthesis demonstrated that there was consistent evidence indicating the benefit of bilateral implantation for sound localization. One study demonstrated improvements in language development, although other studies found no significant improvements. The authors noted that the currently available evidence consisted solely of cohort studies that compared a bilaterally implanted group with a unilaterally implanted control group, with only one study providing a clear description of matching techniques to reduce bias.

In 2013, Eze published a systematic review comparing outcomes for cochlear implantation for children with developmental disability with those without developmental disability.[46] The authors noted that while approximately 30% to 40% of children who receive cochlear implants have developmental disability and that evidence about outcomes in this group was limited. Their review included 13 studies that compared receptive or expressive language outcomes in children with cochlear implants with and without developmental disability. The included studies were heterogeneous in terms of comparator groups and outcome measures, precluding data pooling and meta-analysis. In a structured systematic review, the authors reported that seven of the eligible studies demonstrated a significantly poor cochlear implant outcome in children with developmental disability, while the remaining studies reported no significant difference in outcomes between the groups.

Humphriss (2013) published a systematic review evaluating outcomes after cochlear implantation among pediatric patients with auditory neuropathy spectrum disorder (ANSD), a sensorineural hearing disorder characterized by abnormal auditory brainstem response with preserved cochlear hair cell function as measured by otoacoustic emissions testing.[47] The authors identified 27 studies that included an evaluation of cochlear implantation in patients with ANSD, including 15 noncomparative studies, one that compared children with ANSD who received a cochlear implant with children with ANSD with hearing aids, and 12 that compared children with ANSD who received a cochlear implant with children with severe sensorineural hearing loss who received a cochlear implant. Noncomparative studies were limited in that most (11/15) did not include a measure of speech recognition before cochlear implantation. Among the comparative studies, those comparing cochlear implantation to “usual care”, typically a hearing aid, provided the most information about effectiveness of cochlear implantation among patients with ANSD; the one small study that used this design found no significant differences between the groups. Overall, the authors suggested that further RCT evidence is needed.

Randomized Trials

In 2016, Smulder conducted a small prospective multi-center randomized trial to evaluate the benefits of bilateral implants compared to unilateral implants in adults with postlingual deafness, including 38 patients.[48] At one-year follow-up, there were no significant differences between groups on the speech-in-noise or the consonant-vowel-consonant test. The bilaterally implanted group performed significantly better when noise came from different directions ($p < 0.001$) and was better able to localize sounds ($p < 0.001$) compared to the unilaterally

implanted group. These results were consistent with the patients' self-reported hearing capabilities. The results were consistent at a two year follow up, reported in 2017.[49]

Nonrandomized Studies

Adults

Numerous case series have been published on adult patients with bilateral cochlear implants.[50-58] Most but not all studies report slight to modest improvements in sound localization and speech intelligibility with bilateral cochlear implants especially with noisy backgrounds but not necessarily in quiet environments. In addition, depression scores improved in cochlear implant patients from pre-implantation to 12 months post-treatment (geriatric depression scale improvement: 31%, 95% CI 10% to 47%) in a prospective observational study including 113 patients with postlingual hearing loss, of whom 50 were treated with cochlear implants and 63 with hearing aids.[59]

When reported, the combined use of binaural stimulation improved hearing in the range of one to four decibels or 1 to 2%. While this improvement seems slight, any improvement in hearing can be considered beneficial in the deaf. However, this improvement may not outweigh the significant risks of a second implantation. In addition, similar binaural results can be achieved with a contralateral hearing aid, assuming the contralateral ear has speech recognition ability. A number of studies have reported benefits for patients with a unilateral cochlear implant with hearing aid (HA) in the opposite ear.

Children

Several recent publications have evaluated bilateral cochlear implants in children.[60-62] These studies, ranging in size from 91 to 961 patients, generally report improved speech outcomes with bilateral implantation, compared with unilateral implantation. In a retrospective case series of 73 children and adolescents who underwent sequential bilateral cochlear implantation with a long (>five year) interval between implants, performance on the second implanted side was worse than the primary implanted side, with outcomes significantly associated with the interimplant interval.[53, 57, 63-69]

Adults and Children

Ching (2006) subsequently reported on 29 children and 21 adults with unilateral cochlear implant and a contralateral hearing aid.[51] They noted that both children and adults localized sound better with bilateral inputs.

UNILATERAL HEARING LOSS OR SINGLE SIDED DEAFNESS WITH OR WITHOUT TINNITUS

The FDA has approved the use of two cochlear implant devices in patients with single sided deafness (SSD) or unilateral hearing loss (UHL).

Systematic Reviews

Daher (2023) completed a SR to assess spatial hearing, tinnitus, and quality-of-life outcomes in adults with single-sided deafness (SSD) with cochlear implantation. A total of 36 studies evaluating CI use in 796 unique adults with SSD (51.3 ± 12.4 yr of age at time of implantation) were included. The mean duration of deafness was 6.2 ± 9.6 years. There was evidence of

improvement for speech recognition in noise using different target-to-masker spatial configurations, with the largest benefit observed for target-to-masker configurations assessing head shadow (mean,1.87-6.2 dB signal-to-noise ratio). Sound source localization, quantified as root-mean-squared error, improved with CI use (mean difference [MD], -25.3 degrees; 95% confidence interval [95% CI], -35.9 to -14.6 degrees; $p < 0.001$). Also, CI users reported a significant reduction in tinnitus severity as measured with the Tinnitus Handicap Inventory (MD, -29.97; 95% CI, -43.9 to -16.1; $p < 0.001$) and an improvement in spatial hearing abilities as measured with the Spatial, Speech, and Qualities of Hearing questionnaire (MD, 2.3; 95% CI, 1.7 to 2.8; $p < 0.001$).The authors conclude that CI use offer improvements in speech recognition in noise, sound source localization, tinnitus, and perceived quality of life in adults with SSD.

Idriss (2022) published a SR evaluating the effectiveness of cochlear implants in single-sided deafness with disabling tinnitus when conventional treatments fail to alleviate tinnitus.[70] A total of 31 studies were included and were divided into two categories according to whether tinnitus was assessed as a primary complaint or not. In all studies, cochlear implantation, evaluated using subjective validated tools, succeeded in reducing tinnitus significantly. A short-(3 months) and long-(up to 72 months) term tinnitus suppression was reported. When the cochlear implant is disactivated, complete residual tinnitus inhibition was reported to persist up to 24 h. The results followed a similar pattern in studies where tinnitus was assessed as a primary complaint or not. The results followed a similar pattern in studies where tinnitus was assessed as a primary complaint or not. The authors conclude that cochlear implantation is effective in reducing disabling tinnitus in single-sided deafness patients. The studies included were mostly observational, there was heterogeneity of assessment tools used and a small sample size.

Oh (2022) reported on a SR and meta-analysis of cochlear implantation in adults with single-sided deafness.[71] A total of 50 studies with 674 patients (3 to 45 patients meeting inclusion criteria per study) were included. Of these, 41 were prospective cohort studies, seven were retrospective cohort studies, and two were case series. A meta-analysis of speech perception outcomes, which included five studies, found a standardized mean difference (SMD) post-versus pre-implantation of 2.8 (95% CI 2.16 to 3.43), with some evidence of publication bias. A meta-analysis of QoL, which included eight studies, found a significant improvement, with an SMD of 0.68 (95% CI 0.45 to 0.91), and no evidence of publication bias. Meta-analysis of sound localization (seven studies; SMD, -1.13 [95% CI -1.68 to -0.57]), and tinnitus score reduction (seven studies; SMD -1.32 [95% CI -1.85 to -0.80]) also reported significant improvements. Limitations include the small sample sizes of included studies, imprecise definitions of single-sided deafness used across studies, and heterogeneity in outcomes measured, follow-up time frames, and etiology of single-sided deafness.

Donato (2021) published a SR with meta-analysis evaluating the efficacy of bone conduction devices and cochlear implantation in single-sided deafness, through the evaluation of speech discrimination in noise, sound localization and tinnitus suppression.[72] As a secondary outcome, patient satisfaction is also assessed. Nineteen articles with a total of 210 patients (95 patients with bone conduction devices and 115 in the cochlear implantation group) were included. Both children and adults were included. Sound localization was significantly better with CI with an average improvement of 13.9 degrees compared to an average of 2.31 degrees with BCD. For tinnitus, symptoms were decreased an average of 37.97 points for CI patients and decreased an average of 9.89 points for patients with BCD. The CI group reported statistically significant improvements overall, in ease of communication, and in

reverberation subscales. The BCD group reported statistically significant improvements for sound discrimination in noise. The authors conclude that both CI and bone conduction devices are effective in patients with single sided deafness. They also suggest that BCD should continue to be considered in the treatment of these patients because patient satisfaction is greater in environments with background noise. And that BCD is associated with a faster and more comfortable rehabilitation process.

Assouly (2021) published a systematic review of cochlear implantation for tinnitus.[73] A total of seven prospective cohort studies, with 105 total subjects (range 10 to 26) met inclusion criteria. Two studies had a moderate risk of bias and five had serious risk of bias. Due to considerable methodological and statistical heterogeneity (I^2>75%), no meta-analysis was performed. Each included study reported a statistically significant improvement in tinnitus distress (measured via questionnaire). The only reported adverse event was worsening of tinnitus loudness following implantation in one participant.

Benchetrit (2021) published a systematic review and meta-analysis evaluating audiological and patient-reported outcomes in children <18 years with single-sided deafness (SSD).[74] Twelve observational studies evaluating 119 children (mean age [standard deviation], 6.6 [4.0] years) were included. Clinically meaningful improvements in speech perception in noise (39/49 [79.6%]) and in quiet (34/42 [81.0%]) were reported. Sound localization improved significantly following implantation (mean difference [MD], -24.78°; 95% CI, -34.16° to -15.40°; I^2 = 10%). Compared to patients with congenital SSD, patients with acquired SSD and shorter duration of deafness reported greater improvements in speech and hearing quality. Patients with longer duration of deafness were also more likely to be device nonusers (MD, 6.84; 95% CI, 4.02 to 9.58).

A health technology assessment was published in 2020 to evaluate clinical benefits and harms, cost-effectiveness, budget impact, and patient preferences and values related to implantable devices for single-sided deafness and conductive or mixed hearing loss. [75] For adults and children with single-sided deafness, cochlear implantation when compared with no treatment improves speech perception in noise (% correct responses: 43% vs. 15%, p < .01; moderate grade), sound localization (localization error: 14° vs. 41°, p < .01; moderate grade), tinnitus (Visual Analog Scale, loudness: 3.5 vs. 8.5, p < .01; moderate grade), and hearing-specific quality of life (Speech Spatial and Qualities of Hearing Scale, speech: 5.8 vs. 2.6, p = .01; spatial: 5.7 vs. 2.3, p < .01; moderate grade); for children, speech and language development also improve (moderate grade). The authors conclude that based on evidence of moderate quality, cochlear implantation implants and bone-conduction implants improve functional and patient-important outcomes in adults and children with single-sided deafness and conductive or mixed hearing loss. And that among people with single-sided deafness, cochlear implants may be cost-effective compared with no intervention, but bone-conduction implants are unlikely to be.

Levy (2020) published a systematic review of cochlear implantation for tinnitus in SSD.[76] A total of 17 studies including 247 patients met inclusion criteria. The mean age was 50.2 years (range 23 to 71). Tinnitus outcomes were measured using the Tinnitus Handicap Inventory (THI). Based on six studies, an improvement of 35.4 points (95% CI -55.8 to -15.0, p<0.001) was reported. Based on 13 studies reporting on subjective improvement, with proportions weighted based on patients per study, 14.9% (CI 6.4 to 26.1) of patients reported complete resolution of tinnitus, 74.5% (CI 63.1 to 84.5) reported partial improvement; 7.6% (CI 4.1 to

12.6) of patients had no change in severity, and 3.0% (CI 1.0 to 6.7) reported worsening of their tinnitus.

A 2019 SR published by Peter identified 13 studies that met inclusion criteria and evaluated the influence of cochlear implantation on tinnitus in patients with single-sided deafness.[77] All identified studies were cohort studies. They mainly reported tinnitus questionnaire scores using the THI. Overall, of the 153 included patients, 34.2% demonstrated complete suppression, 53.7% demonstrated an improvement, 7.3% demonstrated a stable value, and 4.9% showed an increase of tinnitus. No patients reported an induction of tinnitus.

Peters (2016) and Cabral (2016) published SRs evaluating the effectiveness of cochlear implants in all ages[78] and in children[79] with unilateral hearing loss. Both reviews were inconclusive as there was significant clinical heterogeneity within the studies, primarily prospective or case series studies with small sample sizes, and the lack of high level of evidence. Both indicate the need for further research.

In 2015, van Zon published a systematic review of studies evaluating cochlear implantation for single-sided deafness or asymmetric hearing loss.[80] The authors reviewed 15 studies, nine of which (n=112 patients) were considered high enough quality to be included in data review. The authors identified no high-quality studies of cochlear implantation in this population. Data were not able to be pooled for meta-analysis due to high between-study heterogeneity, but the authors conclude that studies generally report improvements in sound localization, quality of life scores, and tinnitus after cochlear implantation, with varying results for speech perception in noise.

In 2014, Vlastarakos published a systematic review of the evidence related to cochlear implantation for single-sided deafness.[81] The authors included 17 studies, including prospective and retrospective comparative studies, case series and case reports that included 108 patients. The authors report that sound localization is improved after cochlear implantation, although statistical analysis was not included in some of the relevant studies. In most patients (95%), unilateral tinnitus improved. The authors note that most of the studies included had short follow-up times, and evaluation protocols and outcome measurements were heterogeneous.

In 2014, Blasco and Redleaf published a systematic review and meta-analysis of studies evaluating cochlear implantation for unilateral sudden deafness.[82] The review included nine studies with a total of 36 patients. In pooled analysis, subjective improvement in tinnitus occurred in 96% of patients (of 27 assessed), subjective improvement in speech understanding occurred in 100% of patients (of 16 assessed), and subjective improvement in sound localization occurred in 87% of patients (of 16 assessed). However, the small number of patients in which each outcome was assessed limits any conclusions that may be drawn.

Randomized Trials

Marx (2021) conducted a small open-label, multicenter RCT of cochlear implantation (n=25) versus initial observation and treatment abstention (n=26) in adult patients with single-sided deafness or asymmetric hearing loss following failure of prior treatment with contralateral routing of the signal (CROS) hearing aids or bone-conduction devices.[83] Primary outcomes included HRQOL, auditory-specific quality of life, and tinnitus severity as assessed after six months of treatment. Both EQ-5D visual analog scale and auditory-specific quality of life indices significantly improved in the cochlear implant arm. However, no significant difference in

overall EQ-5D descriptive component scores were noted between groups. Mean improvement was most pronounced in subjects with associated severe tinnitus. A clinical rationale for the minimum clinical improvement in quality of life (0.8 SD) was not reported. No significant difference for speech recognition in noise or horizontal localization was noted between groups at six months, indicating no significant effect on binaural hearing within this timeframe.

Peters (2021) randomized 120 adults with single-sided deafness (median duration, 1.8 years) into three treatment groups for the "Cochlear Implantation for siNGLE-sided deafness" (CINGLE) trial: cochlear implant (n=29); first bone-conduction devices, then CROS (n=45); and first CROS, then bone-conduction devices (n=46).[84] Patients with a maximum 30 dB hearing loss in the best ear and a minimum 70 dB hearing loss in the poor ear with duration of single-sided deafness between 3 months and 10 years were eligible for inclusion. After the initial cross-over period, 25 patients were allocated to bone-conduction devices, 34 patients were allocated to CROS, and 26 patients preferred no treatment. Seven patients did not receive their allocated treatment. For the primary outcome, speech perception in noise from the front, a statistically significant improvement was noted for the cochlear implant group at three and six months compared to baseline. At three months follow-up, the cochlear implant group performed significantly better than all other groups. At six months, the cochlear implant group performed significantly better than the bone-conduction devices and no treatment groups but no significant difference was observed between the cochlear implant group and the CROS group. Sound localization improved in the cochlear implant group only. All treatment groups improved on disease-specific quality of life compared to baseline. The study is limited by small sample size, device heterogeneity, loss to follow-up, and lack of allocation concealment. Study follow-up through five years is ongoing.

Nonrandomized Studies

Arras (2022) published a study comparing spatial hearing skills in children (n=47) across three groups: 12 SSD + CI (median age 4.7 years, range 3.9 to 7.7 years), 9 SSD-no CI (median age 4.8 years, range 3.9 to 7.0 years), and 26 normal hearing (median age 5.3 years, range 3.9 to 8.1 years).[85] Most SSD + CI children had approximately 3 years of experience with their CI at the time of their first assessment (median time 3.1 years). Only the child with acquired SSD had less than 2.5 years of experience with the device when first tested (1.9 years). The authors conclude that the implanted group exhibited improved speech perception in noise abilities and better sound localization skills, compared to their non-implanted peers. On average, the children wore their device approximately nine hours a day. They recommend further follow-up to understand the long-term benefit of a cochlear implant for children with prelingual SSD. The study is limited sample size and heterogeneity of the participant groups.

Brown (2022) published results from the Childhood Unilateral Hearing Loss (CUHL) prospective, single-arm trial.[86] Twenty children aged 3-12 with moderate to profound sensorineural hearing loss and poor speech perception (word score <30%) in one ear and normal hearing in the contralateral ear were enrolled. CNC word score perception in quiet improved significantly from 1% to 50% (p<.0001) at 12 months after activation. Speech perception in noise by BKB-SIN score also significantly improved by 3.6 dB in head shadow (p<.0001), 1.6 dB in summation (p=.003), and 2.5 dB in squelch (p=.0001). By 9 months, localization improved by 26°. Significant improvements were also found in SSQ speech (p=.0012), qualities of hearing (p=.0056), and spatial hearing subscales (p<.0001). Improvements in fatigue were not statistically significant. Study limitations include use of a

single-arm study design, small sample size, and incomplete comparison to best-aided hearing at baseline, including enrollment of never aided subjects.

In January of 2022, the FDA approved to expand the indication for the Nucleus 24 Cochlear Implant system to include individuals aged five years and older with single-sided deafness (SSD) or asymmetric hearing loss (AHL).[87] Data were combined from a feasibility study (n=10) and RWE (n = 32) conducted across four sites. There were 23 subjects with post-operative data available for the first co-primary endpoint, and 38 with data available for the second co-primary endpoint. The authors concluded that the effectiveness data demonstrated that for most subjects, the cochlear implant provided clinical benefit both in noise and with localization.

Benitez (2021) conducted a retrospective case review study to determine the effect of CI in patients with SSD of different age groups.[88] Twenty-three post-lingually deaf children (ages 6-12 years) and 21 adult patients with single-side deafness were included. The authors reported the results as follows: In children the most common etiology was idiopathic sensory-neural hearing loss. Children showed positive results in the Auditory Lateralization Test. In the Speech Test, word recognition in noise improved from 2% preoperatively to 61.1% at a mean follow-up of 1 year (S0 condition) in children [test with signal in CI side 60% and signal normal hearing side (plugged) 31%]. For adults, the most common etiology was idiopathic sudden sensorineural hearing loss (SNHL). Positive results in the Auditory Lateralization Test were found. With respect to the Speech Test in quiet conditions: Word recognition in noise improved from 5.7% preoperatively to 71.8% at a mean follow-up of 1 year [test with signal in CI side 68% and signal normal hearing side (plugged) 41%]. No adverse events were reported during the study period. No differences were found between children and adults in all tests in this study. The authors conclude that Cochlear implantation in post-lingually deaf adults and children with SSD can achieve a speech perception outcome comparable with CI in conventional candidates. They also note that careful patient selection and counseling regarding potential benefits are important to optimize outcomes.

Rauch (2021) published the results of a retrospective study to investigate the audiological improvement, subjective benefit (parents/caregivers and children), identify long-term non-users outcome and identify critical age of cochlear implantation in congenital SSD.[89] Children (n=11) with congenital SSD were implanted with a CI. The authors report that nine children use their CI (> 8 h/day) and two became nonusers. In children aged below 3 years and 2 months at surgery, there was a substantial long-term increase in speech discrimination and subjective benefit. Children over 4 years and 4 months at CI surgery improved partially in audiological/subjective measurements. Among children above 5 years, the SSQ score did not improve despite further slight improvement in speech discrimination long-term. The authors conclude a critical age for CI surgery below 3 years in children with congenital SSD for successful hearing rehabilitation.

Poncet-Wallet (2020) conducted a multicentered prospective, non-randomized intervention study to investigate the audiological and tinnitus outcomes of cochlear implantation (CI) in adults with single-sided deafness (SSD) and tinnitus.[90] Twenty-six patients (from six clinics) with SSD and incapacitating tinnitus (Tinnitus Handicap Inventory [THI] >58) underwent cochlear implantation. The first month of white noise stimulation triggered a significant improvement in THI scores (72±9 to 55±20, $p<0.05$). After 1 year of standard CI stimulation, 23 patients (92%) reported a significant improvement in tinnitus. This improvement started 1 to 2 months after CI and exceeded 40% improvement for 14 patients (54%). Average speech-in-

noise perception after 1 year significantly improved for the 23 patients who completed these measures. The authors conclude that CI is efficacious to reduce the handicap of patient with SSD and incapacitating tinnitus, leading to a decrease in reported tinnitus and partial restoration of binaural hearing abilities.

Dillon (2020) conducted a prospective clinical trial evaluating 20 subjects with asymmetric hearing loss (AHL), defined as a hearing loss of ≥ 70 dB HL in the ear to be implanted and between 35 and 55 dB HL in the contralateral ear.[91] Patients were required to fail initial treatment with traditional or bone-conduction hearing aids. Subjects underwent cochlear implantation with the MED-EL Synchrony Standard electrode array. Significant subjective benefit was reported by patients within one month of implantation. At the 12-month interval, spatial hearing localization was significantly improved ($p<0.001$). Masked sentence recognition was found to improve at the 12-month interval in the SoNcontra configuration ($p<0.001$), but there was no significant difference in the SoNo or SoNci spatial configurations. Subjects demonstrated a significant improvement in CNC word recognition between one and six months ($p=0.002$) and 6 and 12 months ($p=0.010$). Findings were compared with previously published data for patients in the unilateral hearing loss cohort of this study.[92] Significant main effects of cohort were found for localization performance and spatial configuration in masked sentence recognition, indicating that the magnitude of benefit for these outcomes was reduced for subjects with AHL.[91] In 2019, Dillon published a clinical update reporting on the prevalence of low-frequency hearing preservation with the use of standard long electrode arrays (MED-EL Corporation) in a subset of 25 patients (12 with unilateral hearing loss) from earlier cohorts.[93] Unaided hearing thresholds at 125 Hz were compared between the preoperative and initial activation intervals in 24 participants to assess the change in low-frequency hearing. At activation, a significant elevation in the unaided hearing thresholds at 125 Hz was noted ($p<0.001$), with the majority of subjects (n=16) demonstrating no response to stimulus. The remaining nine participants maintained an unaided low-frequency hearing threshold of ≤ 95 dB, and 5/9 participants met the fitting criterion of ≤ 80 dB for electric-acoustic stimulation (EAS) at initial activation. An additional three participants demonstrated improvement in unaided low-frequency hearing thresholds at latter monitoring intervals. It is uncertain whether identifying patients with preservation of low-frequency hearing can help predict individuals that may benefit from EAS vs standard cochlear implants.

Galvin III (2019) reported data from on FDA-approved study of cochlear implantation in 10 patients with SSD.[94] Patients were implanted with the MED-EL Concerto Flex 28 device. Speech perception in quiet and noise, localization, and tinnitus severity were measured prior to implantation at one, three, and six months postactivation. Performance was assessed with both ears (binaural), with the implanted ear alone, and the normal hearing alone. No patient had previous experience with a contralateral routing of signal (CROS) or bone conduction device (BCD) system. Mean improvement for consonant-nucleus-consonant (CNC) word recognition vs baseline was 66.8%, 76.0%, and 84.0% at one, three, and six months postactivation, respectively. The normal hearing ear performed significantly better compared to the implanted ear for all outcome measures at all intervals ($p<0.05$). Audiological performance of the implanted ear at one, three, and six months postactivation was significantly better compared to baseline ($p<0.05$), with no significant difference across postactivation intervals ($p>0.05$). The change in root mean square error (RMSE) in localization with binaural listening postactivation reduced by 6.7, 7.6, and 11.5 degrees at one, three, and six months postactivation. Binaural performance was significantly improved compared to the normal hearing ear alone at all postactivation time intervals ($p<0.05$). Tinnitus visual analog scale (VAS) scores significantly decreased with the implant on at all postactivation time intervals

(p<0.05). Significant improvements on SSQ scores were reported for the Speech (p=0.003), Spatial (p<0.001), and Quality (p=0.034) subtests. Global scores were not reported. Adverse events were reported in 5/10 participants, including facial nerve stimulation, periorbital edema, mild postoperative balance disturbance, postauricular pain, and unresolved taste disturbance. The study is limited by small sample size.

Peter (2019) published the results of a Swiss multicenter study assessing cochlear implantation for use in adult patients in post-lingual single-sided deafness, defined as a hearing loss of 70 dB hearing level (HL) in the mean thresholds of 0.5, 1, 2, and 4 kHz in the affected ear, and 25 dB HL or better in the frequencies from 125 to 2 kHz and 35 dB HL or better from 4 to 8 kHz in the normally hearing contralateral ear.[95] A total of 10 patients were evaluated. Two years post-implantation, 90% of patients used their implant regularly for an average of more than 11 hours per day. Twelve months postactivation, speech from the front and noise at the healthy ear achieved a 2.7 dB improvement (p=0.0029). Speech to the implanted ear and noise from the front achieved a 1.5 dB improvement (p=0.018). The mean sound localization error of all participants was improved by 10.2 degrees (p=0.030) at 12 months postactivation. One participant experienced a loss in low-frequency residual hearing from surgery, resulting in poorer localization performance after surgery with an increased error of 11.3 degrees. Tinnitus severity decreased significantly 12 months postactivation from 41.2 points (SD 26.5) preoperatively to 23.0 points (SD 17.5; p=0.004) on the Tinnitus Handicap Inventory (THI). Quality of life measures showed a significant improvement on the global subscale of the WHO Quality of Life questionnaire (p=0.007). The Speech, Spatial, and Qualities of Hearing Scale questionnaire (SSQ) indicated a significant improvement from 4.2 to 6 (p=0.004) in speech comprehension and from 3 to 5.3 (p=0.009) in spatial hearing. No significant difference was noted in the subscale qualities of hearing (6.2 to 6.9; p=0.13). The scores of the patients on the three subscales were significantly lower than for the normal hearing control group, with an average speech comprehension score of 8.7 (p=0.001), an average spatial hearing of 8.6 (p<0.001), and an average qualities of hearing score of 9.1 (p=0.005). Adverse events were not reported.

In July 2019, the FDA approved to expand the indication for the MED-EL Cochlear Implant System to include individuals aged five years and older with single-sided deafness (SSD) or asymmetric hearing loss (AHL). Approval was based on supporting evidence from a comprehensive literature review and a clinical feasibility study conducted at one site. In this prospective, non-blinded, repeated measures study, 40 subjects were implanted with the MED-EL CONCERT or SYNCHRONY Cochlear Implant System. Twenty patients each were enrolled into the SSD and AHL groups. All 20 patients completed testing in the SSD group. One patient withdrew from the AHL group and one patient had not yet completed follow-up at the time of data analysis. Patients were required to have previous experience of at least one month in duration with a conventional hearing aid, bone conduction device, or CROS device. Exclusion criteria included Meniere's disease with intractable vertigo, tinnitus as the primary concern for cochlear implantation, and severe or catastrophic score on the THI. Aided word recognition in the ear to be implanted was required to be 60% or less as measured with a 50-word CNC word list. Speech perception and localization were evaluated at baseline and at 1, 3, 6, 9, and 12 months post-operatively utilizing CNC word recognition and AzBio sentence tests. For patients in the AHL group, sound field testing was completed with a hearing aid in the contralateral ear. Quality of life measures included the SSQ, THI, and Abbreviated Profile of Hearing Aid Benefit (APHAB) scales. Primary effectiveness measures were comparisons of speech perception and localization performance between the bilateral, preoperative, unaided/best-aided condition and the bilateral, 12-month post-operative cochlear implant (CI) +

normal hearing (NH) or hearing aid (HA) condition. Nine device or procedure related adverse events were reported. Most frequently reported adverse events included vertigo/dizziness/imbalance (22.5%) and unrelated infection (7.5%). The data is limited by small sample size and including only adult subjects only and the effectiveness endpoints were not prespecified. Given these limitations, the clinical data collected from the UNC study are not sufficient on their own to support the generalization of the clinical outcomes to the proposed, intended adult and pediatric populations, and support the requested SSD/AHL indication expansion.

The FDA decision was further supported by a literature search yielding six publications comprising a total of 58 adults with SSD (n=50 of which implanted with MED-EL devices) and a total of 52 adults with AHL (n=37 of which implanted with MED-EL devices).[97] The candidacy criterion of ages five and older was based on a literature search yielding five publications comprising a total of 26 children with SSD (n=5 of which implanted with a MED-EL device) and a total of nine children with AHL. While the overall benefits of CI in children with SSD and AHL included improved performance in speech perception in quiet and noise, sound localization, and subjective measures of quality of life – these results are limited to primarily case series with small sample sizes, heterogeneous in methodology and outcome assessment, and at high risk of bias in self-reported measures. The FDA has required MED-EL to conduct a post-marketing study to continue to assess the safety and efficacy of the implant in a new enrollment cohort of adults and children.

Buss (2018) published the results of an FDA clinical trial that investigated the potential benefit of cochlear implant (CI) for use in adult patients with moderate-to-profound unilateral sensorineural hearing loss and normal to near-normal hearing on the other side.[92] The study population was 20 CI recipients with one normal or near-normal ear (NH) and the other met criterion for implantation (CI). All subjects received a MED-EL standard electrode array, with a full insertion based on surgeon report. They were fitted with an OPUS 2 speech processor. This group was compared to 20 normal hearing persons (control group) that were age-matched. Outcome measures included: sound localization on the horizontal plane; word recognition in quiet with the CI alone, and masked sentence recognition when the masker was presented to the front or the side of normal or near-normal hearing. The follow-up period was 12-months. While the majority of CI recipients had at least one threshold ≤ 80dB prior to implantation, only three subjects had these thresholds after surgery. For CI recipients, scores on consonant-nucleus-consonant (CNC) words in quiet in the impaired ear rose an average of 4% (0 to 24%) at the postoperative test to a mean of 55% correct (10 to 84%) with the CI alone at the 12-month test interval.

Arndt (2017) published a single center cohort study to provide evidence of successful treatment of SSD and asymmetric hearing loss with a CI compared to the untreated, monaural hearing condition and the therapy options of brain computer interface (BCI) and contralateral routing of signals (Bi)CROS devices.[98] A total of 85 patients (45 with SSD and 40 patients with asymmetric hearing loss) were treated with a CI. Monaural speech comprehension in noise and localization ability were examined with (Bi)CROS-Hearing Aid and BCI devices (on a test rod) both preoperatively and at 12 months after CI switch-on. At the same intervals, subjective evaluation of hearing ability was conducted using the Speech, Spatial and Qualities of Hearing Scale (SSQ). The authors report that binaural rehabilitation with CI was successful. Also, patients with long-term acquired deafness (>10 years) demonstrated a benefit from CI comparable to that observed in patients with shorter-term deafness.

A 2016 study from Sladen reported on a retrospective review of prospectively-collected data of short-term (six-month) follow-up for 23 adults and children with single-sided deafness from a variety of mechanisms who received a cochlear implant.[99] In the implanted ear, CNC word recognition improved significantly from pre-implantation to three months post-activation (P=0.001). However, for AzBio sentence understanding in noise (+5 dB signal-to-noise [SNR]), there was no significant improvement from pre-implantation to six months post-activation.

Also in 2016, Rahne reported on a retrospective review of four children and 17 adults with single-sided deafness treated with cochlear implants and followed for 12 months.[100] Sound localization with aided hearing improved from pre-implantation to aided hearing for all individuals. The Speech recognition threshold in noise (signal-to-noise) ratio improved from -1.95 dB (CI off, SD: 2.7 dB) to -4.0 dB after three months (SD 1.3 dB, P<0.05), with continued improvements through six months.

In 2016, Mertens reported a case series including 23 individuals who received cochlear implants for single-sided deafness with tinnitus.[101] Eligible patients had either single-sided deafness or asymmetric hearing loss and ipsilateral tinnitus. Subjects had a mean eight years of experience with their cochlear implant (range, 3 to 10 years). Patients demonstrated improvements in VAS from baseline (mean score, 8) to one month (mean score: 4; p<0.01 vs baseline) and three months (mean score: 3; p<0.01 vs baseline) after the first fitting. Tinnitus scores improved from baseline to three months post fitting (55 vs 31, p<0.05) and were stable for the remainder of follow-up.

In 2015, Ramos Macias reported results of a prospective multicenter study with repeated measures related to tinnitus, hearing, and quality of life, among 16 individuals with unilateral hearing loss and severe tinnitus who underwent cochlear implantation.[102] All patients had a severe tinnitus handicap (THI score ≥ 58%). Eight (62%) of the 13 patients who completed the six-month follow-up visit reported a lower tinnitus handicap on the THI score. Perceived loudness/annoyingness of the tinnitus was evaluated with a 10-point VAS. When the CI was on, tinnitus loudness decreased from 8.4 preoperatively to 2.6 at the six-month follow-up; 11 of 13 patients reported a change in score of three or more.

In 2015, Arndt reported outcomes for 20 children who underwent cochlear implantation for single-sided deafness, which represented a portion of their center's cohort of 32 pediatric patients with single-sided deafness who qualified for cochlear implants.[103] Repeated-measure analyses of hearing data sets were available for 13 implanted children, excluding five who had undergone surgery too recently to be evaluated and two children who were too young to be evaluated for binaural hearing benefit. There was variability in the change in localization ability across the tested children. Self- (or child-) reported hearing benefit was measured with the Speech, Spatial and Qualities of Hearing Scale (SSQ). Significant improvements were reported on the child and parent evaluations for the scale's three subcategories: speech hearing, spatial hearing, hearing quality, and total hearing.

In 2013, Hansen reported results of a prospective study of cochlear implantation for severe-to-profound single-sided sensorineural hearing loss in 29 patients, 10 of whom had single-sided deafness due to Meniere's disease.[104] Performance was compared pre- to post-implant within each subject; outcomes were measured at three-, six-, and 12-months postoperatively. Patients showed significant improvements in CNC word and AzBio sentence scores showed improvement in the implanted ear pre-and post-implant. For the 19 patients with pre- and post-

operative data available, the average improvement on CNC word score was 28% (range: -26% to 64%). The average AzBio score improvement was 40% (range: -57% to 92%).

Tavora-Vieira (2013) reported results of a prospective case series that included nine post-lingually deaf subjects with unilateral hearing loss, with or without tinnitus in the ipsilateral ear, with functional hearing in the contralateral ear, who underwent cochlear implantation.[105] Speech perception was improved for all subjects in the “cochlear implant on” state compared with the “cochlear implant off” state, and subjects with tinnitus generally reported improvement.

Section Summary

The available evidence for the use of cochlear implants in improving outcomes for patients with single sided deafness or unilateral hearing loss, with or without tinnitus includes SRs, open label RCTs with small sample sizes, two feasibility studies, prospective and retrospective studies, and two guidelines (one for adults and one for children). The FDA recently approved two devices for cochlear implantation for UHL or SSD. Two feasibility studies with single-sided deafness or asymmetric hearing loss demonstrated improvements in sound perception, sound localization, and subjective measures of quality of life compared to baseline conditions. Although data is limited to small sample sizes and heterogeneity of methodology and outcome measures, the use of cochlear implant in SSD or UHL may improve outcomes such as speech recognition in noise, sound source localization, tinnitus, and perceived quality of life in some patients.

Cochlear Restoration

The optimal timing of cochlear implantation in children is of particular interest given the strong associations between hearing and language development. While there is current research investigating the ability to restore hearing by stimulating cochlear hair cell regrowth, cochlear implantation damages the cochlea and eliminates the possibility of cochlear restoration. However, the potential to restore cochlear function is not foreseeable in the near future; therefore, if implantation of cochlear implants is felt to be most beneficial at a younger age when the nervous system is “plastic”, this potential development seems too far in the future to benefit young children who are current candidates for a cochlear implant.

HYBRID COCHLEAR IMPLANTATION

Systematic Review

Santa Maria (2014) conducted a systematic review and meta-analysis of hearing outcomes after various types of hearing-preservation cochlear implantation, including implantation hybrid devices, cochlear implantation with surgical techniques designed to preserve hearing, and the use of post-operative systemic steroids.[106] The study included 24 studies, but only two studies focused specifically on a hybrid cochlear implant system, and no specific benefit from a hybrid system was reported.

Nonrandomized Studies

The pivotal trial for the Med-EL EAS system was a prospective, multi-center, non-randomized, non-blinded, repeated measures clinical study of 73 subjects at 14 U.S. sites, implanted with either SONATA FLEX24 or a PULSAR FLEX24.[4] Final outcomes were reported in 2018 by Pillsbury.[107] Sixty-seven of 73 subjects (92%) completed outcome measures at 3, 6, and 12 months postactivation. A 30 dB or less low-frequency pure-tone average shift was experience

by 79% and 97% were able to use the acoustic unit at 12 months postactivation. In the EAS condition, 94% of subjects performed similarly or demonstrated improvement (85%) compared to preoperative performance on City University of New York sentences in noise at 12 months. Ninety-seven percent of subject performed similarly or improved (85%) on CNC words in quiet. Improvements in speech perception scores were statistically significant ($p<0.001$). The Abbreviated Profiled of Hearing Aid Benefit (APHAB) was administered preoperatively and at 12 months postactivation; 60 subjects completed the APHAB assessment at each time point. The mean score on the APHAB Global Scale improved by 30.2%, demonstrating a significant reduction in perceived disability ($p<0.001$). Thirty-five device-related adverse events were reported for 29 of 73 subjects (39.7%). The most frequently observed adverse event was profound/total loss of residual hearing, which occurred in 8 of 73 subjects (11.0%).

The pivotal trial for the Nucleus® Hybrid™ L24 Cochlear Implant System, published by Roland in 2016, was a prospective, multi-center, one-arm, non-randomized, non-blinded, repeated-measures clinical study of 50 subjects at 10 U.S. sites.[108] Performance was compared pre- to post-implant within each subject; outcomes were measured at three-, six-, and 12-months postoperatively. Post-operatively, patients' hearing was evaluated in three states: Hybrid (simultaneous electric and acoustic stimulation in the implanted ear via the Hybrid L24 including the acoustic component), Bimodal (electric stimulation only using the Hybrid L24 minus the acoustic component with contralateral acoustic stimulation), and Combined (electric and acoustic stimulation via the Hybrid L24 and contralateral acoustic stimulation). Results from the Bimodal and Combined conditions were grouped into an "Everyday Listening" category, which was not prospectively defined by the manufacturer. All 50 subjects enrolled underwent device implantation and activation. One subject had the device explanted and replaced with a standard cochlear implant between the three- and six- month follow up visit due to profound loss of low frequency hearing; an additional subject was explanted before the 12-month follow up visit and two additional subjects were explanted after 12 months. For the two primary effectiveness endpoints, CNC word-recognition score and AzBio sentence-in-noise score, a measure of sentence understanding in noisy environments, there were significant within-subject improvements from baseline to six-month follow up. The mean improvement in CNC word score was 35.7% (95% confidence interval [CI] 27.8% to 43.6%); for AzBio score, the mean improvement was 32.0% (95% CI 23.6% to 40.4%) For safety outcomes, 71 adverse events were reported, most commonly profound/total loss of hearing (occurring in 44% of subjects) with at least one adverse event occurring in 34 subjects (68%).

Five-year outcomes for the pivotal trial were reported by Roland in 2018.[109] Thirty-two out of 50 subjects (64%) enrolled in the postapproval study. Out of the 18 subjects who did not participate, six had been explanted and reimplanted with a long electrode array, two discontinued for unrelated medical reasons, two withdrew for other reasons, four declined to continue follow-up evaluations, and four chose not to participate in the postapproval study. At five years postactivation, 94% of subjects had measurable hearing and 72% continued to use electric-acoustic stimulation with functional hearing in the implanted ear, and 6% had a total loss. Changes from pre-operate hearing to six months were statistically significant ($p<0.001$), but changes six months through five years postactivation were not statistically different ($p>0.05$). Acoustic component amplification was utilized by 84% and 81% of patients at 12 and three years postactivation, respectively. Mean CNC word recognition in quiet scores were significantly improved over the preoperative condition at each postactivation interval ($p<0.001$). However, mean scores did not significantly differ after 12 months postactivation. At five years postactivation, 94% performed the same or better in unilateral CNC word scores, whereas 6% demonstrated a decline in performance. For bilateral CNC word scores, 97% performed the

same or better, whereas one subject showed a decline in performance. The Speech, Spatial, and Qualities of Hearing Questionnaire (SSQ) was implemented to measure subjective implant satisfaction and benefit. Scores significantly improved and remained stable through all postactivation intervals ($p<0.001$).

In 2016, Gantz published outcomes from a multicenter, longitudinal study evaluating outcomes with the Nucleus Hybrid S8 featuring a shorter cochlear array.[110] Eighty-seven subjects received an implant. At 12 months postactivation, five subjects had total hearing loss, whereas functional hearing was maintained by 80%. CNC word scores demonstrated 82.5% of subjects had experience a significant improvement in the hybrid condition. Improvement in speech understanding in noise were demonstrated in 55% of subjects. Fourteen patients requested implant explantation due to various reasons of dissatisfaction with the device. These patients were re-implanted with a standard-length Nucleus Freedom cochlear implant. CNC scores prior to loss of residual hearing were missing for six subjects. CNC scores following re-implantation were missing for two additional subjects. Similar or better CNC scores following re-implantation were observed in five of the six remaining subjects.

In 2015, Friedmann conducted a retrospective review that included 22 subjects implanted with a cochlear implant with either a standard electrode (n=12) or the Nucleus Hybrid L24 electrode (n=10).[111] At one year post-implant, 30% patients with the Hybrid-L and 58% patients with the standard electrode lost residual acoustic hearing resulting in a profound hearing loss in the implanted ear. The authors reported that while hearing preservation rates with the hybrid electrode tended to be better, among recipients who lost residual hearing, speech perception was better in those with the longer standard electrode.

Lenarz (2013) reported results of a prospective multi-center European study evaluating the Nucleus Hybrid™ L24 system.[112] The study enrolled 66 adults with bilateral severe-to-profound high frequency hearing loss. At one year post-operatively, 65% of subjects had significant gains in speech recognition in quiet and 73% had significant gains in noisy environments. Compared with the cochlear implant hearing alone, residual hearing significantly increased speech recognition scores.

Gifford (2013) compared hearing outcomes pre- and post-implantation for 44 adult cochlear implant recipients with preserved low-frequency hearing in two test conditions: cochlear implant plus low-frequency hearing in the contralateral plus low-frequency hearing in the contralateral ear (bimodal condition) and cochlear implant plus low-frequency hearing in both ears (best-aided condition).[113] The authors reported that there were small but statistically significant differences in improvements in adaptive sentence recognition and speech recognition in a noisy “restaurant” environment, suggesting that the presence of residual hearing is beneficial.

A small number of studies in a small number of patients suggest that a hybrid cochlear implant system is associated with improvements in hearing of speech in quiet and noise. However, there are currently no available studies that compare the use of a standard hearing aid with a hybrid cochlear implant, which would be an appropriate comparison to determine if a hybrid device improves outcomes for patients who currently have hearing loss, but might not be candidate for a cochlear implant. In addition, there is only limited data to suggest that the preservation of residual hearing associated with a hybrid device is associated with improved outcomes compared with a standard cochlear implant.

Section Summary

Prospective and retrospective studies using a single-arm, within-subjects comparison pre- and postintervention have suggested that a hybrid cochlear implant system is associated with improvements in hearing of speech in quiet and noise. For patients who have high-frequency hearing loss but preserved low-frequency hearing, the available evidence has suggested that a hybrid cochlear implant improves speech recognition better than a hearing aid alone. Some studies have suggested that a shorter cochlear implant insertion depth may be associated with preserved residual low-frequency hearing, although there is uncertainty about the potential need for reoperation following hybrid cochlear implantation if there is a loss of residual hearing. Studies reporting on long-term outcomes and results of re-implantation are lacking.

PRACTICE GUIDELINE SUMMARY

AMERICAN ACADEMY OF OTOLARYNGOLOGY- HEAD AND NECK SURGERY

In 2020, the American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS) published a revised position statement on cochlear implants. The Academy "considers unilateral and bilateral cochlear implantation as appropriate treatment for adults and children over 9 months of age with severe to profound hearing loss who have failed a trial with appropriately fit hearing aids."[114]

In 2020, the AAO-HNS published a position statement on pediatric cochlear implants.[115] The Academy states that "there is ample evidence that early cochlear implantation of children with sensorineural hearing loss (SNHL) for whom hearing aids provide inadequate access to sound is advantageous." The statement goes on to say that "Children with bilateral severe to profound SNHL (4-frequency PTA > 80 dB HL or 2-frequency PTA > 85) will not receive adequate benefit from amplification and are candidates for bilateral cochlear implantation. Children with this degree of SNHL, including infants between 6 and 12 months, should receive cochlear implants as soon as practicable."

AMERICAN ACADEMY OF AUDIOLOGY

In July 2019, the American Academy of Audiology published clinical practice guidelines on cochlear implants.[116] These guidelines include recommendations regarding cochlear implant evaluation. They recommend determining unaided air conduction and bone conduction thresholds using developmentally appropriate assessment measures. They additionally recommend determining auditory speech perception using appropriately fit amplification using developmentally appropriate assessment measures. Other recommendations are included regarding non-audiologic evaluation prior to implantation, and surgical and post-surgical roles for the audiologist.

AMERICAN COCHLEAR IMPLANT ALLIANCE TASK FORCE

In 2022 the American Cochlear Implant Alliance Task Force published two guidelines for clinical assessment and management of cochlear implantation for SSD. One for adults [117] and a separate guideline for children.[118] The guidelines for adults with SSD has16 recommendations for preoperative evaluation and post-activation assessment and management of adults with SSD, including:

1. It is recommended that individuals with sudden and/or rapid progression of SSD undergo standard medical workup and monitoring to determine if the hearing spontaneously improves or is recoverable with treatment, and that cochlear implantation should not occur earlier than 3 to 6 months after the sudden hearing loss to allow ample time for potential recovery of hearing. The potential exception to this is cases exhibiting evidence of progressive ossification (e.g., meningitis, after vestibular schwannoma resection, otic capsule fracture) where early implantation may be advantageous.

2. Consideration of the potential for significant bilateral hearing loss is warranted, as well as the benefits of early implantation of the impaired hearing ear for long-term performance benefit.

The guidelines for children with SSD include 13 recommendations for preoperative evaluation and post-activation assessment and management of adults with SSD, including:1. Cochlear implantation to address SSD in an ear with cochlear nerve deficiency is contraindicated. Accurate diagnosis of nerve deficiency is important because it is present in almost half of children with SSD. Therefore, high resolution 3D MRI of the internal auditory canals is recommended rather than computer tomography alone.

2. Cochlear implantation should be considered a priority for children at risk of hearing loss progression in the better hearing ear. Children with SSD due to bacterial meningitis should be implanted promptly.

3. Younger age at implantation is expected to be advantageous in children with SSD. Children with longer lengths of deafness may experience fewer benefits and should be counseled as such. The impact of age and length of deafness is not yet fully understood in this population.

4.A CI evaluation is recommended for children with a unilateral three frequency pure tone average (3FPTA) of >60 dB HL and/or an aided SII < 0.65 because these children are unlikely to receive adequate benefit from traditional amplification.

SUMMARY

There is enough research to show that cochlear implants improve health outcomes, specifically, speech reception (especially in noise) and sound localization, for some patients who have severe to profound bilateral sensorineural hearing loss. Therefore, cochlear implants may be considered medically necessary in specific patients with bilateral hearing loss who meet the policy criteria.

The current research on cochlear implantation in patients diagnosed with enlarged vestibular aqueducts (EVA) has limitations. Despite these limitations, there is enough research to show that cochlear implants improve health outcomes, specifically, speech recognition, for patients with EVA. In addition, early placement of cochlear implants avoids atrophy and preserves hearing patients with EVA with moderate hearing loss. Therefore, cochlear implants may be considered medically necessary in patients with EVA when policy criteria are met.

The current research on hybrid cochlear implant/hearing aid systems has limitations. Despite these limitations, there is enough research to show that hybrid cochlear implant/hearing aid

systems improve health outcomes, specifically, speech recognition, for patients aged 18 years or older who have high frequency sensorineural hearing loss with preserved low frequency hearing. Therefore, hybrid cochlear implant/hearing aid systems may be considered medically necessary in specific patients with high frequency sensorineural hearing loss with preserved low frequency hearing who meet the policy criteria.

There are currently no cochlear implants that have approval from the U.S. Food and Drug Administration (FDA) for use in patients who are younger than 9 months of age. There is not enough research to show that cochlear implants improve health outcomes in patients younger than 9 months of age and it is unclear that the benefits of early cochlear implantation outweigh the risk of surgery and anesthesia in these very young patients. In addition, there are no clinical practice guidelines from U.S. professional societies that recommend cochlear implantation in these very young patients. Therefore, cochlear implantation in patients younger than 9 months of age is considered not medically necessary.

The current research on cochlear implantation in patients diagnosed with unilateral hearing loss (UHL) including single sided deafness (SSD) or Asymmetric Hearing Loss (AHL) has limitations. Despite these limitations, there is enough research to show that cochlear implants improve health outcomes for patients with UHL. Therefore, cochlear implants may be considered medically necessary in patients with UHL when policy criteria are met.

Bilateral or unilateral cochlear implants and hybrid cochlear implant/hearing aid systems do not improve health outcomes in all people with hearing loss, bilateral or single sided. Therefore, cochlear implants and hybrid cochlear implant/hearing aid systems, bilateral or unilateral, are considered not medically necessary when the policy criteria are not met.

Implant replacement, including replacement parts or upgrades to existing cochlear implants and/or components may be considered medically necessary only in those patients whose response to the existing device is inadequate to the point of interfering with activities of daily living, including school or work. Replacement of an existing cochlear implant device is considered not medically necessary when the policy criteria are not met.

Cosmetic and Reconstructive Procedures

Effective: April 1, 2024

Next Review: May 2024
Last Review: February 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Cosmetic procedures are performed to alter or reshape normal body structures in order to improve appearance.

Reconstructive surgery is primarily performed to improve or correct a functional impairment.

NOTE: This policy is not intended to address treatment of gender dysphoria which is addressed in the Gender Affirming Interventions for Gender Dysphoria medical policy, Medicine, Policy No. 153, which may be applicable.

MEDICAL POLICY CRITERIA

Notes:

- Many member contracts have very specific language regarding covered reconstructive services and excluded cosmetic procedures. Specific member contract language has precedence over medical policy, and requests for coverage of potentially cosmetic services should be reviewed by applicable member contract language.
- Specific services may be addressed in separate medical policies. Please see cross references below.

I. The following criteria may be applied when member contract language is not specific:

A. If the intervention is intended to treat a functional impairment and if no other contract exclusions apply, it may be considered **medically necessary**.

B. If the intervention is not intended to treat a functional impairment, the cause of the condition must be determined, for example, accident/injury/trauma, post-treatment, congenital anomaly, disease. If the cause is included in the definition of reconstructive services in the benefits contract language, then the treatment may be covered.

C. If the intervention is not intended to treat a functional impairment, the cause of the condition must be determined, for example, accident/injury/trauma, post-treatment, congenital anomaly, disease. If the cause is *not* included in the definition of reconstructive services in the benefits contract language, then the treatment is considered **cosmetic**.

The following flow chart may be used as a guide to interpreting benefits language.

CODES

NOTE: CPT codes 17106-17108 are used for the destruction of vascular proliferative lesions only. If the treatment does not destroy the lesion, or if a lesion is not considered a "vascular proliferative lesion" (e.g., hypervascular, hypertrophic, or keloid scars), then the treatment should not be reported using these codes. Unlisted code 17999 *(Unlisted procedure, skin, mucous membrane and subcutaneous tissue)* should be reported instead.

Codes	Number	Description
CPT	11920	Tattooing, intradermal introduction of insoluble opaque pigments to correct color defects of skin, including micropigmentation; 6.0 sq cm or less
	11921	Tattooing, intradermal introduction of insoluble opaque pigments to correct color defects of skin, including micropigmentation; 6.1 to 20.0 sq cm
	11922	Tattooing, intradermal introduction of insoluble opaque pigments to correct color defects of skin, including micropigmentation; each additional 20.0 sq cm, or part thereof
	11950	Subcutaneous injection of filling material (eg, collagen); 1 cc or less
	11951	Subcutaneous injection of filling material (eg, collagen); 1.1 to 5.0 cc
	11952	Subcutaneous injection of filling material (eg, collagen); 5.1 to 10.0 cc
	11954	Subcutaneous injection of filling material (eg, collagen); over 10.0 cc
	15769	Grafting of autologous soft tissue, other, harvested by direct excision (eg, fat, dermis, fascia)
	15771	Grafting of autologous fat harvested by liposuction technique to trunk, breasts, scalp, arms, and/or legs; 50 cc or less injectate
	15772	Grafting of autologous fat harvested by liposuction technique to trunk, breasts, scalp, arms, and/or legs; each additional 50 cc injectate, or part thereof (List separately in addition to code for primary procedure)
	15773	Grafting of autologous fat harvested by liposuction technique to face, eyelids, mouth, neck, ears, orbits, genitalia, hands, and/or feet; 25 cc or less injectate
	15774	Grafting of autologous fat harvested by liposuction technique to face, eyelids, mouth, neck, ears, orbits, genitalia, hands, and/or feet; each additional 25 cc injectate, or part thereof (List separately in addition to code for primary procedure)
	15775	Punch graft for hair transplant; 1 to 15 punch grafts
	15776	Punch graft for hair transplant; more than 15 punch grafts
	15819	Cervicoplasty
	15824	Rhytidectomy; forehead
	15825	Rhytidectomy; neck with platysmal tightening (platysmal flap, P-flap)
	15826	Rhytidectomy; glabellar frown lines
	15828	Rhytidectomy; cheek, chin and neck
	15829	Rhytidectomy; superficial musculoaponeurotic system (SMAS) flap

15832	Excision, excessive skin and subcutaneous tissue (includes lipectomy); thigh
15833	Excision, excessive skin and subcutaneous tissue (includes lipectomy); leg
15834	Excision, excessive skin and subcutaneous tissue (includes lipectomy); hip
15835	Excision, excessive skin and subcutaneous tissue (includes lipectomy); buttock
15836	Excision, excessive skin and subcutaneous tissue (includes lipectomy); arm
15837	Excision, excessive skin and subcutaneous tissue (includes lipectomy); forearm or hand
15839	Excision, excessive skin and subcutaneous tissue (includes lipectomy); other area
15876	Suction assisted lipectomy; head and neck
15877	Suction assisted lipectomy; trunk
15878	Suction assisted lipectomy; upper extremity
15879	Suction assisted lipectomy; lower extremity
17106	Destruction of cutaneous vascular proliferative lesions (eg, laser technique); less than 10 sq cm
17107	Destruction of cutaneous vascular proliferative lesions (eg, laser technique); 10.0 to 50.0 sq cm
17108	Destruction of cutaneous vascular proliferative lesions (eg, laser technique); over 50.0 sq cm
17380	Electrolysis epilation, each 30 minutes
17999	Unlisted procedure, skin, mucous membrane and subcutaneous tissue
19355	Correction of inverted nipples
21137	Reduction forehead; contouring only
21138	Reduction forehead; contouring and application of contouring material or bone graft (includes obtaining autograft)
21139	Reduction forehead; contouring and setback of anterior frontal sinus wall
21230	Graft; rib cartilage, autogenous, to face, chin, nose or ear (includes obtaining graft)
21244	Reconstruction of mandible, extraoral, with transosteal bone plate (eg, mandibular staple bone plate)
21245	Reconstruction of mandible, or maxilla, subperiosteal implant; partial
21246	Reconstruction of mandible, or maxilla, subperiosteal implant; complete
21248	Reconstruction of mandible or maxilla, endosteal implant (eg, blade, cylinder); partial
21249	Reconstruction of mandible or maxilla, endosteal implant (eg, blade, cylinder); complete
21270	Malar augmentation, prosthetic material
21280	Medial canthopexy
21282	Lateral canthopexy
21295	Reduction of masseter muscle and bone (eg, for treatment of benign masseteric hypertrophy); extraoral approach
21296	Reduction of masseter muscle and bone (eg, for treatment of benign masseteric hypertrophy); intraoral approach
26590	Repair macrodactylia, each digit
31830	Revision of tracheostomy scar
41510	Suture of tongue to lip for micrognathia (Douglas type procedure)
49250	Umbilectomy, omphalectomy, excision of umbilicus
54360	Plastic operation on penis to correct angulation
67950	Canthoplasty
67999	Unlisted procedure, eyelids
69090	Ear piercing
69300	Otoplasty, protruding ear, with or without size reduction

HCPCS	G0429	Dermal filler injection(s) for the treatment of facial lipodystrophy syndrome (LDS) (e.g., as a result of highly active antiretroviral therapy)

Medical Policy Manual Surgery, Policy No. 12.01

Panniculectomy

Effective: July 1, 2023

Next Review: May 2024
Last Review: May 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Panniculectomy refers to the removal of excess skin and subcutaneous tissue typically from the abdominal area.

MEDICAL POLICY CRITERIA

Note: Member contract language takes precedent over medical policy. Member contracts for covered services vary and may exclude weight loss surgery and all associated, services, supplies, and/or complications.

I. Panniculectomy may be considered **medically necessary** when all of the following Criteria (A.-D.) are met:

   A. Submission of photographs documenting significant pannus which hangs below the level of the pubis; and

   B. The pannus causes a chronic and persistent skin condition (e.g., intertriginous dermatitis, panniculitis, cellulitis or skin ulcerations) that is refractory to at least 3 months of medical treatment and associated with at least one episode of cellulitis requiring systemic antibiotics (oral and/or intravenous). In addition to good

hygiene practices, treatment should also include topical antifungals, topical and/or systemic corticosteroids; and

C. The pannus causes functional physical impairment documented to interfere with activities of daily living (see Policy Guidelines); and

D. Clinical documentation of stable weight for at least six months or at least 18 months after bariatric surgery.

II. Panniculectomy which does not meet the above Criteria I. is considered **cosmetic.**

III. Abdominoplasty with or without panniculectomy is considered **cosmetic**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Activities of Daily Living (ADLs) Definition: Instrumental ADLs are defined as feeding, bathing, dressing, grooming, meal preparation, household chores, and occupational tasks that are required as a daily part of job functioning.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine whether the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- The specific functional physical impairment caused by the pannus
- Front and lateral view photographs demonstrating redundant/excessive skin and the size of the pannus
- Clinical documentation about the nature and extent of the chronic and persistent skin condition that is refractory to at least three months of medical treatment [at least one episode of cellulitis requiring systemic antibiotics (oral and/or intravenous) and good hygiene practices including topical antifungals, topical and/or systemic corticosteroids]
- Any bariatric surgery procedure performed within the past three years, including date of procedure
- Clinical documentation of stable weight for at least six months or at least 18 months after bariatric surgery

CROSS REFERENCES

1. Cosmetic and Reconstructive Surgery, Surgery, Policy No. 12

BACKGROUND

This procedure is often performed after substantial weight loss as a result of bariatric surgery or diet. According to the American Society of Plastic Surgeons, “abdominoplasty, typically performed for cosmetic purposes, involves the removal of excess skin and fat from the pubis to the umbilicus or above, and may include fascial plication of the rectus muscle diastasis and a neoumbilicoplasty. Panniculectomy involves the removal of hanging excess skin/fat in a transverse or vertical wedge but does not include muscle plication, neoumbilicoplasty or flap elevation. ”[1] There is limited evidence and clinical practice guidelines which indicate when

panniculectomy may be appropriate due to functional impairment.[2, 3] Typically no functional impairment is associated with pannus development.

Pectus Excavatum and Carinatum Treatment

Effective: April 1, 2024

Next Review: May 2024
Last Review: March 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Pectus excavatum, commonly referred to as "funnel chest," is a chest wall malformation in which the sternum is depressed inward, causing midline narrowing of the thoracic cavity. In contrast, pectus carinatum describes a deformity in which there is protrusion of the anterior chest wall.

MEDICAL POLICY CRITERIA

I. Surgical repair of pectus excavatum may be considered **medically necessary** in children or adults when at least two of the following medical necessity criteria are met:

   A. Documented progression of the deformity with associated symptoms.

   B. Pulmonary function studies indicate components of restrictive airway disease.

   C. Haller index greater than 3.25 at end-inspiration. This Haller index is the ratio derived from a chest CT or magnetic resonance imaging (MRI) scan by dividing the transverse diameter by the anterior-posterior diameter.

   D. Cardiac evaluation (electrocardiogram [EKG], chest CT, and/or echocardiogram) demonstrates compression-caused mitral valve prolapse, abnormal rhythm, conduction abnormalities, or significant cardiac deformity.

II. Surgical repair of pectus excavatum that does not meet at least two of the criteria in I.A. – I. D. above is considered **not medically necessary**.

III. Surgical repair of pectus carinatum is considered **not medically necessary**.

IV. The use of orthotic braces for the treatment of pectus carinatum is considered **not medically necessary**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

CROSS REFERENCES

1. Cosmetic and Reconstructive Surgery, Surgery, Policy No. 12

BACKGROUND

Although pectus excavatum may be visually prominent, in most cases the loss of volume is not significant and does not interfere with ventilation. Pectus excavatum is occasionally associated with upper or lower airway obstruction; however, when this condition is successfully treated or resolves spontaneously, the pectus deformity may lessen or disappear. Pectus excavatum may also be associated with segmental bronchomalacia, and in some patients, cardiac function may be adversely affected. In many children, the heart is shifted leftward, and in the rare patient, cardiac function may be adversely affected.

Surgical correction of pectus excavatum is not physiologically beneficial for the vast majority of patients; surgery is most often sought due to psychological and cosmetic concerns. However, for some patients with extreme deformity, operative interventions may be indicated for functional reasons.

Pectus carinatum may also be visually prominent but is not generally associated with any respiratory or cardiac functional deficits, and surgery and bracing are typically requested for psychological and cosmetic concerns.

SUMMARY

There is enough research to show that surgical repair of pectus excavatum may improve health outcomes for individuals with the severity and functional impairment outlined in the policy criteria. Therefore, surgical repair of pectus excavatum may be considered medically necessary to when policy criteria are met.

Surgical repair of pectus excavatum is not clinically needed when the severity and functional impairment outlined in the policy criteria are not demonstrated. Therefore, when policy criteria are not met, surgical repair of pectus excavatum is considered not medically necessary.

Surgical repair or bracing of pectus carinatum is not clinically needed, as the condition is not associated with functional impairment that requires surgical intervention. Therefore, surgical repair or bracing of pectus carinatum is considered not medically necessary.

Medical Policy Manual Surgery, Policy No. 12.03

Ventral (Including Incisional) Hernia Repair

Effective: December 1, 2023

Next Review: May 2024
Last Review: July 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Ventral hernias occur in the abdomen and develop when a portion of the lining of the peritoneum pushes through a weak area of the abdominal wall fascia. This results in a protrusion which can be filled with intra-abdominal fat or intestine. An incisional hernia is a protrusion of tissue that forms in a prior surgical incision in the abdomen.

MEDICAL POLICY CRITERIA

Notes:

- Umbilical hernias have a specific ICD-10 code (K42) and should not be coded as a ventral hernia.
- Epigastric, spigelian, and lumbar hernias do not have specific ICD-10 codes and are reported by the non-specific ventral hernia code K43.
- An incarcerated hernia is defined as: a hernia in which the intraperitoneal contents are trapped or twisted within the hernia sac.
- A ventral hernia at the site of a prior surgery is considered an incisional hernia.

I. Surgical repair of a ventral (including incisional) hernia may be considered **medically necessary** in symptomatic patients when there is documentation that one or more of the following Criteria is met:
   A. Hernia associated pain of documented severity to interfere with activities of daily living (see Policy Guidelines); or
   B. Bowel obstruction or strangulation; or
   C. Incarceration; or
   D. Thinning of the overlying skin; or
   E. Loss of abdominal domain (see Policy Guidelines).

II. Surgical repair using the component separation technique (CST) may be considered **medically necessary** for a large (defined as width greater than or equal to 10 cm) midline ventral (including incisional) hernia (see Policy Guidelines).

III. Surgical repair of a ventral (including incisional) hernia is considered **not medically necessary** when Criterion I. is not met.

IV. Surgical repair of an abdominal wall defect, including a ventral or incisional hernia, using the component separation technique (CST) is considered **not medically necessary** when Criterion II. is not met.

V. Surgical repair of an asymptomatic ventral (including incisional) hernia found incidentally during surgery is considered **not medically necessary**.

VI. Surgical repair of diastasis recti is considered **cosmetic**.

VII. Abdominoplasty and related procedures, including but not limited to fascial plication, surgical imbrication, and tightening of lax fascia, are considered **cosmetic**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

- Loss of abdominal domain is defined as 50% of the abdominal viscera reside outside the abdominal cavity.[1]
- The component separation technique (CST) is based on subcutaneous lateral dissection, fasciotomy lateral to the rectus abdominis muscle, and dissection on the plane between external and internal oblique muscles with medial advancement of the block that includes the rectus muscle and its fascia. This release allows for medial advancement of the fascia and closure of up to 20 cm-wide defects in the midline area. Extraperitoneal or retrorectus placement of mesh or preparation for placement of mesh is not considered CST.
- Activities of Daily Living (ADLs) definition: ADLs are defined as feeding, bathing, dressing, grooming, meal preparation, household chores, and occupational tasks that are required as a daily part of job functioning.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and physical/chart notes
- Documentation of the impact of hernia related pain on impaired activities of daily living (ADL, including the specific ADL) and how pain impacts performance
- Current symptomology and description of associated functional physical impairment if applicable
- Diagnostic testing results as applicable to request and associated policy criteria
- Photographs as applicable to request and associated policy criteria
- If the component separation technique is being performed, documentation of the location and size of the hernia in centimeters.

CROSS REFERENCES

1. Cosmetic and Reconstructive Surgery, Surgery, Policy No. 12
2. Correct Coding Guidelines, Reimbursement Policy, Administrative, Policy No. 129

BACKGROUND

Ventral hernias are usually acquired when pressure is applied to an area of the abdomen which is weakened. They can occur spontaneously, known as a primary hernia, or at the site of a previous surgical incision, known as an incisional hernia.

Abdominal wall hernias (Epigastric, Umbilical, Lumbar and Spigelian) are defined by their anatomical location. Patients who are obese, older, under-weight, pregnant, have ascites or other factors which increase intra-abdominal pressure may be predisposed to developing abdominal hernias. Most hernias are acquired; however, the occurrence of umbilical hernias in infants is considered a congenital defect which usually resolves before the age of two. Children with persistent symptoms may require surgical repair.

Diastasis recti is defined as increased distance between the right and left rectus abdominis muscles that is created by the stretching of the collagen sheath (the linea alba) connecting the two rectus abdominis muscles. Diastasis recti is not considered a hernia as there is no fascial defect.

In general, small, asymptomatic hernias do not require surgical repair. Adults with larger symptomatic hernias should be considered for ventral hernia repair. Over time, hernia symptoms may develop and include pain, bowel obstruction, incarceration, thinning of the overlying skin, strangulation, and displacement of abdominal contents into the hernia itself, known as loss of abdominal domain.

LOSS OF ABDOMINAL DOMAIN

Loss of abdominal domain is defined as 50% of the abdominal viscera reside outside the abdominal cavity.[1]

COMPONENT SEPARATION TECHNIQUE

The component separation technique (CST) is a surgical method that may be used to repair large, complicated ventral hernias using a rectus abdominis muscle advancement flap. A defect width greater than or equal to 10 cm is classified as a large hernia by the European

Hernia Society.[2] This surgical technique is based on subcutaneous lateral dissection, fasciotomy lateral to the rectus abdominis muscle, and dissection on the plane between external and internal oblique muscles with medial advancement of the block that includes the rectus muscle and its fascia. This release allows for medial advancement of the fascia and closure of up to 20 cm-wide defects in the midline area. Mesh reinforcement is often used in recurrent repairs where the abdominal defect is too large and there is a large amount of tension on the CST repair. CST is not typically used as an initial surgical approach for small primary ventral hernia repairs.

SUMMARY

There is enough evidence to show that the surgical repair of a ventral hernia improves health outcomes for symptomatic patients meeting criteria. Therefore, surgical repair of a ventral hernia may be considered medically necessary in symptomatic patients when policy criteria are met.

The component separation technique is a method that may be used to repair large (greater than 10 centimeters) midline ventral hernias. Therefore, surgical repair of large (greater than or equal to 10 centimeters in width) midline ventral or incisional hernias using the component separation technique may be considered medically necessary. Surgical repair of an abdominal wall defect, including but not limited to ventral or incisional hernias that are less than 10 centimeters in width using the component separation technique is considered not medically necessary.

There is not sufficient evidence that surgical repair of asymptomatic ventral (including incisional) hernias improves health outcomes. Therefore, surgical repair of asymptomatic ventral (including incisional) hernias is considered not medically necessary. Surgical repair of diastasis recti, abdominoplasty, and related procedures, including but not limited to fascial plication, surgical imbrication, and tightening of lax fascia, are considered cosmetic.

CODES

NOTE:

- Laparoscopic (including robotic) or open ventral (including incisional) hernia repair may be reported with CPT codes listed below depending on the size of defect and the indication.
- The separation component (CST) is reported with CPT code 15734 when performed open. When performed by laparoscopic technique, it is reported by unlisted CPT code 49659 with reference to CPT code 15734.

Codes	Number	Description

Medical Policy Manual Surgery, Policy No. 12.05

Blepharoplasty, Repair of Blepharoptosis, and Brow Ptosis Repair

Effective: July 1, 2023

Next Review: May 2024
Last Review: May 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Blepharoplasty is a surgical procedure performed on the upper and/or lower eyelids to remove or repair excess tissue that obstructs the field of vision. Blepharoptosis repair involves repair of drooping of the eyelid and can include shortening or advancement of the elevator muscle of the eyelid. These procedures may also be performed for cosmetic purposes in the absence of visual field obstruction.

MEDICAL POLICY CRITERIA

Note: Blepharoplasty CPT codes and policy criteria do not apply to eyelid retraction.

I. One surgical session for either unilateral or bilateral blepharoplasty, repair of blepharoptosis, and/or brow ptosis repair may be considered **medically necessary** when one or more of the following Criteria is met.

   A. Blepharoplasty and repair of blepharoptosis may be considered **medically necessary** when one or more of the following Criteria (1. or 2.) is met:

1. Trichiasis, ectropion or entropion for an affected upper or lower lid when documented by lateral and full-face photographs clearly showing the affected lid(s); or
2. Anophthalmia when there is clinical documentation that the upper eyelid position interferes with the fit of a prosthesis in the socket.

B. Unilateral or bilateral upper lid blepharoplasty or repair of blepharoptosis may be considered **medically necessary** for reconstructive purposes when all of the following Criteria (1.- 4.) are met:
1. Documentation of clinically decreased vision with functional impairment due to visual field loss; and
2. Prior to manual elevation of redundant upper eyelid skin (taping), the superior visual field, in at least one eye is less than or equal to 20 degrees. Examinations may be either automated or hand drawn, but need to clearly document multiple (including central axis) specific visual points not seen; and
3. With taping of the eyelids, in at least one eye, superior visual fields improve by at least 12 degrees; and
4. Photographs taken in the pupillary plane with a primary gaze (looking straight ahead) that demonstrate pupillary obstruction in at least one eye.

C. Brow ptosis repair including open and endoscopic procedures may be considered medically necessary for reconstructive purposes when both of the following Criteria (1. and 2.) are met:
1. At least one eye meets either Criterion I.A. or I.B. above; and
2. Frontal and lateral facial photographs demonstrate the eyebrow is below the supraorbital rim.

II. Surgical session(s) in excess of one, for unilateral or bilateral blepharoplasty, repair of blepharoptosis, and/or brow ptosis repair is considered **not medically necessary**.

III. Unilateral or bilateral upper lid blepharoplasty, repair of blepharoptosis, and brow ptosis repair is considered **not medically necessary** in either of the following scenarios:
A. Criterion I. above is not met; or
B. There is documentation of unstable related disease process, such as myasthenia gravis or a thyroid condition.

IV. Blepharoplasty of the lower lids for excessive skin is considered **not medically necessary.**

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine whether the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

Trichiasis, ectropion or entropion

- Any congenital or anatomical issue causing issues with vision
- Lateral and full-face photographs

Anophthalmia

- Clinical documentation that the upper eyelid position interferes with the fit of a prosthesis in the socket

Blepharoplasty for all other reasons

- Any disease process that can affect vision (e.g. myasthenia gravis or thyroid condition) or documentation to support absence of such disease process
- Clinical documentation of functional impairment due to vision loss
- Clinical documentation of visual field testing and examinations including 0-20 degrees as well as above 20 degrees, documenting:
    - Points of vision seen and not seen (optimal), or points not seen as long as clearly identified and including points on the central axis., and
    - Proof that taping improves vision enough to meet criteria guidelines
- Clear direct frontal and lateral photographs in the pupillary plane with gaze in the primary position (looking straight ahead) that are consistent with the above visual fields and examinations
- Clinical documentation that surgical repair will be completed in one session (surgery)
- Clinical documentation to support the procedure is for the upper lid only

Brow Ptosis

- Photographs demonstrate the eyebrow is below the supraorbital rim

CROSS REFERENCES

1. Cosmetic and Reconstructive Surgery, Surgery, Policy No. 12

BACKGROUND

Functional visual impairment occurs when excess upper eyelid tissue overhangs the upper eyelid margin and results in significant superior visual field obstruction. Visual field studies (VFs) are used to determine the degree of obstruction. VFs should be measured both with and without elevation of the excess tissue to determine the extent of visual field defect at rest and the amount of improvement that may be obtained from blepharoplasty. VFs with points of vision seen and not seen is optimal; however, the plan will accept VFs with only points not seen as long as clearly identified and must include points on the central axis.

Cahill (2011) published a report by the American Academy of Ophthalmology, on functional indications for upper eyelid ptosis and blepharoplasty surgery.[1] Thirteen studies were included. The authors stated that there are certain indicators that predict surgery outcomes, including margin reflex distance of 1 (MRD(1)) of 2mm or less and superior visual field loss of at least 12 degrees or 24%.

Medical Policy Manual Surgery, Policy No. 12.28

Rhinoplasty

Effective: September 1, 2023

Next Review: May 2024
Last Review: July 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Rhinoplasty surgery reshapes the nose and is usually considered cosmetic. Reconstructive rhinoplasty may be performed to improve nasal respiratory function and/or to correct anatomic abnormalities caused by birth defects, disease or trauma.

MEDICAL POLICY CRITERIA

Notes:

- Member contracts for covered services vary. Member contracts may have specific language defining congenital and developmental anomalies. Member contract language takes precedence over medical policy.
    - A congenital anomaly is defined as an anomaly that is present at birth (e.g., cleft palate).
    - Developmental anomalies are conditions that develop some time after birth.

I. Initial or revision rhinoplasty may be considered **medically necessary** for reconstruction of a nasal deformity in only **one or more** of the following circumstances:

A. Secondary to a congenital anomaly, including but not limited to facial cleft; or

B. After tumor resection; or

C. After trauma which causes significant functional impairment, including but not limited to displaced nasal bone fracture severe enough to cause symptomatic nasal airway obstruction; or

D. Symptomatic nasal airway obstruction (i.e., difficulty breathing related to nasal passage obstruction) when all of the following Criteria (1. – 3.) are met:

1. There is significant bony obstruction of one or both nares documented by an advanced imaging modality such as computed tomography (CT) or magnetic resonance imaging (MRI); and
2. Septoplasty, vestibular stenosis, alar collapse, and/or turbinectomy surgeries are not expected to resolve the bony deformity; and
3. Nasal airway obstruction is poorly responsive to a documented six-week trial of conservative medical management (e.g., topical/nasal corticosteroids, antihistamines).

II. Excision and/or shaving of rhinophyma maybe considered **medically necessary** when there is documented evidence (i.e., imaging studies and/or anterior - posterior, lateral and inferior photographs) demonstrating functional airway obstruction).

III. Initial or revision rhinoplasty is considered a **cosmetic** procedure unless Criterion I. is met.

IV. Excision and/or shaving of rhinophyma is considered a **cosmetic** procedure unless Criterion II. is met.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine whether the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- Condition causing the need for rhinoplasty
- If not caused by congenital anomaly, including but not limited to facial cleft or tumor:
  - Computed tomography (CT), magnetic resonance imaging (MRI) or other advanced imaging documenting significant obstruction of one or both nares
  - Conservative medical management provided, timeline and outcomes
  - Any surgeries performed, with outcomes or documentation of why septoplasty, vestibular stenosis, alar collapse, and/or turbinectomy surgeries alone are not expected to resolve the nasal deformity.
- Documentation of airway obstruction for rhinophyma treatment (i.e., imaging studies and/or photographs with a minimum of one each: anterior - posterior, lateral and inferior views).

Laser Treatment for Port Wine Stains

Effective: July 1, 2023

Next Review: May 2024
Last Review: May 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Port wine stain (PWS) is a capillary malformation that begins as a pale pink flat area (macular lesion) in childhood and grows as the patient ages.

MEDICAL POLICY CRITERIA

I. Laser treatment may be considered **medically necessary** for port wine stains.

II. Destruction of cutaneous vascular lesions for removal of telangiectasias (spider veins) is considered **cosmetic**.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could our impact review and decision outcome:

Medical records related to history and physical/chart notes documenting presence of port wine stain.

CROSS REFERENCES

1. Cosmetic and Reconstructive Surgery, Surgery, Policy No. 12

BACKGROUND

Common areas for port wine stains (PWS) to appear are on the face over the areas of the first and second trigeminal nerves and the eyes or mouth. It is common to see a PWS overlying an arteriovenous, arterial or venous malformation. The abnormal blood vessels within the PWS become progressively more dilated in size, which results in the lesion becoming dark purple and elevated in some instances. Nodules and hypertrophy may develop in the soft tissue underlying the PWS. Nodules may continue to grow and can bleed easily if traumatized. PWS persists into adult life and is associated with systemic abnormalities such as glaucoma.

Treatment of a PWS in its macular stage will prevent the development of the hypertrophic component of the lesion. Laser treatment of a PWS diminishes the existing blood vessels making them smaller, fewer in number, and less likely to progress in size.

Chemical Peels

Effective: September 1, 2023

Next Review: May 2024
Last Review: July 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

A chemical peel refers to a controlled removal of varying layers of the epidermis and superficial dermis with the use of a 'wounding' agent, such as phenol or trichloroacetic acid (TCA).

MEDICAL POLICY CRITERIA

EPIDERMAL CHEMICAL PEELS

I. Epidermal chemical peels with 50 - 70% alpha hydroxy acids may be considered **medically necessary** as a treatment of active acne that has failed to respond to a trial of topical and/or oral antibiotic acne therapy.

II. Epidermal chemical peels with 50 - 70% alpha hydroxy acids are considered **not medically necessary** as a first-line treatment of active acne.

III. Epidermal chemical peels that do not meet Criterion I. or II. above, including but not limited to the treatment of photoaged skin, wrinkles, or acne scarring, are considered **cosmetic**.

DERMAL CHEMICAL PEELS

I. Dermal chemical peels may be considered **medically necessary** to treat numerous (>10) actinic keratoses or other premalignant skin lesions, when treatment of the

individual lesions becomes impractical.

II. Dermal chemical peels are considered **not medically necessary** to treat less than 10 actinic keratoses or other premalignant skin lesions.

III. Dermal chemical peels that do not meet Criterion I. or II. above, including but not limited to treatment of end-stage acne scarring, are considered **cosmetic**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

CROSS REFERENCES

1. Cosmetic and Reconstructive Surgery, Surgery, Policy No. 12

BACKGROUND

The most common indication for chemical peeling is as a treatment of photoaged skin, correcting pigmentation abnormalities, solar elastosis, and wrinkles. However, chemical peeling has also been used as a treatment for various stages of acne and multiple actinic keratoses when treatment of individual lesions is not feasible.

An epidermal peel may be used to remove fine, subtle lines, soften the appearance of enlarged pores, improve the skin texture and lighten hyper-pigmentary disorders. Multiple epidermal peels (also referred to as chemical exfoliation) may also be used in patients with active acne.

Dermal peels may be used to treat deep wrinkling, actinic damage, or actinic keratoses. Acne scarring has also been treated with dermal peels.

Reconstructive Breast Surgery/Mastopexy, and Management of Breast Implants

Effective: September 1, 2022

Next Review: August 2022
Last Review: April 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Policy provides breast reconstruction and implant management criteria based on Public Law 105-277, the Women's Health and Cancer Rights Act of 1998.

MEDICAL POLICY CRITERIA

Notes:

- Contractual limitations and exclusions may apply to both reconstructive and cosmetic procedures, to illnesses and conditions initially occurring prior to coverage, and to complications of non-covered procedures.
- For the purposes of this policy, mastectomy is defined as complete or partial, including lumpectomy.
- Some codes listed may have specific criteria to be met in other medical policies (e.g., reduction mammaplasty), or may not be considered medically necessary for any indication. See Cross References to confirm the correct policy is applied.
- This policy does not address procedures related to gender affirming interventions for gender dysphoria. See Cross References for the correct policy to be applied.

I. Reconstructive breast surgery of a diseased or injured breast may be considered **medically necessary** when either of the following criteria is met and the treating physician recommends it:

   A. After prophylactic or therapeutic mastectomy

   B. After accidental injury or trauma to the breast resulting in significant malformation

II. Reconstructive breast surgery of an unaffected breast to achieve symmetry with the contralateral breast may be considered **medically necessary** when reconstruction of the contralateral diseased or injured breast was medically necessary as defined in Criterion I. above and it is recommended by the treating physician.

III. Breast implant explantation and/or replacement may be considered **medically necessary** when the implant(s) was/were placed during reconstructive breast surgery that was medically necessary as defined in Criterion I. Explantation of implant(s) requires documentation of the original indication for implantation.

IV. Breast revision surgery, including breast implant explantation and/or replacement, following a cosmetic primary breast procedure is considered **cosmetic** when one or more of Criteria I., II., or III. is not met.

V. Mastopexy is considered **cosmetic** when medical necessity Criteria I., II., or III. are not met.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

BACKGROUND

Reconstructive breast surgery is defined as those surgical procedures which are intended to restore the normal appearance of the breast after surgery, accidental injury, or trauma. The most common indication for reconstructive breast surgery is mastectomy. In contrast, cosmetic breast surgery is defined as surgery intended to alter or enhance the appearance of a breast which does not have a significantly altered appearance due to surgery, accidental injury, or trauma. Reduction mammoplasty and surgery to alter the appearance of a congenital breast abnormality are examples of breast surgeries which may be cosmetic. (See Surgery Policy No. 60, Reduction Mammoplasty and Surgery Policy No. 12, Cosmetic and Reconstructive Surgery).The most common type of reconstructive breast surgery is insertion of a silicone gel-filled or saline-filled breast implant, either inserted immediately at the time of mastectomy -or sometime afterward in conjunction with the previous use of a tissue expander. Significant local complications of breast implants, such as contracture, may require removal of the implant. Other types of reconstruction include nipple/areola reconstruction, nipple tattooing, and/or the use of autologous tissue, such as a transverse rectus abdominis myocutaneous flap (TRAM procedure) or a latissimus dorsi flap. In addition, mastopexy, reduction mammoplasty, or

implant on the contralateral breast may be performed in order to achieve symmetry with the reconstructed breast.

POSITION STATEMENT

This policy is written to assist in interpreting Public Law 105-277, the Women's Health and Cancer Rights Act of 1998[1] which requires all health insurance carriers that cover mastectomies to also cover the following in a manner determined in consultation with the attending physician and patient:

- All stages of reconstruction of the breast on which the mastectomy was performed
- Surgery and reconstruction of the contralateral breast to produce a symmetrical appearance
- Prostheses
- Treatment of physical complications of mastectomy, including lymphedema

SUMMARY

Reconstructive breast surgery of a diseased or injured breast may be considered medically necessary after prophylactic or therapeutic mastectomy or after accidental injury or trauma to the breast resulting in significant malformation when the treating physician recommends it.

Reconstructive breast surgery of an unaffected breast to achieve symmetry with the contralateral breast may be considered medically necessary when reconstruction of the contralateral diseased or injured breast was medically necessary as defined in policy criteria and it is recommended by the treating physician.

Breast implant explantation and/or replacement may be considered medically necessary when the implant(s) was/were placed during reconstructive breast surgery that was medically necessary as defined in policy criteria.

Breast revision surgery, including breast implant explantation and/or replacement, following a cosmetic primary breast procedure is considered cosmetic when medical necessity criteria are not met.

Mastopexy is considered cosmetic when medical necessity criteria are not met.

CODES

NOTE:

- Codes 15769, 15771, and 15772 should be reported for autologous fat grafting for reconstructive breast surgery as code 20926 was deleted 1/1/2020.
- CPT codes 11950, 11951, 11952, and 11954 [subcutaneous injection of filling material (eg, collagen)], 19366 (breast flap graft other technique), 19380 (revision of reconstructed breast), and 19499 (unlisted code) are not reported for breast fat grafting.
- For autologous fat grafting ***with additional*** adipose-derived stem cells (aka, stem cell enrichment), see Cross References to confirm correct criteria is applied.

Codes	Number	Description
CPT	11920	Tattooing, intradermal introduction of insoluble opaque pigments to correct color defects of skin, including micropigmentation; 6.0 sq. cm or less
	11921	Tattooing, intradermal introduction of insoluble opaque pigments to correct color defects of skin, including micropigmentation; 6.1 to 20.0 sq cm
	11970	Replacement of tissue expander with permanent implant
	11971	Removal of tissue expander(s) without insertion of implant
	15769	Grafting of autologous soft tissue, other, harvested by direct excision (eg, fat, dermis, fascia)
	15771	Grafting of autologous fat harvested by liposuction technique to trunk, breasts, scalp, arms, and/or legs; 50 cc or less injectate
	15772	Grafting of autologous fat harvested by liposuction technique to trunk, breasts, scalp, arms, and/or legs; each additional 50 cc injectate, or part thereof (List separately in addition to code for primary procedure)
	19316	Mastopexy
	19318	Breast reduction
	19325	Breast augmentation with implant
	19328	Removal of intact breast implant
	19330	Removal of ruptured implant, including implant contents (eg, saline, silicone gel)
	19340	Insertion of breast implant on same day of mastectomy, (ie, immediate)
	19342	Insertion or replacement of breast implant on separate day from mastectomy
	19350	Nipple/areola reconstruction
	19355	Correction of inverted nipples
	19357	Tissue expander placement in breast reconstruction, including subsequent expansion(s)
	19361	Breast reconstruction; with latissimus dorsi flap
	19364	Breast reconstruction; with free flap (eg, fTRAM, DIEP, SIEA, GAP flap)
	~~19366~~	~~Breast reconstruction with other technique~~ (Deleted 01/01/2021)
	19367	Breast reconstruction; with single-pedicle transverse rectus abdominis myocutaneous (TRAM) flap
	19368	; requiring separate microvascular anastomosis (supercharging)
	19369	Breast reconstruction; with bipedicled transverse rectus abdominis myocutaneous (TRAM) flap
	19370	Revision of peri-implant capsule, breast, including capsulotomy, capsulorrhaphy, and/or partial capsulectomy
	19371	Peri-implant capsulotomy, breast, complete, including removal of all intracapsular contents
	19380	Revision of reconstructed breast (eg, significant removal of tissue, re-advancement and/or re-inset of flaps in autologous reconstruction or significant capsular revision combined with soft tissue excision in implant-based reconstruction)
		Preparation of moulage for custom breast implant

Codes	Number	Description
	19499	Unlisted procedure, breast
	L8039	Breast prosthesis, not otherwise specified
	L8600	Implantable breast prosthesis, silicone or equal
	S2066	Breast reconstruction with gluteal artery perforator (GAP) flap, including harvesting of the flap, microvascular transfer, closure of donor site and shaping the flap into a breast, unilateral
	S2067	Breast reconstruction of a single breast with "stacked" deep inferior epigastric perforator (DIEP) flap(s) and/or gluteal artery perforator (GAP) flap(s), including harvesting of the flap(s), microvascular transfer, closure of donor site(s) and shaping the flap into a breast, unilateral
	S2068	Breast reconstruction with deep inferior epigastric perforator (DIEP) flap or superficial inferior epigastric artery (SIEA) flap, including harvesting of the flap, microvascular transfer, closure of donor site and shaping the flap into a breast, unilateral

Spinal Cord and Dorsal Root Ganglion Stimulation

Effective: January 1, 2024

Next Review: April 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Standard and high-frequency spinal cord stimulation, as well as dorsal root ganglion stimulation, delivers electrical stimulation to the spinal cord using implanted electrodes to block pain sensation. Dorsal root ganglion stimulation is different from spinal cord stimulation in terms of the placement of the electrodes.

MEDICAL POLICY CRITERIA

Notes:

- Spinal cord stimulation should be initiated with a *trial period* of spinal cord stimulation with a *temporarily implanted* lead and may be followed by *permanent implantation*. This policy addresses these services as one combined episode beginning with the temporary placement.
- Please see the Regulatory Status section for a list of standard (non-high frequency), high-frequency, and dorsal root ganglion devices.

I. Spinal cord stimulation (standard or high frequency) may be considered **medically necessary** for severe and chronic refractory neuropathic pain of the trunk or limbs, *other than* critical limb ischemia, when one of the following Criteria is met:

A. Other treatment modalities (pharmacological, surgical, psychological, or physical, if applicable) have been tried and failed; or

B. Other treatment modalities are judged to be unsuitable or contraindicated.

II. Revision(s) to an existing spinal cord stimulator may be considered **medically necessary** after the device has been placed.

III. The replacement of all or part of an existing spinal cord stimulator and/or generator is considered **medically necessary** when the existing spinal cord stimulator and/or generator is malfunctioning, cannot be repaired, and is no longer under warranty.

IV. Replacement of all or part of an existing spinal cord stimulator and/or generator is considered **not medically necessary** when Criterion III. is not met.

V. Spinal cord stimulation is considered **not medically necessary** for severe and chronic refractory neuropathic pain of the trunk or limbs when Criterion I. is not met.

VI. Spinal cord stimulation is considered **investigational** for all other indications, including but not limited to treatment of the following: critical limb ischemia, cancer-related pain, central deafferentation pain (related to CNS damage from a stroke or spinal cord injury), headache including chronic cluster headaches, nociceptive pain (resulting from irritation, not damage to the nerves), postherpetic neuralgia, and visceral pain.

VII. Dorsal root ganglion stimulation may be considered **medically necessary** for severe and chronic refractory pain of the trunk or limbs due to type I or type II complex regional pain syndrome, including reflex sympathetic dystrophy or causalgia, when one of the following Criteria is met:

A. Other treatment modalities (pharmacological, surgical, psychological, or physical, if applicable) have been tried and failed; or

B. Other treatment modalities are judged to be unsuitable or contraindicated.

VIII. Revision(s) to an existing dorsal root ganglion stimulator may be considered **medically necessary** after the device has been placed.

IX. The replacement of all or part of an existing dorsal root ganglion stimulator and/or generator is considered **medically necessary** when the existing dorsal root ganglion stimulator and/or generator is malfunctioning, cannot be repaired, and is no longer under warranty.

X. Replacement of all or part of an existing dorsal root ganglion stimulator and/or generator is considered **not medically necessary** when Criterion IX. is not met.

XI. Dorsal root ganglion stimulation is considered **not medically necessary** for severe and chronic refractory pain of the trunk or limbs due to type I or type II complex regional pain syndrome, including reflex sympathetic dystrophy or causalgia, when Criterion VII. is not met.

XII. Dorsal root ganglion stimulation is considered **investigational** for all other indications, including but not limited to treatment of the following: critical limb ischemia, cancer-related pain, central deafferentation pain (related to CNS damage from a stroke or spinal cord injury), headache including chronic cluster headaches, nociceptive pain (resulting from irritation, not damage to the nerves), postherpetic neuralgia, and visceral pain.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- Current Symptomology
- Documentation of other treatment modalities (pharmacological, psychological, surgical, or physical if applicable) tried and failed or judged to be unsuitable or contraindicated

CROSS REFERENCES

2. Occipital Nerve Stimulation, Surgery, Policy No. 174
3. Implantable Peripheral Nerve Stimulation for Chronic Pain of Peripheral Nerve Origin, Surgery, Policy No. 205

BACKGROUND

Spinal cord stimulation (SCS; also called dorsal column stimulation) involves the use of low-level epidural electrical stimulation of the spinal cord dorsal columns. The neurophysiology of pain relief after SCS is uncertain but may be related to either activation of an inhibitory system or to blockage of facilitative circuits. SCS has been used in a wide variety of chronic refractory pain conditions, including pain associated with cancer, failed back pain syndromes, arachnoiditis, and complex regional pain syndrome (i.e., chronic reflex sympathetic dystrophy). There has also been interest in SCS as a treatment of critical limb ischemia, primarily in patients who are poor candidates for revascularization and in patients with refractory chest pain.

SCS devices consist of several components: (1) the lead that delivers the electrical stimulation to the spinal cord; (2) an extension wire that conducts the electrical stimulation from the power source to the lead; and (3) a power source that generates the electrical stimulation. The lead may incorporate from 4 to 8 electrodes, with 8 electrodes more commonly used for complex pain patterns. There are two basic types of power source. One type, the power source (battery), can be surgically implanted. The other, a radiofrequency receiver, is implanted, and the power source is worn externally with an antenna over the receiver. Totally implantable systems are most commonly used.

The patient's pain distribution pattern dictates at what level in the spinal cord the stimulation lead is placed. The pain pattern may influence the type of device used; for example, a lead with 8 electrodes may be selected for those with complex pain patterns or bilateral pain. Implantation of the spinal cord stimulator is typically a 2-step process. Initially, the electrode is temporarily implanted in the epidural space, allowing a trial period of stimulation. Once treatment effectiveness is confirmed (defined as at least 50% reduction in pain), the electrodes and radio-receiver/transducer are permanently implanted. Successful SCS may require extensive programming of the neurostimulators to identify the optimal electrode combinations and stimulation channels.

Traditional SCS devices use electrical stimulation with a frequency on the order of 100 to 1000 Hz. In 2015, an SCS device, using a higher frequency of electrical stimulation (10,000 Hz) than

predicate devices was approved by the U.S. Food and Drug Administration (FDA) through the premarket approval process. The high-frequency stimulation is proposed to be associated with fewer paresthesias, which are a recognized effect of SCS. In addition, in 2016, FDA approved a clinician programmer "app" that allows an SCS device to provide stimulation in "bursts" rather than at a constant rate. Burst stimulation is proposed to provide pain relief with fewer paresthesias. The burst stimulation device works in conjunction with standard SCS devices. With the newly approved app, stimulation is provided in five 500-Hz burst spikes at a rate of 40 Hz, with a pulse width of 1 ms.

Another variation on SCS stimulation is the wireless injectable stimulator. These miniaturized neurostimulators are transforaminally placed at the dorsal root ganglion (DRG) and are used to treat pain. DRG are located between spinal nerves and the spinal cord on the posterior root and are believed to play an important role in neuropathic pain perception. Two systems have received approval or clearance from FDA.

REGULATORY STATUS

A large number of neurostimulator devices, some used for spinal cord stimulation (SCS), have been approved by the U.S. Food and Drug Administration (FDA) through the premarket approval (PMA) process. Examples of fully implantable SCS devices approved through the PMA process include the Cordis programmable neurostimulator (Cordis Corp., Downers Grove, IL), approved in 1981, the Itrel□ (Medtronic, Minneapolis, MN), approved in 1984, the Genesis and Eon devices (St Jude Medical) in 2001 and the Precision Spinal Cord Stimulator (Advanced Bionics, Switzerland), approved in 2004. FDA product code: LGW.

In May 2015, the Nevro Senza™ Spinal Cord Stimulator (Nevro Corp., Menlo Park, CA), a totally implantable neurostimulator device, was approved by FDA for the following indications: chronic intractable pain of the trunk and/or limbs, including unilateral or bilateral pain associated with the following: failed back surgery syndrome (FBSS), intractable low back pain, and leg pain. This device uses a higher frequency of electrical stimulation (10 kHz) than standard devices.

Two wireless injectable neurostimulators have been approved or cleared by FDA. In February 2016, FDA approved the Axium Neurostimulator System (Spinal Modulation, Menlo Park, CA) through the PMA process. The device is indicated as an aid the management of moderate-to-severe intractable pain of the lower limbs in adults with complex regional pain syndrome types 1 and II. In August 2016, the Freedom Spinal Cord Stimulator (Stimwave Technologies, Fort Lauderdale, FL) was cleared by FDA through the 510(k) process for treating chronic, intractable pain of the trunk and/or lower limbs.

In October 2016, FDA approved BurstDR stimulation (St Jude Medical, Plano, TX), a clinician programmer application that provides intermittent "burst" stimulation for patients with certain St Jude SCS devices.

EVIDENCE SUMMARY

The principal outcomes for treatment of pain are symptom relief and improved functional level. Relief of pain is a subjective outcome and can be influenced by nonspecific effects, placebo response, the natural history of the disease, and regression to the mean. Therefore, randomized controlled trials (RCTs) are important to control for nonspecific effects and to determine whether any treatment effect provides a significant advantage over the

placebo/sham treatment or other treatments. Appropriate comparison groups depend on the condition being treated and may include placebo/sham stimulation, or medical or surgical management.

In the evaluation of the risks for implantable devices, observational studies can provide data on the likelihood of potential complications. The following complications for spinal cord stimulation (SCS) have been reported:[1]

- Lead migration, connection failure, generator failure, and/or lead breakage
- Superficial and deep infection with or without abscess
- Hematoma
- Nerve injury

The following evidence summary focuses on the investigational indications noted in criteria III, as listed above.

CANCER-RELATED PAIN

In 2015, Peng published an update to their 2013 systematic review, to evaluate the effectiveness of SCS for cancer-related pain compared with standard care using conventional analgesic medication.[2, 3] The literature search yielded 430 initial articles; however, just 18 were deemed relevant to include in the review. No RCTs were identified that evaluated the efficacy of SCS in adult patients with cancer-related pain. No new publications were identified, since the four case series[4-7] using a before-after design, with a total of 92 patients, included in the original review. In the absence of randomized controlled studies, the efficacy of SCS for treating cancer-related pain cannot be determined.

CHRONIC REFRACTORY ANGINA

Two populations of patients have been studied: 1) patients who were not considered candidates for a revascularization procedure due to comorbidities or other factors, where SCS was compared to continued medical management; or 2) patients who would be considered candidates for a revascularization procedure for the purpose of symptom relief only, where SCS was compared to coronary artery bypass grafting. Aggregating results across these different patient populations may yield misleading conclusions about treatment effect or patient selection criteria as these patient populations may not be interchangeable (both sets of patients may not be eligible for both procedures). Therefore, the trials included in this review for each of these distinct patient populations are discussed separately below.[8-13]

Systematic Reviews

In 2016, Pan identified 12 RCTs that evaluated SCS in patients with refractory angina pectoris.[14] Most studies had small sample sizes (ie <50 patients) and together there were a total of 476 patients. Reviewers did not report the control interventions reported in the RCTs. Pooled analyses favored the SCS group in most cases for exercise time after intervention, pain level (VAS score) and angina frequency, but there was not a significant difference between intervention and control groups on physical limitation and angina stability.

A 2015 systematic review by Tsigaridas included nine RCTs evaluating SCS for refractory angina, seven of which compared SCS to low or no stimulation and two of which compared SCS to alternative medical or surgical therapy for angina.[15] Similar to the Taylor et al. review described below, the authors found that most RCTs were small and variable in quality based

on assessment with the modified Jadad score. The authors reported: “two of the RCTs were of high quality; two were of low quality and the remaining ones were of intermediate quality.” Most trials which compared SCS to low or no stimulation, found improvements in outcomes with SCS; however, given limitations in the evidence base, the authors concluded that larger multicenter RCTs are needed to assess the efficacy of SCS for angina.

In 2009 Taylor published a systematic review of five randomized controlled trials comparing active SCS with placebo (four studies) or no treatment (one study).[16] The studies included for analysis were judged to be of moderate or poor quality (based on a lack of reported treatment randomization and/or treatment blinding among cited limitations). Follow-up ranged from 48 hours to two-months and study size ranged from 22 to 30 patients. Primary outcomes identified by the review included impact on health-related quality of life, functional class and exercise capacity. Of these outcomes, active treatment was significantly associated with improvement in exercise capacity and health-related quality of life. No other differences between groups were identified. However, these results are limited by the moderate to poor quality of the reviewed studies which, because of their small sample sizes and limited follow-up duration, do not answer questions about the long-term durability of this type of treatment. In addition, the lack of distinction between placebo- and natural history- controlled groups does not allow for isolation of any treatment benefit of SCS over and beyond that conferred by placebo alone.

In 2008, a systematic review of the literature based on the Swedish Council on Technology Assessment in Health Care report on SCS in severe angina pectoris was published.[17] Seven controlled studies (five randomized), two follow-up reports, and a preliminary report, as well as two nonrandomized studies determined to be of medium-to-high quality were included in the review.

- The largest RCT[11-13] included 104 subjects and compared SCS and coronary artery bypass graft (CABG) in patients accepted for CABG and who were considered to have only symptomatic indication (i.e., no prognostic benefit) for CABG, according to the American College of Cardiology/American Heart Association guidelines, to run an increased risk of surgical complications, and to be unsuitable for percutaneous transluminal coronary angioplasty. Between-group differences on nitrate consumption, anginal attack frequency, and self-estimated treatment effect were not statistically significant at the 6-month follow-up. At the 5-year follow-up, significantly fewer patients in the CABG group were taking long-acting nitrates, and between-group differences on quality of life and mortality were not significant.
- A 2006 report by McNab compared SCS and percutaneous myocardial laser revascularization (PMR) in a study with 68 subjects.[10] Thirty subjects in each group completed a 12-month follow-up, and differences on mean total exercise time and mean time to angina were not significant. Eleven participants in the SCS group and 10 in the PMR group had no angina during exercise.
- The remaining RCTs included in the systematic review included 25 or fewer subjects.

Randomized Controlled Trials

Patient populations had failed back surgery syndrome, diabetic neuropathy, and complex regional pain syndrome. The comparators were primarily conventional medical management, although one RCT compared spinal cord stimulation with reoperation for failed back surgery syndrome, and another compared spinal cord stimulation with physical therapy. All RCTs reported results at 6 months. The most common primary outcome reported was a responder

outcome of 50% reduction in pain; Kemler (2000) reported absolute change in visual analog scale pain score.[18] Consistent with clinical practice, RCTs included a trial period of spinal cord stimulation, usually a few days to a week. Patients not reporting improvement in pain during the trial period did not continue receiving spinal cord stimulation during the remainder of follow-up. In most RCTs, these patients were included in the intention-to-treat analyses either as failures to respond or using imputation techniques. All RCTs with the responder primary outcomes reported clinically and statistically significant differences in the primary outcomes at 6 months, favoring spinal cord stimulation (spinal cord stimulation range, 39%-63% vs. comparator range, 5%-12%). Outcomes measuring the reduction in analgesic use were consistently numerically larger for spinal cord stimulation but not statistically significant in all studies. Four of the 5 studies did not report differences in functional, quality of life, or utility outcomes. Device-related complications ranged from 17% to 32%, with the most common being infection and discomfort or pain due to positioning or migration of electrodes or leads. However, two studies reported dural puncture headaches and Slangen (2014) reported a dural puncture headache ending in death.[19] Two studies reported longer-term results for both treatment groups. In each, results continued to favor spinal cord stimulation at 2 years, but for 1 with 5 years of follow-up, results were not statistically significant at 5 years.

In another small pilot RCT, conducted by Eldabe in 2016 to address uncertainties related to recruitment, outcome measures, and care standardization for a larger trial comparing SCS to usual care for refractory angina, enrollment was planned for 45 patients, but the trial failed to meet its enrollment target.[20] Among the 29 patients randomized to SCS (n=15) or usual care (n=14), there were no significant differences in primary or secondary outcomes between groups, but the trial was underpowered.

In 2012 Zipes published the results from a multi-center, single-blind RCT (n=68) which compared high SCS (two-hours of stimulation four times per day) versus sham SCS (one-minute of stimulation once per day) among patients with angina who were not candidates for revascularization.[21] The study was terminated (at 6 months) due to slow enrollment and per the Data Safety Monitoring Board recommendation that the study be terminated for futility based on an interim data analysis. The 68 subjects who underwent SCS implantation were randomized to either high stimulation (n=32) or low stimulation (control group; n=36). The low-stimulation control was designed so that patients would feel paresthesia, but the effect of stimulation would be subtherapeutic. Major adverse cardiac events (MACE) and rate of angina attacks were the primary outcomes of interest, along with total exercise time and exercise time to onset of angina. At 6 months an intention-to-treat analysis was conducted; data was available only for 58 of the 68 subjects (85%) No differences were found between groups in any of the outcomes, prompting the researchers to conclude the SCS was not more effective than placebo. However, long-term differences between groups are still not known as the study was terminated early. In addition, the small sample size may have been underpowered for assessing clinically meaningful differences.

In 2011 Lanza reported on a small RCT in which 25 patients were randomly assigned to 1 of 3 treatment groups: SCS with standard levels of stimulation (n=10), SCS with low-level stimulation (75% to 80% of the sensory threshold) (n=7), or SCS with very low intensity stimulation (n=8).[22] Thus, patients in groups 2 and 3 were unable to feel sensation during stimulation. After a protocol adjustment at 1 month, patients in the very low intensity group were re-randomized to one of the other groups after which there were 13 patients in the standard stimulation group and 12 patients in the low-level stimulation group. At the 3-month follow-up (2 months after re-randomization), there were statistically significant between-group

differences in 1 of 12 outcome variables. There were a median of 22 angina episodes in the standard stimulation group and 10 in the low-level stimulation group (p=0.002), indicating evidence for a significantly higher rate of angina episodes with standard SCS treatment. Non-significant variables included use of nitroglycerin, quality of life (VAS), Canadian Cardiovascular Society angina class, exercise-induced angina, and five sub-scales of the Seattle angina questionnaire. The small sample size and short-term follow-up does not permit conclusions about the long-term safety and effectiveness of SCS in these patients.

Section Summary

Numerous small RCTs have evaluated SCS as a treatment for refractory angina. While some studies have reported benefit, most have not. In two of the larger, more recent RCTs that enrolled more than 100 patients reported no benefit on the primary outcomes. Overall, this evidence is mixed and is not sufficient to allow conclusions on whether health outcomes are improved.

CRITICAL LIMB ISCHEMIA

Critical limb ischemia (CLI) is described as pain at rest or the presence of ischemic limb lesions. If the patient is not a suitable candidate for limb revascularization (typically due to insufficient distal run-off), it is estimated that amputation will be required in 60-80% of these patients within a year. Spinal cord stimulation has been investigated in this small subset of patients as a technique to relieve pain and decrease the incidence of amputation.

Systematic Reviews

In 2015, Aub Dabrh conducted a systematic review of non-revascularization-based treatments, including SCS, for patients with critical limb ischemia also included five RCTs.[23] In pooled analysis, the authors found that SCS was associated with reduced risk of amputation (odds ratio [OR], 0.53; 95% CI, 0.36 to 0.79). However, the reviewers concluded that there was “relatively low quality of the evidence mainly due to imprecision (ie, small sample size and wide CIs) and the risk of bias.”

A 2013 update of a systematic review from the Cochrane group on use of SCS in non-reconstructible chronic critical leg ischemia (NR-CCLI) included 10 articles of six studies with a total of 444 patients.[24] None of the studies were blinded due to the nature of the treatment. One of the studies was non-randomized and one included only patients with ischemic ulcers. Treatment groups received SCS along with the same standard nonsurgical treatment as the control groups. At 12, 18 and 24 months follow-up individual studies showed a trend toward a better limb salvage that did not reach statistical significance. However, when results were pooled, a small but significant decrease in amputations was found for the SCS group at 12 months follow-up (pooled risk difference (RD): -0.11, 95% confidence interval: -0.20 to -0.02). The 11% difference in the rate of limb salvage means that 9 patients would need to be treated to prevent one additional amputation (number needed to treat [NNT]: 9, 95% CI: 5 to 50). Upon excluding results from the non-randomized trial from the analysis, the treatment difference for the group treated with SCS was no longer significant (pooled RD: -0.09, 95% confidence interval: -0.19 to 0.01). When results from the study with patients in Fontaine stage IV (the most severe stage of critical limb ischemia) were excluded, the direction of treatment benefit switched (from negative to positive, RD: 0.13, 95% CI 0.02 to 0.23), indicating evidence for increased risk of amputation following treatment with SCS.

Outcomes for pain relief and ulcer healing could not be pooled and the researchers reported mixed findings. Quality of life was unchanged in both control and treatment groups. The overall risk of complications or additional SCS treatment was 17%. Nevertheless, the report concluded that "There is evidence that SCS is better than conservative treatment alone to achieve amputation risk reduction, pain relief and improvement of the clinical situation" in patients with chronic critical leg ischemia. This seemingly incongruous conclusion may be explained by the authors' conclusion that, "The benefits of SCS against the possible harm of relatively mild complications and costs must be considered." A potential conflict of interest was noted for the principal investigator, who was part of the non-randomized study included in the analysis. Published comments by Klomp and Steyerberg strongly criticized the inclusion of this non-randomized trial, along the exclusion of data from a randomized study from the pooled analysis, stating:[25]

The same meta-analysis, performed with a different amputation data input of five randomized studies [instead of 4 RCTs and a non-randomized study], generated a risk difference of -0.07 (95% CI: -0.17 to +0.03) instead of -0.13 (95% CI: -0.22 to -0.04). The main conclusion, that spinal cord stimulation is better than conservative treatment alone in achieving a reduction in amputation risk, is not justified. If SCS is beneficial, the magnitude of the effect is very small.

In 2009, Klomp and colleagues published a meta-analysis of the same five RCTs identified in the 2013 Cochrane review.[26] The authors did not find a statistically significant difference in the rate of amputation in the treatment and control groups. There was a relative risk of amputation of 0.79 and a risk difference of -0.07 (p=0.15). They found insufficient evidence that SCS is more efficacious than best medical treatment alone. They also conducted additional analyses of data from their 1999 RCT to identify factors associated with a better or worse prognosis. They found that patients with ischemic skin lesions had a higher risk of amputation compared to patients with other risk factors. There were no significant interactions between this or any other prognostic factor. The analyses did not identify any subgroup of patients who might benefit from SCS.

In 2009, Simpson systematic review described above also reviewed studies on SCS for treatment of inoperable critical limb ischemia.[27] Four RCTs met inclusion criteria; comparators were conventional medical management (CMM)[28-31], oral analgesics[32], or prostaglandin E1 injection[33]. The authors concluded that evidence for a treatment difference was found in reduction of analgesics up to six months, but not at 18 months. However, no between-group differences were found in pain relief, limb survival, health-related quality of life, or any other outcomes.

Randomized Controlled Trials

There have been no new randomized trials published since those included in the systematic reviews summarized above.

Conclusion

A number of small RCTs of SCS versus usual care have been completed on patients with critical limb ischemia. In pooled analyses of these RCTs, SCS did not result in a significantly lower rate of amputation, although one systematic review and meta-analysis did report a significant difference. This evidence is not sufficient to conclude that SCS improves outcomes for patients with critical limb ischemia.

HEART FAILURE

Randomized Controlled Trials

In 2016, Zipes reported the results of the DEFEAT-HF trial, a prospective, multicenter, single-blind RCT trial comparing SCS with active stimulation to sham control in patients with New York Heart Association functional class III heart failure with a left ventricular ejection fraction of 35% or less.[34] Sixty-six patients were implanted with an SCS and randomized in a 3:2 manner to SCS ON (n=42) or SCS OFF (sham; n=24). For the study's primary end point (change in left ventricular end systolic volume index from baseline to six months), there was no significant difference between groups (p=0.30). Other end points related to heart failure hospitalization and heart failure-related QOL scores and symptoms did not differ significantly between groups. After completion of the six month randomization period, all subjects received active SCS stimulation. From baseline to 12 months of follow-up, there were no significant echocardiographic treatment effects in the overall patient population in echocardiographic parameters (p=0.36). The study was originally powered based on a planned enrollment of 195 implanted patients, but enrollment was stopped early due to enrollment futility. The nonsignificant difference between groups may have been the result of underpowering. However, the absence of any treatment effects or between-group differences are further suggestive of a lack of efficacy of SCS for heart failure.

Findings of a small pilot crossover RCT evaluating SCS for heart failure were published in 2014 by Torre-Amione.[35] Eligibility included symptomatic heart failure despite optimal medical therapy, left ventricular ejection fraction less than 30%, hospitalization or need for intravenous inotropic support in the past year, and inability to walk more than 450 meters on a six-minute walk test. All patients had an implanted heart device. Nine patients underwent SCS implantation. The efficacy of SCS therapy was assessed by changes in patient symptoms, LV function, and BNP level. In all cases, ICD sensing, detection, and therapy delivery were unaffected by SCS. Symptoms were improved in the majority of patients with SCS, while markers of cardiac structure and function were, in aggregate, unchanged. Two patients had minor implant-related events and no reported implant-related HF exacerbations or hospitalizations. These small, preliminary pilot studies were intended to report first-in-human feasibility and safety to support further study. RCTs with large sample sizes and long-term follow-up are needed to draw conclusions on the safety and effectiveness of the therapy for this indication.

Nonrandomized Studies

In 2015 Tse performed a small, nonrandomized, prospective, multicenter pilot trial in male patients with New York Heart Association (NYHA) class III HF, left ventricular ejection fraction (LVEF) 20%-35%, and implanted defibrillator device who were prescribed stable optimal medical therapy.[36] Seventeen patients underwent implantation of a SCS device (cases) and four patients who did not fulfill the study criteria served as nontreated controls. At six-month follow up, no deaths or device-device interactions were reported. Composite score improved by 4.2 ± 1.3 in all cases, and 11 cases (73%) showed improvement in ≥4 of 6 efficacy parameters, including NYHA class ($p = 0.002$); peak maximum oxygen consumption ($p = 0.013$); LVEF ($p<0.001$); and LV end-systolic volume ($p = 0.002$). No improvements were observed in the four controls.

DORSAL ROOT GANGLION STIMULATION

Systematic Review

Stelter (2021) published a systematic review of 28 reports consisting of 354 patients evaluating the evaluating the efficacy of dorsal root ganglion stimulation for non-complex regional pain syndromes.[37] The authors reported that the majority of patients demonstrated at least a 50% mean pain reduction at their last follow-up time following treatment. Additional outcomes assessed including physical function, quality of life, and pain medication use also showed significant improvements.

Deer (2020) published a systematic literature review of three studies of dorsal root ganglion neurostimulation for the treatment of pain.[38] This review concluded that dorsal root ganglion neurostimulation has level II evidence (moderate) for treating chronic focal neuropathic pain and complex regional pain syndrome based on 1 high-quality pivotal RCT (ACCURATE) and 2 lower quality studies.

Huygen (2020) reported a pooled analysis of prospective studies of dorsal root ganglion stimulation for the treatment of chronic pain.[39] One RCT was included (ACCURATE) which is described in the following section and 6 prospective, single-arm, observational studies were included. The analysis included 217 patients with a permanent implant at 12-month follow-up. Analysis of pooled data showed an overall weighted mean pain score of 3.4, with 63% of patients reporting ≥50% pain relief. Effectiveness sub-analyses in CRPS-I, causalgia, and back pain resulted in a mean reduction in pain intensity of 4.9, 4.6, and 3.9 points, respectively. The pooled analysis showed a pain score for primary affected region ranging from 1.7 (groin) to 3.0 (buttocks) and responder rates of 80% for foot and groin, 75% for leg, and 70% for back. A substantial improvement in all PROs was observed at 12 months.

Vuka (2019) conducted a systematic review of the use of dorsal root ganglion stimulation for various pain syndromes (for example, complex regional pain syndrome, diabetic and non-diabetic peripheral neuropathy).[40] The literature search, conducted through September 2018, identified 29 studies for inclusion, 1 RCT, (ACCURATE trial; discussed below) and the remaining were case series or case reports. The median sample size was 6 (range 1 to 152). Most of the studies reported positive results with dorsal root ganglion stimulation. No meta-analyses could be conducted.

A systematic review, published in 2013 by Pope, evaluated therapeutics for chronic pain that target the dorsal root ganglion.[41] This review focused on ganglionectomy, and radiofrequency treatment of the dorsal root ganglion, with discussion of electrical stimulation of the DRG as an emerging therapy. Three studies of electrical DRG stimulation were included in the review, two case reports and one nonrandomized feasibility trial. The Deer feasibility trial (described below) prospectively followed 10 patients with chronic, intractable neuropathic pain, over four weeks.[42] Eight of the nine patients who completed the trial experienced a clinically meaningful (>30%) reduction in pain, as measured using a visual analog scale, with an average pain reduction of 70%. Seven of the nine reduced their utilization of pain medication. There were no adverse events reported. The two case studies included in the review described successful treatment of cervicogenic headache, post-herpetic neuralgia, and discogenic pain.

Randomized Controlled Trials

One RCT, the ACCURATE study, compared wireless injectable neurostimulators and standard SCS.[43] The trial, published by Deer in 2016, was a multicenter unblinded noninferiority trial. Eligibility criteria included chronic (≥6 months) intractable (failed ≥2 drugs from different

classes) neuropathic pain of the lower limbs associated with a diagnosis of CRPS or causalgia and no previous neurostimulation. Patients were randomized to receive DRG stimulation with the Axium device or standard SCS. They first underwent a temporary trial of stimulation lasting 3 to 30 days, depending on the protocol at each site. Patients who had 50% or greater reduction in lower limb pain after the temporary trial were eligible for permanent stimulation. Those who failed temporary stimulation exited the trial but were included in the analysis as treatment failures. Implanted patients were followed for 12 months, with assessments at 3, 6, 9, and 12 months postimplant.

A total of 152 patients were randomized and 115 (n=61 DRG, n=54 SCS) had a successful temporary trial and continued to permanent implantation. Twelve-month data were available for 105 patients (55 patients in the DRG group, 50 in the SCS group). The primary outcome was a composite measure of treatment success. Success was defined as: (1) 50% or greater reduction in VAS score from baseline to the end of the trial phase; (2) VAS at 3 months that was 50% or greater lower than baseline; and (3) no stimulation-related neurologic deficits experienced during the study. The noninferiority margin was set at 10%; the trial was designed such that, if the noninferiority end point was met, a superiority analysis was also performed. Treatment success at 3 month was achieved by 55 (81.2%) of 69 patients in the DRG arm and 39 (55.7%) of 70 in the SCS arm. The noninferiority margin was met, and DRG was found to be statistically superior to SCS ($p<0.001$). At the 12-month follow-up, the primary end point was achieved by 49 (74.2%) of 66 in the DRG group and 35 (53%) of 66 in the SCS group and, again, DRG was considered noninferior to SCS and also superior ($p<0.001$). In terms of paresthesias, at 3 months and 12, SCS patients were significantly more likely to report paresthesias in nonpainful areas than DRG patients. At 3 months, 84.7% of DRG patients and 65% of SCS patients reported paresthesias only in their painful areas; at 12 months, these percentages were 94.5% and 61.2%, respectively. Twenty-one serious adverse events occurred in 19 patients (8 in the DRG group, 11 in the SCS group; difference between groups, p=NS). A limitation of the study was that it was unblinded and industry-sponsored, which could potentially bias outcome assessment and reporting.

Mekhail (2019) conducted a sub-analysis on the patients receiving DRG neurostimulation in the ACCURATE study, to evaluate the occurrence and risk factors for paresthesia.[44] Among the 61 patients with DRG implants, the rates of paresthesia at 1 month, 3 months, 6 months, 9 months, and 12 months were 84%, 84%, 66%, 62%, and 62%, respectively. The patients who were parasthesia-free reported similar or better outcomes for pain and quality of life. Risk factors for parasthesia occurrence included higher stimulation amplitudes and frequencies, number of implanted leads, and younger age.

Nonrandomized Studies

Several case series have been published.[45-47] The largest of them are summarized below. Liem (2015) reported on the outcomes of an industry-sponsored multicenter, prospective trial of DRG stimulation at six months[48] and one year.[45] The trial consisted of a run-in period in which 51 participants received DRG stimulation via leads connected to an external stimulator, followed by surgical placement of a fully-implanted neurostimulator in 32 of the 39 patients that achieved 50% or greater pain relief during the run-in period. More than half of the patients with fully implanted DNG stimulators reported at least 50% relief in pain, as measured by visual analog scale. Average pain ratings were 58% lower than baseline at six months and 56% lower at 12 months post-implantation. Patients also reported improved quality of life and mood by questionnaire (EQ-5D-3L and POMS). Over 12 months, there were 86 adverse events

reported in 29 patients, including temporary motor stimulation (12 events), CSF leak (seven events) and infection (seven events). Approximately half of these events were judged by the investigators to be related to the device. Seven subjects had their devices removed and were withdrawn from the study.

A subgroup analysis of the Liem study examined positional effects on paresthesia during DRG stimulation in the 32 patients with implanted neurostimulators.[49] Paresthesia and pain relief achieved with spinal cord stimulation can change as patients change position from upright to prone or supine, causing uncomfortable sensations. This study found no statistically significant difference in paresthesia intensity by body position. In order to truly determine the efficacy and safety of DRG stimulation well designed comparative studies with long-term follow-up must be performed to compare it to standard spinal cord stimulation.

Schu reported on an industry-sponsored multicenter European case series of 29 patients treated with DRG stimulation for chronic neuropathic groin pain.[46] Of the 29 patients who underwent a 30-day trial period, 25 (86.2%) underwent implantation with the Axium DRG device. Final lead placement between T12 and L4 was determined based on patient feedback during paraesthesia mapping. Data analysis was based on the results of 23 patients with a mean follow-up of 27.8 weeks. The average pain reduction was 71.4 ± 5.6%, and 82.6% (19/23) of patients experienced a > 50% reduction in their pain at the latest follow-up. Adverse events were not reported. The authors stated that paraesthesia was largely unaffected by positional changes. Limitations of this study include small sample size, lack of comparative data, and potential bias inherent in pain as a subjective outcome measure.

In 2013 Deer conducted an industry-sponsored case series to evaluate the efficacy and safety of the Axium DRG system in ten patients with chronic intractable pain of the trunk and/ or limbs.[42] The study was conducted across four centers for a period of four weeks. The study protocol and lead implantation procedures were similar to those reported by Liem above; however, only results of trial DRGS over a period of three to seven days were reported. On average, there was a 70% reduction in pain following stimulation ($p = 0.0007$). Eight of the nine patients experienced a clinically meaningful (>30%) reduction in pain, and seven of the nine reduced their pain medication utilization. The study did not consider longer term effects with a permanently implanted device. Seventeen adverse events occurred of which 14 were considered to be device-related; none were thought to be serious.

PRACTICE GUIDELINE SUMMARY

AMERICAN SOCIETY OF INTERVENTIONAL PAIN PHYSICIANS (ASIPP)[50]

In 2013, the ASIPP updated their evidence-based guidelines for interventional techniques in the management of chronic spinal pain. The guidelines included the statement that there is fair evidence in support of SCS in managing patient with failed back surgery syndrome.

AMERICAN COLLEGE OF CARDIOLOGY FOUNDATION AND THE AMERICAN HEART ASSOCIATION (ACCF/AHA)

Guidelines from the American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA) published in 2007 with focused updates in 2011[51] and 2012[52]) for the management of patients with unstable angina/non ST-Elevation myocardial infarction state:

> "Transcutaneous electrical nerve stimulation and spinal cord stimulation for continued pain

despite the implementation of Class I measures may be considered for patients with syndrome X. (Level of Evidence: B)."[53] However, the level of evidence indicates that the "treatment usefulness/ efficacy [is] less well established" and that this recommendation may be based on a single randomized controlled trial or one or more non-randomized studies.

The 2012 updated joint ACCF/AHA guidelines recommend that SCS may be considered for relief of refractory angina in patients with stable ischemia heart disease (Level of evidence: C, defined as very limited populations evaluated and/or only consensus opinion of experts, cases studies, or standard of care).[54] The guidelines conclude:

"Studies of spinal cord stimulation suggest that this technique might have some use as a method to relieve angina in patients with symptoms that are refractory to standard medical therapy and revascularization. There is a paucity of data on the mechanisms and long-term risks and benefits of this therapeutic approach, however."

NEUROPATHIC PAIN SPECIAL INTEREST GROUP OF THE INTERNATIONAL ASSOCIATION FOR THE STUDY OF PAIN[55]

In 2013, the Neuropathic Pain Special Interest Group of the International Association for the Study of Pain (NeuPSIG) published consensus recommendations on management of neuropathic pain. The recommendations supporting the use of SCS for failed back surgery syndrome and for complex regional pain syndrome we rated as weak (quality of evidence moderate to low; strength of recommendation weak to inconclusive). The recommendation for SCS for postherpetic neuralgia was also rated as weak (quality of evidence low; strength of recommendation inconclusive).

INTERNATIONAL NEUROMODULATION SOCIETY[56]

The International Neuromodulation Society convened a Neuromodulation Appropriateness Consensus Committee (NACC) to develop best practices for the use of DRG stimulation for the treatment of chronic pain syndromes. The NACC was comprised of experts in anesthesiology, neurosurgery, and pain medicine. The NACC performed a systematic literature search through June 2017 and identified 29 publications providing evidence for the consensus recommendations. The evidence was graded using the modified Pain Physician criteria and the USPSTF criteria. The NACC report gave a strong recommendation that DRG stimulation is recommended for CRPS type I or type II.

AMERICAN SOCIETY OF PAIN AND NEUROSCIENCE

The American Society of Pain and Neuroscience issued a comprehensive guideline in 2021 on the management of cancer-related pain.[57] The guideline found that spinal cord stimulation may be considered for 1) treatment of refractory cancer pain (Level II-3-C evidence: multiple series compared over time, with or without intervention, and surprising results in noncontrolled experience; treatment is neither recommendable nor inadvisable), and 2) on a case-by-case basis for "pain that is related to cancer treatment such as chemotherapy-induced peripheral neuropathy" (level III-C evidence: clinical experiences-based opinions, descriptive studies, clinical observations, or reports of expert committee; treatment is neither recommendable nor inadvisable).

ASPN also published consensus guidelines on interventional therapies for knee pain in 2022.[58]The guidelines state that "Chronic pain that is refractory to acute treatment is managed

by progressing to spinal cord stimulator, dorsal root ganglion stimulator, or botulinum toxin (Botox) injection." They also include the statement that "DRG [Dorsal Root Ganglion Stimulation] is a safe and effective treatment option for chronic post-surgical and focal neuropathic pain of the knee (ie, complex regional pain syndrome [CRPS]); Level I, Grade A, Consensus Strong."

Consensus guidelines on interventional therapies for back pain were also published in 2022 and made the following recommendations for SCS: following lumbar surgery (Level I-A, Grade A), treatment of non-surgical low back pain (Level I-C, Grade B), and treatment of lumbar spinal stenosis (Level I-C, Grade C).[59]

SUMMARY

SPINAL CORD STIMULATORS

There is enough research to show that spinal cord stimulation (SCS) including high frequency SCS for the treatment of chronic trunk or limb pain, when all other treatment modalities have failed to adequately reduce symptoms may improve health outcomes. In addition, practice guidelines recommend SCS for select patients. Therefore, SCS including temporary and the potential permanent implantation may be considered medically necessary for treatment of chronic refractory pain of the trunk or limbs when policy criteria are met.

In certain situations, a spinal cord stimulator may require revision after it has been placed. In these cases, revision may be medically appropriate to allow for the proper functioning of the device. Therefore, revision(s) to an existing spinal cord stimulator may be considered medically necessary after the device has been placed.

In certain situations, a spinal cord stimulator may no longer be able to perform its basic function due to damage or wear. When a stimulator is out of its warranty period and cannot be repaired adequately to meet the patient’s medical needs, replacement of the device may be medically appropriate. Therefore, replacement of all or part of a spinal cord stimulator may be considered medically necessary when device replacement Criteria are met.

When a stimulator is in its warranty period or can be repaired or adapted adequately to meet the patient’s medical needs, replacement of the device is not medically appropriate. Therefore, replacement of all or part of a spinal cord stimulator is considered not medically necessary when device replacement Criteria are not met.

When criteria are not met, spinal cord stimulation for severe and chronic refractory neuropathic pain of the trunk or limbs is not clinically appropriate and is therefore considered not medically necessary.

There is not enough research to show that spinal cord stimulation (SCS), including standard or high frequency, in the treatment of conditions not related to severe and chronic refractory pain of the trunk or limbs improves health outcomes or is more effective than standard of care. Therefore, the use of SCS, including standard or high frequency is investigational for the treatment of all other conditions not related to severe and chronic refractory pain of the trunk or limbs.

DORSAL ROOT GANGLION STIMULATORS

There is enough research to show that dorsal root ganglion (DRG) stimulation for the treatment of chronic trunk or limb pain, when all other treatment modalities have failed to adequately reduce symptoms may improve health outcomes. In addition, practice guidelines recommend DRG stimulation for select patients. Therefore, DRG stimulation may be considered medically necessary for treatment of chronic refractory pain of the trunk or limbs when policy criteria are met.

In certain situations, a dorsal root ganglion stimulator may require revision after it has been placed. In these cases, revision may be medically appropriate to allow for the proper functioning of the device. Therefore, revision(s) to an existing spinal cord stimulator may be considered medically necessary after the device has been placed.

In certain situations, a dorsal root ganglion stimulator may no longer be able to perform its basic function due to damage or wear. When a stimulator is out of its warranty period and cannot be repaired adequately to meet the patient's medical needs, replacement of the device may be medically appropriate. Therefore, replacement of all or part of a spinal cord stimulator may be considered medically necessary when device replacement Criteria are met.

When a stimulator is in its warranty period or can be repaired or adapted adequately to meet the patient's medical needs, replacement of the device is not medically appropriate. Therefore, replacement of all or part of a dorsal root ganglion stimulator is considered not medically necessary when device replacement Criteria are not met.

When criteria are not met, dorsal root ganglion stimulation for severe and chronic refractory pain of the trunk or limbs due to type I or type II complex regional pain syndrome, including reflex sympathetic dystrophy or causalgia, is not clinically appropriate and is therefore considered not medically necessary.

For all other indications, there is not enough research to show that dorsal root ganglion (DRG) stimulation is safer and/or more effective than standard of care when policy criteria are not met. Therefore, the use of dorsal root ganglion stimulation is considered investigational when policy criteria are not met.

CODES

NOTE: HCPCS code C1823 is NOT the correct code to use for reporting these services. Please refer to the codes listed below for guidance.

Codes	Number	Description
		Insertion or replacement of percutaneous electrode array, spinal, with integrated
	0785T	Revision or removal of neurostimulator electrode array, spinal, with integrated neurostimulator
		Electronic analysis with simple programming of implanted integrated neurostimulation system (eg, electrode array and receiver), including contact

Codes	Number	Description
		group(s), amplitude, pulse width, frequency (Hz), on/off cycling, burst, dose lockout, patient-selectable parameters, responsive neurostimulation, detection algorithms, closed-loop parameters, and passive parameters, when performed by physician or other qualified health care professional, spinal cord or sacral
	0789T	Electronic analysis with complex programming of implanted integrated neurostimulation system (eg, electrode array and receiver), including contact group(s), amplitude, pulse width, frequency (Hz), on/off cycling, burst, dose lockout, patient-selectable parameters, responsive neurostimulation, detection algorithms, closed-loop parameters, and passive parameters, when performed by physician or other qualified health care professional, spinal cord or sacral nerve, 4 or more parameters
	63655	Laminectomy for implantation of neurostimulator electrodes, plate/paddle, epidural
	63662	Removal of spinal neurostimulator electrode plate/paddle(s) placed via laminotomy or laminectomy, including fluoroscopy, when performed
	63664	Revision including replacement, when performed, of spinal neurostimulator electrode plate/paddle(s) placed via laminotomy or laminectomy, including fluoroscopy, when performed
		Insertion or replacement of spinal neurostimulator pulse generator or receiver, requiring pocket creation and connection between electrode array and pulse
	63688	Revision or removal of implanted spinal neurostimulator pulse generator or receiver, with detachable connection to electrode array
		Electronic analysis of implanted neurostimulator pulse generator/transmitter (eg, contact group[s], interleaving, amplitude, pulse width, frequency [Hz], on/off cycling, burst, magnet mode, dose lockout, patient selectable parameters, responsive neurostimulation, detection algorithms, closed loop parameters, and passive parameters) by physician or other qualified health care professional; with brain, cranial nerve, spinal cord, peripheral nerve, or sacral nerve,
	95971	;with simple spinal cord, or peripheral nerve (eg, sacral nerve) neurostimulator pulse generator/transmitter, programming by physician or other qualified health care professional
		;with complex spinal cord, or peripheral (eg, sacral nerve) neurostimulator pulse generator/transmitter programming by physician
HCPCS	C1767	Generator, neurostimulator (implantable), nonrechargeable
	C1822	Generator, neurostimulator (implantable), high frequency, with rechargeable battery and charging system
		Generator, neurostimulator (implantable), includes closed feedback loop leads
	L8678	Electrical stimulator supplies (external) for use with implantable neurostimulator, per month

Codes	Number	Description
	L8680	Implantable neurostimulator electrode, each
	L8685	Implantable neurostimulator pulse generator, single array, rechargeable, includes extension
	L8686	Implantable neurostimulator pulse generator, single array, nonrechargeable, includes extension
	L8687	Implantable neurostimulator pulse generator, dual array, rechargeable, includes extension
	L8688	Implantable neurostimulator pulse generator, dual array, nonrechargeable, includes extension

Medical Policy Manual Surgery, Policy No. 52

Ventricular Assist Devices and Total Artificial Hearts

Effective: March 1, 2024

Next Review: December 2024
Last Review: January 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Ventricular assist devices and total artificial hearts provide mechanical circulation for patients with end-stage heart disease who are waiting for, or cannot survive, a heart transplant.

MEDICAL POLICY CRITERIA

Note: This policy does not address the use of percutaneous ventricular assist devices (pVADs) which may be considered medically necessary.

I. Implantable ventricular assist devices (i.e., LVADs, RVADs and BiVADs)

A. Implantable ventricular assist devices with FDA PMA, 510(k), or HDE clearance may be considered **medically necessary** for any of the following indications (1.-3.):

1. As a bridge to transplantation for patients who meet all of the following criteria:

a. Currently listed as a heart transplantation candidate or undergoing evaluation to determine candidacy for heart transplantation; and

b. Not expected to survive until a donor heart can be obtained; or

2. For use in the post-cardiotomy setting in patients who are unable to be weaned off cardiopulmonary bypass; or
3. As destination therapy in patients meeting all of the following criteria (a.- e.):
    a. End-stage heart failure; and
    b. New York Heart Association (NYHA) Class III heart failure with dyspnea upon mild physical activity or NYHA Class IV (NYHA Class III = marked limitation of physical activity; less than ordinary activity leads to symptoms. NYHA Class IV = inability to carry on any activity without symptoms; symptoms may be present at rest.); and
    c. Left ventricular ejection fraction 25% or less; and
    d. One of the following criteria is met:
        i. Inotrope-dependent; or
        ii. Cardiac index is less than 2.2 liters per minute per meter squared while not on inotropes; and
    e. One of the following criteria is met:
        i. On optimal medical management, including beta-blockers and/or ACE inhibitors if not contraindicated, for at least 45 of the last 60 days and are failing to respond; or
        ii. Advanced heart failure for at least 14 days and dependent on intra-aortic balloon pump for 7 days or more.

B. Ventricular assist devices and aortic counterpulsation devices are considered **investigational** in all other circumstances, including but not limited to the use of a non-FDA approved device.

II. Total Artificial Hearts

A. Total artificial hearts with FDA PMA, 510(k), or HDE clearance may be considered **medically necessary** as a bridge to heart transplantation in patients meeting all of the following criteria:
1. Have biventricular failure; and
2. Currently listed as heart transplantation candidate or undergoing evaluation to determine candidacy for heart transplantation; and
3. Not considered a candidate for a univentricular or biventricular support device; and
4. Have no other reasonable medical or surgical treatment options; and
5. Not expected to survive until a donor heart can be obtained.

B. Total artificial hearts are considered **investigational** in all other circumstances, including but not limited to the following:
1. Use as destination therapy; or
2. Use of a total artificial heart that does not have FDA PMA, 510(k), or HDE clearance

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- For Implantable Ventricular Assist Devices:
    - Documentation as to whether this is a bridge to heart transplant, being used post-cardiotomy for patient who is unable to be weaned of cardiopulmonary bypass, or as destination therapy
    - For destination therapy:
        - Documentation of end-stage heart failure, documentation of ejection fraction, documentation of inotrope dependency or cardiac index score when not on inotropes, documentation of optimal medical management or documentation of advanced heart failure and dependency on an intra-aortic balloon pump, and current NYHA classification, including duration of NYHA classification, symptoms, and treatments tried.
- For Total Artificial Heart:
    - Documentation that this is a bridge to heart transplant and patient has biventricular failure; is listed as heart transplant candidate or undergoing evaluation to determine candidacy for heart transplant; is not considered a candidate for univentricular or biventricular support device; has no other reasonable medical or surgical treatment options; and is not expected to survive until a donor heart can be obtained

BACKGROUND

VENTRICULAR ASSIST DEVICES (VADS)

Biventricular, Right Ventricular, and Left Ventricular Devices

There are three kinds of ventricular assist devices: biventricular (BiVADs), right ventricular (RVADs), and left ventricular (LVADs). Surgically implanted ventricular assist devices (VADs) are attached to the native heart and vessels to provide temporary mechanical circulatory support by augmenting cardiac output. LVADs to support the left ventricle are the most commonly used VADs, but right ventricular and biventricular devices may also be used. LVADs are most commonly used as a bridge to transplantation for those patients who are not expected to survive without mechanical support until a heart becomes available. LVADs may also be used as a bridge to recovery in patients with reversible conditions affecting cardiac output (e.g., post-cardiotomy cardiogenic shock). More recently, given the success of LVADs for prolonged periods of time, there has been interest in using LVADs as permanent

"destination" therapy for patients with end-stage heart disease who are not candidates for human heart transplantation due to age or other comorbidities.

Aortic Counterpulsation Devices

Intra-aortic balloon pump (IABP) devices have been developed as a treatment for cardiogenic shock. IABPs consist of a helium-filled balloon placed in the aorta that deflates during cardiac systole to increase forward blood flow. The inflation and deflation of the balloon is computer-controlled and can be regulated by either a pressure-sensing catheter or an electrocardiogram. These devices have not been FDA approved.

TOTAL ARTIFICIAL HEARTS

The total artificial heart (TAHs) replaces the native ventricles and is attached to the pulmonary artery and aorta; the native heart is typically removed. TAHs may be implanted temporarily as a bridge to heart transplantation or permanently as destination therapy in those who are not candidates for transplantation.

The CardioWest™ Total Artificial Heart is a temporary TAH, which is used in the inpatient hospital setting as a bridge to heart transplantation. The CardioWest TAH is implanted after the native ventricles have been excised. The AbioCor® Implantable Replacement Heart is a permanent TAH currently available as destination therapy for people who are not eligible for a heart transplant and who are unlikely to live more than a month without intervention. The device has an internal battery that allows the recipient to be free from all external connections for up to one hour. The system also includes two external batteries that allow free movement for up to two hours. During sleep and while batteries are being recharged, the system can be plugged into an electrical outlet. In order to receive the AbioCor® artificial heart, in addition to meeting other criteria, patients must undergo a screening process to determine if their chest volume is large enough to hold the two-pound device which is too large for about 90% of women and many men.

REGULATORY STATUS

Device Name	Device Type	Manufacturer	FDA Approval	Indication
HeartMate II®	LVAD	Thoratec Corp.	PMA	Bridge to transplant and destination therapy
HeartMate 3™	LVAD	Thoratec Corp.	PMA	Bridge to transplant and destination therapy
Thoratec® IVAD	BiVAD	Thoratec Corp.	PMA + Supplement	Bridge to transplant and postcardiotomy
Centrimag®	RVAD	Thoratec Corp.	PMA	Postcardiotomy, bridge to decision
Novacor®	LVAD	World Heart, Inc.	PMA	Bridge to transplant
DeBakey VAD® Child	LVAD	MicroMed Technology, Inc.	HDE	Bridge to transplant in children 5-16 years of age
EXCOR® Pediatric System	BiVAD	Berlin Heart, Inc.	HDE	Bridge to transplant, pediatric (newborns to teens)

Device Name	Device Type	Manufacturer	FDA Approval	Indication
Jarvik 2000	LVAD	Jarvik Heart, Inc.	*IDE-Investigational*†	
AutoCat 2 WAVE® IABP System	IABP	Arrow Intl., Inc.	none	
Maquet CS300™ IABP	IABP	Maquet Cardiovascular, LLC	none	
SynCardia Temporary TAH (formerly called CardioWest™)	Temporary total artificial heart	SynCardia Systems, Inc.	510(k)	Bridge to transplant – for use inside the hospital
AbioCor® TAH	Implantable Replacement Heart System	AbioMed, Inc.	HDE	Destination therapy

†FDA Investigational Device Exemption (IDE) is not considered a full FDA approval. Devices with an IDE designation are considered investigational.

In August 2015, the U.S. Food and Drug Administration (FDA) published a safety communication about serious adverse events with implantable left ventricular assist devices.[1]

In August 2016, HeartWare® recalled its VAD Pumps due to a design flaw that was deemed by FDA as potentially causing serious injuries or death (class I recall). The devices affected were manufactured and distributed from March 2006 and May 2018. The device was discontinued in 2021 due to evidence demonstrating a higher frequency of neurological adverse events and mortality compared to other devices. FDA product codes: 204 and 017. Additional FDA class I and II recalls associated with the HeartWare VAD have been issued in since the HeartWare® was discontinued in 2021.[2]

A class I recall was issued for the HeartMate 3™ in April 2018 affecting all manufacturing dates. FDA product code: DSQ.

Although adverse events have been reported, the FDA recognizes “that LVADs are life-sustaining, life-saving devices for patients with advanced left ventricular heart failure. When used for the currently approved indications in appropriately selected patients, we believe the benefits of these LVADs continue to outweigh the risks”.

EVIDENCE SUMMARY

The principal outcome associated with treatment of refractory heart failure (HF) is to prolong survival, either temporarily as a bridge to decision, recovery, or heart transplantation, or permanently as a replacement for the damaged heart in patients who are not candidates for heart transplantation.

VENTRICULAR ASSIST DEVICES

BRIDGE TO TRANSPLANTATION, LEFT VENTRICULAR ASSIST DEVICES

Systematic Reviews

A systematic review (SR) published in 2011 supported the conclusions reached in the 1996 BCBSA TEC assessment.[3, 4] The 2011 review included 31 observational studies that compared outcomes of transplant in patients who did and did not have pre-transplant left ventricular assist devices (LVADs). Survival at one year was more likely in patients who had LVAD treatment, but this benefit was confined to patients who received an intra-corporeal device (relative risk [RR] 1.8, 95% confidence interval [CI] 1.53 to 2.13). For patients treated with an extracorporeal device, the likelihood of survival was not different from patients who were not treated with an LVAD (RR 1.08, 95% CI 0.95 to 1.22). There was no difference in the risk of rejection between patients who did and did not receive LVAD treatment.

Nonrandomized Studies

Adult PatientsAdditional reports not included in the 1996 TEC assessment or the 2011 SR are consistent with the above analysis.[5-7] It should be recognized that left ventricular assist devices cannot change the number of patients undergoing heart transplantation due to the fixed number of donor hearts. However, the LVAD will categorize its recipient as a high priority heart transplant candidate. Currently available LVADs consist of pulsatile devices that require both stiff power vent lines that perforate the skin and bulky implantable pump chambers. There is considerable research interest in developing non-pulsatile axial flow systems that have the potential for small size and low-noise levels.[8-13]

Pagani (2021) used Medicare claims data to analyze survival outcomes in patients who received different LVADs between January 2014 and December 2018, with followup through December 2019.[14] Of 4195 patients who received implants, there were 117 (14.3%) deaths among 821 Heartmate3™ patients, 375 (20.4%) deaths among 1840 Heartmate II® patients, and 375 (24.5%) deaths among 1534 patients with other VADs. The adjusted hazard ratio for mortality at 1-year (confirmed in a propensity score matched analysis) for the HeartMate 3 versus HeartMate II® was 0.64 (95% CI; 0.52 to 0.79, p<.0001) and for the HeartMate 3™ versus other-VADs was 0.51 (95% CI; 0.42 to 0.63, p<.0001).

Aissaoui (2018) published an observational study comparing 224 patients in Germany and France with end-stage heart failure who received VAD as first option (group I, n=83) or either heart transplantation or medical therapy as first option (group II, n=141).[15] The estimated two-year survival was 44% for group I and 70% for group II (p<0.001). The study was limited by the lack of randomization and possible patient selection bias.

Grimm (2016) compared outcomes for patients based on the duration of LVAD use, using data from the United Network for Organ Sharing database.[16] Of the 1,332 included patients, 130 (9.8%) were classified as short duration (< 90 days), 729 (54.7%) were classified as intermediate duration (90 to 365 days), and 473 (35.5%) were classified as long duration (>365 days). A greater proportion of patients in the intermediate and long duration groups were considered functionally independent prior to transplantation compared with the short duration patients. There was no difference in 30-day survival, six-month survival, or one-year survival between the groups. Also, despite worse renal function in the intermediate and long-term groups, there was no difference between groups in new-onset post-transplant renal failure.

Another report by Grimm (2016),which used the United Network for Organ Sharing database, suggested that patients bridged to transplant with an LVAD have better outcomes than those bridged with TAH or biventricular assist devices.[17] Cheng (2016) compared BiVAD to TAH outcomes in this database, and found similar wait-list survival between the groups.[18]

Deo (2014) reported no significant differences in outcomes for 37 patients bridged to transplant with a ventricular assisted device (VAD) and 70 patients who underwent a heart transplant directly.[19] In 2013, Slaughter reported combined outcomes for patients included in the HeartWare® bridge-to-transplant study.[20] The study included 322 patients with heart failure, eligible for heart transplant, who received the HeartWare® (140 patients from the original study; 190 patients in the continue-access protocol) who were monitored to outcome or had completed 180 days of follow-up at the time of this analysis. Survival at 60, 180, and 360 days was 97%, 91%, and 84%, respectively. The most common adverse events were respiratory dysfunction, arrhythmias, sepsis, and driveline exit-site infections. Patients generally had improvements in quality of life measures.

Aaronson (2012) reported results of a multicenter, prospective study of a newer generation LVAD, the HeartWare®, which is a smaller, continuous flow centrifugal device that is implanted in the pericardial space.[21] The study enrolled 140 patients who were awaiting heart transplantation who underwent HeartWare® implantation. A control group of 499 subjects was comprised of patients drawn from the Interagency Registry for Mechanically Assisted Circulatory Support (INTERMACS) database, which collects data on patients who receive FDA-approved durable mechanical circulatory support devices. The study's primary outcome was defined as survival on the originally implanted device, transplantation, or explantation for ventricular recovery at 180 days. Secondary outcomes were comparisons of survival between groups and functional, quality of life, and adverse event outcomes in the HeartWare® group. Success occurred in 90.7% of the HeartWare® group and 90.1% of controls ($p<0.001$, noninferiority with a 15% margin). Serious adverse events in the HeartWare® group included, most commonly, bleeding, infections, and perioperative right heart failure.

Evidence suggests that the HeartMate II® axial achieves similar or better results than the earlier pulsatile HeartMate I model. In six reports with samples ranging from 32 to 279 patients, most participants received the new device as a bridge to transplantation.[22-27] Survival rates at six months and one year were 67% to 87%, and 50% to 80%, respectively. These rates are similar to those reported from INTERMACS.[28] An additional report from INTERMACS comparing the HeartMate II® to other LVAD devices for patients who received them with a bridge to transplantation indication reported that 80% and 91% of HeartMate II® and other LVAD patients reached transplant, cardiac recovery, or ongoing LVAD support by six months.[29] One report, however, compared HeartMate I and HeartMate II® recipients at a single center, finding the same one year survival and similar rates of subsequent development of right heart failure.[24] Serious adverse events occurring after HeartMate II® implantation included bleeding episodes requiring reoperation, stroke, infection, and device failure. A European study that included 67 bridge to transplant patients and 31 destination therapy patients found similar one-year survival rates in the two groups: 63% and 69%, respectively. A report on HeartMate II® recipients at a single institution found that out of 250 LVAD patients between November 2011 and June 2016, 6% (16) required a device pump exchange during the study period, and all but one patient survived until hospital discharge.[30]

Pediatric Patients

Systematic Review

Palazzolo (2022) published a SR to analyze current landscape of pediatric mechanical circulatory assist (MCA) devices.[31] They included 27 devices including VADs, Fontan assist devices and TAHs. The authors conclude that there is still not sufficient pump technology that

meets the constraints of a pediatric population such as patient sizes, increased cardiovascular demand with growth and physiologic heterogeneity of congenital heart disease.

Publications on children using VADs as a bridge to transplantation have reported positive outcomes. For example, a retrospective study of all children listed for a heart transplant at a single center between 1993 and 2009 found that mortality dropped significantly after the availability of VADs.[32] Davies (2008) reported that pediatric patients requiring a pretransplantation VAD had similar long-term survival to those not receiving mechanical circulatory support.[33]

A retrospective registry study by Jeewa (2018) assessed long-term outcomes for pediatric VAD use as a bridge to transplantation in patients from the Berlin Heart investigational device exemption trial.[34] These patients (n=109) were compared with matched controls from the Pediatric Heart Transplant Study who did not require mechanical circulatory support (n=166). There was no significant difference between the groups for five-year survival (81% for VAD, 88% for non-VAD, p=0.09) or for rates of infection or rejection.

Bulic (2017) identified all U.S. children between 1 and 21 years of age at heart transplant between 2006 and 2015 for dilated cardiomyopathy who were supported with an LVAD or vasoactive infusions alone at the time of heart transplant from the Organ Procurement and Transplant Network registry (n=701).[35] Children receiving LVAD were older, on a higher level of hemodynamic support, more likely to be on dialysis and waited long to receive a donor heart than children receiving vasoactive infusions. Functional status as measured by the median Karnofsky Performance Scale at heart transplant was higher for children receiving LVAD compared with vasoactive infusion (6 vs 5, p<0.001) and children receiving LVAD were more likely to be discharged from the hospital at the time of transplant. The percent of children having stroke at the time of transplant was higher in those receiving LVAD (3% vs 1%, p=0.04).

Almond (2013) reported results from a prospective, multicenter registry to evaluate outcomes in children who received the Berlin Heart EXCOR® device as a bridge to transplant.[36] All patients were followed up from the time of EXCOR® implantation until transplantation, death, or recovery. The study included 204 children, 67% of whom received the device under compassionate use. Survival at 12 months on EXCOR® support was 75%, including 64% who survived to transplantation, 6% who recovered (device explanted and patient survived 30 days), and 5% alive with the device in place. In a follow-up study which evaluated 204 children from the same registry, Jordan reported relatively high rates of neurologic events in pediatric patients treated with the EXCOR® device (29% of patients), typically early in the course of device use.[37] A 2016 report on this group included 358 bridge-to-transplant EXCOR® patients, and found that short- and mid-term post-transplant survival in these patients was similar to that of patients who did not receive pre-transplant mechanical circulatory support.[38]

Wehman (2016) reported on post-transplant survival outcomes for pediatric patients who received a VAD, extracorporeal membrane oxygenation (ECMO), or no mechanical circulatory support, in the pre-transplant period.[39] The study included 2,777 pediatric patients who underwent heart transplant from 2005 to 2012, who were identified through the United Network for Organ Sharing Database, of whom 428 were bridged with VADs and 189 were bridged with ECMO. In unadjusted analysis, the actuarial five-year survival was highest in the direct-to-transplant group (77%), followed by the VAD group (49%) and then the ECMO group (35%). In a proportional hazards model to predict time to death, restricted to the first four months post-

transplant, ECMO bridging was significantly associated with higher risk of death (adjusted hazard ratio [HR] 2.77 vs direct-to-transplant, 95% CI 2.12 to 3.61, p<0.0001). However, a model to predict time to death excluding deaths in the first four months post-transplant, the bridging group was not significantly associated with risk of death.

Section Summary

In adults, the evidence on the efficacy of LVADs as bridge to transplant consists of numerous nonrandomized studies comparing different LVADs devices among patients who have no other treatment options. In children, the evidence consists of several nonrandomized studies. These studies report that substantial numbers of patients survive the transplant in situations in which survival would not be otherwise expected. Despite the lack of high-quality studies, this evidence is sufficient to determine that outcomes are improved in patients who have no other options for survival.

VENTRICULAR ASSIST DEVICES AS BRIDGE TO RECOVERY

VADs may have a role in bridging patients to recovery, particularly if there is reverse remodeling of the left ventricle. Several additional studies have investigated the role of VADs in bridging patients to decision.

Systematic Reviews

Reid (2022) published an SR with meta analysis to evaluate the outcomes for patients undergoing right ventricular assist device (RVAD) implantation following left ventricular assist device (LVAD) implantation.[40] A total of 35 studies were included (3260 patients). The primary endpoint was mortality during the hospital stay and at follow-up. Mortality reported at short-term as well at long-term was 19.66% (CI 15.73-23.59%) and 33.90% (CI 8.84-59.96%) in LVAD respectively versus 45.35% (CI 35.31-55.4%) $p \leqslant 0.001$ and 48.23% (CI 16.01-80.45%) $p = 0.686$ in LVAD/RVAD group respectively. The authors conclude temporary RVAD implantation following LVAD is associated with decreased in-hospital, as well as short-term survival as compared to isolated LVAD implantation. The analysis is limited due to incomplete reporting, small sample sizes, and that the LVAD/RVAD cohorts are likely to be sicker and therefore have a higher mortality.

A scoping review with meta-analysis of selected studies was completed to examine the impact of 3rd generation LVADs on quality of life.[41] Eleven articles met the inclusion criteria. Three were randomized trials and eight were retrospective and registry studies. A meta-analysis was completed on four studies which included the EroQOL 5L tool at 6 months post LVAD implantation and reported a mean difference increase of 28.9 points (95% CI: 26.71 – 31.41). The authors conclude that the improved QOL support use of LVAD not only for prognosis but also for symptom control. The data are limited by lack of randomized studies and limited number of studies included in the meta-analysis.

Nonrandomized Studies

Support from VADs was originally indicated for the treatment of postcardiotomy cardiogenic shock in patients who could not be weaned from cardiopulmonary bypass. VAD use in this setting is temporary and brief, lasting between 1.4 and 5.7 days. The overall salvage rate for this indication is low, at approximately 25%; however, without VAD support, patients with refractory postcardiotomy cardiogenic shock would experience 100% mortality.[7, 42, 43]

Agrawal (2018) published a retrospective cohort study evaluating the 30-day readmissions of 2,510 patients undergoing LVAD implantation.[44] Of the patients who met the inclusion criteria, 788 (31%) were readmitted within 30 days after surviving initial index hospitalization. Cardiac causes accounted for 23.8% of readmissions, 13.4% due to heart failure, and 8.1% to arrhythmias. Infection (30.2%), bleeding (17.6%), and device-related causes (8.2%) comprised the 76.2% of non-cardiovascular causes for readmission. The study's limitations relate to the nature of nonclinical data collection and gaps in current subject knowledge.

A retrospective cohort study by Adesyiun (2017) assessed LVAD complications and overall effect on mortality to determine factors associated with development of early and long-term complications.[45] Utilizing logistic regression and Cox proportional hazards analyses at univariable and multivariable stages, the study found 24% of patients developed early complications and 18.5% developed both early and late complications. There was a significant association between death and early complications (p=0.017), while the additional presence of two or more complications produced a 2.7-fold increase in mortality odds (p=0.016). Mortality odds increased by 20% with each subsequent complication (p=0.004). The study was limited in that, during its long, 13-year team span, practice associated with LVAD maintained had changed but were not address by the study. Further limitations include the difficulty in determining the strictness to which a patient might have met the complication definitions, as well as the small sample size of the study.

Kawajiri (2017) evaluated the outcomes of patients with end-stage heart failure who had conventional surgery as opposed to transplant or mechanical support.[46] A total of 133 patients of this retrospective cohort study were identified with left ventricular ejection fraction (LVEF) less than 20% and VO2 max < 14 mL/min/m^2 and, after initial referral for advanced therapies, were instead offered a conventional procedure. Of the originally identified 133 patients, 68 were determined transplant eligible. Actuarial survival at 5 and 10 years was 72% and 39%, respectively, after 12% in-hospital mortality. Outcomes were acceptable for conventional cardiac surgery in highly selected patients with end-stage HF, and long-term survival was comparable with advanced surgical therapies. The study was limited by a small study population, its nonclinical nature, and the potential underestimation the VAD/transplant mortality by measuring survival dates starting from first surgery as opposed to date of decision.

Raju (2017) focused their retrospective cohort study on consecutive LVAD patients who received more than one year of total LVAD support time.[47] During the study period, 103 patients received LVADs, 37 received LVAD support for more than one year, and 18 received support for more than two years. Average support time was 786 days. Mortality and hospital readmissions were used to determine the efficacy of continuous-flow LVADs. During a median follow-up of two years, the one-year conditional survival was 74%. Readmission reasons were due to major infection (24%), major bleeding (19%), and device malfunction/thrombosis (13%), and totaled 112 completed readmission procedures, 60% of which were done in 13% (n=5) of patients. The study had the limitations of a descriptive retrospective analysis and small sample size, and quality of life (QOL) self-assessments would have provided necessary patient perspective.

Takayama (2014) reported outcomes for a retrospectively-defined cohort of 143 patients who received a CentriMag® VAD as a "bridge to decision" for refractory cardiogenic shock due to a variety of causes.[48] Patients were managed with a bridge-to-decision algorithm. Causes of cardiogenic shock included failure of medical management (n=71), postcardiotomy shock (n=37), graft failure post-heart transplantation (n=2), and right ventricular failure post-

implantable LVAD (n=13). The device configuration was biventricular in 67%, isolated right VAD in 26%, and isolated left VAD in 8%. After a mean duration of support of 14 days (interquartile range 8 to 26 days), 30% of patients had myocardial recovery, 15% had device exchange to an implantable VAD, and 18% had a heart transplantation.

Acharya (2016) reported on patients who underwent VAD placement in the setting of acute myocardial infarction (AMI) who were enrolled in the Interagency Registry for Mechanically Assisted Circulatory Support (INTERMACS) registry, a prospective national registry of FDA-approved durable mechanical circulatory support devices.[49] Patients who had an AMI as the admitting diagnosis or a major myocardial infarction (MI) as a hospital complication that resulted in VAD implantation (n=502) were compared with patients who underwent VAD implantation for non-AMI indications (n=9,727). Patients in the AMI group were generally sicker at baseline, with higher rates of smoking, severe diabetes, and peripheral vascular disease, but had fewer cardiac surgeries and recent cardiovascular hospitalizations. Most AMI patients (53.8%) were implanted with a “bridge-to-candidacy” strategy. At one-month post VAD, 91.8% of the AMI group were alive with the device in place. At one-year post-VAD, 52% of the AMI group were alive with the device in place, 25.7% had received a transplant, 1.6% had their VAD explanted for recovery, and 20.7% died with the device in place. Another retrospective study of 15,138 patients in the INTERMACS registry found that the incidence of recovery was significantly higher in bridge-to-recovery patients than in non-bridge-to-recovery patients (11.2% vs 1.2%, p<0.0001).[50]

Topkara (2016) reported a similar analysis of 13,454 INTERMACS adults with implants between June 2006 and June 2015 without TAH, pulsatile-flow LVAD, or heart transplant.[51] Device explant rates for cardiac recovery were 0.9% at one-year, 1.9% at two-year, and 3.1% at three-year follow-up. An additional 9% of patients demonstrated partial cardiac recovery.

In a smaller single-center retrospective cohort study, Mohamedali (2015) reported outcomes for 48 patients treated with biventricular support with the CentriMag® device as a “bridge to decision”, 18 of whom had biventricular support with venoarterial (VA) extracorporeal membrane oxygenation (ECMO), while the remainder received just biventricular VAD support.[52] Overall, 23 patients were explanted, nine to recovery, 14 to a durable LVAD, with three additional patients explanted for withdrawal of care. However, given that the study included patients who received VA ECMO, it is difficult to assess the relative impact of VAD support alone.

Six studies using the Centrimag® RVAD included between 12 and 32 patients, the majority of whom received biventricular devices.[43, 53-57] Indications and numbers of patients in these five studies were: support for post-cardiotomy cardiogenic shock (bridge to recovery), bridge to long-term device implantation (n=9), treatment of right heart failure in patients who previously received LVADs, bridge to later decision when neurologic status is clarified, and acute donor graft failure. The mean time on mechanical circulatory support ranged from 9.4 days to 46.9 days. The 30-day mortality rates were between 17% and 63%. The proportion of patients discharged from the hospital was between 30% and 83%. Major complications included bleeding requiring reoperation, sepsis, and stroke. No device failures were observed in these studies.

In a prospective multicenter study to assess myocardial recovery in patients with LVAD implantation as a bridge to transplant, Maybaum (2007) evaluated 67 patients with heart failure who had undergone LVAD implantation for severe heart failure.[58] After 30 days, patients

demonstrated significant improvements compared with pre-LVAD state in LVEF (17.1% vs 34.12%, p<0.001), left ventricular end-diastolic diameter (7.1 cm vs 5.1 cm, p<0.001), and left ventricular mass (320 g vs 194 g, p<0.001). However, only 9% of patients demonstrated enough recovery to have their LVAD explanted.

In a 2006 study, a series of 15 patients with severe heart failure due to nonischemic cardiomyopathy underwent implantation of LVADs, along with medical management designed to enhance myocardial recovery.[59] Eleven of 15 patients had enough myocardial recovery to undergo LVAD explantation; two patients died after explantation. Among those who survived, the cumulate rate of freedom from recurring heart failure was 100% and 88.9%, respectively, at one- and four-years post explantation. The same group subsequently reported results of their LVAD explantation protocol among patients with severe heart failure due to nonischemic cardiopathy who had nonpulsatile LVADs implanted.[60] They included 20 patients who received a combination of angiotensin converting enzyme ACE inhibitors, beta blockers, and adosterol antagonists followed by the β2-agonist clenbuterol. One patient was lost to follow-up and died after 240 days of support. Of the remaining 19 patients, 12 (63.2%) were successfully explanted after a mean 286 days; estimated survival without heart failure recurrence was 83.3% at one and three years.

Section Summary

The studies previously outlined indicate that a subset of patients who receive a VAD as a bridge to transplant demonstrate improvements in their cardiac function, sometimes to the point that they no longer require the VAD. However, questions remain about defining and identifying the population most likely to experience cardiac recovery with VAD placement. One clearly defined population in which the potential for myocardial recovery exists is in the postcardiotomy setting. Current evidence is insufficient to allow the identification of other heart failure patient populations who might benefit from the use of a VAD as a specific bridge-to-recovery treatment strategy. Ongoing research studies are addressing this question, along with protocols for transitioning patients off VAD use.

LEFT VENTRICULAR ASSIST DEVICES AS DESTINATION THERAPY

Technology Assessment

The policy statement regarding LVADs as destination therapy was initially based on a 2002 TEC assessment[61] that offered the following observations and conclusions:

- The available evidence comes from a single, well-designed and rigorously conducted randomized trial, known as the REMATCH study.[62] The study was a cooperative effort of Thoratec, Columbia University and the National Institutes of Health.

- The randomized trial found that patients with end-stage heart failure who are not candidates for cardiac transplantation have significantly better survival on an LVAD compared with treatment by optimal medical therapy. Median survival was improved by approximately 8.5 months. Serious adverse events were more common in the LVAD group, but these appear to be outweighed by this group's better outcomes on function. NYHA Class was significantly improved, as was quality of life among those living to 12 months.

- LVAD patients spend a greater relative proportion of time inside the hospital than medical management patients do, but the survival advantage would mean a longer absolute time outside the hospital.

Randomized Controlled Trials

The MOMENTUM 3 trial compared HeartMate 3™ centrifugal continuous-flow device with the HeartMate II® axial continuous-flow device in patients indicated for circulatory support as a bridge to transplant or destination therapy; inclusion criteria included 1) NYHA Class III heart failure with dyspnea upon mild physical activity or NYHA Class IV; 1) left ventricular ejection fraction ≤ 25%; 3) inotrope-dependent OR cardiac index <2.2 liters/min/m2 while not on inotropes plus on optimal medical management for at least 45 of the last 60 days and failing to respond or with advanced heart failure for at least 14 days and dependent on intra-aortic balloon pump for ≥7 days.[63, 64] HeartMate 3 ™ received PMA approval as a bridge to transplant therapy in August 2017 and as destination therapy in October 2018. The destination therapy indication was based on 2-year results from MOMENTUM 3, which showed superiority of the HeartMate 3 device compared to HeartMate II on the composite primary outcome, survival at two years free of disabling stroke or reoperation to replace a malfunctioning device (relative risk 0.84; 95% CI, 0.78–0.91, p<.001). Prevalence of stroke at 2 years was lower in the HeartMate 3 than the HeartMate 2® group (10.1% vs 19.2%; p=.02). Measures of functional capacity and Health-Related QOL did not differ between the two devices at six months.

A prespecified subgroup analysis of MOMENTUM 3 published in 2020 did not find differences in outcomes based on preoperative categories of bridge to transplant, bridge to transplant candidacy, or destination therapy.[65] Additionally, nearly 15% of those initially deemed transplant ineligible were eventually transplanted within 2 years of follow-up, supporting that clinical categorizations based on transplant eligibility should no longer be used. Park (2005) published a further follow-up of patients in the REMATCH trial, mentioned in the above TEC assessment, which found that survival and quality of life benefits were still apparent with extended two-year follow-up.[66]

Slaughter (2009) published data from an unblinded randomized multicenter trial.[67] Subjects were randomized to continuous-flow or pulsatile-flow devices on a 2:1 block-randomization basis. The primary outcome measured was a composite endpoint of two-year survival, free of disabling stroke or need for device replacement. Continuous-flow patients (n=134) reached the primary outcome at a rate of 46% (95% CI 38 to 55) compared to pulsatile-flow patients (n=66) rate of 11% (95% CI 3 to 18), which was a significant difference (p<0.001). Analysis of constituent factors indicated that a lower rate of devices needing replacement in the continuous-flow group had the largest effect on the composite endpoint; two-year death rate also favored this device (58% vs. 24%, p=0.008). Stroke and death (within two years of implantation) were similar in the two groups (stroke rate 12% and death rate 36%). Quality of life scores were also similar in the two groups. Although unblinded, this randomized trial adds to the evidence favoring continuous-flow devices.

Nonrandomized Studies

Jorde (2014) published results from an FDA-required postapproval study of the HeartMate II® device for destination therapy.[68] The study included the first 247 HeartMate II® patients identified as eligible for the device as destination therapy, outcomes and adverse events did not differ significantly from those treated in the original trial, which compared patients who

received the HeartMate II® to earlier generation devices (Slaughter [2009], described below).[67] Survival in the postapproval cohort was 82% and 69% at one and two years postoperatively, respectively.

A subsequent prospective observational study comparing LVAD support (n=97) with optimal medical therapy (n=103) for patients with heart failure not requiring inotropes also reported superior survival and health-related quality of life in LVAD-treated patients.[69] Twelve-month survival was 80% in the LVAD group, compared with 63% in the best medical therapy group (p=0.022).

In addition, other case series suggest continuing improvement in outcomes related to ongoing improvements in the device and in patient management.[70] However, the durability of the HeartMate device used in the REMATCH trial is a concern; for example, at one participating institution, all six long-term survivors required device change-outs. Next generation devices consisting of smaller continuous flow devices are eagerly anticipated.

Section Summary

The primary evidence on the efficacy of LVADs as destination therapy in patients who are not transplant candidates is from the REMATCH study. This study reported that the use of LVADs led to improvements in survival, quality of life, and functional status.

The evidence on the comparative efficacy of continuous-flow vs pulsatile-flow devices consists of an RCT and several nonrandomized comparative studies. The RCT reported fairly large differences in a composite outcome measure favoring the continuous-flow devices, with increases in revision and reoperation rates for the pulsatile device group being the largest factor driving the difference in outcomes.[67] Other nonrandomized comparative studies, including a database study with large numbers of patients, have not reported important differences in clinical outcomes between devices.

CONTINUOUS-FLOW VS PULSATILE-FLOW DEVICES

Nonrandomized Studies

Mehra (2022) published a five year observational follow-up study in patients with Fully Magnetically Levitated vs Axial-Flow Left Ventricular Assist Devices in the MOMENTUM 3 Randomized Trial.[71] A total of 477 patients (295 enrolled between June 2019 and April 2021 and 182 provided limited data) of 536 patients still receiving LVAD support at 2 years contributed to the extended-phase analysis (median age, 62 y; 86 [18%] women). The 5-year Kaplan-Meier estimate of survival to transplant, recovery, or LVAD support free of debilitating stroke or reoperation to replace the pump in the centrifugal-flow vs axial-flow group was 54.0% vs 29.7% (hazard ratio, 0.55 [95% CI, 0.45-0.67]; P < .001). Overall Kaplan-Meier survival was 58.4% in the centrifugal-flow group vs 43.7% in the axial-flow group (hazard ratio, 0.72 [95% CI, 0.58-0.89]; P = .003). Serious adverse events of stroke, bleeding, and pump thrombosis were less frequent in the centrifugal-flow pump group. The authors conclude that these findings support the use of the fully magnetically levitated LVAD.

A post-pivotal trial continuous access protocol was initiated as a single-arm prospective study to assess the reproducibility of HeartMate3™ LVAD outcomes across centers used in the MOMENTUM 3 trail.[72] A total of 515 patients were included in the pivotal cohort. The primary outcomes for this extended study were survival to transplant, recovery, or ongoing LVAD support, free of disabling stroke or reoperation to replace or remove a malfunctioning pump, at

2 years post-implant. At 2 years post-implant, a similar proportion of patients in the continuous access group versus the pivotal cohort achieved the composite endpoint (76.7% vs 74.8%; adjusted HR, 0.87; 95% CI, 0.71 to 1.08; p=.21). Pump exchange rates were low in both cohorts with 98.4% of the continuous access cohort and 96.9% of the pivotal cohort being free of pump replacement at 2 years. Overall survival at 2 years was 81.2% in the continuous access cohort compared to 79% in the pivotal cohort. After controlling for baseline demographics between cohorts, the adjusted HR for continuous access versus pivotal cohort was 0.84 (95% CI, 0.67 to 1.06; p=.15). Survival based on if the HeartMate3 ™ was used as a bridge to transplant or as destination therapy was similar between the continuous access and pivotal trial cohorts (bridge to transplant adjusted HR, 0.70; 95% CI, 0.43 to 1.14; p=.15; destination therapy adjusted HR, 0.89; 95% CI, 0.68 to 1.16; p=.38). This additional trial in a larger cohort reproduced similar results to the initial MOMENTUM 3 study, especially in individuals using VADs as destination therapy.

Dell'Aquila (2014) compared outcomes for patients treated with a third-generation continuous flow device, the HeartWare® device, with those for patients treated with earlier generation devices in a single-center study.[73] Comparison-group patients received either an earlier generation continuous flow device or a pulsatile flow device. Of 287 patients who received VAD support from 1993 to 2012, 52 received a HeartWare® device, 76 an earlier generation continuous flow device, and 159 a pulsatile device. Survival was significantly better for patients who received a third-generation device, with 24 months survival of 70.4%, compared with 33.7% for patients who received an earlier generation continuous flow device and 33.8% for patients who received a pulsatile flow device (p=0.013). The difference in survival associated with third generation devices was more pronounced for higher scores on the INTERMACs scale.

Nativi (2011) published a nonrandomized comparison of pulsatile versus continuous flow devices using data from the registry of the International Society for Heart and Lung Transplantation on 8,557 patients undergoing transplant.[74] Comparisons were made among patients receiving a pulsatile LVAD, a continuous flow LVAD, and no LVAD. Two time periods were used for analysis, the first was pre-2004, when nearly all LVADs were pulsatile devices, and post-2004 when continuous use devices began to be used in clinical care. There was a significantly greater risk of mortality in the first time period compared to the second time period (RR 1.30, 95% CI 1.03 to 1.65, p=0.03). When analysis was confined to the second time period, there was no significant improvement in survival for the continuous group compared to the pulsatile group (RR 1.25, 95% CI 1.03 to 1.65, p=0.03).

Other nonrandomized studies that have compared outcomes from different types of LVADs have been smaller and/or focused on physiologic outcomes.[75-78] In some of these studies, the continuous flow devices exhibit greater improvement in physiologic measures, but none of these studies have reported significant differences between devices in clinical outcomes.

Section Summary

The evidence of the comparative efficacy of centrifugal continuous-flow vs axial continuous-flow devices consists of two RCTs of two different centrifugal continuous-flow devices. The MOMENTUM3 trial compared HeartMate 3™ centrifugal continuous-flow device with the HeartMate II® axial continuous-flow device in patients indicated for circulatory support as a bridge to transplantation or destination therapy. HeartMate 3™ has been recalled. The ENDURANCE trial compared HeartWare® centrifugal continuous-flow device with the

HeartMate II® axial continuous-flow device in patients indicated for circulatory support as destination therapy. HeartWare® is FDA-approved for bridge to transplantation. Both trials found the centrifugal device to be noninferior to the axial device for the primary, composite outcome including measures of survival, freedom from disabling stroke and freedom from device failure. While there are fewer device failures with the centrifugal devices without significant increase in disabling stroke, the HeartWare® device was associated with increased risk of any stroke over a period of two years.

The evidence on the comparative efficacy of continuous-flow vs pulsatile-flow devices consists of one RCT and several nonrandomized comparative studies. The RCT reported fairly large differences in a composite outcome measure favoring the continuous flow devices, with increases in revision and reoperation rates for the pulsatile device group being the largest factor driving the difference in outcomes. Other nonrandomized comparative studies, including one database study with large numbers of patients, have not reported differences between devices on clinical outcomes.

AORTIC COUNTERPULSATION DEVICES

Intra-aortic balloon pump (IABP) devices have been developed as a treatment for cardiogenic shock. IABPs consist of a helium-filled balloon placed in the aorta that deflates during cardiac systole to increase forward blood flow. The inflation and deflation of the balloon is computer-controlled and can be regulated by either a pressure-sensing catheter or an electrocardiogram. These devices have not been FDA approved, and therefore the evidence for these devices is not reviewed in detail.

TOTAL ARTIFICIAL HEARTS

BRIDGE TO TRANSPLANTATION

Nonrandomized Studies

In 2004, the CardioWest Total Artificial Heart™ (now called the SynCardia Total Artificial Heart) received FDA approval for use as a bridge to transplant. The approval was based on the results of a nonrandomized, prospective study of 81 patients.[79] Patients had failed inotropic therapy and had biventricular failure and thus were not considered appropriate candidates for an LVAD. The rate of survival to transplant was 79%, which was considered comparable to the experience with LVAD in patients with left ventricular failure. The mean time from entry into the study until transplantation or death was 79.1 days.

Other case series have been reported on outcomes of the TAH as a bridge to transplant. For example, Copeland reported on 101 patients treated with the SynCardia artificial heart as a bridge to transplant.[80] All patients either met established criteria for mechanically assisted circulatory support or were failing medical therapy on multiple inotropic drugs. The mean support time was 87 days, with a range of 1 to 441 days. Survival to transplant was 68.3% (69/101). Of the 32 deaths prior to transplant, 13 were due to multiple organ failure, 6 were due to pulmonary failure, and four were due to neurologic injury. Survival after transplant at 1, 5, and 10 years, respectively, was 76.8%, 60.5%, and 41.2%.

DESTINATION THERAPY

In currently available studies, the AbioCor® Implantable Replacement Heart has only been used as destination therapy for end-stage patients with congestive heart failure.

Nonrandomized Studies

Torregrossa (2014) reported on 47 patients who received a TAH at 10 worldwide centers and had the device implanted for more than one year.[81] Patients were implanted for dilated cardiomyopathy (n=23), ischemic cardiomyopathy (n=15), and "other" reasons (n=9). Over a median support time of 554 days (range, 365-1373 days), 34 patients (72%) were successfully transplanted, 12 patients (24%) died while on device support, and one patient (2%) was still supported. Device failure occurred in five patients (10%). Major complications were common, including systemic infection in 25 patients (53%), driveline infections in 13 patients (27%), thromboembolic events in nine patients (19%) and hemorrhagic events in seven patients (14%). Two of the deaths occurred secondary to device failure.

Dowling (2004) reported on the first seven patients in the AbioCor® clinical trial.[82] The 30-day survival rate was 71% compared with the predicted survival rate of 13% with only medical therapy. At 60 days, 43% were still alive and as of July 2006 two patients were still alive 234 and 181 days postoperatively and remain hospitalized. Deaths were due to intraoperative bleeding at the time of implantation, cerebrovascular accidents, pulmonary embolism, and multiorgan failure. No reports of serious device malfunction have been reported for the seven patients. Frazier (2004) reported information on four additional patients receiving the AbioCor®.[83] Using the same inclusion criteria as in the above RCT the device supported three patients for greater than 100 days, whereas a fourth patient expired at 53 days. There were no device related problems reported.

SECTION SUMMARY

There is little evidence on the use of TAH as a bridge to transplantation, or as destination therapy, compared with the use of LVADs. The type of evidence on bridge to transplant is similar to that for LVADs (i.e., case series reporting substantial survival rates in patients without other alternatives). Therefore, this evidence is sufficient to conclude that TAH improves outcomes for these patients similar to LVADs and is a reasonable alternative for patients who require bridge to transplantation but who are ineligible for other types of support devices. Although TAHs show promise for use as destination therapy in patients who have no other treatment options, the available data on their use is extremely limited. There is insufficient evidence on the use of TAH as destination therapy to support conclusions about the efficacy of TAH in this setting.

PRACTICE GUIDELINE SUMMARY

SOCIETY FOR CARDIOVASCULAR ANGIOGRAPHY AND INTERVENTIONS

In 2015, the Society for Cardiovascular Angiography and Interventions (SCAI), the Heart Failure Society of America (HFSA), the Society of Thoracic Surgeons (STS), the American Heart Association (AHA), and the American College of Cardiology (ACC) published a clinical expert consensus statement on the use of percutaneous mechanical circulatory support (MCS) devices in cardiovascular care.[84] This statement addressed intra-aortic balloon pumps (IABPs), left atrial (LA)-to-aorta assist device (eg, TandemHeart), left ventricle (LV)-to-aorta assist devices (eg, Impella), extracorporeal membrane oxygenation (ECMO), and methods of right-sided support. Specific recommendations are not made, but the statement reviews the use of MCS in patients undergoing high-risk percutaneous intervention (PCI), those with cardiogenic shock, and those with acute decompensated heart failure.

AMERICAN ASSOCIATION FOR THORACIC SURGERY/INTERNATIONAL SOCIETY FOR HEART AND LUNG TRANSPLANTATION[85]

In 2020, the American Association for Thoracic Surgery/International Society for Heart and Lung Transplantation published guidelines on selected topics in mechanical circulatory support. The guidelines noted that "Compared with IABP, contemporary percutaneous circulatory support devices provide a significant increase in cardiac index and mean arterial pressure; however, reported 30-day outcomes are similar." The level of evidence was graded at B and class of evidence was graded IIA.

AMERICAN COLLEGE OF CARDIOLOGY FOUNDATION / AMERICAN HEART ASSOCIATION / HEART FAILURE SOCIETY OF AMERICA (ACCF/AHA/HFSA)[86]

The 2013 ACCF/AHA practice guidelines for the management of heart failure included the recommendations below related to MCS which includes LVADs. All of these recommendations were rated II.a., level of evidence B, defined as a recommendation in favor of the treatment being useful, with some conflicting evidence from a single RCT or nonrandomized studies.

- MCS is considered beneficial in carefully selected patients with stage D heart failure with reduced ejection fraction (HFrEF) as a bridge to transplantation or recovery.
- Nondurable mechanical cardiac support including percutaneous and extracorporeal VADs are considered "reasonable" as a bridge to recovery or a bridge to decision for carefully selected patients with HFrEF with acute, profound hemodynamic compromise.
- Durable (permanent) MCS is considered reasonable to prolong survival for carefully selected patients with stage D HFrEF.

The guidelines note that, although optimal patient selection for MCS is an area of investigation, general indications for referral for MCS therapy include patient with LVEF<25% and NYHA class III-IV functional status despite guideline-directed medical therapy (GDMT) including cardiac resynchronization therapy (CRT), when indicated, with either high predicted one- to two-year mortality or dependence on continuous parenteral inotropic support.

In 2017, the ACCF/AHA/HFSA published a focused update of the 2013 recommendations released by the ACCF and AHA.[87] LVAD was one of several treatment options recommended for patients with refractory NYHA class III or IV heart failure (stage D). If symptoms were not improved after guideline-directed management and therapy, which included pharmacologic therapy, surgical management and/or other devices, then LVAD was presented as an additional treatment option. The 2017 update focused on changes in sections regarding biomarkers, comorbidities, and prevention of heart failure, while many of the previous recommendations remained unchanged.

The AHA/ACC/HFSA published updated guidelines in 2022 to consolidate the 2013 and 2017 guidelines and to provide contemporary evidence.[88] The use of LVADs in patients with stage D HF is an included focus. The guidelines provide the highest class of recommendation (COR =1) and strongest level of evidence (LOE = A) that In select patients with advanced HFrEF with NYHA class IV symptoms who are deemed to be dependent on continuous intravenous inotropes or temporary MCS, durable LVAD implantation is effective to improve functional status, QOL, and survival. (Class or Recommendation (COR) level 1 and Level of Evidence (LOE) = A. Additionally, In select patients with advanced HFrEF who have NYHA class IV

symptoms despite GDMT, durable MCS can be beneficial to improve symptoms, improve functional class, and reduce mortality (COR II A; LOE B-R). Where COR A is high quality evidence from more than 1 RCT; B-R: Moderate-quality evidence from 1 or more RCTs; B-NR: Moderate-quality evidence from 1 or more well-designed, well-executed nonrandomized studies, observational studies, or registry studies. The updated guidelines are silent on the use of artificial hearts.

THE HEART FAILURE SOCIETY OF AMERICA (HFSA)

The HFSA published guidelines in 2010 on surgical approaches to the treatment of heart failure. The guidelines are based on evidence and expert opinion.[79] The following recommendations were made regarding ventricular assist devices:

- Bridge to transplantation: Patients awaiting heart transplantation who have become refractory to all means of medical circulatory support should be considered for a mechanical support device as a bridge to transplant. (Strength of Evidence B - cohort and case-control studies)
- Bridge to recovery: Patients with refractory HF and hemodynamic instability, and/or compromised end-organ function, with relative contraindications to cardiac transplantation or permanent mechanical circulatory assistance expected to improve with time or restoration of an improved hemodynamic profile should be considered for urgent mechanical circulatory support as a "bridge to decision." These patients should be referred to a center with expertise in the management of patients with advanced HF. (Strength of Evidence C - expert opinion)
- Destination Therapy: Permanent mechanical assistance using an implantable assist device may be considered in highly selected patients with severe HF refractory to conventional therapy who are not candidates for heart transplantation, particularly those who cannot be weaned from intravenous inotropic support at an experienced HF center. (Strength of Evidence B - cohort and case-control studies)

SUMMARY

VENTRICULAR ASSIST DEVICES

There is enough research to show that implantable ventricular assist devices (VADs) as a bridge to transplantation or recovery, or as destination therapy, improve health outcomes in some patients with heart failure who might not otherwise survive. Therefore, implantable VADs may be considered medically necessary when the policy criteria are met.

There is not enough research to show that ventricular assist devices or aortic counterpulsation devices improve health outcomes for people with heart failure or other heart conditions when policy criteria are not met. Therefore, the use of ventricular assist devices or aortic counterpulsation devices when policy criteria are not met is considered investigational.

TOTAL ARTIFICIAL HEARTS

There is enough research to show that the use of a total artificial heart (TAH) as a bridge to heart transplantation improves survival and quality of life for patients in some specific

situations. Therefore, total artificial hearts may be considered medically necessary as a bridge to heart transplantation when policy criteria are met.

There is not enough research to show that total artificial hearts (TAHs) as destination therapy improves health outcomes for patients. Therefore, the use of TAHs as destination therapy is considered investigational.

CODES

Note: There is no specific code for reporting prolonged extracorporeal percutaneous transseptal ventricular assist device; the appropriate code for reporting this procedure is 33999.

Codes	Number	Description
CPT	33927	Implantation of a total replacement heart system (artificial heart) with recipient cardiectomy
	33928	Removal and replacement of total replacement heart system (artificial heart)
	33929	Removal of a total replacement heart system (artificial heart) for heart transplantation (list separately in addition to code for primary procedure)
	33975	Insertion of ventricular assist device; extracorporeal, single ventricle
	33976	Insertion of ventricular assist device; extracorporeal, biventricular
	33977	Removal of ventricular assist device; extracorporeal, single ventricle
	33978	Removal of ventricular assist device; extracorporeal, biventricular
	33979	Insertion of ventricular assist device, implantable intracorporeal, single ventricle
	33980	Removal of ventricular assist device, implantable intracorporeal, single ventricular
	33981	Replacement of extracorporeal ventricular assist device, single or biventricular, pump(s), single or each pump
	33982	Replacement of ventricular assist device pump(s); implantable intracorporeal, single ventricle, without cardiopulmonary bypass
	33983	Replacement of ventricular assist device pump(s); implantable intracorporeal, single ventricle, with cardiopulmonary bypass
	33990	Insertion of ventricular assist device, percutaneous, including radiological supervision and interpretation; left heart, arterial access only
	33991	Insertion of ventricular assist device, percutaneous, including radiological supervision and interpretation; left heart, both arterial and venous access, with transseptal puncture
	33992	Removal of percutaneous left heart ventricular assist device, arterial or arterial and venous cannula(s), at separate and distinct session from insertion
	33993	Repositioning of percutaneous right or left heart ventricular assist device with imaging guidance at separate and distinct session from insertion
	33995	Insertion of ventricular assist device, percutaneous, including radiological supervision and interpretation; right heart, venous access only
	33997	Removal of percutaneous right heart ventricular assist device, venous cannula, at separate and distinct session from insertion
	33999	Unlisted procedure, cardiac surgery
HCPCS	L8698	Miscellaneous component, supply or accessory for use with total artificial heart system
	Q0477 – Q0509	Ventricular assist device accessories, code range

Medical Policy Manual Surgery, Policy No. 58

Bariatric Surgery

Effective: February 1, 2024

Next Review: October 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Bariatric surgery is a major surgical intervention which aims to reduce weight, eliminate or improve comorbid conditions, and maintain weight loss in obese patients who have failed to achieve weight loss through lifestyle modifications.

MEDICAL POLICY CRITERIA

Note: Member contracts for covered services vary. Member contract language takes precedence over medical policy.

I. Bariatric surgery may be considered **medically necessary** in the treatment of obesity when all of the following criteria (A. and B.) are met**:**

A. All of the general Criteria (1.- 4.) must be met:

1. At the start of the medically-supervised, nonsurgical weight reduction program, one of the following must be met:

a. BMI greater than or equal to 40 kg/(meter squared); or

b. BMI greater than or equal to 35 kg/(meter squared) with at least one of the following comorbid conditions:

i. Type II diabetes mellitus; or

ii. Poorly controlled hypertension despite optimal medical management; or

iii. Coronary artery disease; or

iv. Obstructive sleep apnea as defined by an AHI equal to or greater than 15 per hour; and

2. The patient meets one of the following age requirements:
   a. Greater than or equal to 18 years; or
   b. Less than 18 years of age and has attained Tanner 4 or 5 pubertal development and one of the following must be met:
      i. BMI greater than or equal to 140 percent of the 95th percentile for age and sex; or
      ii. BMI greater than or equal to 120 percent of the 95th percentile for age and sex with at least one of the comorbid conditions listed in Criterion I.A.1.b.
3. Documentation of active participation for a total of at least 3 consecutive months in a structured, medically supervised pre-operative training program. The program must be provided by or approved and monitored under the supervision of the bariatric program.

   Documentation from the clinical medical records must indicate that the structured medical supervision meets all of the following Criteria:
   a. Program participation occurs during a total of at least 3 consecutive months within the 12 months prior to the request for surgery; and
   b. Include at least 2 visits for medical supervision, during the 3 consecutive months of program participation. One visit must occur at the initiation, and another at least 3 months later (90 days); and
   c. Be provided by an MD, DO, NP, PA, or RD in conjunction with the bariatric program; and
   d. Include assessment and counseling concerning weight, nutrition and diet that should be related to the type of planned bariatric surgery, exercise, and behavior modification; and
4. Preoperative evaluation to include both of the following:
   a. A licensed psychologist, psychiatrist, LCSW/LICSW, licensed masters-level counselor, or NP in a behavioral health practice, documents the absence of significant psychopathology that can limit an individual's understanding of the procedure or ability to comply with medical/surgical recommendations (e.g., active substance abuse, eating disorders, schizophrenia, borderline personality disorder, uncontrolled depression); and
   b. Clinical documentation that the patient is an appropriate candidate for the surgery and is committed to the treatment plan; and

B. The request is for one of the following procedures:

1. Sleeve gastrectomy as a stand-alone procedure; or
2. Gastric bypass using a Roux-en-Y anastomosis with an alimentary limb of 150 cm or less
3. Biliopancreatic bypass with duodenal switch in patients ages greater than or equal to 18 years with BMI greater than or equal to 50 kg/(meter squared)

II. Reoperation may be considered **medically necessary** when one or more of the following criteria (A. or B.) are met:

A. Reoperation with revision of a bariatric procedure (i.e. sleeve gastrectomy, biliopancreatic bypass with duodenal switch, or gastric bypass), conversion of a sleeve gastrectomy to a gastric bypass using a Roux-en-Y anastomosis with an alimentary limb of 150 cm or less, or adjustable gastric band removal when one or more of the following documented significant complications is present:

1. Leak or bowel perforation, including band erosion; or
2. Documentation of band migration (slippage), that cannot be corrected with fluid adjustment.; or
3. Band infection; or
4. Obstruction exceeding the inherent obstruction of the original bariatric procedure, documented by imaging or endoscopic findings; or
5. Staple-line failure (such as, Gastro-gastric fistula); or
6. Weight loss to 90% or less of ideal body weight; or
7. One or more of the following severe, clinically-objective conditions that have been unresponsive to optimal medical management for at least 4 months:
   a. Severe esophagitis (may include Barrett's esophagus); or
   b. Cameron lesion(s); or
   c. Gastro-jejunal anastomotic ulcer(s).

B. Removal of adjustable gastric band with conversion to a gastric bypass using a Roux-en-Y anastomosis with an alimentary limb of 150 cm or less when Criterion I. A. is met. Note: Criterion I. A. must be met during the period after placement of the adjustable gastric band.

III. Sleeve gastrectomy, biliopancreatic bypass with duodenal switch, or gastric bypass using a Roux-en-Y anastomosis with an alimentary limb of 150 cm or less is considered **not medically necessary** when Criterion I. above is not met including but not limited to biliopancreatic bypass with duodenal switch in patients younger than 18 years of age or in patients with BMI less than or equal to 50kg/(meter squared).

IV. The vertical banded gastroplasty and adjustable gastric banding are no longer a standard of care and are therefore considered **not medically necessary**.

V. Reoperation or conversion of a prior bariatric procedure is considered **not medically necessary** when Criterion II. is not met, including but not limited to reoperation for

early satiety, nausea, patient dissatisfaction, or gastroesophageal reflux disease (GERD).

VI. Repair of sliding or paraesophageal hiatal hernia when performed at the time of any bariatric surgery would be considered **a component of and incidental** to the primary bariatric surgery.

VII. The following procedures are considered **investigational** for the treatment of:

A. Obesity including distal or partial gastrectomy (other than standard sleeve gastrectomy) performed with or without gastroduodenostomy, gastrojejunostomy, or Roux-en-Y reconstruction; and gastric restrictive procedure without gastric bypass for obesity (other than sleeve gastrectomy)

B. Obesity using only hiatal hernia repair including repair of sliding or paraesophageal hernia.

C. Any condition *other than obesity* (e.g. gastroesophageal reflux disease or gastroparesis) including sleeve gastrectomy, biliopancreatic bypass with duodenal switch or gastric bypass using a Roux-en-Y anastomosis.

D. Any condition including but not limited to obesity and gastroesophageal reflux disease:

1. Mini-gastric bypass (gastric bypass using a Billroth II type of anastomosis)
2. Distal gastric bypass (long limb gastric bypass, i.e., >150 cm)
3. Biliopancreatic bypass (i.e., the Scopinaro procedure)
4. Duodenal switch with single anastomosis, D-Loop surgery, or stomach intestinal pylorus sparing surgery (SIPS)
5. Two-stage bariatric surgery procedures (e.g., sleeve gastrectomy followed by gastric bypass, sleeve gastrectomy followed by biliopancreatic diversion, removal of gastric band followed by sleeve gastrectomy or gastric bypass)
6. Any combination of adjustable gastric banding (e.g., Fobi pouch with silastic band) or adjustable gastric banding with Roux-en-Y gastric bypass, or sleeve gastrectomy, or other bariatric surgical procedure.
7. Parietal cell separating gastrojejunostomy
8. Gastric plication

VIII. Endoscopic procedures are considered **investigational** for the following:

A. As the primary bariatric procedure

B. Secondary bariatric procedures (See Policy Guidelines) to treat complications of primary bariatric surgery including but not limited to weight gain due to a large gastric stoma or large gastric pouch and dumping syndrome.

C. Balloon dilatation of strictures when Criterion II.A.4 is not met.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Examples of endoscopic devices/procedures include but are not limited to the following:

1. StomaphyX (EndoGastric Solutions, Inc)
2. ROSE procedure (Restorative Obesity Surgery, Endoscopic)
3. EndoCinch (Bard)
4. EndoSurgical Operating System (EOS) (USGI Medical, Inc.)
5. Sclerotherapy of stoma
6. Endoscopic gastroplasty
7. Endoscopically placed duodenal-jejunal sleeve
8. Endoscopic stoma revision
9. Gastric balloon systems
10. AspireAssist
11. OverStitch Endoscopic Suturing System (Apollo Endosurgery, Inc.)

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION:

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could our impact review and decision outcome:

1. If patient is less than 18 years of age, documentation is provided of Tanner 4 or 5 pubertal development. For patients under 18 years of age, greater consideration should be given to psychosocial and informed consent issues.
2. Clinical documentation of a medically supervised nonsurgical pre-operative training program approved and monitored under the supervision of the healthcare practitioner providing medical oversight, that includes:
    A. BMI at the start of the program
    B. Comorbid conditions
    C. The program occurred during at least 3 consecutive months within the 12 months prior to request for surgery
    D. At least 2 visits for medical supervision during the 3 consecutive months of program participation. One visit must occur at the initiation, and another at least 3 months later.
    E. Assessment and counseling concerning weight, diet, exercise and behavior modification
    F. Documentation the program was provided by an MD, DO, NP, PA, or RD under the supervision of the bariatric program.
3. Preoperative evaluation by a licensed psychologist, psychiatrist, LCSW/LICSW, licensed masters-level counselor, or NP in behavioral health that includes:

A. Documentation of the absence of significant psychopathology that can limit an individual's understanding of the procedure or ability to comply with medical/surgical recommendations (e.g., active substance abuse, eating disorders, schizophrenia, borderline personality disorder, uncontrolled depression)

4. Clinical documentation that the patient is an appropriate candidate for the surgery and is committed to the treatment plan.
5. History and Physical including current medications.
6. Specific procedure being requested.
7. For Reoperation, Revision or Removal requests:
   A. Complication present
   B. Interventions attempted. NOTE: For band migration (slippage), that cannot be corrected with manipulation or adjustment. Records must demonstrate that manipulation or adjustment to correct band slippage has been attempted.
   C. Imaging or endoscopic findings. NOTE: For obstruction, records must demonstrate endoscopic findings or imaging has been performed.
   D. For severe esophagitis, Cameron lesions, or gastro-jejunal anastomotic ulcers, documentation must demonstrate medical management has been tried for at least 4 months.

BACKGROUND

Levels of overweight and obesity are currently determined by Body Mass Index (BMI) – which is calculated as weight (kg) / height (meters) squared. A normal BMI range is 18.5 to < 25.0 kg/m^2) – overweight and obesity is classified as follows:

Overweight:	25 to < 30.0 kg/m^2
Obesity:	Class I: 30 to < 35.0 kg/m^2
	Class II: 35 to < 40 kg/m^2
	Class III: ≥ 40.0 kg/m^2 (also referred to as severe obesity)

Note: BMI may be calculated by using the BMI calculator.

Individuals with class III obesity are at high risk for developing weight-related complications such as diabetes, hypertension, obstructive sleep apnea, and various types of cancers (colon, prostate, breast, uterus, and ovaries). In addition, class III obesity is associated with a shortened life span.[1]

The first-line treatment of severe obesity involves dietary and lifestyle changes. Although this strategy may be effective in some patients, a majority of patients with severe obesity do not achieve significant weight loss through lifestyle modifications. In addition, the weight loss may

not be durable, as only a small number of patients are able to comply with the changes on a long-term basis. When conservative measures fail, some patients may consider surgery for severe obesity (bariatric surgery).

Several bariatric procedures have been developed, but based on the underlying mechanism of weight loss, all fall into one or both of the following categories:

Restrictive procedures

- Decrease the size of the stomach and limit food intake

Malabsorptive procedures

- Limit the absorption of calories and nutrients by altering the way food moves through the intestinal track

Multiple variants exist, differing in the reconfiguration of the small intestines and consequently the extent of malabsorption.

The following table briefly summarizes different bariatric procedures:

Procedure	CPT Code	Description
Gastric Bypass with Roux-en-Y Anastomosis (RYGBP) AKA: Proximal or Short Limb Gastric Bypass	43846 43644	• Involves both restrictive and malabsorptive components: o A small gastric pouch is created from the upper part of the stomach by segmentation or resection to restrict the amount of food that can be ingested o The mid portion of the jejunum is divided and the cut end of the distal limb (≤ 150 cm) is attached to the gastric pouch outlet (Roux limb). The cut end of the proximal limb (the limb consisting of the duodenum and proximal jejunum) is attached to the side of the Roux limb (the limb connected to the pouch). This creates the Y configuration of the small intestine, allowing food to bypass the duodenum and proximal jejunum, resulting in malabsorption.
Distal (Long Limb) Gastric Bypass	43847	• The procedure involves both restrictive and malabsorptive components and is a variant of the standard gastric bypass with the longer (>150 cm) Roux limb. The longer the Roux limb, the greater the bypass of the small intestine and consequently the degree of malabsorption.
Biliopancreatic Diversion (Bypass) Procedure AKA Scopinaro procedure	43847	• Involves both restrictive and malabsorptive components: o Subtotal (distal) gastrectomy creates small gastric pouch at the top of the stomach to limit food intake o A long limb Roux-en-Y anastomosis (>150 cm) results in the biliopancreatic juices being diverted into the distal ileum, significantly increasing malabsorption • Designed to preferentially inhibit the absorption of fat • Only partially reversible
Biliopancreatic Diversion (Bypass) with Duodenal Switch (BPD-DS)	43845	• This procedure is an adaptation of the standard biliopancreatic bypass: o The restrictive component involves subtotal gastrectomy resulting in a tube or sleeve-like stomach remnant that leaves the pyloric valve and the initial segment of duodenum intact. o The long limb Roux-en-Y anastomosis (>150 cm) provides malabsorption in this variant as well, but the distal ileum is connected to the duodenal segment leading from the stomach sleeve, instead of the stomach pouch itself.
Laparoscopic duodenal switch with single anastomosis AKA Single loop duodenal switch	No specific CPT code	• Restrictive and malabsorptive procedure • Simplified version of the BPD-DS procedure • Surgery consists of: o Creation of a small gastric pouch by section the curvature of the stomach o Duodenum is transected while keeping the pylorus intact o A 1-loop duodenal switch is performed with creation of a 200-250 cm anastomosis
Mini-Gastric Bypass	no specific code	• The procedure is a variant of the gastric bypass and involves both restrictive and malabsorptive components: o The stomach is segmented to create a small gastric pouch similar to traditional gastric bypass o Instead of creating a Roux-en-Y anastomosis, the loop of jejunum is anastomosed directly to the stomach pouch (similar to a Billroth II procedure)
Sleeve Gastrectomy	43775	• Greater curvature of the stomach is resected resulting in a gastric remnant shaped like a tube or sleeve. • The pyloric sphincter is preserved leaving stomach function unaltered. • Not reversible • Can be performed as: o A stand-alone procedure (restrictive) o The first part of a two-stage surgical procedure for the very high-risk patients (BMI ≥50 kg/m^2) who need to lose some weight before they can proceed with a malabsorptive procedure (most commonly BPD-DS or RYGBP)

Procedure	CPT Code	Description
Adjustable Gastric Banding	43770-43774 43886-43888	• Restrictive procedure • An adjustable, external, constrictive band is wrapped around the upper portion of the stomach to create a small stomach pouch • The band can be adjusted through a subcutaneous access port, foregoing the need to enter the gastric cavity when adjusting the band • The least invasive and least technically complex bariatric procedure • Lap-Band® (original applicant, Allergan, Inc.; sold to Apollo Endosurgery, Inc.) and the REALIZE™ (Ethicon Endo-Surgery, Inc.) have received approval from the U.S. Food and Drug Administration (FDA).
Vertical Banded Gastroplasty AKA Vertically banded gastric partition or Gastric stapling	43842	• The vertical banded gastroplasty is no longer a standard of care. • Restrictive procedure • Surgical stapling is used to create a small, vertical gastric pouch at the top of the stomach • The pouch outlet (stoma) is reinforced with an external mesh collar
Endoscopic (Endoluminal) Bariatric Procedures	43290, 43291	• The access to the stomach is gained through the mouth, so no incisions are necessary. • Endoluminal procedures being developed: o Primary bariatric procedure o Revision (e.g. for treatment of enlarged gastric stoma and/or enlarged gastric pouches that may be associated with weight gain after bariatric surgery) • Examples of the endoscopic revision bariatric procedures include: o Gastroplasty using an endoscopically guided stapler (reduces the size of the gastric pouch) o Placement of gastric balloon (soft, silicone balloon inserted into the stomach and filled with sterile saline to induce feeling of satiety) o Placement of duodenal-jejunal sleeve (sleeve placed inside duodenum and upper jejunum to prevent contact between food and the intestine). • StomaphyX®, an endoscopically guided system intended for tissue plication and ligation, has received 510(k) FDA approval. The device is also being investigated for endoscopic treatment of gastroesophageal reflux. • OverStitch™ Endoscopic Suturing System is intended for endoscopic placement of sutures and approximation of soft tissue, and has received FDA approval. The system may be used as an incisionless revision surgery, with the intent to reduce the size of a stomach pouch that has stretched out following a previous bariatric procedure.
Laparoscopic Gastric Plication	No specific CPT code	• Sutures are laparoscopically placed over the greater curvature (laparoscopic greater curvature plication) or anterior gastric region (laparoscopic anterior curvature plication) to create a tube-like stomach. • The procedure involves 2 main steps: o Mobilization of the greater curvature of the stomach, and o Suture plication of the stomach to achieve gastric restriction

EVIDENCE SUMMARY

- Roux-en-Y Gastric Bypass (RYGBP)

  The Roux-en-Y gastric bypass is a commonly performed procedure with the most accumulated evidence in the published literature.[2] Consequently, in order to determine the safety and efficacy of other bariatric surgical procedures, they need to be compared to RYGBP in well-designed, well-executed randomized controlled trials (RCTs).

- Laparoscopic Adjustable Gastric Banding (LAGB)

  RCT data comparing LAGB and RYGBP are limited, however:

  - LAGB is reversible and the least invasive of all bariatric procedures.
  - Weight loss following LAGB is less than what is usually seen following RYGBP.
  - LAGB has low perioperative complications; however inadequate weight loss or long term complications of band erosion, slippage, or malfunction may require additional surgery.

- Sleeve Gastrectomy (SG)

  - SG has gained acceptance in clinical practice and is a commonly performed procedure.
  - SG offers an alternative to adjustable gastric banding with potentially greater weight loss but without the complications associated with malabsorptive procedures, such as RYGBP.

- Other Bariatric Surgical Procedures

  Randomized Controlled Trials

  Very few randomized controlled trials compared other bariatric procedures with RYGBP. Overall, the trials were of poor quality and the findings unreliable due to at least one of the following design flaws:

  - The trials had very small study populations, limiting the ability to rule out the role of chance as an explanation of findings.
  - The randomization scheme was either inadequate or not explained. Inadequate randomization of study participants may result in unequal distribution of potential confounders, such as clinical characteristics, which in turn may affect the outcome.
  - The studies have short follow-up times so there is no long-term (5-10 years or longer) evidence regarding:

    - durability of weight loss
    - complications (e.g. metabolic side effects, nutritional deficiencies, anastomotic ulcers, esophagitis, procedure-specific complications such as band erosion)
    - resolution of comorbidities (e.g. diabetes, hypertension, obstructive sleep apnea, increased cholesterol)
    - need for reoperations

- Short-term complications, adverse events, morbidity, resolution of comorbidities, and reoperation rates are inconsistently reported, limiting conclusions and comparisons across studies.
- There is limited understanding of appropriate patient selection criteria for each of the non-RYGBP bariatric procedures (e.g. superobese patients vs. morbidly obese patients).

Nonrandomized Studies

Although the published, peer-reviewed literature on non-RYGBP bariatric procedures is voluminous, it consists mostly of case series and retrospective, nonrandomized comparisons. Evidence from these studies is unreliable due to design flaws, such as non-random allocation of treatment, lack of adequate comparison groups, and short-term follow-up. In addition, the inconsistent reporting of weight loss, resolution of comorbidities, adverse events, morbidity, and reoperation rates further limit meaningful comparisons across these studies.

- Bariatric Surgery in the Pediatric Population

  Overall, there is enough evidence on the role of bariatric surgery in treating pediatric patients with severe obesity. Moreover, the evidence mostly comes from small, nonrandomized and therefore unreliable studies. Specifically:

  - There is enough evidence that bariatric surgery leads to clinically significant, long-term sustained weight loss and resolution of obesity-related comorbidities in the pediatric population.
  - There is still a lack of evidence regarding the long-term potential impact of bariatric procedures on growth and development in the pediatric population.

- Bariatric Surgery as a Treatment for Gastroesophageal Reflux Disease (GERD)

  In order to determine the safety and efficacy of bariatric surgical procedures as treatments for GERD, they need to be compared to standard medical or surgical treatments of this condition in well-designed, well-executed randomized controlled trials.

- Endoscopic Bariatric Procedures

  There is insufficient evidence to determine the safety and efficacy of any endoluminal procedure as either a primary bariatric procedure or a revision procedure. The published evidence is limited and consists of only a few case series and randomized trials with a high risk of bias.

- Multidisciplinary Approach to the Clinical Management of Bariatric Surgery Patients

  The National Institutes of Health/National Heart, Lung, and Blood Institute (NIH/NHLBI) clinical practice guidelines state the importance of a multidisciplinary approach to the clinical management of bariatric surgery patients. Comprehensive programs should address nursing, nutrition, exercise, behavior modification, and psychological support, and they should provide lifelong follow-up for treated patients.[1]

- Bariatric Surgery Centers of Excellence

The published evidence indicates that high volume bariatric centers are more likely to be successful in achieving optimal outcomes and lower complication and mortality rates than low volume bariatric centers.[3-5] These data have led to national efforts to establish bariatric surgery centers of excellence by the American Society for Metabolic and Bariatric Surgery, the American College of Surgeons, and the BlueCross BlueShield Association.

The following literature appraisal is based on randomized controlled trials (RCT), Blue Cross Blue Shield Association (BCBSA) Technology Evaluation Center (TEC) Assessments, Cochrane reviews, Agency for Healthcare Research and Quality (AHRQ) comparative effectiveness reviews, Washington State Health Technology Assessment and evidence-based guidelines.

DISTAL (LONG LIMB) GASTRIC BYPASS

SYSTEMATIC REVIEWS

The 2005 Blue Cross Blue Shield Association (BCBSA) Technology Evaluation Center (TEC) Assessment identified six comparative trials of long limb gastric bypass with Roux-en-Y anastomosis (LL-RYGBP) vs. standard RYGBP.[2] However, only two were randomized controlled trials (RCT). The assessment determined that there was not sufficient evidence to reach conclusions on the efficacy and safety of LL-RYGBP compared to standard RYGBP:

- In both RCTs, there was no significant difference in weight loss between the two groups at 1 year.
- The evidence for the super obese (BMI ≥50 kg/m^2) population was weak and did not allow conclusions concerning whether LL-RGYBP is superior in this subgroup of patients
- The adverse events were poorly reported in all comparative studies. Some of the reports contradicted one another.
- There was no definite cut-off for “long” vs. “standard” limb, making comparisons even more challenging.

RANDOMIZED CONTROLLED TRIALS

Salman (2023) published a single site RCT comparing outcomes of one-anastomosis gastric bypass (OAGB) and long BPL RYGB regarding weight loss and comorbidity resolution.[6] This study included 62 patients equally allocated to OAGB or long BPL RYGB, with no dropouts during follow-up. At 6 months, there was no statistically significant difference between the two groups regarding postoperative BMI ($p = 0.313$) and the EBWL ($p = 0.238$). There was comparable remission of diabetes, hypertension, OSA, joint pain, and low back pain. Seven patients in the OAGB group experienced reflux symptoms ($p = 0.011$), which were managed by proton pump inhibitors. The authors noted that long BPL RYGB should be preserved for cases whom are more risky for bile reflux.

One RCT evaluated the effectiveness of the distal gastric bypass for weight loss and control of comorbidities.[7] The study included only severely obese patients (BMI ≥50 kg/m^2). There was no significant difference in the control or improvement of hypertension, sleep apnea, or gastroesophageal reflux disorder between the patients who underwent long-limb (Roux limb = 250 cm) and short-limb gastric bypass (Roux limb = 150 cm). In addition, there was no difference in excess weight loss between the groups. Although the study reports better control of lipid disorders and diabetes in patients who underwent the long-limb gastric bypass, several design flaws undermine the reliability of the study findings:

- The small study population (n=105) limits the ability to rule out the role of chance as an explanation of findings.
- The randomization scheme was not explained. Inadequate randomization of study participants may result in unequal distribution of potential confounders, such as clinical characteristics.
- The short-term follow-up limits conclusions regarding the long-term complications and the effectiveness of the distal gastric bypass in controlling weight loss and comorbidities.
- The study included only super obese patients limiting the generalizability of the study findings to other patient populations (i.e. morbidly obese).
- The need for nutritional supplementation after the surgery was reported for the two treatment groups, but there was a failure to include statistical testing for this outcome.

NONRANDOMIZED STUDIES

A number of nonrandomized studies (retrospective comparisons, case series) describe the experiences of patients undergoing distal gastric bypass.[2, 8-10] As noted at the beginning of the evidence section, conclusions cannot be reached from these studies as the evidence is considered unreliable.

SECTION SUMMARY

Evidence regarding long limb gastric bypass with Roux-en-Y anastomosis (LL-RYGBP) vs. standard RYGBP is limited to three RCTs which showed either no benefit to the LL approach compared to the RYGBP and/or had numerous methodological limitations. In addition, without a standardized cut-off for long vs. standard limb length, comprehensive assessment of the long limb procedure is unlikely. Therefore, current evidence is insufficient to recommend LL-RYGBP over standard RYGBP, including in individuals with class III obesity.

BILIOPANCREATIC BYPASS AND BILIOPANCREATIC BYPASS WITH DUODENAL SWITCH

SYSTEMATIC REVIEWS

In 2013, Colquitt updated a 2009 Cochrane review[11] which compared outcomes for a variety of surgical weight loss procedures.[12] Two RCTs were identified which assessed outcomes of biliopancreatic diversion with duodenal switch (BPD-DS) compared to RYGBP. At a mean three year follow-up, data from the two trials were pooled (n= 107) and the following conclusions were reached:

- BPD-DS resulted in significantly greater weight loss than RYGBP.
- Quality of life measures were similar between the two groups.
- Reoperation rates were higher in the BPD-DS group (16.1%-27.6%) compared to the RYGBP group (4.3%-8.3%), with one death reported in the BPD-DS group.

The 2005 BCBSA TEC Assessment identified only one comparative trial that compared RYGBP with BPD-DS.[2] Although the trial included 237 RYGBP and 113 BPD-DS patients, it was not a randomized clinical study (the choice of the surgery was determined by surgeon and/or patient) and it followed participants for only one year. The TEC Assessment did not find this data sufficient to determine the risk/benefit ratio for this procedure or that it results in greater weight loss than RYGBP:

- The % estimated weight loss (EWL) at one year was the same for both the RYGBP and BPD-DS groups.
- Data on short-term adverse events was limited, except for the mortality and wound infection rates which were equivalent in both groups.
- More anastomotic leaks were reported in BPD-DS group.
- Long-term complications were not reported.
- Nutritional concerns were not adequately addressed. This is of concern because BPD-DS further reduces fat absorption, affecting the absorption of fat soluble vitamins.

RANDOMIZED CONTROLLED TRIALS

Moller (2023) published a RCT comparing long-term outcome of BPD/DS and RYGB in patients with super obesity (BMI > 50 kg/m2).[13] This is a 13- to 17-year follow-up study of a single-center, single-blinded randomized trial in which 47 patients (BMI > 48 and eligible for bariatric surgery) were randomized 1:1 to BPD/DS and RYGB (25 men, 24 BPD/DS, 39.1 ± 9.9 years, BMI 54.5 ± 6.1 kg/m2). The primary outcome was weight loss. Thirty-four (18 BPD/DS) of the living 42 patients (81.0%) participated. BPD/DS resulted in higher BMI loss (20.4 ± 7.9 vs. 12.4 ± 8.6, p = .008) and higher percent of total body weight loss (37.5% ± 12.2 vs. 22.8% ± 14.8, p = 0.004). BPD/DS was associated with lower fasting glucose, glycated hemoglobin (HbA1c), and low-density lipoprotein (LDL) as well as lower hemoglobin. Adverse events were more common after BPD/DS (2.7 vs. 0.9 per patient, p = 0.004). The global assessment tool BAROS (Bariatric Analysis and Reporting Outcome System) demonstrated superior scores for BPD/DS (p = 0.047).

Two prospective randomized trials compared the experiences of obese patients undergoing RYGBP vs. BPD. The first trial compared weight loss, metabolic deficiencies, and resolution of comorbidities in morbidly obese patients undergoing RYGBP vs. a variant of BPD (BPD with RYGBP).[14] The study reports comparable nutritional deficiencies between the two procedures. Although better weight loss and resolution of diabetes and hypercholesterolemia was reported in the BPD group, several design flaws undermine the reliability of the study findings:

- The study employed an inadequate randomization scheme: the report states that patients were chosen to undergo RYGBP or BPD, but fails to provide any further explanation of how the treatment was assigned. Inadequate randomization of study participants may result in unequal distribution of potential confounders, such as clinical characteristics.
- The RYGBP group had a significantly higher level of preexisting comorbidities (p = 0.01), suggesting a difference between the treatment groups that may have affected the outcome.
- The small study population (65 patients/surgery group) limits the ability to rule out the role of chance as an explanation of findings.
- The short-term follow-up (2 years) limits conclusions regarding the long-term metabolic complications and the long-term effectiveness of the BPD in controlling weight loss and comorbidities.

Another small randomized trial (n=60) compared laparoscopic RYGBP and BPD-DS for superobese patients (BMI 50-60 kg/m^2).[15] The study found comparable 30-day perioperative safety and greater weight loss following BPD-DS in the first year.

In 2015, long-term 5-year follow-up results were published on data from 55 patients (92%).[16] Results indicated a mean reduction of body mass index was greater with duodenal switch compared to bypass (mean between-group difference was 8.5 [95% CI, 4.9-12.2; P < .001]); however, duodenal switch was associated with more surgical, nutritional and gastrointestinal adverse effects.

NONRANDOMIZED STUDIES

A number of non-randomized studies (retrospective comparisons, case series) describe the experiences of patients undergoing biliopancreatic diversion with or without duodenal switch.[17-35] Many of these studies show successful weight loss after BPD compared to other bariatric procedures.

SLEEVE GASTRECTOMY

There are various types of gastrectomy, which include distal, partial (including sleeve gastrectomy) or complete gastrectomy which may be performed with or without gastroduodenostomy, gastrojejunostomy, or Roux-en-Y reconstruction. There is insufficient evidence regarding the use of gastrectomy, other than sleeve gastrectomy, as a treatment of obesity. Numerous studies were identified which evaluated outcomes of these alternative gastrectomy methods as a treatment of other conditions, including gastric cancer; however, no studies or clinical practice guidelines were identified which evaluated the efficacy of these alternative types of gastrectomy as a treatment of obesity. Therefore, the following evidence review will focus on the use of sleeve gastrectomy as a treatment of obesity, in the context of systematic reviews and well-designed randomized controlled trials:

SYSTEMATIC REVIEWS

Numerous recent systematic reviews have compared SG and RYGB with regard to effects on weight, comorbidities, and complications.

Osland (2023) systematic review and meta-analysis of RCTs to investigate the comparative 5-year outcomes of both procedures in adults.[36] Three RCTs (LVSG=254, LRYGB=255) met inclusion criteria and reported on chronic disease outcomes. Improvement and/or resolution of hypertension favored LRYGB (odds ratio 0.49, 95% CI 0.29, 0.84; p = 0.03). Trends favoring LRYGB were seen for type 2 diabetes and dysplidemia, and LVSG for sleep apnea and back/joint conditions (p >0.05). The certainty of evidence associated with each assessed outcome ranged from low to very low, in the setting of 'some' to 'high' bias assessed as being present. The authors conclude that the limited certainty of the evidence does not allow for strong clinical conclusions to be made at this time regarding benefit of one procedure over the other.

Kermansaravi (2023) published an umbrella review with meta-analyis comparing the safety and efficacy of sleeve gastrectomy versus Roux-en-Y gastric bypass in elderly (>60 years) with severe obesity.[37] The umbrella review included six meta-analyses. The risk of early-emerging and late-emerging complications decreased by 55% and 41% in the patients underwent SG than in those receiving RYGB, respectively. The chance of the remission of hypertension and obstructive sleep apnea, respectively increased by 43% and 6%, but type-2 diabetes mellitus decreased by 4% in the patients underwent RYGB than in those receiving SG. RYGB also increased excess weight loss by 15.23% in the patients underwent RYGB than in those receiving SG. The authors conclude that lower levels of mortality and early-emerging and late-

emerging complications were observed in the older adults undergoing SG than in those receiving RYGB, which was, however, more efficient in term of weight loss outcomes and recurrence of obesity-related diseases.

Vanetta (2023) published a SR and meta-analysis evaluate the safety and success of same day discharge following SG and RYGB.[38] A total of 14 studies with 33,403 patients who underwent SDD SG (32,165) or RYGB (1238) were included in the qualitative synthesis. Seven studies with 5000 patients who underwent SDD SG were included in the quantitative analysis, and pooled proportions (PPs) were calculated for the outcomes of interest. The SDD success rate was 63%-100% (PP: 99%) after SG and 88%-98.1% after RYGB. The readmission rate ranged from 0.6% to 20.8% (PP: 4.0%) after SDD SG and 2.4%- 4.0% after SDD RYGB. Overall morbidity, reoperation, and mortality were 1.1%-10% (PP:4.0%), 0.3%-2.1% (PP: 1.0%), and 0%- 0.1% (PP: 0%), respectively, for SDD SG, and 2.5%-4.0%,1.9%-2.5%, and 0%- 0.9%, respectively, for SDD RYGB. SDD after SG seems feasible and safe. The outcomes of SDD RYGB seem promising, but the evidence is limited to draw definitive conclusions. Selection criteria and perioperative protocols must be standardized to adequately introduce this practice.

Gu (2020) completed a meta-analysis of the medium- and long-term effects of laparoscopic SG and RYGB.[39] The evaluation included 9038 patients from 28 studies. Overall, 5 year follow-up results revealed that laparoscopic RYGB was associated with an improvement in percentage of EWL and remission of T2D, hypertension, and dyslipidemia as compared to laparoscopic SG.

Han (2020) also published a systematic review and meta-analysis involving 18 studies (N=2917) that compared weight loss and comorbidity resolution between laparoscopic SG and RYGB.[40] Results from this analysis revealed no significant difference in EWL or T2D resolution between the 2 procedures. Laparoscopic RYGB was found to be superior to SG with regard to dyslipidemia, hypertension, and GERD management; however, patients who underwent laparoscopic SG experienced fewer postoperative complications and reoperation rates.

Sharples (2020) performed a systematic review and meta-analysis evaluating long-term (5 years) outcomes of RYGB and SG.[41] Overall, both RYGB and SG resulted in sustained weight loss and comorbidity control with RYGB associated with a greater percent EWL, improved dyslipidemia outcomes, and a reduced incidence of GERD (Table 5).

Shenoy (2020) published a systematic review and meta-analysis of 9 studies that compared laparoscopic SG and RYGB in 2240 elderly (>55 years) patients.[42] Results revealed no significant differences between the 2 bariatric procedures with regard to the rate of early complications (3.6% LSG versus 5.8% LRYGB; p=0.15) and mortality (0.1% versus 0.8%; p=0.27). Additionally, there was no difference in EWL between the procedures at 1 year; however, the authors recommended SG for high-risk elderly patients due to the reduced mortality and complication rates with this procedure.

Another systematic review and meta-analysis by Xu (2020) involving 19 studies also concluded that SG was the preferable option for elder obese patients 60 years and older as it was found to be non-inferior to RYGB with regard to efficacy, but overall had an improved safety profile.[43]

Osland (2017) published a systematic review and meta-analysis of RCTs comparing laparoscopic vertical SG with RYGB.[44] The literature search, conducted from 2000 to November 2015, identified 9 RCTs for inclusion (N=865 patients). Four trials were included in meta-analyses comparing percent EWL between the 2 groups. Results at both 6- and 12-month follow-ups showed that the procedures are comparable. Osland (2020) recently published a continuation of their work that focused exclusively on long-term (5 year) weight outcomes of laparoscopic vertical SG versus RYGB.[45] This systematic review and meta-analysis included 5 studies (SG=520; RYGB=508) and results revealed that a statistically significant BMI loss was seen with both SG: -11.37 kg/m^2 (range: -6.3 to -15.7 kg/m^2) and RYGB: -12.6 kg/m^2 (range: -9.5 to -15.4 kg/m^2) at 5 years. However, differences in reporting parameters limit the ability to reliably compare outcomes using statistical methods and the results may have been impacted by large dropout rates and per protocol analyses of the 2 largest included studies.

In 2017, Juodeikis evaluated five-year results following sleeve gastrectomy in a systematic review of the literature through May 2016.[46] The review was conducted according to PRISMA guidelines. Twenty studies were included for evaluation, however, only one study was a randomized controlled trial. Of the 2,713 patients included amongst all the studies combined, 1,626 reached at least five years follow-up (duration ranged from 5-11 years follow-up). Although mean percentage excess weight loss of greater than 56% was achieved at each time point from 5 to 11 years' time, the review was substantially limited by the lack of RCT data.

In 2016, Osland compared the efficacy of Roux-En-Y gastric bypass versus vertical sleeve gastrectomy in randomized controlled trials.[44] Six RCTs performed between 2005 and 2015 were included (N = 695; 347 for SG and 348 for RYGB). The authors summarized recent publications, without pooled analysis. Although the results stated comparable efficacy and improvement or resolution in comorbidities, the authors also noted the significant limitation of short follow-up time (one year, with significant loss of follow-up), and lack of blinding in five of the six studies included. In 2017, Osland published an additional meta-analysis, again comparing vertical sleeve gastrectomy in RCT's to LRYGB (N=865 patients; 437 for SG and 428 for LRYGB).[47] The authors concluded once again that a significant gap exists in the literature with respect to well-designed studies using intent-to-treat analysis.

In 2015, Zhang published a separate review comparing LSG to laparoscopic RYGBP (LRYGBP) which included 21 studies involving 18,766 morbidly obese patients.[48] Data regarding percentage of excess weight loss (%EWL), resolution or improvement of comorbidities, and adverse events were pooled. Although no difference in %EWL was observed between the two groups in the first 6 months-1.5 year follow-up, LRYGBP achieved higher %EWL compared to LSG ($p<0.05$). Except for improvements in type 2 diabetes, comorbidities did not differ significantly between the two groups. Adverse events were more frequent following Roux-en-Y bypass (OR for major complication: 1.29; 95% CI 1.22 to 3.22; $P<0.01$). Results of this review must be interpreted with caution as 13 of the 21 included studies were nonrandomized, limiting the ability to control for confounding factors.

A 2014 review by Zellmer compared complication rates of laparoscopic RYGBP to LSG in 61 publications which included 10,906 laparoscopic RYGBP patients and 4,816 LSG patients.[49] Authors reported similar leak and mortality rates in both groups; laparoscopic RYGBP (leak: 1.9%, mortality: 0.4%) vs. LSB (leak: 2.3%, mortality: 0.2%).

The 2013 Cochrane review of bariatric surgery identified only one randomized controlled trial that compared sleeve gastrectomy to gastric bypass with Roux-en-Y anastomosis (RYGBP).[11, 12, 50] This very small (n=32) and short trial that followed participants for only 1 year reported that:

- Weight loss and BMI were similar between the two procedures, but % excess weight loss was greater with sleeve gastrectomy.
- Two patients had diabetes at baseline, both in the RYGBP group. The condition was resolved at 1 year in both patients. The outcome of other comorbidities reported at baseline was not reported for the RYGBP or SG groups.
- Although the study reported no conversions to open surgery and no intraoperative and postoperative complications, the other complications and additional operative procedures were not reported.
- The study did not assess a two-stage approach using sleeve gastrectomy prior to another bariatric procedure and consequently no conclusions about the two-stage approach could be made.
- The short duration of the follow-up results in underestimation of the impact of late complications and the need for revision surgery.

In 2013, Trastulli published a systematic review of randomized trials that compared sleeve gastrectomy to other bariatric procedures.[51] A total of 15 RCTs with 1191 patients were included. In six trials laparoscopic sleeve gastrectomy (LSG) was compared to laparoscopic RYGBP. The authors reported mean complication rates with sleeve gastrectomy of 12.1% (range 10%-13.2) compared with 20.9% with laparoscopic gastric bypass (range 10%-26.4%). Percentage of excess weight loss ranged from 49%-81% with sleeve gastrectomy compared with 62.1%-94.4% with laparoscopic gastric bypass. Included studies which compared LSG to laparoscopic RYGBP were small[52-54] (n<60) and several contained a risk for bias which included unclear blinding, randomization methods and outcome data.

A 2013 meta-analysis by Li pooled data from five trials, four of which were included in the Trastulli review, to compare the impact of these procedures on type 2 diabetes rates.[55] Laparoscopic Roux-en-Y gastric bypass was associated with higher rates of type 2 diabetes remission and greater estimated weight loss, but higher rates of complications.

RANDOMIZED CONTROLLED TRIALS

Pajecki (2023) published three year outcomes of a RCT comparing SG and RYGBP in obese patients older than 65 years.[36] Of the 36 patients who underwent randomization, none were lost to follow-up through the 36 months of data collection. The baseline mean BMI was 45 ± 5.2 kg/m2. Weight loss was significantly better after LRYGB compared to LSG in the third year of follow-up, both on %TWL (30.3 ± 2.2% vs. 17.2 ± 2.2%, p = 0.001) and %EWL (63.1 ± 4.3 vs. 43.5 ± 6.7%, p = 0.018). After LRYGB, HbA1c (p < 0.001), HDL (p < 0.001), LDL (p = 0.007), and triglyceride (p < 0.001) levels improved significantly. After LSG, a significant difference was only seen in HDL levels (p = 0.004). Adherence to micronutrient supplementation was significantly more frequent in the LSG group (72.2% vs. 22.2%, p = 0.003). Hemoglobin and albumin levels remained stable for both procedures. The data in this study is limited to methodology concerns as all follow-up was via telephone contact only due to COVID-19.

Hofsø (2019) published the results of a single-center, triple-blind RCT comparing the efficacy of Roux-en-Y gastric bypass (RYGB) (n=54) vs sleeve gastrectomy (SG)(n=55) on diabetes

remission and ß-cell function in patients with obesity and T2D. Inclusion criteria included previously verified BMI ≥35 kg/m2 and current BMI ≥33.0 kg/m2, hemoglobin A1c (HbA1c) ≥6.5% or use of antidiabetic medications with HbA1c ≥6.1%, and age ≥18 years. One-year follow-up was completed by 107 (98%) of 109 patients, with 1 patient in each group withdrawing after surgery. In the intention-to-treat population, diabetes remission rates were superior in the gastric bypass group than in the sleeve gastrectomy group (risk difference 27%; relative risk [RR] 1.57). Results were similar in the per-protocol population (risk difference 27%; RR 1.57). The two procedures had a similar beneficial effect on ß-cell function.

Peterli (2018) published a randomized study of adults with morbid obesity treated with either laparoscopic sleeve gastrectomy (SG) or Roux-en-Y gastric bypass (RYGB).[56] Two hundred five patients treated at four bariatric centers were randomly assigned to receive SG (n=101) or RYGB (n=104) with 5-year follow-up. Excess BMI loss was 61.6% for SG and 68.3% for RYGB. Gastric reflux remission was seen in 25.0% of SG and 60.4% of RYGB patients. Reoperations or interventions were necessary for 15.8% in the SG group and 22.1% of the RYGB group. The study was limited by the lack of analysis of diabetes remission information and the results may not be generalizable.

Salminen (2018) published a randomized trial (SLEEVEPASS) comparing 5-year outcomes of morbidly obese patients who underwent either laparoscopic sleeve gastrectomy (SG; n=121) or Roux-en-Y gastric bypass (RYGB; n=119).[35] Five-year estimated mean percentage excess weight loss was 49% for sleeve gastrectomy and 57% for gastric bypass. For SG and RYGB, respectively, rates of remission of type 2 diabetes were 37% and 45%. Medication for hypertension was discontinued in 20/68 (29%) SG patients and 37/73 (51%) RYGB patients. Overall 5-yr morbidity rate was 19% for SG and 26% for RYGB, and there was no significant difference in QOL between groups. The study was limited by the following: the study having a higher reoperation rate for sleeve gastrectomy than other trials reported, approximately 20% of patients were lost to follow-up, and there was a lack of reliable information for diabetes duration at baseline.

CLINICAL PRACTICE GUIDELINES

In 2012, the American Society for Metabolic & Bariatric Surgery (ASMBS) updated their position statement on *Sleeve Gastrectomy as a Bariatric Procedure.*[57] The ASMBS recognizes sleeve gastrectomy as an acceptable option as a primary bariatric procedure and as a first stage procedure in high risk patients as part of a planned staged approach. In addition, the group noted that substantial comparative and long-term data have now been published which demonstrate durable weight loss, improved medical comorbidities, long-term patient satisfaction, and improved quality of life after SG. However, the ASMBS Statement does not include a critical appraisal of the reviewed evidence.

SECTION SUMMARY

Recent systematic reviews of existing trials indicate sleeve gastrectomy (SG) is a comparable procedure to RYGBP. Although the evidence regarding SG with RYGBP compared to standard RYGBP is limited by short-term follow-up, SG has become a recognized surgical option in clinical practice for the treatment of morbid obesity.

ADJUSTABLE GASTRIC BANDING

SYSTEMATIC REVIEWS

Park (2019) conducted a systematic review with a network meta-analysis evaluating the comparative efficacy of various bariatric surgery techniques against standard-of-care in the treatment of morbid obesity and diabetes.[58] The literature search was conducted through February 2018, identifying 45 RCTs for inclusion on Roux-en-Y gastric bypass (RYGB; 2 studies), sleeve gastrectomy (SG; 3 studies), laparoscopic adjustable gastric band (LAGB; 5 studies), and biliopancreatic diversion with duodenal switch (BPD-DS; 3 studies vs RYGB). Based on 33 trials, superior efficacy for % excess weight loss compared to standard-of-care was seen for BPD-DS (mean difference [MD] 38.2%), RYGB (MD 32.1%), and SG (MD 32.5%) at 6 months post procedure. LAGB was not superior to standard-of-care (MD -0.2%). At 3 years post-procedure, superior efficacy for %EWL compared to standard-of-care was seen for RYGB (MD 45%) and SG (MD 39.2%). BPD-DS (RR 7.51), RYGB (RR 7.51), and SG (RR 6.69) were all superior to standard-of-care with respect to remission rates at 3-5 years post-procedure and remission rates were not significantly different among procedures. SG was found to have a relatively lower risk of adverse events compared to RYGB.

A 2017 systematic review by Kang reported results from a network meta-analysis of RCTs evaluating the three most commonly performed bariatric procedures – Roux-en-Y gastric bypass (RYGB), sleeve gastrectomy (SG), and laparoscopic adjustable gastric band (LAGB).[59] The review was conducted with literature through July 2016, and in accordance with PRISMA guidelines. Evidence was synthesized from 11 trials (8 RYGB vs SG; 2 RYGB vs LAGB; 1 SG vs LAGB) in order to evaluate the primary outcome of changes in weight loss, expressed as the mean difference in BMI reduction and in percentage excess weight loss (%EWL) following 1 year after the surgery. The smallest treatment effect was observed in LAGB (8 trials, totalling 656 patients). The mean %EWL for RYGB, SG, and LAGB were 67.3% (n=294), 71.2% (n=209), and 40.6% (n=153), respectively. Heterogeneity between studies was low (as evaluated by calculating the I^2 statistic), and the studies were consistent between direct and indirect comparisons – both demonstrated strengths of the analysis. The study was limited by fewer trials evaluating LAGB, and inclusions of RCTs with a lack of blinding.

The 2013 Cochrane review of bariatric surgery identified three randomized controlled trial that compared laparoscopic adjustable gastric banding (LAGB) to laparoscopic gastric bypass with Roux-en-Y anastomosis (RYGBP).[11, 12, 60] At five-year follow-up, the review reported the following conclusions:

- RYGBP was superior to LAGB on more than one measure of weight loss (% excess weight loss, mean BMI).
- Quality of life measures and comorbidities were not assessed due to the low quality of the evidence.
- RYGBP resulted in a greater duration of hospitalization and a greater number of late major complications.
- One study reported high rates of reoperation for removal of LAGB (9 patients, 40.9%).

In 2012, TEC conducted an updated Assessment, focusing on LAGB in patients with BMIs less than 35 kg/m^2.[61] TEC made the following observations and conclusions:

- The evidence on LAGB for patients with lower BMIs is limited both in quantity and quality. There was only one small randomized, controlled trial, which had methodologic limitations, one nonrandomized comparative study based on registry data, and several case series. Using the GRADE evaluation, the quality of evidence on the comorbidity outcomes was

judged to be low and the quality of the evidence on the weight loss outcomes was judged to be moderate.

- The evidence was sufficient to determine that weight loss following LAGB was greater than with nonsurgical therapy.
- Direct data on improvement in weight-related comorbidities was lacking. The limited evidence was not sufficient to conclude that the amount of weight loss was large enough that improvements in weight-related comorbidities could be assumed.
- There was very little data on quality of life in this population of patients.
- The frequency and impact of long-term complications following LAGB was uncertain, thus it was not possible to determine whether the benefit of LAGB outweighed the risk for this population. TEC concluded that while the short-term safety of LAGB was well-established, the long-term adverse effects occur at a higher rate and are less well-defined.

RANDOMIZED CONTROLLED TRIALS

An updated literature search failed to identify any additional randomized controlled trials that compare LAGB with RYGBP.

NONRANDOMIZED STUDIES

A number of non-randomized studies (retrospective comparisons, case series) describe the experiences of patients undergoing LAGB.[34, 62-69] As noted at the beginning of the evidence section, conclusions cannot be reached as the evidence from these studies is considered unreliable.

SECTION SUMMARY

The evidence regarding the laparoscopic adjustable gastric banding (LAGB) compared to standard RYGBP is limited. Additionally, LAGB may have higher rates of reoperation and revisions. LAGB is no longer considered a standard of care.

LAPAROSCOPIC DUODENAL SWITCH WITH SINGLE ANASTOMOSIS

Several nonrandomized studies were identified which describe the experiences of patients undergoing laparoscopic duodenal switch with single anastomosis (LSDSA).[70-74] As noted at the beginning of the evidence section, conclusions cannot be reached from these studies as the evidence is considered unreliable. Well-designed RCTs which compare LSDSA with RYGBP are needed in order to evaluate the safety and efficacy of this procedure compared to accepted surgical treatments of morbid obesity.

SYSTEMATIC REVIEWS

Balamurugan (2023) published a systematic review comparing the safety and efficacy between Roux-en-Y gastric bypass (RYGB), one anastomosis gastric bypass (OAGB) and single anastomosis duodeno-ileal bypass with sleeve gastrectomy (SADI-S). Eighteen eligible studies were included. Weight loss outcomes were greater with SADI-S (5 years) and OAGB (10 years). SADI-S offered better resolution of diabetes whereas hypertension and dyslipidaemia resolution were better with OAGB. Although early complications and mortality were higher with SADI-S, late complications were more frequent with RYGB. Both SADI-S and OAGB are as effective as RYGB for weight loss, but OAGB offers lesser complications. The authors conclude that more data is imperative to determine the next gold standard procedure.

Nakanishi (2022) published a systematic review of six studies including 1,846 patients with obesity who underwent either single anastomosis duodenal-ileal bypass with sleeve gastrectomy (SADI-S) or a biliopancreatic diversion with duodenal switch (BPD-DS).[75] The BPD-DS group had a greater % excess body mass index loss (MD=-10.16%, 95% confidence interval: -11.80, -8.51) at two years compared with the SADI-S group. There was no difference observed in preoperative comorbidities and remission, including diabetes, hypertension, and dyslipidemia between SADI-S and BPD-DS cohorts. The SADI-S group had shorter hospital stays and fewer long-term complications. The authors concluded that additional randomized trials with extended follow-up periods are necessary to establish the safety and efficacy of the procedure.

Spinos (2021) conducted a systematic review to evaluate the effectiveness of patients who have undergone single-anastomosis duodenal bypass with sleeve gastrectomy/one anastomosis duodenal switch (SADI-S/OADS).[76] There were 14 studies included in the review including five retrospective cohort and nine case series. A total of 1086 patients were included in the analysis with preoperative BMI of 51.3 ± 9.5 kg/m2. The average body mass index (BMI) following SADI-S was 32.1 ± 6.7 kg/m2. Mean total body weight (TBW) loss ranged from 11.3% to 17.3% at three months, 21.5% to 41.2% at 12 months, and 25.8% to 46.3% at 24 months. Mean excess body weight (EBW) loss ranged from 21.8% to 40.2% at three months, 60.9% to 91.0% at 12 months, and 44.3% to 86.0% at 24 months. Mean excess BMI (EBMI) ranged from 9.4% to 31.1% at three months, 17.9% to 86.6% at 12 months, and 19.5% to 80.8% at 24 months. The comorbidity resolution rates were 72.6% for diabetes mellitus, 77.2% for dyslipidemia, 59% for hypertension, 54.8% for obstructive sleep apnea, and 25% for gastroesophageal reflux disease. The most common early postoperative complications after SADI-S included the need for reoperation (3.1%), bleeding (1.1%), wound infection (1.0%), anastomotic leak (0.9%), and intrabdominal collection/abscess (0.6%). Late postoperative complications were the need for reoperation (5.3%) and dumping syndrome (1.3%). The major limitation of this review is that studies were either retrospective cohort studies or case series with short-term follow ups.

CLINICAL PRACTICE GUIDELINES

In 2020, ASMBS published an updated statement on single-anastomosis duodenal switch (SADI-S) "in response to numerous inquiries made...by patients, physicians, society members, hospitals, and others regarding [this procedure] as a treatment for obesity and metabolic diseases."[77] The following recommendations were endorsed regarding SADI-S for the primary treatment of obesity or metabolic disease:

> "SADI-S, a modification of classic Roux-en-Y duodenal switch, is an appropriate metabolic bariatric surgical procedure."
>
> "Publication of long-term safety and efficacy outcomes is still needed and is strongly encouraged, particularly with published details on sleeve gastrectomy size and common channel length."
>
> "There remain concerns about intestinal adaptation, nutritional issues, optimal limb lengths, and long-term weight loss/regain after this procedure. As such, ASMBS recommends a cautious approach to the adoption of this procedure, with attention to ASMBS-published guidelines on nutritional and metabolic support of bariatric patients, in particular for duodenal switch patients."

MINI-GASTRIC BYPASS

SYSTEMATIC REVIEWS

In 2014, Georgiadou published a systematic review regarding the safety and efficacy of laparoscopic mini gastric bypass.[78] The review included a search of the literature through July 2013, and was conducted according to PRISMA guidelines. Ten articles with a total of 4,899 patients were included for review, of which three were comparative studies (two versus LRYGB and one versus LAGB). Excess weight loss at two years ranged from 64.4% ± 8.8% to 80%. Minor postoperative complication rates ranged from 3.6%-7.5%, and major early postoperative complication rates ranged from 0-7%. Authors noted a major concern for postoperative esophagitis and gastritis caused by bile reflux, and the risk for gastric cancer. Overall, the study was limited by the limitations of the included studies (e.g., short term follow-up and noncomparative design).

RANDOMIZED CONTROLLED TRIALS

One small RCT compared the safety and effectiveness of laparoscopic RYGBP and mini-gastric bypass (MGBP).[79] The study found a comparable rate of late complications (>30 days post-op), weight loss, and comorbidity resolution. MGBP was associated with fewer early complications (<30 days post-op). However, the following design flaws undermine reliability of the study findings:

- The small study population (n=80) limits the ability to rule out the role of chance as an explanation of findings.
- Short-term follow-up (2 years) limits comparisons regarding the longer-term complications rates and the effectiveness of the two procedures in controlling weight loss and comorbidities

NONRANDOMIZED STUDIES

In 2017, Plamper reported a comparison of mini gastric bypass and sleeve gastrectomy in super-obese patients (i.e., BMI > 50 kg/m^2) at a single institution.[80] At one-year follow-up, 90.8% (99 of 109) and 78.7% (74 of 94) of the MGB and SG patients were available for follow-up, respectively. Reasons for loss of follow-up were not discussed. One patient in the SG group died within 30 days of the operation due to multi-organ failure after staple line leakage. Percent excess weight loss was statistically significantly greater in the MGB group at 12 months. The authors cited limitations of their review to include the retrospective design, and short-term results.

Several other nonrandomized studies (retrospective comparisons, case series), describe experiences of patients undergoing MGBP.[81-85] As noted at the beginning of the evidence section, conclusions cannot be reached as this evidence is considered unreliable.

SECTION SUMMARY

Data regarding the mini-gastric bypass (MGBP) is limited to a small RCT, prohibiting conclusions regarding the efficacy of this procedure compared to RYGBP.

VERTICAL BANDED GASTROPLASTY (VBG)

VBG has largely been abandoned in the United States due to insufficient weight loss and high reoperation rates (approximately 30%).[11, 86]

HIATAL HERNIA REPAIR

Numerous studies[87-91] were identified which evaluated outcomes of hiatal hernia repair performed in conjunction with other bariatric surgical procedures; however, no studies or clinical practice guidelines were identified which evaluated the efficacy of hiatal hernia repair as an independent treatment of obesity.

CLINICAL PRACTICE GUIDELINES

In 2018, the ASMBS and the American Hernia Society published a consensus guideline on bariatric surgery and hernia surgery.[92] The guideline contained the following conclusions and summary recommendations:

- "There is a significant link between obesity and hernia formation both after abdominal surgery and de novo. There is also evidence that abdominal wall hernia can more commonly present with obstruction or strangulation in patients with obesity."
- "There is a higher risk for complications and recurrence after hernia repair in patients with obesity."
- "In patients with severe obesity and ventral hernia, and both being amenable to laparoscopic repair, combined hernia repair and metabolic/bariatric surgery may be safe and associated with good short-term outcomes and low risk of infection. There is a relative lack of evidence, however, about the use of synthetic mesh in this setting."
- "In patients with severe obesity and abdominal wall hernia that is not amenable to laparoscopic repair, a staged approach is recommended. Weight loss prior to hernia repair is likely to improve hernia repair outcomes. Metabolic/bariatric surgery appears to provide far more significant and rapid weight loss than other modalities and would be a good option for selected patients with severe obesity and large, symptomatic abdominal wall hernia."

The 2022 ASMBS guidelines include the following recommendations: MBS is an effective treatment of clinically severe obesity in patients who need other specialty surgery, such as joint arthroplasty, abdominal wall hernia repair, or organ transplantation.[93]

TWO-STAGE BARIATRIC SURGERY PROCEDURES

Bariatric surgeries that are performed in two stages have been proposed as a treatment option, particularly for patients with “super-obesity” defined as a BMI greater than 50. The rationale for a two-stage procedure is that the risk of an extensive surgery is prohibitive in patients with extreme levels of obesity. Therefore, an initial procedure with low risk, usually a sleeve gastrectomy, is performed first. After a period of time in which the patient loses some weight, thus lowering the surgical risk, a second procedure that is more extensive, such as a biliopancreatic diversion (BD), is performed.

RANDOMIZED CONTROLLED TRIALS

Coffin (2017) published results on the use of intragastric balloon (IGB) prior to a laparoscopic gastric bypass in patients with super-obesity.[56] Patients with BMI greater than 45 kg/m^2 were randomized to an IGB (n=55) or standard medical care (n=60) during the 6 months prior to a

planned laparoscopic gastric bypass procedure. Five patients had the IGB removed earlier than 6 months due to complications (n=3) or patient request (n=2). Patients receiving IGBs during the first 6 months of the study experienced significantly more BMI reduction (2.8 kg/m^2; range 1.7-6.2 kg/m^2) than patients receiving standard care (0.4 kg/m^2; range 0.3-2.2 kg/m^2). Weight loss during months 6 through 12, after the laparoscopic gastric bypass procedure, was greater in the patients who received standard of care before the procedure. Duration of hospitalization after laparoscopic gastric bypass and quality of life did not differ between groups.

NONRANDOMIZED STUDIES

Case series on two-stage procedures for patients undergoing sleeve gastrectomy (SG) as the initial procedure generally did not report on the second-stage operation, and in those that did, only a minority of patients undergoing the first stage actually proceeded to the second-stage surgery. For example, Cottam[94] reported on 126 patients with a mean BMI of 65 who underwent laparoscopic SG as the first portion of a planned two-stage procedure. A total of 36 patients (29%) proceeded to the second-stage procedure, which was laparoscopic gastric bypass. In a similar study, Alexandrou.[95] reported on 41 patients who underwent SG as the first stage of a planned 2-stage procedure. After 1-year follow-up, 12 patients (29%) achieved a BMI less than 35 and were not eligible for the second-stage procedure. Of the remaining 28 patients, 10 (24% of total) underwent the second-stage procedure. The remaining 18 patients (44% of total) were eligible for, but had not undergone, the second-stage procedure at the last follow-up.

Patients who undergo two-stage procedures are at risk for complications from both procedures. Silecchia.[96] described the complication rates in 87 patients undergoing a stage I SG followed by a BPD in 27 patients. For the first stage of the operation, 16.5% of patients had complications of bleeding, fistula, pulmonary embolism, acute renal failure, and abdominal abscess. For the 27 patients who underwent the second-stage BPD, major complications occurred in 29.6% including bleeding, duodenoileal stenosis, and rhabdomyolysis.

SECTION SUMMARY

The current evidence does not indicate that a two-stage bariatric surgery procedure improves outcomes for patients with extreme levels of obesity. There is no evidence to suggest that weight loss is improved or that complications are reduced by this approach. A majority of patients who received SG as the initial procedure lost sufficient weight during the first year such that a second procedure was no longer indicated. In addition, patients undergoing a two-stage procedure are at risk for complications from both procedures; therefore, it is possible that overall complications are increased by this approach.

ENDOSCOPIC (ENDOLUMINAL) BARIATRIC PROCEDURES

SYSTEMATIC REVIEWS

Several systematic reviews of RCTs evaluating intragastric balloon (IGB) devices for the treatment of obesity have been published; none was limited to FDA-approved devices.[97-99]Weitzner (2023) published a SR comparing the efficacy of endoscopic bariatric procedures as compared to other existing treatments.[100] Thirty-seven studies (15,639 patients) were included. Intragastric balloons achieved greater %TBWL with a range of 7.6-14.1% compared to 3.3-6.7% with lifestyle modification at 6 months, and 7.5-14.0% compared to 3.1-7.9%, respectively, at 12 months. When endoscopic sleeve gastroplasty (ESG) was compared to

laparoscopic sleeve gastrectomy (LSG), ESG had less %TBWL at 4.7-14.4% compared to 18.8-26.5% after LSG at 6 months, and 4.5-18.6% as compared to 28.4-29.3%, respectively, at 12 months. For the AspireAssist, there was greater %TBWL with aspiration therapy compared to lifestyle modification at 12 months, 12.1-18.3% TBWL versus 3.5-5.9% TBWL, respectively. All endoscopic interventions had higher adverse events rates compared to lifestyle modification. The authors conclude that endoscopic therapies result in greater weight loss compared to lifestyle modification, but not as much as bariatric surgery.

Loo (2022) published a systematic review evaluating the utility of intragastric balloon as a bridge therapy to bariatric surgery in patients with severe obesity.[101] A total of 13 studies were included and the IGB resulted in a BMI reduction of 6.60 kg/m2 and post-operative complication rate of 8.13%. There was no evaluation of the risk reduction for subsequent bariatric surgeries or an assessment of long-term weight loss outcomes after the use of the bridge therapy. Additional follow-up and long-term studies are needed to assess the utility of IGB as a bridge therapy to bariatric surgeries.

Kotinda (2020) published a systematic review and meta-analysis that evaluated the efficacy of IGB devices in comparison to sham or lifestyle interventions in overweight and obese adults.[102] Thirteen RCTs with 1,523 patients were included. Results revealed that the mean percent EWL difference between the IGB and control groups was 17.98% (95% CI, 8.37 to 27.58; p<0.001), significantly favoring IGB. IGB was also significantly favored when evaluating the mean percent TWL difference between the groups: 4.40% (95% CI, 1.37 to 7.43; p<0.001). Similarly, the difference in actual weight loss and BMI loss was 6.12 kg and 2.13 kg/m2, respectively. Overall, IGB was found to be more effective than lifestyle intervention alone for weight loss. The majority of included RCTs used one fluid-filled IGB and there was significant heterogeneity between the included studies.

The systematic review by Tate (2017) focused on recent RCTs, published between 2006 and 2016.[103] Additional inclusion criteria were: sham, lifestyle modification, or pharmacologic agent as a comparator; at least 1 outcome of body weight change; and study duration of 3 or more months. Eight RCTs were included in the review, with four contributing to the meta-analysis. The meta-analysis included 777 patients and showed a significant improvement in percent TBWL with IGB compared with control (5.5%; 95% CI, 4.3% to 6.8%). However, there was significant heterogeneity among the trials (I^2=62%), so interpretation of results is limited. The percent TBWL with IGB is lower than expected with RYGB (reported 27%) or with the most efficacious pharmacologic agent (reported 9%).

Saber (2017) identified 20 RCTs reporting weight loss outcomes after IGB implantation or a non-IGB control intervention.[99] IGB was compared with sham in 15 trials, behavioral modification in 4 trials, and pharmacotherapy in 1 trial. In 17 trials, patients received lifestyle therapy in addition to other interventions. Studies were published between 1987 and 2015 and sample sizes varied from 21 to 326 participants. Outcomes were reported between 3 and 6 months. In a meta-analysis of 7 RCTs reporting BMI loss as an outcome, there was a significantly greater BMI loss in the IGB group than in the control group (mean effect size [ES], 1.59 kg/m^2; 95% CI, -0.84 to 4.03 kg/m^2; p<0.001). Findings on other outcomes were similar. A meta-analysis of 4 studies reporting percent EWL favored the IGB group (ES=14.25%; 95% CI, 2.09% to 26.4%; p=0.02). Also, a meta-analysis of 6 studies reporting absolute weight loss favored the IGB group (ES=4.6 kg; 95% CI, 1.6 to 7.6 kg; p=0.003).

Although the review was not limited to FDA-approved devices, older devices were air-filled and newer devices, including the two approved by FDA in 2015, are fluid-filled. Sufficient data were available to conduct a sensitivity analysis of 3-month efficacy data. A meta-analysis of 4 studies did not find a significant difference in weight loss with air-filled IGB devices or a control intervention at 3 months (ES= 0.26; 95% CI, -0.12 to 0.64; p=0.19). In contrast, a meta-analysis of 8 studies of fluid-filled devices found significantly better outcomes with the IGB than with control (ES=0.25; 95% CI, 0.05 to 045; p=0.02).

In 2017, Vargas performed a systematic review of two observational studies with no comparator group combined with results from a multi-center study of 130 consecutive patients.[104] Between the three studies, 330 endoscopic transoral outlet reduction (TORe) cases were performed with the Apollo OverStitch system. TORe was performed in patients experiencing weight regain following RYGB. Study quality was evaluated using the Newcastle-Ottawa Quality Assessment Scale for cohort studies; all were rated to be of moderate overall quality. Using a random effects model, the pooled absolute weight loss at 6, 12, and 18–24 months was 9.5 kg (95% CI 7.9–11.1), 8.4 kg (95% CI 6.5–10.3), 8.4 kg (95% CI 5.9–10.9), respectively. Given the fluctuation of absolute weight loss reported between timelines by each of the three studies, longer term follow-up would aid in evaluating the overall efficacy of TORe.

A systematic review of the effect of EndoBarrier® on weight loss and diabetic outcomes was published in 2015.[105] There were five small RCTs included with a total of 235 individuals (range, 18-77) and follow-up ranging from 12 to 24 weeks. The comparators were diet and/or other lifestyle modifications, and 2 studies had sham controls. All studies were judged to be at high risk of bias using the Cochrane risk of bias tool. Combined results demonstrated that the EndoBarrier® group had 12.6% greater EWL (95% CI, 9.0 to 16.2) compared to medical therapy. For diabetic outcomes, there were trends toward greater improvement in the EndoBarrier® group that did not reach statistical significance. The mean difference in HgA1c was -0.8% (95% CI, -1.8 to 0.3) and the relative risk of reducing or discontinuing diabetic medications was 3.28 (95% CI, 0.54 to 10.73).

RANDOMIZED CONTROLLED TRIALS

In June 2016 the AspireAssist (Aspire Bariatrics, King of Prussia, PA) weight loss therapy system was approved by the FDA to assist in weight reduction in adults aged 22 and older with a BMI of 35.0-55.0 kg/m^2 who have failed to achieve and maintain weight loss with non-surgical weight loss therapy. Feasibility data for the AspireAssist was reported by Sullivan and colleagues in 2013.[106] Preliminary results from the ongoing PATHWAY Pivotal Trial (sponsored by Aspire Bariatrics) are included in the FDA Summary of Safety and Effectiveness Data, though results have not been published in peer-reviewed literature at this point in time.[107]

In 2014, Eid reported results from a single-center RCT of the StomaphX device compared with a sham procedure for revision procedures in patients with prior weight loss after Roux-en-Y gastric bypass at least two years earlier.[108] Enrollment was initially planned for 120 patients, but the trial was stopped prematurely after 1-year follow up was completed by 45 patients in the StomaphyX group and 29 patients in the sham control group after preliminary analysis failed to achieve the primary efficacy endpoint in at least 50% of StomaphyX patients. The primary efficacy end point (reduction in pre-Roux-en-Y gastric bypass excess weight by 15% or more, excess BMI loss, and BMI less than 35, at 12 months post-procedure) was achieved by 10/45 (22.2%) of the StomaphyX group and 1/29 (3.4%) of the sham control group

(P<0.01). Conclusions regarding the use of the StomaphX device as a primary procedure for the treatment of obesity may not be drawn due to the discontinuation of the trial and the limited use of the device as a revision procedure in patients who had failed a prior bariatric surgery.

In 2014, Koehestanie published results from an RCT of duodenal-jejunal bypass liner (DJBL) treatment in comparison with dietary intervention for obesity and type 2 diabetes mellitus (T2DM).[109] A total of 77 patients were included in the trial with 38 patients randomized to 6 months DJBL in combination with dietary intervention and 39 patients were randomized to dietary interventions only. The total study duration for both groups was 12 months, including 6 months of post-DJBL removal follow-up. At 6 months follow-up, prior to DJBL removal, the DJBL group lost a higher percentage of excess weight compared to the dietary only group, 32% (22%-46.7%) vs. 16.4% (4.1%-34.6%) respectively. However, better HbAIc levels improvement was observed in the dietary only group compared to the DJBL at both 6 and 12 month follow-ups. Conclusions are limited in this study as both groups underwent dietary interventions limiting the isolation of the effects of DJBL upon obesity and type 2 diabetes.

In 2013, Sullivan reported results from a small feasibility pilot RCT (n=18) comparing the AspireAssist siphon assembly (Aspire Bariatrics, King of Prussia, PA) combined with lifestyle therapy (AT) versus lifestyle therapy (LT) alone.[106] Only fourteen subjects completed the 12-month trial (10 in the AT group and four in the LT group). Although weight loss in the AT group was greater at 52 weeks than the LT group (18.6% ± 2.3% of body weight vs 5.9% ± 5.0%) the study was limited by the very small sample size, and unblinded design. The study was partially funded by the manufacturer. The authors all disclosed having previously performed contracted research for the manufacturer of the device and one author also disclosed having consulted on a pivotal trial for the company.

In 2013, Fuller published a small RCT (n=66) which evaluated intragastric balloons (IGB) compared to behavioral modification as a treatment of obesity.[110] Subjects were either randomized to IGB and 12 months behavior modification (BH) and or 12 months BH alone. At six months the IGB treatment group demonstrated superior weight loss compared to the BH group (-14.2 vs. -4.8; P < 0.0001). However, at 12 months the difference in weight loss between groups, although still statistically significant, diminished (-9.2 vs. -5.2; P = 0.007). There were numerous adverse events related to IGB placement which typically resolved in two weeks. Limitations of this study include a relatively small population size and short-term follow-up with which to evaluate the lasting effects of weight reduction with IGB. In addition, RCTs which evaluate IGB to other standard surgical treatments of obesity are needed.

Additional, small RCTs assessing IGB were identified[111-113]; however, large, long-term data remain lacking with which to evaluate the safety and sustained benefit of IGB in weight reduction compared to conservative measures and accepted bariatric procedures.

NONRANDOMIZED STUDIES

A small number of non-randomized studies, primarily case series, describe experiences of patients undergoing different endoluminal procedures, such as endoscopic gastroplasty and endoscopically placed sleeves, gastric balloons or tissue anchors.[104, 114-131] As noted at the beginning of the evidence section, conclusions cannot be reached as this evidence is considered unreliable.

LAPAROSCOPIC GASTRIC PLICATION

Similar to the data for endoscopic bariatric procedures, the data for laparoscopic gastric plication (also known as laparoscopic gastric imbrication) is limited to case series and case reports and few, small RCT's.

RANDOMIZED CONTROLLED TRIALS

Sullivan (2017) published results from the ESSENTIAL trial, a randomized sham-controlled trial evaluating the efficacy and safety of endoscopic gastric plication.[132] Patients (N=332) were randomized 2:1 to the active or sham procedure. All patients were provided low-intensity lifestyle therapy. The primary end point was total body weight loss (TBWL) at 12-month follow-up. The mean difference in TBWL for patients receiving the procedure compared with patients receiving the sham procedure was 3.6% (95% CI, 2.1% to 5.1%). Significant differences between the active and sham groups were also reported in a change in weight from baseline, percent excess weight loss, BMI, and improvement in diabetes. No significant differences were detected in improvements in hyperlipidemia or hypertension between the treatment groups.

Talebpour (2017) randomized patients to laparoscopic gastric plication (n=35) or laparoscopic SG (n=35).[133] Patients were followed for 2 years. Both procedures were equally effective based on weight reduction outcomes. Adverse events (eg, nausea, hair loss, vitamin D deficiency, iron deficiency) were similar between groups. One death due to pulmonary thromboembolism occurred in the gastric plication group.

NONRANDOMIZED STUDIES

Additional studies describe patient outcomes after different laparoscopic plication procedures.[134-138] As noted at the beginning of the evidence section, conclusions cannot be reached as this evidence is considered unreliable.

REVISION BARIATRIC SURGICAL PROCEDURES

There are a number of reasons why patients who are treated with accepted forms of bariatric surgery may not lose weight or may regain weight that is initially lost. These reasons include issues of adherence (compliance), as well as technical (structural) issues. A number of studies[139-142] have evaluated the efficacy of revision procedures after failed bariatric surgery and reported satisfactory weight loss and resolution of co-morbidities with somewhat higher complication rates than for primary surgery. However, criteria for classifying what constitutes a failed, primary bariatric procedure, has not been clearly established.[143]

Vitiello (2023) published a SR with meta-analysis comparing weight loss and gastroesophageal reflux disease (GERD) remission after one-anastomosis gastric bypass (OAGB) versus Roux-en-Y gastric bypass (RYGB) as revisional procedures after laparoscopic sleeve gastrectomy (LSG).[144] Six retrospective comparative articles were included. Weight loss analysis showed a mean difference = 5.70 (95% CI 4.84-6.57) in favor of the OAGB procedure (p = 0.00001) with no significant heterogeneity (I2 = 0.00%). There was no significant risk difference (RD) for leak, bleeding, or marginal ulcer after the two revisional procedures. After conversion to OAGB, remission from GERD was 68.6% (81/118), and it was 80.6% (150/186) after conversion to RYGB with a RD = 0.10 (95% CI -0.04, 0.24; p = 0.19), with high heterogeneity (I2 = 96%). De novo GERD was 6.3% (16/255) after conversional OAGB, and it was 0.5% (1/180) after conversion to RYGB with a RD = -0.23 (95% CI -0.57, 0.11; p = 0.16), with high heterogeneity (I2 = 92%).

Franken (2023) published a SR with meta-analysis evaluating revisional techniques for addressing weight regain and insufficient weight loss after Roux-en-Y gastric bypass through a systematic review and meta-analysis.[145] Thirty-nine studies were included: four studies reported on argon plasma coagulation, four studies on transoral outlet reduction, nine studies on transoral outlet reduction + argon plasma coagulation, four studies on pouch/gastrojejunal anastomosis revision, five on laparoscopic gastric banding, two studies on laparoscopic gastric banding + pouch resizing, 10 on distalization-RYGB, and one on duodenal switch. All techniques resulted in short-term clinically relevant weight loss. Endoscopic procedures had a short follow-up and resulted in modest and temporary weight loss. Surgical revision techniques were successful for weight loss in longer term follow-up, at the expense of high complication rates.

Kermansaravi (2021) published a systematic review of 1,771 patients from 26 studies evaluating the efficacy of one anastomosis/mini gastric bypass (OABG-MGB) as a revisional procedure.[146] Mean initial BMI was 45.7 which decreased to 30.5 at five year follow up with remission of type 2 diabetes reaching 78.1%. Leakage was the most common complication in the included patients and 7.4% of patients developed de novo GERD following OABG-MGB. Although the authors concluded that OAGB-MGB is a safe and effective choice for revisional bariatric surgery, RCTs on this topic are needed as currently only retrospective cohort studies with heterogenous data are available.

Parmar (2020) published a systematic review of 1,075 patients (n=17 studies) who underwent one anastomosis/mini gastric bypass as a revisional bariatric procedure after failure of a primary LAGB and SG.[147] No RCTs were available on this topic and no meta-analyses were performed as part of this systematic review. The most commonly reported reason for revisional surgery was poor response (81%) followed by gastric band failure (35.9%), GERD (13.9%), intolerance (12.8%), staple line disruption (16.5%), pouch dilatation (17.9%), and stomal stenosis (10.3%). Results revealed that after the revisional OABG-MGB, the mean percent EWL was 50.8% at 6 months, 65.2% at one year, 68.5% at two years, and 71.6% at five years. Resolution of comorbidities after OAGB-MGB was significant with 80.5% of patients with T2D, 63.7% of patients with hypertension, and 79.4% of patients with GERD reporting resolution. The overall readmission rate following OAGB-MGB was 4.73%, the mortality rate was 0.3%, and the leak rate was 1.54%. Although the authors concluded that OAGB-MGB is a safe and effective choice for revisional bariatric surgery, RCTs on this topic are needed as currently only retrospective cohort studies with heterogenous data are available.

In 2018, Almalki published a retrospective analysis of patients diagnosed with failed restrictive procedure who underwent revision bariatric surgery.[47] One hundred sixteen patients between 2001 and 2015 had revision RY gastric bypass (R-RYGB) or revision single-anastomosis (mini-) gastric bypass (R-RSAGB); the primary indications for revisional procedures were weight regain (50.9%), inadequate weight loss (31%), and intolerance (18.1%). Major complications occurred in 12 patients without significant difference between groups. At one year after revision surgery, the R-SAGB group (76.8% EWL) showed better weight loss than R-RYGB (32.9% EWL). In the 37.1% of patients available for follow-up at five years, R-SAGB had significantly lower hemoglobin levels than R-RYGB (8.2 ± 3.2 g/dl vs 12.8 ± 0.5 g/dl). The study was limited by its retrospective nature, relatively short follow-up time, and lack of consideration of data related to patient compliance.

In 2016, Dang reported results from a systematic review and meta-analysis comparing revisional single-step versus two-step bariatric surgery from laparoscopic adjustable gastric

banding (LAGB) to Roux-en-Y gastric bypass (RYGB) or sleeve gastrectomy (SG).[148] Single-step procedures involved revisional surgery wherein the LAGB was removed and replaced by RYGB or SG in the same operation; two-step procedures allowed a delay before the second bariatric procedure was performed. Although the authors found comparable rates of complications, morbidity and mortality between the one- and two-step procedures, the study was not designed to evaluate differences in patient outcomes between the second bariatric procedure (i.e., RYGB vs SG).

In 2014, Sudan reported safety and efficacy outcomes for reoperative bariatric surgeries using data from a national registry, the Bariatric Outcomes Longitudinal Database.[149] The Bariatric Outcomes Longitudinal Database is a large multi-institutional bariatric surgery-specific database to which data was submitted from June 2007 through March 2012 by 1,029 surgeons and 709 hospitals participating in the Bariatric Surgery Centers of Excellence (BSCOE) program. Surgeries were classified as primary or reoperative bariatric surgery. Reoperations were further divided into corrective operations (when complications or incomplete treatment effect of a previous bariatric operation was addressed but the initial operation was not changed) or conversions (when an index bariatric operation was changed to a different type of bariatric operation or a reversal restored original anatomy.) There were a total of 449,473 bariatric operations in the database of which 420,753 (93.6%) operations had no further reoperations (primary operations) while 28,270 (6.3 %) underwent reoperations. Of the reoperations, 19,970 (69.5%) were corrective operations and 8,750 (30.5%) were conversions. The primary bariatric operations were Roux-en-Y gastric bypass (N=204,705, 49.1 %), adjustable gastric banding (N=153,142, 36.5 %), sleeve gastrectomy (N=42,178, 10 %), and BPD±DS (N=4,260, 1 %), with the rest classified as miscellaneous. Adjustable gastric banding was the most common primary surgery among conversions (57.5% of conversions; most often [63.5%] to Roux-en-Y gastric bypass). Compared with primary operations, mean length of stay was longer for corrections (2.04±6.44 vs 1.8±4.9, P<0.001) and for conversions (2.86±4.58 vs 1.8±4.9, P<0.001). The mean % excess weight loss at one year was 43.5 % after primary operation, 39.3 % after conversions, and 35.9 % after corrective operations (statistical comparison not reported). One-year mortality was higher for conversions compared with primary operations (0.31% vs 0.17%, P<0.001), but not for corrections compared with primary operations (0.24% vs0.17%, P=NS). One-year serious adverse event rates were higher for conversions compared with primary operations (3.61% vs 1.87%, P<0.001), but not for corrections compared with primary operations (1.9% vs 1.87%, P=NS). The authors conclude that reoperation after primary bariatric surgery is relatively uncommon, but generally safe and efficacious when it occurs.

As part of the American Society for Metabolic and Bariatric Surgery Revision Task Force, Brethauer conducted a systematic review of reoperations after primary bariatric surgery that included 175 studies, most of which were single-center retrospective reviews.[150] The review was primarily descriptive, but the authors made the following conclusions:

> "The current evidence regarding reoperative bariatric surgery includes a diverse group of patient populations and procedures. The majority of the studies are single institution case series reporting short- and medium-term outcomes after reoperative procedures. The reported outcomes after reoperative bariatric surgery are generally favorable and demonstrate that additional weight loss and co-morbidity reduction is achieved with additional therapy. The risks of reoperative bariatric surgery are higher than with primary bariatric surgery and the evidence highlights the need for careful patient selection and surgeon expertise."

REVISION OR REMOVAL OF ADJUSTABLE GASTRIC BAND

Evidence regarding the indications for band removal or revision procedure is primarily limited to small cohort[151] and case series studies; however, reoperation or removal rates are estimated to range from 4.1%- 53%, depending on the time of reported follow-up.[152-155] Several of the largest cohort studies have reported the following complications which resulted in reoperation or band removal:

Arapis reported the following complications in 87 patients who underwent reoperation:[156] chronic dilatation of the proximal gastric pouch (27 patients - 14.5%), acute dilatation (21 patients - 11.3%), intragastric migration of the prosthesis (6 patients - 3.2%), reflux esophagitis (6 patients - 3.2%), infection of the gastric band (1 patient - 0.5%), and Barrett's esophagus (1 patient - 0.5%).

Perathoner reported on 108 patients who underwent laparoscopic conversion of gastric banding to gastric bypass due to the following complications: band migration, inadequate weight loss, pouch dilation, band leakage, band intolerance, band infection and esophageal dilation.[157]

Other reported complications included: band erosion,[154, 158, 159] gastric obstruction,[12] and gastric slippage.[154, 159]

Avriel reported major respiratory complications and chronic disease development in 30 patients who underwent LAGB.[160] Reported complications included aspiration pneumonia (19 patients) including pulmonary abscess (4 patients) and empyema (2 patients), exacerbation of asthma (3 patients), hemoptysis (1 patient), interstitial lung disease (5 patients) and bronchiectasis (3 patients). However, the impact of LAGB upon the development of these conditions is unclear given that 83% of the patients smoked or had a smoking history (mean pack years 34).

Studies which evaluated band conversion to a second bariatric surgery primarily indicated that bypass was the preferred revision surgery due to better long-term outcomes compared to sleeve gastrectomy.[161-164] In one large retrospective study published in 2014, bypass was compared to sleeve gastrectomy after band removal and conversion.[165] National Surgical Quality Improvement Project data from 2005-2011 were analyzed and included 495 patients who converted from LAGB to bypass and 130 patients who converted to sleeve gastrectomy. Conversion to bypass was not associated with higher morbidity or mortality compared to primary RYGB; however, conversion to sleeve gastrectomy was independently associated with a higher rate of major complications and mortality compared to primary sleeve gastrectomy (OR 8.02, 95 % CI 1.08-59.34, p = 0.04).

SECTION SUMMARY

For surgical revision of bariatric surgery after failed treatment, evidence from nonrandomized studies suggests that revisions are associated with improvements in weight similar to those seen in primary surgery. However, evidence from large long-term studies is required to determine the appropriate clinical indications for band removal or reoperation.

BARIATRIC SURGERY IN PATIENTS WITH DIABETES WITH BMI < 35KG/M²

SYSTEMATIC REVIEWS

Zhou (2023) published a SR comparing the effect of surgical and nonsurgical treatment on patients with a BMI < 35 kg/m2 to reach diabetes remission.[166] Seven studies were included (544 participants) of which five reported number of patients reaching diabetes remission. Bariatric surgery is more effective than non-surgical treatment to reach diabetes remission [OR 25.06, 95%CL 9.58-65.54]. Bariatric surgery was more likely to result in reductions in HbA1c [MD -1.44, 95%CL (-1.84) - (-1.04)] and FPG [MD -2.61, 95%CL (-3.20) - (-2.20)]. Bariatric surgery resulted in reductions in BMI [MD -3.14, 95%CL (-4.41) - (-1.88)], which was more significant in individuals of Asian race. Limitations include time frame for data collection (different years) resulting in criteria difference defining T2DM remission, inconsistent follow-up time and small sample sizes.

In 2015 Muller-Stich published a systematic review comparing surgical versus medical treatment of type II diabetes in patients with a BMI less than 35 kg/m².[167] The analysis included data from five RCTs and six observational studies for a total of 702 patients. The follow-up of included studies ranged from 12-36 months. Authors concluded that surgery was associated with higher diabetes remission rate (OR: 14.1, 95% CI: 6.7–29.9, P < 0.001), higher rate of glycemic control (OR: 8.0, 95% CI: 4.2–15.2, P < 0.001) and lower HbA1c level (MD: −1.4%, 95% CI −1.9% to −0.9%, P < 0.001) compared to medical treatment. However, results are limited by inclusion of studies in which the BMI of some patients was greater than 35 kg/m² and short-term follow-up, limiting conclusion regarding the long-term benefits of bariatric surgery upon glycemic control.

In 2013, the Agency for Healthcare Research and Quality (AHRQ) published a comparative effectiveness review of bariatric surgery and nonsurgical therapy in adults with metabolic conditions, including diabetes, and a BMI of 30.0-34.9 kg/m².[168] The report evaluated key issues which included the effectiveness of bariatric surgery compared to nonsurgical therapies, short and long-term effects in symptom control and racial and demographic disparities regarding benefits and harms of surgery in patients with metabolic conditions and a BMI of 30.0-34.9 kg/m². Evidence was gathered from global literature searches, reference mining and titles identified from external sources. A total of 24 studies reported bariatric surgery results, with a majority of studies evaluating RYGBP or LAGB procedures in diabetic patients with a BMI of 30-35 kg/m². The AHRQ report concluded that there was moderate strength evidence of efficacy for certain bariatric procedures as a treatment for diabetes in the short term. However, the report noted that the evidence contained many limitations, “(m)ost importantly, very few studies of this target population have long-term follow-up. Only two studies followed patients for more than 2 years; one has a followup rate of only 13.8 percent and the other includes only seven patients. Thus, we have almost no data on long-term efficacy and safety.” In addition, the AHRQ report noted the lack of evidence on major clinical outcomes such as all-cause mortality, cardiovascular risks, or peripheral arterial disease. Although short-term studies suggest an improvement in glucose control, the AHRQ report pointed out that, “…the available evidence from the diabetes literature indicates it may be premature to assume that controlling glucose to normal or near normal levels completely mitigates the risk of microvascular and macrovascular events. Thus, claims of a “cure” for diabetes based on glucose control within 1 or 2 years require longer term data before they can be substantiated.”

RANDOMIZED CONTROLLED TRIALS

Since the publication of the AHRQ report, two RCTs have been reported on bariatric surgery compared to medical therapy in diabetic patients with a BMI between 30-40 kg/m².

Ikramuddin performed an unblinded RCT of gastric bypass versus intensive medical therapy on 120 patients with type II diabetes for at least 6 months and an HgbA1C of at least 8.0%.[169] Patients were followed for 12 months with the primary endpoint being a composite of HgA1C less than 7.0%, low-density lipoprotein (LDL) cholesterol less than 100 mg/dl and systolic blood pressure less than 130 mm Hg. A total of 28 patients in the surgery group achieved the primary outcome compared to 11 patients in the medical therapy group (odds ratio [OR]: 4.8, 95% CI: 1.9-11.7). The percent of patients achieving HgbA1C of less than 7.0% was 75% in the surgery group compared to 32% of patients in the medical therapy group (OR: 6.0, 95% CI: 2.6-13.9). There were 22 serious complications in the surgery group, including 4 perioperative complications, compared to 15 serious complications in the medical group. A limitation of this study was that results were not provided separately for patients who were above and below a BMI of 35 kg/m², thus restricting conclusions regarding the benefits of bariatric surgery compared to medical management in diabetic patients with a BMI < 35 kg/m².

In 2014, Prikh published a small (n=57), short-term (6-month follow-up) RCT which compared intensive medical weight management to bariatric surgery in patients with a BMI of 30-35 kg/m² and type 2 diabetes.[170] Significant improvements in primary outcome measures of homeostatic model of insulin resistance and higher diabetes remission rates were observed in the surgical group compared to the MWM group. Additional small RCTs have been identified;[171] however, larger, long-term RCTs are needed to confirm these findings.

In 2015, Mingrone published results of a small (n=60) RCT comparing long-term outcomes of either medical treatment or surgery by Roux-en-Y gastric bypass or biliopancreatic diversion in patients with type II diabetes.[172] A total of 53 patients were included in the 5-year follow-up assessment. Primary outcome measures included the rate of diabetes remission at 2 years which was defined as glycated HbA1c concentration of 6.5% or less (≤47.5 mmol/mol) and a fasting glucose concentration of 5.6 mmol/L or less without active pharmacological treatment for 1 year. At 5-year follow-up 19 (50%) of the 38 surgical patients (7 of 19 [37%] in the gastric bypass group and 12 of 19 in the [63%] bilipancreatic diversion group) maintained diabetes remission at 5 years, compared with none of the 15 medically treated patients (p=0.0007). Fifteen incidents of hyperglycemic relapse occurred in 34 surgical of the patients who achieved 2-year remission, suggesting continued monitoring of glycemic control may be necessary. Authors also reported that both surgical procedures were associated with significantly lower plasma lipids, cardiovascular risk, and medication use and no late complications or deaths.

CLINICAL PRACTICE GUIDELINES

American College of Cardiology, American Heart Association, and the Obesity Society

In 2013, the American College of Cardiology (ACC), American Heart Association (AHA), and the Obesity Society published guidelines on the management of obesity and overweight in adults.[173] The guidelines were based upon a high-quality systematic review of the evidence which included transparent methods for grading the strength of the evidence and subsequent recommendations. The guidelines make the following recommendations related to bariatric surgery:

> “For adults with a BMI >40kg/m2 or BMI >35 kg/m2 with obesity-related comorbid conditions who are motivated to lose weight and who have not responded to behavioral treatment (with or without pharmacotherapy) with sufficient weight loss to achieve targeted health outcome goals, advise that bariatric surgery may be an appropriate option to improve health and offer referral to an experienced bariatric surgeon for consultation and

evaluation." (Grade A: Indicating a strong recommendation, indicating there is a high certainty based on the evidence that the net benefit is substantial).

"For individuals with a BMI <35 kg/m2, there is insufficient evidence to recommend for or against undergoing bariatric surgical procedures." (No recommendation given, indicating there is insufficient evidence or evidence is unclear or conflicting).

American Association of Clinical Endocrinologists, the Obesity Society, and American Society for Metabolic & Bariatric Surgery

In 2022 the American Association of Clinical Endocrinology published an updated Clinical Practice Guideline: Developing a Diabetes Mellitus Comprehensive Care Plan.[174] They include the following recommendations:

- Persons with a BMI 35 kg/m2 and one or more severe obesity-related complications remediable by weight loss, including T2D, high risk for T2D (insulin resistance, prediabetes, and/or metabolic syndrome), poorly controlled hypertension, NAFLD/NASH, OSA, osteoarthritis of the knee or hip, and urinary stress incontinence, should be considered for a bariatric procedure.

- Persons with BMI 30 to 34.9 kg/m2 and T2D with inadequate glycemic control despite optimal lifestyle and medical therapy should be considered for a bariatric procedure.

In 2019, an update to the 2013 joint guidelines were published by the American Association of Clinical Endocrinologists, the Obesity Society, and American Society for Metabolic & Bariatric Surgery (AACE/ASM/Obesity Society) regarding the perioperative nutritional, metabolic and nonsurgical support of the bariatric surgery patient.[175, 176] Recommendations regarding which patients should be offered bariatric surgery indicated the following:

- "Patients with a BMI≥40 kg/m^2 without coexisting medical problems and for whom bariatric surgery would not be associated with excessive risk should be eligible for a bariatric procedures."

- "Patients with a BMI≥35 kg/m^2 and 1 or more severe obesity-related complications remediable by weight loss, including T2D, high risk for T2D, poorly controlled hypertension, nonalcoholic fatty liver disease/nonalcoholic steatohepatitis, OSA, osteoarthritis of the knee or hip, and urinary stress incontinence, should be considered for a bariatric procedure."

- "Patients with the following comorbidities and BMI≥35 kg/m^2 may also be considered for a bariatric procedure, though the strength of evidence is more variable; obesity-hypoventilation syndrome and Pickwickian syndrome after a careful evaluation of operative risk; idiopathic intracranial hypertension; GERD; severe venous stasis disease; impaired mobility due to obesity, and considerably impaired quality of life."

- "Patients with BMI of 30 to 34.9 kg/m^2 with T2D with inadequate glycemic control despite optimal lifestyle and medical therapy should be considered for a bariatric procedure; current evidence is insufficient to support recommending a bariatric procedure in the absence of obesity." or metabolic syndrome may also be offered a bariatric procedure although current evidence is limited by the number of subjects studied and lack of long-term data demonstrating net benefit."

- "The BMI criterion for bariatric procedures should be adjusted for ethnicity (eg, 18.5 to 22.9 kg/m^2 is normal range, 23 to 24.9 kg/m^2 overweight, and ≥25 kg/m^2 obesity for Asians)." “There is insufficient evidence for recommending a bariatric surgical procedure specifically for glycemic control alone, lipid lowering alone, or cardiovascular disease risk reduction alone, independent of BMI criteria.”
- "Bariatric procedures should be considered to achieve optimal outcomes regarding health and quality of life when the amount of weight loss needed to prevent or treat clinically significant obesity-related complications cannot be obtained using only structured lifestyle change with medical therapy."

American Society for Metabolic & Bariatric Surgery[93]

The American Society for Metabolic and Bariatric Surgery (ASMBS), in combination with International Federation for the Surgery of Obesity and Metabolic Disorders (IFSO), updated their guideline on indications for metabolic and bariatric surgery. They recommend the following:

- Metabolic and bariatric surgery (MBS) is recommended for individuals with a BMI greater than or equal to 35 kg/m^2 regardless of presence, absence, or severity of co-morbidities.
- MBS should be considered for individuals with metabolic disease and BMI of 30-34.9 kg/m^2
- BMI thresholds should be adjusted in the Asian population such that a BMI greater than or equal to 25 kg/m^2 suggests clinical obesity and individuals with a BMI greater than or equal to 27.5 kg/m^2 should be offered MBS.

Institute for Clinical Systems Improvement

In 2014, the Institute for Clinical Systems Improvement (ICSI) published revised guidelines regarding the diagnosis and management of type 2 diabetes mellitus in adults and indicated:[177]

A clinician may recommend a patient diagnosed with T2DM and a BMI >35 kg/m^2 consider bariatric surgery if diabetes or comorbidities are difficult to control with lifestyle and pharmacologic therapy. [Quality of Evidence: Moderate, Strength of Recommendation: Weak]

SECTION SUMMARY

Evidence regarding the efficacy of bariatric surgery as a treatment for diabetes in patients with a BMI< 35 kg/m² primarily consists of small cases series with short-term follow-up as noted in the AHRQ report. Since the publication of these reports a single RCT was identified which was limited by the inclusion of obese (BMI 35-40 kg/m²) and non-obese (BMI 30-34.9 kg/m²) patients, precluding conclusions regarding the clinically non-obese population. Clinical practice guidelines have recommended bariatric surgery in diabetic patients who do not meet the clinical definition of obesity; however, a lack of long-term data was noted. There are clinical concerns about durability and long-term outcomes at 5 to 10 years as well as potential variation in observed outcomes in community practice versus clinical trials. Overall, the current evidence does not demonstrate the safety and efficacy of bariatric surgery as a treatment for diabetes in patients with a BMI< 35 kg/m².

ADOLESCENT AND PEDIATRIC BARIATRIC SURGERY

SYSTEMATIC REVIEWS

Wu (2023) published a SR with meta-analysis aimed to evaluate the long-term outcomes of bariatric surgery in adolescents with obesity.[178] They included 29 cohort studies (4970 patients with age ranges from 12- 21 years). Body mass index ranged from 38.9 to 58.5 kg/m2. Females were the predominant gender (60.3%). After at least 5-year of follow-up, the pooled BMI decline was 13.09 kg/m2 (95%CI 11.75-14.43), with sleeve gastrectomy (SG) was 15.27 kg/m2, Roux-en-Y gastric bypass (RYGB) was 12.86 kg/m2, and adjustable gastric banding (AGB) was 7.64 kg/m2. The combined remission rates of type 2 diabetes mellitus (T2DM), dyslipidemia, hypertension (HTN), obstructive sleep apnea (OSA), and asthma were 90.0%, 76.6%, 80.7%, 80.8%, and 92.5%, (95%CI 83.2-95.6, 62.0-88.9, 71.5-88.8, 36.4-100, and 48.5-100), respectively. Postoperative complications were underreported. Combined with the current study, we found a low level of postoperative complications. Iron and vitamin B12 deficiencies were the main nutritional deficiency complications identified so far.The authors conclude that for adolescents with severe obesity, bariatric surgery (especially RYGB and SG) is an effective treatment option. After at least five years of follow-up, bariatric surgery in adolescents showed a desirable reduction in BMI and significant remission of T2DM, dyslipidemia, and HTN. Surgical and nutrition-related complications still need to be further explored by more long-term studies.

Qi (2017) published a SR and meta-analysis on the use of bariatric surgery for the treatment of adolescents with obesity. 49 studies were identified for inclusion and study quality was assessed using the Newcastle-Ottawa Scale. Age of patients ranged from 14 to 20 years. BMI ranged from 34 to 63 kg/m2. Overall results showed significant improvements in BMI as well as glycemic and lipid control with various bariatric surgery techniques. RYGB showed the largest improvements compared with other procedures, with LAGB and sleeve gastrectomy also showing improvements in this population.

The 2007 Washington State Health Technology Assessment evaluated the published, peer reviewed scientific literature describing bariatric surgery in the pediatric population.[179] Data from 17 studies that enrolled a total of 553 pediatric patients were included. Only one study was clearly prospective. Eight studies reported outcomes after LAGB, six after RYGBP, two after VBG, and one after banded bypass. The report concluded that:

- The evidence that LAGB for morbidly obese pediatric patients leads to sustained and clinically significant weight loss compared to non-operative approaches was weak at the longest follow-up after surgery (1.7 to 3.3 years).
- The evidence that RYGBP for morbidly obese pediatric patients leads to sustained and clinically significant weight loss compared to non-operative approaches was weak at the longest follow-up after surgery (1 to 6.3 years).
- The evidence was insufficient to permit quantitative estimates of the precise amount of weight loss after any bariatric surgical procedure for pediatric patients.
- The evidence was insufficient to permit any conclusions about weight loss after other bariatric surgical procedures for pediatric patients.
- The evidence was insufficient to permit any conclusions about weight loss in specific age subgroups (18-21, 13-17, 12 or less) within the pediatric population.

- The evidence that LAGB for morbidly obese pediatric patients does resolve comorbid conditions linked to obesity (diabetes, hypertension) compared to non-operative approaches was weak.
- The evidence that RYGBP for morbidly obese pediatric patients does resolve comorbid conditions linked to obesity (diabetes, hypertension) compared to non-operative approaches was weak.
- The evidence was insufficient to permit quantitative estimates of the likelihood of comorbidity resolution, quality of life improvement, or survival after any bariatric surgical procedure for pediatric patients.
- The evidence was insufficient to permit any conclusions about comorbidity resolution in specific age subgroups (18-21, 13-17, 12 or less) within the pediatric population.
- The LAGB studies reported no in-hospital or postoperative death. However, the most commonly reported complication was band slippage. Reoperations were performed on 7.9% of the LAGB patients to correct various complications (band slippage, intragastric migration, port/tubing problems).
- The RYGBP studies reported one postoperative death. The most frequently reported complication was related to malnutrition and micronutrient deficiency. In addition, potentially life-threatening complications (shock, pulmonary embolism, severe malnutrition, bleeding, gastrointestinal obstructions) were reported.
- The evidence was insufficient to permit any conclusions on potential impacts of bariatric surgery on growth and development of pediatric patients.
- The evidence was insufficient to permit any conclusions on potential harms in specific age groups (18-21, 13-17, 12 or less).

In summary, the assessment found that longer term, prospective collection of data on physical growth, quality of life, weight loss, persistence or resolution of comorbid conditions, and long-term survival are needed in order to fully understand the role of bariatric surgical procedures in treating morbidly obese pediatric patients.

In 2013, Black published a systematic review and meta-analysis of 23 studies (22 nonrandomized) that included 637 young patients (age 6-18 years) who underwent bariatric surgery.[180] Although significant weight loss was reported at the 1-year follow-up, limitations of the evidence were similar to those reported in the Washington State Health Technology Assessment. Included studies were limited by small sample size with a median number of 24 patients per study (range: 10-108) and short-term follow-up (range: 6-12 months). Authors reported that complications were inconsistently reported and indicated that, “long-term, prospectively designed studies, with clear reporting of complications and comorbidity resolution, alongside measures of [health-related quality of life], are needed to firmly establish the harms and benefits of bariatric surgery in children and adolescents.”

In 2015, the Washington State Health Technology Assessment compared various bariatric procedures and also re-examined the role of bariatric surgery in children and adolescents upon obesity related comorbidities.[181] The group concluded that there was, “a lack of both short- and long-term data demonstrating effectiveness for any bariatric surgery procedure in both children and adolescents.” Only two studies were identified which were deemed to be of sufficient quality and only one of those was a RCT. In addition, no comparative studies were identified which evaluated any bariatric procedure exclusively in children (under 13 years).

Additional reviews were identified; however, conclusions were limited due to a lack of long-term follow-up.[182-186]

RANDOMIZED CONTROLLED TRIALS

Jarvholm (2023) published a small randomized, open-label, multicentre trial (The adolescent morbid obesity surgery 2; AMOS2).[187] Adolescents aged 13-16 years with a BMI of at least 35 kg/m2, who had attended treatment for obesity for at least 1 year, passed assessments from a pediatric psychologist and a pediatrician, and had a Tanner pubertal stage of at least three, were randomly assigned (1:1) to MBS or intensive non-surgical treatment. 25 (19 females and six males) were randomly assigned to receive MBS and 25 (18 females and seven males) were assigned to intensive non-surgical treatment. Three participants (6%; one in the MBS group and two in the intensive non-surgical treatment group) did not participate in the 2-year follow-up, and in total 47 (94%) participants were assessed for the primary endpoint. Mean age of participants was 15·8 years (SD 0·9) and mean BMI at baseline was 42·6 kg/m2 (SD 5·2). After two years, BMI change was -12·6 kg/m2 (-35·9 kg; n=24) among adolescents undergoing MBS (Roux-en-Y gastric bypass [n = 23], sleeve gastrectomy [n = 2]) and -0·2 kg/m2 (0·4 kg; [n = 23]) among participants in the intensive non-surgical treatment group (mean difference -12·4 kg/m2 [95% CI -15·5 to -9·3]; p < 0·0001). Five (20%) patients in the intensive non-surgical group crossed over to MBS during the second year. Adverse events (n=4) after MBS were mild but included one cholecystectomy. Regarding safety outcomes, surgical patients had a reduction in bone mineral density, while controls were unchanged after 2 years (z-score change mean difference -0·9 [95% CI -1·2 to -0·6]). There were no differences between the groups in vitamin and mineral levels, gastrointestinal symptoms (except less reflux in the surgical group), or in mental health at the 2-year follow-up.

A small randomized trial compared the outcomes of gastric banding with an optimal lifestyle program in adolescents 14-18 years of age with a BMI >35.[188] Although the study reports that gastric banding resulted in greater percentage achieving a loss of 50% of excess weight, several flaws undermine the reliability of the study findings:

- The small study population (n=50) limits the ability to rule out the role of chance as an explanation of findings.
- The study had significant loss to follow-up suggesting a difference that may affect the outcome.
- Short-term follow-up (2 years) limits comparisons regarding the longer-term complications rates and the effectiveness of the procedure in controlling weight loss and comorbidities.

NONRANDOMIZED STUDIES

Studies with short follow-up time

A small number of nonrandomized comparative studies reported significant weight loss and resolution of some of the comorbidities in pediatric patients undergoing bariatric surgery.[189-191] However, the studies were small and had a very short follow up time. In 2014, Inge reported results from Teen-Longitudinal Assessment of Bariatric Surgery (Teen-LABS) study, a prospective, multicenter observational study of bariatric surgery in patients aged 19 or under.[192] The study enrolled 242 participants, with mean age 17.1 and median BMI 50.5 (IQR 45.2-58.2) at the time of operation. All patients had at least 1 obesity-related comorbidity, most commonly dyslipidemia (74%), followed by sleep apnea (57%), back and joint pain (46%), hypertension (45%), and fatty liver disease (37%). Roux-en-Y gastric bypass, adjustable gastric banding, and vertical sleeve gastrectomy were performed in 66.5%, 5.8%, and 27.7%, respectively. Within 30 days of surgery, 20 major complications occurred in 19 patients (7.9%),

most of which were perioperative complications. The cohort will be followed to assess longer-term outcomes.

Studies with mid-term follow-up time

Alqahtani (2021) conducted a prospective, noncomparative, cohort study analyzing durability of weight loss and comorbidity resolution, growth velocity, and adverse events associated with LSG in children and adolescents with severe obesity over 10 years.[193] Children and adolescents with class II or III obesity underwent LSG between 2008 and 2021. Overall, 2504 children and adolescents were included, with a mean age ± standard deviation (SD) 15.7 ± 3.7 years (range, 5 to 21 years) at the time of operation. In the 15- to 18-year age group specifically, there were 1517 children enrolled (61%). Mean ± SD baseline BMI was 44.8 ± 12.6 kg/m2, with a BMI z-score of 3.0 ± 0.5, representing 165% above the 95th percentile for age and sex, on average. In the overall cohort in the short- (1 to 3 years, n = 2051), medium- (4 to 6 years, n=1268), and long-term (7 to 10 years, n = 632) follow-up, mean %EWL was 82.3% ± 20.5%, 76.3% ± 29.1%, and 71.1% ± 26.9%, respectively. At baseline, 263 patients (10.5%) were diagnosed with T2D, 227 (9.1%) were diagnosed with dyslipidemia, and 377 (15.1%) had hypertension. At long-term follow-up, complete comorbidity remission was observed in 74% of T2D cases, 59% of dyslipidemia cases, and 64% of hypertension cases. Mean height z-score change at short-, medium-, and long-term follow-up was 0.1 ± 0.5, 0.1 ± 1.2, and 0.0 ± 0.8, respectively, representing no significant change in growth velocity at each follow-up stage (p= 0.95, p= 0.21, and p= 0.40, respectively). There were 27 (1%) reported adverse events within the first 90 days after operation, including 2 patients with a staple line leak, 22 patients with nausea and vomiting, and three patients with signs of metabolic neuropathy, with no procedure-related mortality. None of those patients with adverse events had long-standing sequelae or disability.

Dumont (2018) published a retrospective study of obese adolescents who underwent LAGB. Between 2006 and 2015, 97 consecutive teenagers (average age at surgery 17.2 ± 0.7 years; mean BMI of 44.9 ± 6.1 kg/m^2) who had achieved full growth and sexual maturity and had previously failed a medical nutritional and dietary management program for at least 1 year were enrolled in the study. After a mean follow-up time of 56.0 ± 22.0 months, mean total weight loss was 20.0 ± 16.6% and mean excess weight loss was 46.6 ± 39.5%. Nineteen patients underwent band removal (mean 43.0 ± 28.0 months). No limitations to the study were reported.

Two observational studies with mid-term follow-up times (≤10 and ≤8 years) reported experiences of pediatric patients undergoing LAGB (sample size 41 and 107 respectively).[194, 195] The first study found that weight loss was initially successful and resulted in resolution of some comorbidities, but it slowly increased over the time and ultimately was unsatisfactory in many patients. The second study reported 65.5% excess weight loss at eight years. Both studies reported high complication and reoperation rates (Lanthaler: 46% patients had complications that required reoperation; Mittermaier: 46% patients had complications and 29% required reoperation).

CLINICAL PRACTICE GUIDELINES FOR PEDIATRIC BARIATRIC SURGERY

American College of Physicians

The 2005 American College of Physicians (ACP) evidence-based guideline on use of bariatric surgery in adolescents and children states that the current evidence on surgical treatment of

pediatric populations is limited to a few case series which do not permit quantitative analysis.[196] Further, the guideline states that it is unclear whether extrapolation of adult data for bariatric surgery to the pediatric population is appropriate and that RCTs are needed (and feasible) to establish the role of bariatric surgery in this population.

American Academy of Pediatrics

In 2023, the American Academy of Pediatrics (AAP) published their first evidence-based clinical practice guideline for the evaluation and treatment of children and adolescents (ages two to 18 years) with obesity.[187] The recommendations put forth in the guideline are based on evidence from RCTs and comparative effectiveness trials, along with high-quality longitudinal and epidemiologic studies gathered in a systematic review process described in their methodology. The AAP's recommendation related to bariatric surgery is below:

"Pediatricians and other PHCPs [pediatric health care providers] should offer referral for adolescents 13 years and older with severe obesity (BMI ≥ 120% of the 95th percentile for age and sex) for evaluation for metabolic and bariatric surgery to local or regional comprehensive multidisciplinary pediatric metabolic and bariatric surgery centers (Grade C Evidence Quality)."

They list indications for adolescent metabolic and bariatric surgery that align with the 2019 indications.

American Heart Association

In 2013, the American Heart Association (AHA) published a statement regarding severe obesity in children and adolescents which concluded:[197]

> “Current treatment approaches using lifestyle modification and medications to reduce BMI and improve chronic disease risk factors are insufficient for most patients and significant residual risk (unacceptably high BMI and risk factor levels) remains. Although experts recommend stepped intensification of interventions, the “step” after behavior-based and pharmaceutical interventions to the next established alternative, bariatric surgery, is unacceptably large because of its limited applicability and availability.”

The AHA indicated that the following evidence was needed before bariatric surgery could be widely recommended in children and adolescents:

> “Generation of additional safety and efficacy data (especially long-term) on bariatric surgery, including studies describing improvements in vascular structure and function, insulin resistance, and β-cell function.”

Society of American Gastrointestinal and Endoscopic Surgeons

The 2008 the Society of American Gastrointestinal and Endoscopic Surgeons (SAGES) evidence-based guidelines state:[198]

> “RGB is well tolerated and produces excellent weight loss in patients younger than 18 years with 10-year follow-up… Well-designed prospective studies are just emerging to better define the place for adolescent bariatric surgery.”

This statement is based on eight publications of which six are retrospective studies, each with less than 35 participants and most with limited follow-up. Two of the supporting articles are opinion papers.

Endocrine Society

In 2017, the Endocrine Society published an updated clinical practice regarding the assessment, treatment, and prevention of pediatric obesity.[199] The guideline was developed according to the GRADE system. The following statements were given a rating of "we suggest", i.e., weak recommendations, and were based on "very low quality" to "low quality" evidence. Given the evidence quality, and the suggestion as opposed to a *recommendation*, the following statements are ultimately, expert opinion.

For pre-adolescent children, pregnant or breast-feeding adolescents (and those planning on becoming pregnant within two years of surgery), and in any patient who has not mastered the principles of healthy dietary and activity habits and/or has unresolved substance abuse, eating disorder or untreated psychiatric disorder, the Society suggests against bariatric surgery.

The Endocrine Society suggests that bariatric surgery be considered for adolescents only under the following conditions:

- The patient has attained Tanner 4 or 5 pubertal development and final or near-final adult height, the patient has a BMI of >40 kg/m2 or has a BMI of >35 kg/m2 and significant, extreme comorbidities
- extreme obesity and comorbidities persist despite compliance with a formal program of lifestyle modification, with or without pharmacotherapy
- psychological evaluation confirms the stability and competence of the family unit [psychological distress due to impaired quality of live (QOL) from obesity may be present, but the patient does not have an underlying untreated psychiatric illness]
- the patient demonstrates the ability to adhere to the principles of healthy dietary and activity habits
- there is access to an experienced surgeon in a pediatric bariatric surgery center of excellence that provides the necessary infrastructure for patient care, including a team capable of long-term follow-up of the metabolic and psychosocial needs of the patient and family.

Institute for Clinical Systems Improvement

In 2013, ICSI published updated guidelines regarding the prevention and management of obesity for children and adolescents.[200] The group noted that, "there is limited information on the long-term efficacy and safety of bariatric surgery in children and adolescents." However, ICSI concluded that bariatric surgery may be considered at centers of excellence when specific criteria where met and should not be considered in preadolescent children.

National Heart, Lung and Blood Institute

In 2011, National Heart, Lung and Blood Institute (NHLBI) published guidelines regarding cardiovascular health and risk reduction in overweight and obese children and adolescents which indicated bariatric surgery may be considered:[201]

> "For adolescents with BMI far above 35 kg/m2 and associated comorbidities, bariatric surgery on a research protocol, in conjunction with a comprehensive lifestyle weight loss program, improved weight loss, BMI, and other outcomes—such as IR, glucose tolerance, and cardiovascular (CV) measures—in a small case series."

This guideline is based on a Grade D recommendation which is defined as, “Expert opinion, case reports, or reasoning from first principles (bench research or animal studies).”

American Society of Bariatric and Metabolic Surgery

In 2022, the ASMBS updated their guideline on indications for metabolic and bariatric surgery.[93] They noted that prospective data demonstrated durable weight loss and maintained co-morbidity remission in patients as young as five years of age. Additionally, the ASMBS stated that metabolic and bariatric surgery do not negatively impact pubertal development or linear growth, and therefore a specific Tanner stage and bone age should not be considered a requirement for surgery. Other statements supported 2018 recommendations, including that syndromic obesity, developmental delay, autism spectrum, or a history of trauma would not be considered a contraindication to bariatric surgery in children or adolescents.

In 2018, ASBMS published an update to the 2012 guideline.[202] Summary of major changes in the guideline included:

- "Vertical sleeve gastrectomy has become the most used and most recommended operation in adolescents with severe obesity for several reasons, near-equivalent weight loss to RYGB in adolescents, fewer reoperations, better iron absorption, and near-equivalent effect on comorbidities as RYGB in adolescents. However, given the more extensive long-term data available for RYGB, we can recommend the use of either RYGB or VSG in adolescents. Long-term outcomes of GERD after vertical sleeve gastrectomy are still not well understood."
- "There are no data that the number of preoperative weight loss attempts correlated with success after metabolic/bariatric surgery. Compliance with a multidisciplinary preoperative program may improve outcomes after metabolic/bariatric surgery but prior attempts at weight loss should be removed as a barrier to definitive treatment for obesity."
- "The use of the most up to date definitions of childhood obesity are as follows: (1) BMI cut offs of 35 kg/m^2 or 120% of the 95th percentile with a comorbidity, or (2) BMI >40 kg/m^2 or 140% of the 95th percentile without a comorbidity (whichever is less). Requiring adolescents with a BMI >40 to have a comorbidity (as in the old guidelines) puts children at a significant disadvantage to attaining a healthy weight. Earlier surgical intervention (at a BMI <45 kg/m^2) can allow adolescents to reach a normal weight and avoid lifelong medication therapy and end organ damage from comorbidities."
- "Certain comorbidities should be considered in adolescents, specifically the psychosocial burden of obesity, the orthopedic diseases specific to children, GERD, and cardiac risk factors. Given the poor outcomes of medical therapies for T2D in children, these comorbidities may be considered an indication for metabolic/bariatric surgery in younger adolescents or those with lower obesity percentiles."
- "Vitamin B deficiencies, especially B1 appear to be more common in adolescents both preoperatively and postoperatively; they should be screened for and treated. Prophylactic B1 for the first 6 months postoperatively is recommended as is education of patients and primary care providers on the signs and symptoms of common deficiencies."
- "Developmental delay, autism spectrum, or syndromic obesity should not be a contraindication to metabolic/bariatric surgery. Each patient and caregiver team will need to be assessed for the ability to make dietary and lifestyle changes required for surgery. Multidisciplinary teams should agree on the specific needs and abilities of the

given patient and caregiver and these should be considered on a case-by-case basis with the assistance of the hospital ethics committee where appropriate."

- "Because metabolic/bariatric surgery results in better weight loss and resolution of comorbidities in adolescents at lower BMI's with fewer comorbidities, referrals should occur early, as soon as a child is recognized to suffer from severe obesity disease (BMI >120% of the 95th percentile or BMI of 35). Prior weight loss attempts, Tanner stage, and bone age should not be considered when referring patients to a metabolic/bariatric surgery program."
- "Unstable family environments, eating disorders, mental illness, or prior trauma should not be considered contraindications for metabolic/bariatric surgery in adolescents; however, these should be optimized and treated where possible before and surrounding any surgical intervention for obesity."
- "Routine screening of alcohol use is imperative across all procedures. Conservative clinical care guidelines, which strongly advocate abstinence, while appropriate, must also include information for this age group on harm reduction (i.e., lower consumption levels, how to avoid or manage situations related to alcohol-related harm) to mitigate clinical and safety risks. Risks of nicotine should be discussed and smoking or vaping nicotine should be discouraged."
- "The recognition of obesity as a chronic disease that requires multimodal therapies justifies the treatment of such a disease in a multidisciplinary team that can provide surgical, pharmacologic, behavioral, nutritional, and activity interventions. Pharmacologic therapies as adjuncts to surgical therapies may provide improved outcomes long term in the pediatric population; more studies are needed.

SECTION SUMMARY

There is evidence to suggest bariatric surgery may provide the benefits of weight reduction and improved comorbidities compared to non-surgical treatments in the obese children and adolescents.

GASTROESOPHAGEAL REFLUX DISEASE

This section focuses on evidence related to gastroesophageal reflux disease (GERD) as it relates to bariatric procedures as a treatment for obesity. See Cross References section, above, for policies focused on treatment of GERD.

SYSTEMATIC REVIEWS

In 2016, Osland compared the efficacy of Roux-En-Y gastric bypass versus vertical sleeve gastrectomy in randomized controlled trials.[44] Six RCTs performed between 2005 and 2015 were included (N = 695; 347 for SG and 348 for RYGB). The authors summarized recent publications, citing worsened GERD symptoms following sleeve gastrectomy in patients with preoperative symptoms, and new symptoms in 9% of patients with no previous symptoms. Preexisting GERD in those who undergo sleeve gastrectomy is noted as being the cause of frequent revisional surgeries, and high rates of surgical complications. In addition those with preexisting GERD were found to have failure to achieve weight loss, and failure to resolve weight related comorbidities such as diabetes, obstructive sleep apnea, and hypertension.

In 2016, Oor reported results from a systematic review and meta-analysis of studies reporting prevalence of GERD symptoms, the use of anti-reflux medication, and/or outcome of esophageal function tests before and after laparoscopic sleeve gastrectomy (LSG) in patients

with a BMI of more than 35.[203] Pooled data from seven studies using validated symptom questionnaires for new-onset of GERD symptoms resulted in a 20% incidence following LSG (follow-up time ranging from one- to 60-months). There was heterogeneity amongst these studies (I^2=68%). For difference in prevalence of GERD before and after LSG, the pooled risk difference was found to be 4.3%; with heterogeneity present (I^2=89%). Of the 24 studies reviewed, the authors found new-onset GERD symptom incidence to range from zero to 34.9%. The authors therefore concluded that LSG could induce serious GERD symptoms in patients with no preoperative GERD complaints. The heterogeneity found in analyses may be due to a lack of a standardized approach to LSG, as well has the variability in follow-up length. The authors also noted that range in prevalence of GERD symptoms may be in part due to the variability in reported preoperative BMI, as the LSG will be a more technically challenging procedure in those with a BMI of 60 kg/m^2 versus those with a BMI of 40 kg/m^2.

Li and colleagues (2016) conducted a systematic review and meta-analysis comparing Roux-en-Y gastric bypass (LRYGB) with LSG for treating morbid obesity.[204] Randomized controlled trials and nonrandomized studies were included. Amongst five studies that reported GERD resolution post-operation (147 in the LRYGB group and 93 in the LSG group), symptoms resolved significantly more after LRYGB as compared to LSG (OR = 8.99, 95% CI 4.77-16.95). Heterogeneity was not detected between these groups (I^2 = 48% P=0.12).

NONRANDOMIZED STUDIES

Several nonrandomized studies have retrospectively reviewed weight reduction and GERD symptoms following Roux-en-Y gastric bypass surgery for treatment of morbid obesity.[205-210] Authors have reported reduction in self-reported GERD symptoms, prescribed medications, and weight loss. As demonstrated in small case series, in combination with takedown of fundoplication, Roux-en-Y gastric bypass for morbid obesity has been effective in weight reduction as well as self-reported GERD symptom improvement.[208, 209] Evidence regarding high incidence of GERD following laparoscopic adjustable gastric banding and laparoscopic sleeve gastrectomy makes Roux-en-Y gastric bypass the ideal procedure in the presence of already existing reflux symptoms.[46, 211-215]

CLINICAL PRACTICE GUIDELINES

Society of American Gastrointestinal and Endoscopic Surgeons (SAGES)

The SAGES clinical practice guidelines for the surgical treatment of GERD (2010) state the following:[216]

> Due to concerns for higher failure rates after fundoplication in the morbidly obese patient (BMI >35 kg/m2) and the inability of fundoplication to address the underlying problem (obesity) and its associated comorbidities, gastric bypass should be the procedure of choice when treating GERD in this patient group (Grade B). The benefits in patients with BMI > 30 is less clear and needs further study.

SECTION SUMMARY

Systematic review of GERD symptoms following laparoscopic sleeve gastrectomy (LSG) as a treatment for severe obesity is limited by heterogeneity in the technical approach to the procedure, therefore presenting statistical challenges to analyzing pooled results. In comparing LSG with Roux-en-Y gastric bypass (RYGB) directly, GERD symptoms resolve significantly more post-RYGB as compared to LSG. In the presence of GERD, the Society of American

Gastrointestinal and Endoscopic Surgeons (SAGES) clinical practice guidelines state that gastric bypass is the procedure of choice in patients who are morbidly obese. In those who are not morbidly obese, evidence does not indicate that bariatric surgery is an appropriate treatment for GERD, and SAGES states this is an area in need of further study.

SAFETY OF BARIATRIC SURGERY

GENERAL SURGICAL RISKS

Bariatric procedures are associated with all the potential risks of any major abdominal surgical procedure including but not limited to:

- Bleeding
- Death
- Infection
- Injury to internal organs or gastrointestinal tract
- Thromboembolic complications

PROCEDURE-SPECIFIC SURGICAL RISKS

The following table summarizes the most common procedure-specific risks. However, other adverse events are also possible.

RYGBP[2, 217-219]	**LL-RYGBP**[2]	**BPD/BPD-DS**[2, 11, 217]	**SG**[11, 217, 220-223]	**LAGB**[63, 217]	**MGB**[79]	**Endoluminal Procedures**
• Cholecystitis • Depression • Dilated stomach pouch • Dumping syndrome† • Gastritis • Leaks or obstructions at the anastomotic site • Marginal ulcer • Reoperations††† • Staple line failure • Vitamin/mineral deficiencies (iron, folate, B_{12}) • Kidney stones	• All RYGBP risks • Additional unknown risks associated with the greater bypass of the small intestine and consequent increase in malabsorption††	• Dilated stomach pouch • Gastric obstruction • GERD • Leaks or stenoses at anastomotic sites • Malnutrition and/or vitamin deficiencies • Nausea/vomiting • Wound dehiscence	• Abscesses • Frequent vomiting • Gastric fistulas • GERD • Leaking from the stomach pouch • Reoperations††††	• Band slippage • Dilated stomach pouch • Erosion of the device through gastric wall • GERD • Malnutrition and vitamin deficiencies • Nausea and vomiting	• Bile reflux • Gastrojejunostomy leak • Marginal ulcer • Reoperations††† • Vitamin/mineral deficiency	The safety concerns are specific to the endoluminal procedure performed: <u>Transoral circular stapler (SurgASSIST®):</u>[224] • Bowel obstruction • Intra-abdominal adhesions <u>Dduodenal-jejunal bypass sleeve (DJBS):</u>[117] • Abdominal pain • Implant site inflammation • Nausea and vomiting <u>TOGa system endoscopic stapling:</u>[118] • Nausea • Vomiting • Pain • Transient dysphagia

† Abdominal pain, diarrhea, and/or vomiting shortly after eating due to reduced transit time in the intestine;
††The evidence, especially from the studies with long-term follow-up, is limited and not much is known about the long-term complications of LL-RYGBP;
†††Due to insufficient weight loss or technical issues;

SUMMARY

ROUX-EN-Y GASTRIC BYPASS, BILIOPANCREATIC BYPASS WITH DUODENAL SWITCH, AND SLEEVE GASTRECTOMY

Roux-en-Y gastric bypass is well established in clinical practice as a safe and effective bariatric procedure Sleeve gastrectomy as a stand-alone procedure gained acceptance in clinical practice. Sleeve gastrectomy offers an alternative to adjustable gastric banding with potentially greater weight loss and fewer complications. Therefore, Roux-en-Y gastric bypass, biliopancreatic bypass with duodenal switch, and sleeve gastrectomy may be considered medically necessary in the treatment of class III obesity when policy Criteria are met.

There is not enough research to show that Roux-en-Y gastric bypass, biliopancreatic bypass with duodenal switch, or sleeve gastrectomy improves health outcomes for any condition other than class III obesity. Therefore, Roux-en-Y gastric bypass, biliopancreatic bypass with duodenal switch, and sleeve gastrectomy are considered investigational for the treatment of any condition other than class III obesity, including, but not limited to gastroesophageal reflux disease.

There is not enough research to show that any other bariatric procedures improves health outcomes. Therefore, the use of distal, partial (not including sleeve gastrectomy) or complete gastrectomy with or without gastroduodenostomy, gastrojejunostomy, or Roux-en-Y reconstruction, are considered investigational as a treatment of obesity.

MINI-GASTRIC BYPASS, DISTAL GASTRIC BYPASS, BILIOPANCREATIC BYPASS, AND LAPAROSCOPIC DUODENAL SWITCH WITH SINGLE ANASTOMOSIS

There is not enough research for these procedures on health outcomes. Therefore, mini-gastric bypass, distal gastric bypass, biliopancreatic bypass, and laparoscopic duodenal switch with single anastomosis are considered investigational for the treatment of class III obesity, gastroesophageal reflux disease or any other condition.

HIATAL HERNIA REPAIR

There is not enough research regarding the use of hiatal hernia repair as an independent treatment of obesity. In addition, no evidence-based clinical practice guidelines were identified which addressed the use of hiatal hernia repair as a treatment of obesity. Therefore, hiatal hernia repair is considered investigational as an independent treatment of obesity.

VERTICAL BANDED GASTROPLASTY AND ADJUSTABLE GASTRIC BANDING

Due to higher complications, insufficient weight loss, and high reoperation rates, vertical banded gastroplasty and adjustable gastric banding are no longer considered a standard of care and are therefore considered not medically necessary.

ENDOSCOPIC BARIATRIC PROCEDURES

There is not enough evidence to establish the safety and efficacy of any endoscopic bariatric

procedure. Therefore, endoscopic bariatric procedures are considered investigational for all indications.

LAPAROSCOPIC GASTRIC PLICATION

There is not enough evidence to establish the safety and efficacy of any laparoscopic gastric plication bariatric procedure. Therefore, laparoscopic gastric plication procedures are considered investigational for all indications.

REVISION BARIATRIC SURGICAL PROCEDURES

Research regarding reoperation of a primary bariatric surgery is limited to noncomparative studies without long-term outcome data. In addition, current research shows that the complication and mortality rate is slightly higher in cases of reoperation. However, reoperation appears to be beneficial for patients with serious complications related to the primary bariatric surgery and may be considered medically necessary when Criteria are met.

Research regarding the revision or removal of an adjustable gastric band is limited to noncomparative studies with short-term follow-up. These studies suggest band removal or revision is associated with improvement in band related complications. In addition, studies indicate gastric bypass is the preferred secondary procedure in cases of adjustable band conversion as bypass is associated with fewer complications and lower mortality rates compared to sleeve gastrectomy. Therefore, adjustable gastric band removal and/or conversion to gastric bypass may be considered medically necessary when Criteria are met.

The research is insufficient to determine the safety or efficacy of all other bariatric surgery reoperations or revisions; therefore, reoperations or revisions are considered not medically necessary when Criteria are not met.

TWO-STAGED BARIATRIC PROCEDURES

There is not enough research to establish the safety and efficacy of any two-stage bariatric procedure. Therefore, two-stage bariatric procedures are considered investigational for all indications.

ADOLESCENT AND PEDIATRIC BARIATRIC SURGERY

There is evidence to suggest bariatric surgery may provide the benefits of weight reduction and improved comorbidities compared to non-surgical treatments in children and adolescents under the age of 18 with obesity. Clinical practice guidelines suggest that bariatric surgery may be beneficial for patients under the age of 18 when they have achieved Tanner pubertal development of 4 or 5 and additional consideration is given to the psychosocial and informed consent issues. Therefore, bariatric procedures in patients younger than 18 years of age may be considered medically necessary when Criteria are met.

BARIATRIC SURGERY IN PATIENTS WITH DIABETES WITH BMI < 35KG/M²

Research for the safety and effectiveness of bariatric procedures as a treatment for diabetes in patients with a BMI < 35 kg/m² is limited by small study sizes and short-term follow-up. High-quality studies that include long-term follow-up are needed in order to evaluate the impact of bariatric surgery on health outcomes in this population. In addition, the majority of

evidence-based clinical practice guidelines do not recommend bariatric surgery in diabetic patients with a BMI < 35 kg/m². Therefore, bariatric procedures in diabetic patients with a BMI < 35 kg/m² are considered not medically necessary.

NOTE: Code 43843 should not be reported if there is a more specific bariatric surgery code within code range listed below.

Codes	Number	Description
CPT	0813T	Esophagogastroduodenoscopy, flexible, transoral, with volume adjustment of intragastric bariatric balloon
	43290	Esophagogastroduodenoscopy, flexible, transoral; with deployment of intragastric bariatric balloon
	43291	Esophagogastroduodenoscopy, flexible, transoral; with removal of intragastric bariatric balloon(s)
	43631	Gastrectomy, partial, distal; with gastroduodenostomy
	43632	;with gastrojejunostomy
	43633	;with roux-en-Y reconstruction
	43634	;with formation of intestinal pouch
	43644	Laparoscopy, surgical, gastric restrictive procedure; with gastric bypass and Roux-en-Y gastroenterostomy (roux limb 150 cm or less)
	43645	Laparoscopy, surgical, gastric restrictive procedure; with gastric bypass and small intestine reconstruction to limit absorption
	43659	Unlisted laparoscopy procedure, stomach
	43770	Laparoscopy, surgical, gastric restrictive procedure; placement of adjustable gastric restrictive device (gastric band and subcutaneous port components)
	43771	Laparoscopy, surgical, gastric restrictive procedure; revision of adjustable gastric restrictive device component only
	43772	Laparoscopy, surgical, gastric restrictive procedure; removal of adjustable gastric restrictive device component only
	43773	Laparoscopy, surgical, gastric restrictive procedure; removal and replacement of adjustable gastric restrictive device component only
	43774	Laparoscopy, surgical, gastric restrictive procedure; removal of adjustable gastric restrictive device and subcutaneous port components
	43775	Laparoscopy, surgical, gastric restrictive procedure; longitudinal gastrectomy (ie, sleeve gastrectomy)
	43820	Gastrojejunostomy; without vagotomy

Codes	Number	Description
	43842	Gastric restrictive procedure, without gastric bypass, for morbid obesity; vertical banded gastroplasty
	43843	Gastric restrictive procedure, without gastric bypass, for morbid obesity; other than vertical banded gastroplasty
	43845	Gastric restrictive procedure with partial gastrectomy, pylorus-preserving duodenoileostomy and ileoileostomy (50 to 100 cm common channel) to limit absorption (biliopancreatic diversion with duodenal switch)
	43846	Gastric restrictive procedure, with gastric bypass for morbid obesity; with short limb (150 cm or less) Roux-en-Y gastroenterostomy
	43847	Gastric restrictive procedure, with gastric bypass for morbid obesity; with small intestine reconstruction to limit absorption
	43848	Revision, open, of gastric restrictive procedure for morbid obesity, other than adjustable gastric restrictive device (separate procedure)
	43860	Revision of gastrojejunal anastomosis (gastrojejunostomy) with reconstruction, with or without partial gastrectomy or intestine resection; without vagotomy
	43865	;with vagotomy
	43886	Gastric restrictive procedure, open; revision of subcutaneous port component only
	43887	Gastric restrictive procedure, open; removal of subcutaneous port component only
	43888	Gastric restrictive procedure, open; removal and replacement of subcutaneous port component only
HCPCS	C9784	Gastric restrictive procedure, endoscopic sleeve gastroplasty, with esophagogastroduodenoscopy and intraluminal tube insertion, if performed, including all system and tissue anchoring components
	C9785	Endoscopic outlet reduction, gastric pouch application, with endoscopy and intraluminal tube insertion, if performed, including all system and tissue anchoring components
	S2083	Adjustment of gastric band diameter via subcutaneous port by injection or aspiration of saline

Medical Policy Manual Surgery, Policy No. 60

Reduction Mammaplasty

Effective: November 1, 2022

Next Review: July 2023
Last Review: September 2022

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Reduction mammaplasty is the surgical excision of a substantial portion of the breast, including the skin and underlying glandular tissue, until a clinically normal size is obtained.

MEDICAL POLICY CRITERIA

Notes:

- This policy is not applicable when there has been a prior mastectomy for which the Women's Health & Cancer Rights Act applies. The Reconstructive Breast Surgery/Mastopexy, and Management of Breast Implants policy (Surgery, Policy No. 40 – see Cross References) may be applicable. Please refer to the Surgery, Policy No. 40 for reconstruction after partial or complete mastectomy.
- This policy is not intended to address treatment of gender dysphoria which is addressed in the Transgender Services medical policy (Medicine, Policy No. 153 – see cross references), which may be applicable.

I. Reduction mammaplasty may be considered **medically necessary** when one or more of the following are met:

A. As a preparatory first stage procedure preceding a nipple-sparing mastectomy,

when the amount of breast tissue removed from each breast is at least the minimum in grams per breast for the patient's body surface area (in meters squared using the Mosteller formula) according to the Schnur Sliding Scale (see Policy Guidelines for body surface area/breast weight table); or

B. When all of the following criteria (1. - 3.) are met:

1. The patient is aged 18 years or older; and
2. The amount of breast tissue removed from each breast, not including fat removed by liposuction, must be at least the minimum in grams per breast for the patient's body surface area* according to the Schnur Sliding Scale (see Policy Guidelines), or, in cases of asymmetry where one breast meets criterion but the other breast does not, the combined weight of the tissue removed from both breasts must total at least twice the Schnur Sliding Scale minimum for the patient's body surface area (the health plan may review medical records to confirm the amount of breast tissue removed during the procedure); and
3. Two or more of the following clinical indications have been present for at least 12 months and have failed to respond to appropriate conservative therapy:
    a. Pain in the upper back, neck, shoulders, and/or arms, with all of the following documented in the medical records by the referring provider:
        i. The pain is of long-standing duration and increasing intensity; and
        ii. The pain has been evaluated to determine that it is not associated with another condition such as arthritis, if applicable; and
        iii. The pain is not relieved by at least three months of conservative therapy such as an appropriate support bra with wide straps, exercises, heat/cold treatments and appropriate non-steroidal anti-inflammatory agents/muscle relaxants.
    b. Shoulder grooving not responding to conservative treatment (e.g., wide-strap or support bra).
    c. Intertrigo between the pendulous breasts and the chest wall persisting despite at least three months of conservative dermatologic treatments (e.g., taking steps to eliminate friction, heat, and maceration by keeping skin cool and dry and where appropriate, antimycotic agents).
    d. Kyphosis documented by x-ray.
    e. Ulnar paresthesia not relieved by at least three months of conservative therapy such as an appropriate support bra with wide straps, range of motion exercises, physical therapy, and appropriate non-steroidal anti-inflammatory agents/muscle relaxants.

II. Reduction mammaplasty is considered **not medically necessary** when Criteria I. is not met.

III. Reduction mammaplasty for gynecomastia is considered **not medically necessary**.

IV. The use of liposuction as an additional procedure with breast reduction surgery is considered **not medically necessary**.

V. The use of liposuction as the sole procedure for breast reduction is considered **investigational**.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Mosteller formula: body surface area (m^2) = ([height (cm) x weight (kg)] / 3600)^{½} [1]

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome:

1. Total amount of breast tissue to be removed, include if L/R or bilateral
2. Height and weight
3. Any two of the following detailed in chart notes, history and physical, physical therapy notes, radiologic exams, dermatology treatments notes, and/or any other clinical notes:
    A. Medical records by the referring physician, which include pain in the upper back, neck, shoulders and/or arms with documentation of long standing pain, and detailed notes regarding treatment with at least three months of conservative therapy, and that the pain is not associated with another diagnosis such as arthritis;
    B. Documentation or photograph of shoulder grooving with description of conservative treatment;
    C. Intertrigo despite three months detailed documentation of conservative therapy;
    D. X-ray showing kyphosis;
    E. Ulnar paresthesia despite three months documentation of conservative therapy and outcome with chart notes detailing specific treatment.

BACKGROUND

Female breast hypertrophy, or macromastia, is the development of abnormally large breasts in the female. This condition can cause significant clinical manifestations when the excessive breast weight adversely affects the supporting structures of the shoulders, neck and trunk. Macromastia is distinguished from large, normal breasts by the presence of persistent symptoms such as shoulder, neck, or back pain, shoulder grooving, or intertrigo. This condition can be improved and the associated signs and symptoms can be alleviated by reduction mammaplasty surgery.

EVIDENCE SUMMARY

The following literature appraisal is focused on the investigational technique of reduction mammaplasty by liposuction alone. In order to understand the impact on health outcomes of reduction mammaplasty by liposuction alone, prospective clinical trials are needed, comparing liposuction with standard reduction mammaplasty. These comparisons are necessary in order to understand the safety and efficacy of liposuction and to determine whether liposuction offers advantages over conventional surgical procedures with respect to patient satisfaction, complications, durability, and cosmesis.

While there are some published articles concerning the use of liposuction as the sole procedure for breast reduction, none compare the outcomes of liposuction alone to standard excisional reduction mammaplasty.[2-10] Examples of these articles are detailed below:

Moskovitz (2007) conducted a study of liposuction alone for treatment of macromastia in twenty-four African-American women due to their high risk for complex scar formation following standard excision mammaplasty.[8] The mean aspirate was 1075 cc of fat per breast; however, the before and after liposuction pictures indicate that the participants continued to support large breasts. Outcome measures included the SF-36, EuroQol, Multidimensional Body-Self Relations Questionnaire, McGill Pain Questionnaire and Breast-Related Symptoms Questionnaire. Statistical analysis demonstrated a significant improvement in breast-related symptoms and pain. This was a relatively small, non-randomized trial and patients were not blinded to the intervention. Conclusions concerning the effect of liposuction alone on breast-related symptoms in patients with macromastia cannot be made.

Jakubietz (2011) reported the indications and limitations of this procedure compared to conventional surgical excision.[9] Advantages included selective removal of fat, ease of procedure, and the advantages of less invasive procedures such as faster recovery time and reduced scarring. One disadvantage of liposuction alone included the inability to correct shape and ptosis, making aesthetic results optimal only for young patients. In addition, there are concerns about the extent to which subsequent breast imaging may be impaired, and the possible spread of cancer cells. The authors recommended caution when considering use of this technique.

In summary, high quality evidence on the use of liposuction for reduction mammaplasty has not been identified; comparative trials of sufficient size and duration are needed before any conclusions can be made about the use of this technique for breast reduction.

PRACTICE GUIDELINE SUMMARY

AMERICAN SOCIETY OF PLASTIC SURGEONS

In 2011, the American Society of Plastic Surgeons (ASPS) released an evidence-based clinical practice guideline on the use of reduction mammaplasty.[11] Several clinical questions were addressed, including whether women who did not meet standard health insurance criteria for volume of breast resection experience postoperative relief. On the basis of a single study which compared satisfaction outcomes of women who met standard insurance criteria with women who did not meet such criteria, the society concluded that, “resection volume is not correlated to the degree of postoperative symptom relief.” The society recommended extending the option of reduction mammaplasty to this category of patient. However, among women not meeting standard criteria for resection volume, no comparisons were made between surgical and standard conservative treatment, limiting interpretation of the above findings. Additionally, these recommendations did not specifically address the safety and effectiveness of reduction mammaplasty by liposuction.

SUMMARY

Female breast hypertrophy, or macromastia, is the development of abnormally large breasts in the female, which can cause medical problems. There is enough research to show that reduction mammaplasty can improve health outcomes for certain patients with this condition. Therefore, reduction mammaplasty may be considered medically necessary when policy criteria are met. Reduction mammaplasty as treatment for macromastia is considered not medically necessary when policy criteria are not met.

There is not enough research to show that liposuction mammaplasty can improve health outcomes more than traditional mammaplasty techniques. Therefore, reduction mammaplasty by liposuction alone is considered investigational.

Gynecomastia refers to the benign enlargement of the male breast, mainly due to excessive growth of glandular tissue. Reduction mammaplasty (partial removal) for the treatment of gynecomastia is considered not medically necessary as the current standard of care is for the removal of most or all glandular tissue.

Vagus Nerve Stimulation

Effective: January 1, 2024

Next Review: April 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Vagus nerve stimulation (VNS) involves implantation of an infraclavicular pulse generator that sends weak electric impulses to the left vagus nerve within the carotid sheath in the neck. Transcutaneous (nonimplantable) vagus nerve stimulation has also been proposed as a treatment of a number of conditions.

MEDICAL POLICY CRITERIA

Note: This policy does not apply to vagus nerve **blocking** therapy. See Cross References.

I. Implantable vagus nerve stimulation (VNS) may be considered **medically necessary** as a treatment of medically refractory seizures. Patients must have tried and been unresponsive to or intolerant of at least two antiepileptic drugs.

II. Revision(s) to an existing stimulator may be considered **medically necessary** after the device has been placed.

III. The replacement of all or part of an existing stimulator and/or generator is considered **medically necessary** when the existing stimulator and/or generator is malfunctioning, cannot be repaired, and is no longer under warranty.

IV. Replacement of all or part of an existing stimulator and/or generator is considered **not medically necessary** when Criterion III. is not met.

V. Implantable VNS is considered **investigational** when Criterion I. is not met and for all other indications, including but not limited to essential tremors.

VI. Transcutaneous and non-implantable vagus nerve stimulation devices are considered **investigational** for all indications.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

The information below **must** be submitted for review to determine whether policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- Current Symptomology
- Antiepileptic medications given and response

CROSS REFERENCES

1. Gastric Electrical Stimulation; Surgery, Policy No. 111
2. Responsive Neurostimulation, Surgery, Policy No. 216

BACKGROUND

An implanted VNS device delivers mild electronic impulses via two electrodes connected to the generator and wrapped around the vagus nerve. The stimulator may be programmed in advance or may be activated on demand by placing a magnet against the generator implantation site.

While the mechanisms for the therapeutic effects of VNS are not fully understood, the basic premise of VNS in the treatment of various conditions is that vagal visceral afferents have a diffuse central nervous system projection, and activation of these pathways has a widespread effect on neuronal excitability. An electrical stimulus is applied to axons of the vagus nerve, which have their cell bodies in the nodose and junctional ganglia and synapse on the nucleus of the solitary tract in the brainstem. From the solitary tract nucleus, vagal afferent pathways project to multiple areas of the brain. VNS may also stimulate vagal efferent pathways that innervate the heart, vocal cords, and other laryngeal and pharyngeal muscles, and provide parasympathetic innervation to the gastrointestinal tract.

Other types of implantable vagus nerve stimulators that are placed in contact with the trunks of the vagus nerve at the gastroesophageal junction are not addressed in this evidence review.

REGULATORY STATUS

Implantable VNS Devices

Several VNS therapy systems by Cyberonics Inc. have pre-market approval (PMA) from the U.S. Food and Drug Administration (FDA) for treatment of refractory partial-onset seizures and chronic or recurrent depression, when certain criteria are met. For example, in 1997, the

NeuroCybernetic Prosthesis (NCP®) system was approved for use in conjunction with drugs or surgery “as an adjunctive treatment of adults and adolescents over 12 years of age with medically refractory partial onset seizures.” The VNS Therapy™ System was approved in 2005 “for the adjunctive long-term treatment of chronic or recurrent depression for patients 18 years of age or older who are experiencing a major depressive episode and have not had an adequate response to four or more adequate antidepressant treatments.” FDA product code: LYJ

Non-implantable VNS Devices

Cerbomed has developed a transcutaneous VNS (t-VNS®) system, NEMOS®, that uses a combined stimulation unit and ear electrode to stimulate the auricular branch of the vagus nerve, which supplies the skin over the concha of the ear. Patients self-administer electric stimulation for several hours a day; no surgical procedure is required. The device has not been FDA approved for use in the US.

electroCore, LLC has developed a non-invasive VNS (gammaCore®) released for use by the FDA in April of 2017. The device is indicated for acute treatment of pain associated with episodic cluster and migraine headache in adults using noninvasive VNS on the side of the neck. Product code: PKR

EVIDENCE SUMMARY

VAGUS NERVE STIMULATORS

In order to assess the safety and effectiveness of vagus nerve stimulation (VNS), particularly for indications in which the primary outcomes are subjective (e.g., pain reduction, improved mood, improved functioning), well-designed, randomized controlled trials (RCTs) are necessary. Such trials include double-blinding, appropriate randomization, an appropriate control group (i.e., sham VNS or standard medical treatment), large study populations, adequate follow-up time, and adverse events reporting.

MEDICALLY REFRACTORY SEIZURES

The criteria for VNS for seizures are based on a 1998 BlueCross BlueShield Association (BCBSA) Technology Evaluation Center (TEC) assessment[1], a 2015 Cochrane review[2] which included the five published double-blind randomized controlled trials (RCTs)[3-5], and numerous case series, retrospective reviews, and other non-randomized studies on adult[6-11], pediatric,[12-19] or mixed[20-25] patient populations. More recently, a 2020 Washington Health Care Authority Health Technology Assessment prepared by the Oregon Health and Science University Center for Evidence-based Policy was published on vagal nerve stimulation for the treatment of epilepsy and depression. All three reviews concluded that VNS reduced seizure frequency in patients with drug resistant partial-onset seizures.

The RCTs were large, well-designed multicenter trials that reported an approximate 25% reduction in partial-onset seizure frequency following three months of VNS. Adverse effects were mild and consisted primarily of hoarseness or voice change during “on” periods of stimulation. The remaining literature is limited to numerous non-randomized trials. Although evidence from non-randomized studies are generally considered unreliable for assessing the safety and effectiveness of VNS, the findings from these numerous studies have consistently shown significantly reduced seizure activity in patients with drug-resistant epilepsy. In addition,

clinical practice guidelines from the American Academy of Neurology stated that "…sufficient evidence exists to rank VNS for epilepsy as effective and safe…"[26] Thus, despite the lack of RCTs in the published clinical evidence, VNS has become a recognized standard of care for treatment in selected patients with medically refractory seizures.

REFRACTORY DEPRESSION

Technology Assessments

The 2020 Washington Health Care Authority Health Technology Assessment discussed above in relation to epilepsy also evaluated the effectiveness of VNS in the treatment of refractory depression.[27] Five studies met inclusion criteria, two of which are RCTs. The RCTs were rated to be at moderate risk of bias, one of the nonrandomized studies was at moderate risk of bias, and the two remaining nonrandomized studies had a high risk of bias. Comparators were low-stimulation VNS, sham VNS, and treatment as usual. Two of the RCTs and one of the nonrandomized studies reported on depression severity. No statistically significant differences were reported in the RCTs. In the nonrandomized study, the reported difference in reduction in depressive symptoms was significantly significant, with a greater reduction in the in the VNS plus treatment as usual group. One RCT each reported that high-stimulation VNS had higher rates of response than low-stimulation VNS and VNS and sham VNS had similar rates of response, and a nonrandomized study reported that VNS with TAU may be associated with higher rates of response than TAU alone. Across studies, no differences were reported in rates of suicide, except for one nonrandomized study that reported that VNS may be associated with higher rates of attempted suicide or self-inflicted injury (very-low-quality of evidence). Harms that were noted to be higher in VNS than sham VNS were voice alteration or hoarseness and cough.

A 2006 BCBSA TEC Assessment[28], evaluated the effectiveness of VNS in the treatment of refractory depression compared with continued medical management. The evidence consisted of one case series, one observational study, and one randomized controlled trial. The assessment found that "overall, the evidence supporting efficacy of VNS is not strong."

The randomized controlled trial (RCT) of 221 patients that compared VNS with a sham control (implanted but inactivated VNS) did not show a statistically significant difference between VNS and continued medical therapy in relieving depression symptoms.[29-31] The trial was short and possibly underpowered to detect a smaller amount of VNS benefit. In addition, the adequacy of blinding was questionable. The observational study included a subset of 205 VNS treated patients from the RCT described above who were followed long-term. A separately recruited control group of 124 patients received ongoing treatment for depression.[29, 32] Although the study findings favored the VNS therapy group, this evidence is considered unreliable due to significant methodological limitations including but not limited to the following: 1) Non-randomized allocation of treatment does not control for possible between-group differences in individual patient characteristics; thus, it cannot be ruled out that these differences, rather than the treatments received, were responsible for the observed outcomes; 2) The lack of a sham study group does not control for the expected placebo effects; 3) The inadequate, non-concurrent comparison group does not permit conclusions on the efficacy of VNS compared with placebo or other treatment options, 4) The differences in sites of care between VNS treated patients and controls may introduce response bias. (Analysis performed on subsets of patients cared for in the same sites, and censoring observations after treatment changes, generally showed diminished differences in apparent treatment effectiveness.); and 5)

Differences in concomitant therapy changes cannot be ruled out as an explanation of the observed outcomes.

The case series (Study D-01) was a feasibility study of 60 patients receiving VNS; improvement was reported in depression scores.[33] It is uncertain whether loss to follow-up was addressed adequately in the analysis. In addition, the case series is limited by the lack of an appropriate comparison group.

Systematic Reviews

Bottomley (2020) reported results of a systematic review and meta-analysis of two RCTs (Rush [2005] and Aaronson [2013]), 16 single-arm studies, and four nonrandomized comparative studies of VNS for treatment-resistant depression.[34] The meta-analysis calculated overall pooled effect estimates for VNS and treatment-as-usual groups, respectively, but did not perform quantitative analysis of comparative treatment effects. There was statistically significant heterogeneity. Thus, this meta-analysis provides insufficient evidence to permit comparisons between VNS and the control groups.

In a meta-analysis that included 14 studies, Martin (2012) reported that among the uncontrolled studies in their analysis, 31.8% of subjects responded to VNS treatment.[35] However, results from a meta-regression to predict each study's effect size suggested that 84% of the observed variation across studies was explained by baseline depression severity ($p<0.0001$). The authors concluded that current data was insufficient to determine whether VNS is an effective treatment for depression and noted that positive results from uncontrolled studies may be due to placebo effect.

A 2008 systematic review and meta-analysis for VNS of treatment-resistant depression identified no new RCTs since the pivotal RCT described above, which the authors determined to be inconclusive.[36] As noted above, RCTs are considered the appropriate design for studying VNS for any indication. However, this review also included 17 nonrandomized, open studies which found VNS to be associated with a reduction in depressive symptoms. The authors concluded that, while open studies have reported promising results, further clinical trials are needed to study the mechanism of action and cost-effectiveness, and to confirm the efficacy of VNS in treatment-resistant depression.

Randomized Controlled Trials

No randomized controlled trials published after the search dates of the Washington Health Care Authority Health Technology Assessment were identified.

Nonrandomized Studies

Numerous non-randomized studies evaluated the effectiveness of VNS for the treatment of refractory depression.[33, 36-42] It is not possible to reach reliable conclusions from these studies as they fail to control for the biases discussed above.

TREATMENT OF CHRONIC HEART FAILURE

Systematic Reviews

Sant'Anna (2021) conducted a systematic review and meta-analysis on clinical trials comparing VNS with medical therapy for the management of chronic heart failure with reduced

ejection fraction.[43] Four RCTs and three prospective studies met inclusion criteria (n=1,263). Median follow-up was six months (range: 6 to 16 months). Only data from the RCTs were included in the meta-analysis. The certainty of the evidence based on GRADE characteristics was reported as high for all outcomes. The meta-analysis found significant improvements in New York Heart Association functional class, quality of life, six-minute walk test, and N-terminal-pro brain natriuretic peptide levels in patients treated with VNS compared to sham (Table 1). These studies are limited by a lack of long-term follow-up.

Table 1. Summary of systematic reviews.

Study	Improvement in NYHA functional class	Quality of Life	6-minute walk-test	NT-proBNP levels	Mortality
Sant'Anna (2021)[43]					
Total N	969 (4 RCTs)	450 (3 RCTs)	728 (3 RCTs)	445 (3 RCTs)	1206 (4 RCTs)
Pooled effect (95% CI)	OR, 2.72; (2.07 to 3.57); p<0.0001	MD, -14.18 (-18.09 to -10.28)	MD, 55.46 meters (39.11 to 71.81)	MD, -144.25 (-238.31 to -50.18)	OR, 1.24 (0.82 to 1.89)
I2 (p)	37% (p<0.0001)	49% (p<.0001)	0% (p<0.0001)	65% (p=0.003)	0% (p=0.43)

Randomized Controlled Trials

No RCTs have been published since the search dates of the above SR.

Nonrandomized Studies

In the ANTHEM-HF study (2014), 60 patients with heart failure with reduced ejection fraction were implanted with VNS, randomly assigned to right- or left-sided implantation (n=29 and 31, respectively), and followed for six months.[44] Overall, from baseline to six month follow-up, LV ejection fraction improved by 4.5% (95% confidence interval (CI) 2.4 to 6.6), left ventricular end systolic volume (LVESV) improved by -4.1 mL (95% CI -9.0 to 0.8), LVESD improved by -1.7 mm (95% CI -2.8 to -0.7), heart rate variability improved by 17 ms (95% Ci 6.5 to 28), and six-minute walk distance improved by 56 m (95% CI 37 to 75). Given there was no sham comparator group, it is unclear if the observed improvements may be attributed to VNS or some other confounding factor. A follow-up analysis to ANTHEM-HF by Nearing (2021) evaluated outcomes of VNS at 12, 24, and 36 months.[45] They found that LV ejection fraction improved by 18.7% (p=0.008), 19.3% (p=0.04), and 34.4% (p=0.009) at 12, 24, and 36 months, respectively, with high-intensity VNS. Individuals with low-intensity VNS only had significant improvement in LV ejection fraction at 24 months (12.3%; p=0.04). Although this data is promising, a lack of a no-VNS comparator group precludes drawing conclusions based on findings from the uncontrolled studies.

Several small case series describe VNS treatment outcomes in patients with heart failure; however, for the reasons noted above, evidence from non-randomized studies is considered unreliable in the study of VNS as a treatment for any indication.[46, 47]

TREATMENT OF UPPER-LIMB IMPAIRMENT DUE TO STROKE

Systematic Reviews

Gao (2023) examined VNS+Rehab for improving motor function, mental health and activities of daily living (ADL) postintervention and at the end of follow-up in patients with a stroke.[48]. Seven RCTs involving 263 (analyzed) participants was included. The effect size of VNS+Rehab over Rehab for motor function was medium postintervention (g=0.432; 95% CI 0.186 to 0.678) and large at the end of follow-up (g=0.840; 95% CI 0.288 to 1.392). No difference was found in the effect of VNS+Rehab over traditional rehabilitation for ADL, mental health or safety outcomes. The results suggest VNS+Rehab showed better motor function outcomes in patients after stroke, while no better than Rehab on mental health or ADL.

Ramos-Castaneda (2022) published a systematic review evaluating VNS on upper limb motor recovery after stroke.[49] Three RCTs by Dawson and Kimberley, which are summarized in the section below, were pooled for the analysis evaluating the role of implanted VNS. Results demonstrated that implanted VNS improved upper limb motor function based on Fugl-Meyer Assessment-Upper Extremity (FMA-UE) score when compared to control (mean difference=2.78; 95% CI, 1.38 to 4.18).

Zhao (2022) published a systematic review and meta-analysis of RCTs evaluating vagus nerve stimulation in conjunction with rehabilitation therapies for restoring upper extremity function following stroke.[50] A total of five RCTs (n=178) met inclusion criteria. A significant effect of VNS compared to the control was identified for the primary outcome of Fugl-Meyer Assessment for Upper Extremity (FMA-UE, MD=3.59; 95% CI 2.55 to 4.63; p<0.01). No significant difference between groups in adverse events associated with the device was identified (RR=1.10; 95% CI 0.92 to 1.32; p=0.29).

Randomized Controlled Trials

Vagus Nerve Stimulation (VNS) paired with rehabilitation delivered by the Vivistim® Paired VNS™ System was approved by the FDA in 2021 to improve motor deficits in chronic ischemic stroke survivors with moderate to severe arm and hand impairment. Liu (2022) described the Vivistim implantation procedure, perioperative management, and complications for chronic stroke survivors enrolled in the pivotal trial.[51] The pivotal, multisite, randomized, triple-blind, sham-controlled trial (VNS-REHAB) enrolled 108 participants. All participants were implanted with the VNS device in an outpatient procedure. Thrombolytic agents were temporarily discontinued during the perioperative period. Participants were discharged within 48 hrs and started rehabilitation therapy approximately 10 days after the procedure. The rate of surgery-related adverse events was lower than previously reported for VNS implantation for epilepsy and depression. One participant had vocal cord paresis that eventually resolved. There were no serious adverse events related to device stimulation. Over 90% of participants were taking antiplatelet drugs (APD) or anticoagulants and no adverse events or serious adverse events were reported as a result of withholding these medications during the perioperative period. This study is the largest, randomized, controlled trial in which a VNS device was implanted in chronic stroke survivors.

Dawson (2021) conducted a randomized controlled trial of VNS in patients with upper limb dysfunction after ischemic stroke.[52] Patients with upper-limb dysfunction after ischemic stroke (n=106) were randomly assigned 1:1 to either VNS plus rehabilitation or rehabilitation with sham stimulation. The Fugl-Meyer Assessment-Upper Extremity score increased by 5 points in the VNS group and 2.4 points in the control group (between-group difference, 2.6; 95% CI 1.0 to 4.2; p=0.0014). Ninety days after in-clinic therapy, a clinically meaningful response was achieved in 23 (47%) of 53 patients in the VNS group versus 13 (24%) of 55 patients in the

control group (between-group difference, 24%; 95% CI, 6 to 41; p=0.0098). There was one adverse event of vocal cord paresis related to surgery in the control group.

A similar RCT with a smaller patient population was conducted by the same study group in 2016.[53] Twenty-one subjects were randomized to VNS plus rehabilitation or rehabilitation alone. The mean change in the outcome as assessed by a functional assessment score was +8.7 in the VNS group and +3.0 in the control group (p=0.064). Six patients in the VNS group achieved a clinically meaningful response and four in the control group (p=0.17).

Kimberley (2018) reported results of a randomized, pilot sham-controlled RCT in 17 patients (VNS n=8 and sham VNS, n=9) with arm weakness after ischemic stroke.[54] The mean Fugl-Meyer assessment–upper extremity scores increased by 7.6 with VNS versus 5.3 points with sham at day one (Difference=2.3 points; 95% CI, −1.8 to 6.4; p=0.20) and 9.5 points with VNS versus 3.8 with sham at day 90 (Difference=5.7 points; 95% CI, −1.4 to 11.5; p=0.055). A Fugl-Meyer assessment–upper extremity score change of six points or greater was defined as response; the response rate at day 90 was 88% with VNS versus 33% with sham (p<0.05). There were three serious adverse events related to surgery: wound infection, shortness of breath and dysphagia, and hoarseness because of vocal cord palsy.

Longer-term follow-up studies are needed to evaluate long-term efficacy and safety.

TREATMENT OF TINNITUS

Systematic Review

Stegeman (2021) performed a systematic review of the treatment of tinnitus with vagus nerve stimulation.[55] A total of nine studies were identified, of which five examined transcutaneous VNS and four examined implanted VNS treatment. Two were RCTs, five were cohort studies, and two were case series. Six of the studies used a combined VNS/sound therapy treatment. All included studies had serious risk of bias. Due to heterogeneity in methodology, inclusion criteria, and assessed outcomes, no meta-analysis was completed. Most studies reported a small decrease in tinnitus distress or tinnitus symptom severity.

OTHER INDICATIONS

Nonrandomized Studies

Small case series (n≤40 patients) and one non-randomized comparison study described experiences with VNS in patients with bulimia, anxiety, Alzheimer's disease[56, 57], essential tremor[58], and eating disorders including obesity and food cravings[59]. The utility of VNS added to behavioral management of autism and autism spectrum disorders has been posited but there are no RCTs. For the reasons noted above, evidence from non-randomized studies is considered unreliable in the study of VNS as a treatment for any indication.

NONINVASIVE (TRANSCUTANEOUS) VAGUS NERVE STIMULATORS

Only RCTs and systematic reviews of RCTs will be discussed, as case series are inadequate to determine the effect of the technology.

REFRACTORY EPILEPSY

Wu (2020) reported results of a systematic review and meta-analysis of three RCTs (n=280, range n=60 to 144) of transcutaneous VNS for the treatment of drug-resistant epilepsy.[60] All treatment groups underwent a cymba conchae stimulus at a frequency of 20 to 30-Hz. The control groups received various kinds of sham stimulation at a frequency of 1 HZ, the same frequency stimulation as treatment but at the non-auricular vagus nerve area or no stimulation. Meta-analysis of all three included RCTs found that seizure frequency was significantly reduced with transcutaneous VNS (Mean Difference [MD]=-3.29; 95% CI -6.31 to -0.27). However, meta-analysis of the two RCTs that reported responder rates (undefined) did not find a significant difference between the transcutaneous VNS and control groups (n=238; Odds Ratio [OR]=1.47; 95% CI 0.54 to 4.02]. All three RCTs assessed quality of life using the Quality of Life in Epilepsy Inventory (QOLIE)-31 scale, but found no significant differences between treatment and control groups. Important limitations of the RCTs include imprecision, risk of confounding due to potentially imbalanced use of important nonprotocol interventions (i.e., concomitant antiepileptic drugs), and unacceptable flaws in outcome assessment (i.e., unspecified definition of response, between-group differences in measurement timing, lack of electroencephalography data).

PSYCHIATRIC DISORDERS

Li (2022) published results of an RCT comparing transcutaneous auricular VNS with citalopram for the treatment of major depressive disorder.[61] A total of 107 patients from the outpatient departments of three hospitals in China were randomly assigned to receive t-VNS or citalopram. Treatment was eight weeks of t-VNS, twice per day, plus a four-week follow-up or 12 weeks of citalopram. For the primary outcome of the 17-item Hamilton Depression Rating Scale (HAM-D17) measured every two weeks by trained interviewers blinded to the treatment assignment, although both groups improved significantly, there was no significant group-by-time interaction (95% CI -0.07 to 0.15, p=0.79). There was a significant difference between groups for remission rate at four and six weeks (p=0.007 and p=0.01, respectively), but not at any other time point.

Hein (2013) reported results of two pilot RCTs of a t-VNS device for the treatment of depression, one which included 22 subjects and the other with 15 subjects.[62] In the first study, 11 subjects each were randomized to active or sham t-VNS. At two weeks follow-up, Beck Depression Inventory (BDI) self-rating scores in the active-stimulation group decreased from 27.0 to 14.0 points (p<0.001), while the sham-stimulated patients did not show significant reductions in the BDI (31.0 to 25.8 points). In the second study, seven patients were randomized to active t-VNS and eight patients were randomized to sham t-VNS. In this study, BDI self-rating scores in the active stimulation group decreased from 29.4 to 17.4 points (p<0.05) after two weeks, while the sham-stimulated patients did not show significant change in BDI (28.6 to 25.4 points). The authors do not report direct comparisons in BDI change between the sham- and active-stimulation groups.

Hasan (2015) reported a randomized trial of t-VNS for the treatment of schizophrenia.[63] Twenty patients were assigned either to active t-VNS or to sham treatment for 12 weeks. There was no statistically significant difference in the improvement of schizophrenia status during the observation period.

Shiozawa (2014) conducted a systematic review of studies evaluating the evidence related to transcutaneous stimulation of the trigeminal or vagus nerve for psychiatric disorders.[64] They found four studies that addressed t-VNS for psychiatric disorders and included a total of 84

subjects. Three of the four studies evaluated physiologic parameters in healthy patients and one evaluated pharmaco-resistant epilepsy (Stefan, previously described[65]). The authors also include a fifth study in a data table, although not in their text or reference list (Hein, previously described[62]) Overall, the studies included were limited by small size and poor generalizability.

IMPAIRED GLUCOSE TOLERANCE

Huang (2014) reported results of a pilot RCT of a t-VNS device that provides stimulation to the auricle for the treatment of impaired glucose tolerance.[66] The study included 70 patients with impaired glucose tolerance who were randomized to active or sham t-VNS, along with 30 controls who received no t-VNS treatment. After 12 weeks of treatment, patients who received active t-VNS were reported to have significantly lower two-hour glucose tolerance test results than those who received sham t-VNS (7.5 mmol/L vs 8 mmol/L; p=0.004).

TREATMENT OF UPPER-LIMB IMPAIRMENT DUE TO STROKE

Wu (2020) reported results of a pilot randomized sham-controlled trial of 21 patients (nVNS=10 and sham nVNS, n=11) treated with nVNS for upper limb motor function impairment following subacute ischemic stroke.[67] The mean Fugl-Meyer assessment–upper extremity scores increased by 6.90 with nVNS versus 3.18 points with sham after 15 days of intervention (Difference= -3.72 points; 95% CI −5.12 to -2.32; p≤0.001). The improvement in the mean Fugl-Meyer assessment–upper extremity scores remained significantly higher at both the four-week (+7.70 vs. +3.36; p≤0.001) and the 12-week (+7.40 vs. +4.18; p=0.038) follow-ups. There was only one adverse event noted, which was that one patient in the nVNS group developed skin redness at an electrode point of contact.

PAIN

Natelson (2021) reported results of a small RCT with limited follow-up of nVNS for the treatment of pain and migraine in Gulf War Veterans with Gulf War Illness.[68] During the first 10 weeks, the 27 participants were randomized to receive active or sham nVNS, followed by 10 weeks of open-label trial. No significant differences between active and sham nVNS were identified.

Kutlu (2020) reported results of an RCT that compared a home-based exercise treatment program with or without auricular VNS in 60 female patients in Turkey with fibromyalgia syndrome (auricular VNS n=30 and no auricular VNS n=30).[69] The VNS was delivered at Beykoz Public Hospital's Department of Physical Therapy and Rehabilitation in 30-minute sessions on weekdays for four weeks. The home-based exercise program consisted of strengthening, stretching, isometric, and posture exercises that targeted the body and upper and lower extremities. When added to exercise, auricular VNS did not significantly improve mean scores on the Fibromyalgia Impact Questionnaire (37.27 vs. 41.93; p=0.378) or on any 36-Item Short Form Health Survey subscales (e.g., Physical Function: 80.00 vs. 85.00; p=.167). An important limitation of this RCT is the lack of a sham control group.

CLUSTER HEADACHE

Prevention of Cluster Headaches

Gaul (2016, 2017) reported the results of the PREVA study - a randomized open-label study of nVNS as a prophylactic therapy for chronic cluster headache (CH) in patients diagnosed at least one year prior to enrollment.[70, 71] The study was funded by the device manufacturer. In a

two-week baseline period, all 97 participants received only their individualized standard of care (SoC). Patients were then randomized to a four-week period of SoC with nVNS (n=48) or SoC alone, i.e., control (n=49). Four participants from the SoC with nVNS chose to withdraw; one control participant was removed from the study for failing to meet enrollment criteria. In an optional four-week period following, all participants received SoC with nVNS (n=92); 70 completed the optional period (11 controls discontinued from each group).

Efficacy was evaluated by the mean number of CH attacks per week, defined as the number of attacks during the last two weeks of the randomized phase minus the number of attacks during baseline divided by two. Safety and tolerability were assessed in those who were assigned treatment; and the intent-to-treat (ITT) population was those who had more than one efficacy recording in their home diary after randomization.

In the ITT population (n=45 SoC plus nVNS, n=48 in control) authors reported a mean therapeutic gain of 3.9 fewer CH attacks per week (95% CI 0.5 to 7.2; p=0.02). However, the proportion of participants receiving SoC plus nVNS in the ITT population from the randomized phase with more than 50% response to treatment was 40.0, and in controls who went on to receive treatment in the extension phase, the proportion was 16.7.

During the randomization phase, 38% participants in the SoC plus nVNS group experienced adverse events (AEs), and 27% of controls experienced AEs. In the extension phase, 25% and 24% experienced AEs, respectively. Overall, the most common AEs for any treatment were CH attacks, headache, nasopharyngitis, dizziness, oropharyngeal pain, and neck pain. No serious AEs were considered related to the nVNS device.

The study is limited by a sham placebo control group, which may result in placebo response in the nVNS group. Additionally, the double-blind, study treatment period was less than one month, which limits inference about continued response.

Section Summary

Transcutaneous (or noninvasive) VNS has been investigated for preventing cluster headaches in one RCT. The PREVA study of prevention of cluster headache in patients with chronic cluster headache demonstrated a statistically significant increase in the proportion of patients with a 50% or greater reduction in the mean number of headache attacks and statistically significant reduction in the frequency of attacks for nVNS compared to standard of care with a treatment period of four weeks. There was also an improvement in quality of life as measured by the EQ-5D. However, the study was not blinded.

Treatment of Cluster Headaches

In 2016, Silberstein reported results from the manufacturer funded ACT1 study – a randomized, double-blind, sham-controlled study of nVNS as a treatment for cluster headache (CH).[72] One hundred fifty subjects were randomized to receive sham control or nVNS treatment for less than or equal to one month; completers could enter a three-month nVNS open-label phase. Limitations of this study include that the enrolled population was not reflective of relevant diversity (3.3% Asian, 8% Black, 87.3% white, 1.4% race/ethnicity not reported), a lack of quality of life or functional outcomes, and short follow-up time. In addition, a considerable proportion of patients correctly guessed their treatment allocation after their first treatment, though blinding was found to have improved by the end of the one-month period. The primary end point was response rate, defined as the proportion of subjects who achieved

pain relief (pain intensity of 0 or 1) at 15 minutes after treatment initiation for the first CH attack without rescue medication use through 60 minutes. Secondary end points included the sustained response rate (15 to 60 minutes). Subanalyses of episodic cluster headache (eCH) and chronic cluster headache (cCH) cohorts were prespecified.

During the randomized phase of one month, 14 participants discontinued participation from the treatment group, and 8 in the control group discontinued. In the three-month open label period, 17 and 11 discontinued from the treatment and control groups, respectively. Application site reactions and nervous system AEs occurred more frequently with sham treatment than with nVNS in the double-blind phase. Adverse device effects (ADEs) were reported by 35/150 (nVNS, 11; sham, 24) subjects in the double-blind phase and 18/128 subjects in the open-label phase.

Intent-to-treat analysis included 133 subjects: 60 nVNS-treated (eCH, n=38; cCH, n=22) and 73 sham-treated (eCH, n=47; cCH, n=26). Authors reported a response in 26.7% of nVNS-treated subjects and 15.1% of sham-treated subjects. Response rates were significantly higher with nVNS than with sham for the eCH cohort (nVNS, 34.2%; sham,10.6%; *p*=0.008) but not the cCH cohort (nVNS, 13.6%; sham, 23.1%; *p*=0.48). Sustained response rates were significantly higher with nVNS for the eCH cohort and total population.

In 2018, Goadsby reported on the results of randomized, double-blind, sham-controlled study (ACT2) for the treatment of acute cluster headache attacks.[73] Ninety-two patients with cluster headaches were randomized to nVNS or sham treatment. Patients were further identified as having episodic cluster headaches or chronic cluster headaches and randomized at approximately 1:1 to the nVNS and sham treatment groups. The primary efficacy end point was the ability to achieve pain-free status within 15 minutes of initiation of treatment without use of rescue treatment. There was no difference between nVNS-treated and sham-treated patients in the overall cluster headache study population. Subgroup analysis of the chronic cluster headache population showed no differences between nVNS-treated and sham-treated patients. For the episodic cluster headaches subgroup, nVNS demonstrated a 48% response rate compared with 6% response rate for sham-treated (p<0.01). The interaction p-value for the subgroup analysis was statistically significant (p=0.04).

de Coo (2019) combined the data from ACT1 and ACT2 meta-analytically for the two primary outcomes reported in the two studies.[74] The authors reported an interaction between treatment group and cluster headache subtype in the pooled analysis (p<0.05 for both outcomes).

Section Summary

The ACT1 and ACT2 RCTs compared nVNS to sham for treatment of acute cluster headache in patients including both chronic and episodic cluster headache. The RCTs reported slightly different outcome measures so that consistencies in magnitude of treatment effects cannot be assessed. In ACT1, there was no statistically significant difference in the overall population in the proportion of patients with pain score of 0 or 1 at 15 minutes into the first attack (27% vs. 15%, p=0.10) and no difference in the proportion of patients who were pain-free at 15 minutes in 50% or more of the attacks (12% vs. 7%, p=0.33). However, in the episodic cluster headache subgroup (n=85) both outcomes were statistically significant favoring nVNS although the interaction p-value was not reported. In ACT2 the proportion of attacks with a pain intensity score of 0 or 1 at 30 minutes was statistically significant overall (43% vs. 28%, p=0.05). The proportion of attacks that were pain-free at 15 minutes was similar in the two treatment groups

overall (14% vs. 12%) but a significant interaction was reported (p=0.04). There was a statistically significantly higher proportion of attacks in the episodic subgroup that were pain-free at 15 minutes in the nVNS group compared to sham (48% vs. 6%, p<0.01). Quality of life and functional outcomes have not been reported. Treatment periods ranged from only two weeks to one month with extended open-label follow-up of up to three months. Studies designed to test the effect of nVNS in the episodic subgroup with longer treatment and follow-up and including quality of life and functional outcomes are needed.

There are few adverse events of nVNS and they are mild and transient.

MIGRAINE

Prevention of Migraine Headaches

Diener (2019) published results of the PREMIUM trial, a phase 3, multicenter, sham-controlled RCT conducted in several European countries. Patients who experienced 5 to 12 migraine days per month were included.[75] The study began with a four-week run-in period during which no treatment was administered; 477 participants entered the run-in. The criteria to remain eligible after run-in were not described in the publication. After run-in, 341 participants were randomized (nVNS, n=169 or sham, n=172) to a 12-week double-blind treatment period followed by a 24-week open-label period of nVNS. Patients administered two 120-second stimulations bilaterally to the neck with gammaCore, three times daily. nVNS was not statistically significantly superior to sham with respect to the outcomes of reduction of at least 50% in migraine days from baseline to the last four weeks (32% vs 25%; p=0.19), reduction in number of migraine days from baseline to the last four weeks (-2.3 vs -1.8; p=0.15), or acute medication days (-1.9 vs -1.4; p=0.11) in the intention-to-treat population. Adverse events were reported in 44% of the nVNS group and 53% of the sham group. The PREMIUM II trial was a multicenter, sham-controlled RCT conducted in several U.S. sites and included patients who experienced 8 to 20 headache days per month with at least 5 of the days being migraine days.[76] The study included a 4-week run-in period during which no treatment was administered (N=336). After the run-in period, 231 patients were randomly assigned to receive nVNS (n = 114) or sham (n = 117) therapy during the double-blind period and were part of the intention to treat (ITT) population (ie, had ≥1 study treatment during the double-blind phase). The COVID-19 pandemic led to an early termination of this trial, therefore, the population was approximately 60% smaller than the statistical target for full power. The modified ITT (mITT) population, which included those who were at least 66% adherent to treatment during the double-blind phase, included 56 patients in the nVNS group and 57 in the sham group. Results showed that in the mITT population, nVNS was not statistically significantly superior to sham with respect to the primary outcome of reduction in the number of migraine days per month during weeks 9 through 12 (mean difference=-0.83 days; p=.2329), nor other outcomes such as mean change in the number of headache days or acute medication days. However, in the mITT population, the percentage of patients with at least a 50% reduction in the number of migraine days was significantly greater in the nVNS group (44.87%) than in the sham group (26.81%; p=.048). Furthermore, nVNS was significantly better than sham at decreasing headache impact, as measured by the Headache Impact Test-6 (HIT-6), and at decreasing migraine-related disability, as measured by the Migraine Disability Assessment Scale (MIDAS).

The EVENT trial (Silberstein, 2016) was a feasibility study of prevention with a sample size of 59.[77] It was not powered to detect differences in efficacy outcomes. About twenty percent of participants discontinued treatment after the first two months. The study was supposed to be

blinded, but the sham did not deliver electrical stimulation, which may have compromised the blinding. For the outcome of response, defined as 50% or more reduction in the number of headache days, 10% of the patients in the nVNS group versus 0% in the sham group were responders; statistically testing was not performed.

Section Summary

Three RCTs have evaluated nVNS for prevention of migraine. The EVENT trial was a feasibility study of prevention of migraine that was not powered to detect differences in efficacy outcomes. It does not demonstrate the efficacy of nVNS for prevention of migraine. The PREMIUM trial was a phase 3, multicenter, sham-controlled RCT including 341 randomized participants with a 12-week double-blind treatment period. The results of PREMIUM demonstrated that nVNS was not statistically significantly superior to sham. With respect to the outcomes of reduction of at least 50% in migraine days from baseline to the last four weeks, reduction in number of migraine days from baseline to the last four weeks or acute medication days. The PREMIUM II trial was a multicenter, sham-controlled RCT including 231 randomized participants with a 12-week double-blind treatment period. Results demonstrated that treatment with nVNS was not statistically significantly superior to sham with respect to the primary outcome of reduction in the number of migraine days per month during weeks 9 through 12, nor other outcomes such as mean change in the number of headache days or acute medication days. However, the percentage of participants with at least a 50% reduction in the number of migraine days was significantly greater in the nVNS group than in the sham group. However, interpretation of these findings is limited as it was based on a mITT population of 49% of randomized patients (n= 113 of original 231 participants) due to COVID-19 pandemic-related early termination.

Treatment of Migraine Headaches

The Prospective, Multi-centre, Randomized, Double-blind, Sham-controlled Study of gammaCore® Non-invasive Vagus Nerve Stimulator (nVNS) for the Acute Treatment of Migraine (PRESTO) trial was a multicenter, double-blind, randomized, sham-controlled trial of acute treatment of migraine with nVNS in 248 patients with episodic migraine with/without aura reported by Tassorelli (2018), Grazzi (2018), and Martelletti (2018).[78-80] The primary efficacy outcome was the proportion of participants who were pain-free without using rescue medication at 120 minutes. There was not a statistically significant difference in the primary outcome (30% vs 20%; p=0.07) although it favored the nVNS group. The nVNS group had a higher proportion of patients with decrease in pain from moderate or severe to mild or no pain at 120 minutes (41% vs 28%; p=0.03) and a higher proportion of patients who were pain-free at 120 for 50% or more of their attacks (32% vs 18%; p=0.02). PRESTO results did not include quality of life or functional outcomes and the double-blind treatment and follow-up period was 4 weeks. In the additional four weeks of acute nVNS in the open-label period, rates of pain-free response after the first treated attack (28%,) and pain relief (43.4%) were similar to the rates in the double-blind period. Given the marginally significant primary outcome, lack of quality of life or functional outcomes and limited follow-up, further RCTs are needed.

Section Summary

One RCT has evaluated nVNS for acute treatment of migraine with nVNS in 248 patients with episodic migraine with/without aura. There was not a statistically significant difference in the primary outcome of the proportion of participants who were pain-free without using rescue medication at 120 minutes (30% vs. 20%; p = 0.07). However, the nVNS group had a higher

proportion of patients with decrease in pain from moderate or severe to mild or no pain at 120 minutes (41% vs. 28%; p=0.03) and a higher proportion of patients who were pain-free at 120 for 50% or more of their attacks (32% vs. 18%; p=0.02). There are few adverse events of nVNS and they are mild and transient. Quality of life and functional outcomes were not reported and the double-blind treatment period was four weeks with an additional four weeks of open-label treatment. Given the marginally significant primary outcome, lack of quality of life or functional outcomes and limited follow-up, further RCTs are needed.

OTHER INDICATIONS

Small studies of transcutaneous VNS have also been reported for gastrointestinal dysfunction in Parkinson's disease[81], systemic lupus erythematosus[82], cortical arousal and alertness[83], and delayed neurocognitive recovery in elderly patients.[84] Larger studies are needed to know how well transcutaneous VNS works in these populations.

ADVERSE EVENTS

The most commonly reported adverse effects of VNS have been mild and consist primarily of hoarseness of voice during "on" periods of stimulation, transient throat pain, and coughing. More serious adverse events reported include, but are not limited to direct delivery of the current to the nerve due to generator malfunction; modified synchronization between cardiac and respiratory activity affecting the oxygen delivery to tissues; heart block with ventricular standstill; bradyarrhythmias and severe asystolia; and changes in respiration during sleep.[1, 29, 36, 85-88]

PRACTICE GUIDELINE SUMMARY

AMERICAN PSYCHIATRIC ASSOCIATION

The American Psychiatric Association (APA) (2010, reaffirmed 2015) has level III* recommendations regarding the use of vagus nerve stimulation (VNS) for patients with major depressive disorder.[89] Strategies to address nonresponse during an acute phase of depression include VNS as an additional option for individuals who have not responded to at least four adequate trials of antidepressant treatment, including ECT (electroconvulsive therapy). Maintenance treatment with VNS is also appropriate for individuals whose symptoms have responded to this treatment modality.

* [III] May be recommended on the basis of individual circumstances (As opposed to level I or II which are recommended with substantial and moderate clinical confidence, respectively.)

AMERICAN ACADEMY OF NEUROLOGY

The American Academy of Neurology (AAN) 2013 consensus statement (reaffirmed in 2016 and 2019) states VNS may be considered for seizures in children, for LGS (Lennox-Gastaut-syndrome)- associated seizures, and for improving mood in adults with epilepsy; and VNS may be considered to have improved efficacy over time.[90] These statements are based on Level C evidence, which is defined as, "possibly effective, ineffective or harmful (or possibly useful/predictive or not useful/predictive) for the given condition in the specified population."

DEPARTMENT OF VETERANS AFFAIRS AND THE DEPARTMENT OF DEFENSE

A 2020 clinical practice guideline from the Department of Veterans Affairs and the Department of Defense (VA/DoD) addressed the primary care management of headache. The guideline included a recommendation with a weak strength of evidence which stated, “We suggest non-invasive vagus nerve stimulation for the acute treatment of episodic cluster headache.”

SUMMARY

Vagus nerve stimulation (VNS) has evolved to be a standard of care as a treatment of medically refractory seizures. Therefore, VNS for medically refractory seizures may be considered medically necessary for patients who have had inadequate response to or are intolerant of at least two antiepileptic drugs.

In certain situations, a stimulator may require revision after it has been placed. In these cases, revision may be medically appropriate to allow for the proper functioning of the device. Therefore, revision(s) to an existing stimulator may be considered medically necessary after the device has been placed.

In certain situations, a stimulator may no longer be able to perform its basic function due to damage or wear. When a stimulator is out of its warranty period and cannot be repaired adequately to meet the patient’s medical needs, replacement of the device may be medically appropriate. Therefore, replacement of all or part of a stimulator may be considered medically necessary when device replacement Criteria are met.

When a stimulator is in its warranty period or can be repaired or adapted adequately to meet the patient’s medical needs, replacement of the device is considered not medically necessary.

There is not enough research to make conclusions about the benefit of VNS as a treatment for conditions other than medically refractory seizures. Therefore, VNS is considered investigational for all indications other than selected patients with refractory seizures.

There is not enough research to know if or how well transcutaneous and non-implantable vagus nerve stimulators (nVNS) work to treat people with any condition, including but not limited to cluster headache. This does not mean that they do not work, but more research is needed to know. No clinical guidelines based on research recommend these stimulators for people with cluster headache or any other condition. Therefore, transcutaneous and non-implantable vagus nerve stimulators are considered investigational as a treatment for all indications.

Medical Policy Manual Surgery, Policy No. 84

Deep Brain Stimulation

Effective: May 1, 2025

Next Review: March 2025
Last Review: March 2024

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Deep brain stimulation (DBS) involves the stereotactic placement of electrodes into the brain (e.g., hypothalamus, thalamus, globus pallidus or subthalamic nucleus [STN]).

MEDICAL POLICY CRITERIA

Note: The use of spinal cord stimulation as a treatment of chronic pain is addressed in a separate policy (see Cross References section below).

I. When a multidisciplinary evaluation has confirmed both the medical intractability of the patient's symptoms and the potential value of deep brain stimulation (DBS), unilateral or bilateral DBS may be considered **medically necessary** when **both** of the following criteria (A. and B.) are met:

   A. One of the following is met:

      1. The request is for stimulation of the thalamus in patients with disabling, medically unresponsive tremor due to essential tremor or Parkinson's disease. Disabling, medically unresponsive tremor defined as tremor causing significant limitation in daily activities AND inadequate symptom

control despite optimal medical management for at least three months before implant.

2. The request is for stimulation of the subthalamic nucleus or globus pallidus in patients with previously levodopa-responsive Parkinson's disease and symptoms such as rigidity, bradykinesia, dystonia or levodopa-induced dyskinesias.

3. The request is for stimulation of the subthalamic nucleus or globus pallidus in patients seven years of age or above with disabling, medically unresponsive primary dystonias including generalized and/or segmental dystonia, hemidystonia and cervical dystonia (torticollis). Disabling, medically unresponsive dystonia defined as dystonia causing significant limitation in daily activities AND inadequate symptom control despite optimal medical management for at least three months before implant.

B. The patient does not have a medical condition that requires repeated MRI, OR if a medical condition requires **repeated MRI,** an **MR-conditional device** is used.

II. Unilateral or bilateral deep brain stimulation revision(s) or replacement(s) may be considered **medically necessary** after the device has been placed.

III. Deep brain stimulation is considered **not medically necessary** for essential tremor, Parkinson's disease, medically unresponsive primary dystonias including generalized and/or segmental dystonia, hemidystonia and cervical dystonia (torticollis) when Criterion I. is not met.

IV. Deep brain stimulation is considered **investigational** for all other conditions (see Policy Guidelines).

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

POLICY GUIDELINES

Deep brain stimulation is considered investigational for indications that do not meet the policy criteria above including but not limited to the following:

- Cerebral Palsy
- Chronic pain (e.g., nociceptive pain; neuropathic pain)
- Cognitive decline/dementia due to Parkinson’s Disease
- Epilepsy/intractable seizures
- Huntington’s disease
- Multiple sclerosis
- Neuropsychiatric applications, including but not limited to the following:
    - Anorexia nervosa
    - Anxiety
    - Bipolar Disorder
    - Depression
    - Obsessive-compulsive disorder
    - Schizophrenia
    - Tourette syndrome
    - Alzheimer’s Disease

- Other movement disorders
- Post-traumatic tremor
- Tardive dyskinesia and tardive dystonia
- Traumatic brain injury (TBI)

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and physical/chart notes
- Multidisciplinary evaluations
- Indication for DBS
- Brain region to be stimulated
- Condition that is anticipated to require repeat MRI, if present.
- Name of DBS device

BACKGROUND

Deep brain stimulation (DBS) involves the stereotactic placement of an electrode into the brain (i.e., hypothalamus, thalamus, globus pallidus or subthalamic nucleus [STN]). The electrode is initially attached to a temporary transcutaneous cable for short-term stimulation to validate treatment effectiveness. Several days later the patient returns to surgery for permanent subcutaneous implantation of the cable and a radiofrequency-coupled or battery-powered programmable stimulator. The electrode is typically implanted unilaterally on the side corresponding to the more severe symptoms. However, the use of bilateral stimulation using two electrode arrays is also used in patients with bilateral, severe symptoms.

After implantation, noninvasive programming of the neurostimulator can be adjusted to the patient's symptoms. This feature may be important for patients with Parkinson's disease, whose disease may progress over time, requiring different neurostimulation parameters. Setting the optimal neurostimulation parameters may involve the balance between optimal symptom control and appearance of side effects of neurostimulation, such as dysarthria, disequilibrium or involuntary movements.

DBS has been investigated for a variety of indications as discussed below:

- Alternative to permanent neuroablative procedures, such as thalamotomy and pallidotomy

  The technique has been most thoroughly investigated as an alternative to thalamotomy for unilateral control of essential tremor, and tremor associated with Parkinson's disease (PD). More recently, there has been research interest in the use of deep brain stimulation of the globus pallidus or STN as a treatment of other Parkinsonian

symptoms such as rigidity, bradykinesia or akinesia. Another common morbidity associated with PD is the occurrence of motor fluctuations, referred to as "on and off" phenomena, related to the maximum effectiveness of drugs (i.e., the "on" state) and the nadir response during drug troughs (i.e., the "off" state). In addition, levodopa, the most commonly used antiparkinson drug, may be associated with disabling drug-induced dyskinesias. Therefore, the optimal pharmacologic treatment of Parkinson's disease may involve a balance between optimal effects on Parkinson's symptoms vs. the appearance of drug induced dyskinesias. The effect of DBS on both Parkinson's symptoms and drug-induced dyskinesias has also been studied.

- Treatment of primary and secondary dystonia

  Dystonia is defined as a neurological movement disorder characterized by involuntary muscle contractions, which force certain parts of the body into abnormal, contorted, and painful movements or postures. In primary dystonia, dystonia is the only symptom and is unassociated with other pathology. Secondary dystonia is a dystonia brought on by an inciting event, such as a stroke, trauma, or drugs. Tardive dystonia is a form of drug-induced secondary dystonia. Dystonia can be classified according to age of onset, bodily distribution of symptoms, and cause. Age of onset can occur during childhood or during adulthood. Dystonia can affect certain portions of the body (focal dystonia and multifocal dystonia) or the entire body (generalized dystonia). Torticollis is an example of a focal dystonia. Treatment options for dystonia include oral or injectable medications (i.e., botulinum toxin) and destructive surgical or neurosurgical interventions (i.e., thalamotomies or pallidotomies) when conservative therapies fail.

- Cluster headaches

  Cluster headaches occur as episodic attacks of severe pain lasting from 30 minutes to several hours. The pain is usually unilateral and localized to the eye, temple, forehead, and side of the face. Autonomic symptoms that occur with cluster headaches include ipsilateral facial sweating, flushing, tearing, and rhinorrhea. Cluster headaches occur primarily in men and have been classified as vascular headaches that have been associated with high blood pressure, smoking, and alcohol use. However, the exact pathogenesis of cluster headaches is uncertain. PET scanning and MRI have shown the hypothalamic region may be important in the pathogenesis of cluster headaches. Alterations in hormonal/serotonergic function may also play a role. Treatment of cluster headaches includes pharmacologic interventions for acute episodes and prophylaxis, sphenopalatine ganglion (SPG) blockade and surgical procedures such as percutaneous SPG radiofrequency rhizotomy and gamma knife radiosurgery of the trigeminal nerve.

- Other Neurologic/Psychiatric Conditions

  The role of DBS in treatment of other treatment-resistant neurologic and psychiatric disorders, particularly Tourette syndrome, epilepsy, obsessive-compulsive disorder (OCD), major depressive disorders, bipolar disorder, anorexia, alcohol addiction, and Alzheimer’s disease is also being investigated. Ablative procedures are irreversible and, though they have been refined, remain controversial treatments for intractable illness. Interest has shifted to neuromodulation through DBS of nodes or targets within neural

circuits involved in these disorders. Currently, a variety of target areas are being studied.

REGULATORY STATUS

The U.S. Food and Drug Administration (FDA) has approved a number of deep brain stimulation systems for the treatment of essential tremor and tremor due to PD that is not adequately controlled by medication and is causing significant disability. The following DBS devices have been FDA-approved to treat essential tremor and PD-associated tremors under the Premarket Approval Application (PMA) process:

- Master Percept, Percept PC, And Activa® Deep Brain Stimulation Therapy Systems, with SenSight™ DBS accessories, Medtronic, Inc.
- Brio Neurostimulation System, Abbott St. Jude Medical Infinity™ Deep Brain Stimulation (DBS) system, Abbott (formerly St. Jude Medical).
- Vercise Deep Brain Stimulation System, including Vercise™ PC, Vercise Gevia™, and Vercise Genus™, Boston Scientific

The FDA has approved DBS systems for other indications. The Medtronic DBS System for Epilepsy (Medtronic, Inc) was FDA-approved through the PMA process as an adjunctive therapy for reducing the frequency of seizures in individuals 18 years of age or older diagnosed with epilepsy characterized by partial-onset seizures, with or without secondary generalization, that are refractory to three or more antiepileptic medications.

The Reclaim device (Medtronic, Inc.) was FDA-approved via the Humanitarian Device Exemption (HDE) process for the treatment of severe obsessive-compulsive disorder (OCD).

MR-conditional DBS devices may include the following devices. Please consult company websites for most up-to-date information.

- Medtronic: (*Medtronic DBS systems are MR Conditional and safe in the MR environment as long as certain conditions are met. If the conditions are not met, a significant risk is tissue lesions from component heating, especially at the lead electrodes, resulting in serious and permanent injury including coma, paralysis, or death.)
    - Activa™ RC system
    - Percept™PC neurostimulator
- Boston Scientific (*For the latest version of the safety manual, go to http://www.bostonscientific.com/manuals.)
    - Vercise Gevia™ DBS System

EVIDENCE SUMMARY

The principal outcome for deep brain stimulation (DBS) for any indication is symptom reduction and improved function. Assessment of the safety and efficacy of DBS requires well-designed and well-executed randomized controlled trials (RCTs) comparing DBS with sham or on- versus off- phases to determine the following:

- whether the benefits of DBS outweigh any risks
- whether DBS offers advantages over conventional treatments.

The evidence base is sufficient that deep brain stimulation (DBS) improves the net health outcomes of selected patients with symptoms related to Parkinson's disease, essential tremor, or primary dystonias. DBS has become a standard of care for these patients and may be considered medically necessary when criteria are met. Therefore, the evidence for DBS for these indications will not be reviewed in this policy. Below is a brief synopsis of the evidence for Parkinson's disease, essential tremor, or primary dystonias.

SYMTPOMS ASSOCIATED WITH PARKINSON'S DISEASE

Systematic Reviews and Technology Assessments

The policy for PD and tremor was initially based on two BlueCross BlueShield Association Technology Evaluation Center (TEC) Assessments; a 1997 TEC Assessment focused on unilateral deep brain stimulation of the thalamus as a treatment for tremor[1] and a 2001 TEC Assessment focused on the use of deep brain stimulation of the globus pallidus and subthalamic nucleus for a broader range of Parkinson symptoms.[2]

A number of large systematic reviews have been published on the use of DBS for PD and tremor[3-13] confirming the efficacy of DBS in the control of motor signs and improvement of patients' functionality and quality of life.

Randomized Controlled Trials

There have been additional published RCTs of deep brain stimulation for PD, which continue to report overall positive results [14-23]. Some of these trials suggest that subthalamic stimulation was superior to medical therapy in patients with Parkinson's disease and early motor complications, while others did not find significant differences in overall health outcomes for patients. Surgery related adverse effects addressed in these RCTs indicate that the most common adverse effect is infection.

Nonrandomized Studies

Two new DBS systems with directional leads are currently available (approved by the Food and Drug Administration [FDA] in 2016 and 2017). Directional leads potentially enable clinicians to target more specific areas of the brain to be treated with the direct current. Published evidence consists of several small observational studies, with sample sizes ranging from 7 to 13.[24-27] The studies showed that patients experienced improved tremor scores and improved quality of life (QOL). Compared with historical data from conventional DBS systems, directional DBS widened the therapeutic window and achieved beneficial effects using lower current level. Comparative, larger studies are needed to support the conclusions from these small studies. Data from a large study of 292 patients are expected in 2018.

PRIMARY DYSTONIA

DBS for the treatment of primary dystonia received FDA approval through the Humanitarian Device Exemption (HDE) process.[28] The HDE approval process is available for those conditions that affect less than 4,000 Americans per year. According to this approval process, the manufacturer is not required to provide definitive evidence of efficacy, but only probable benefit. As noted in the FDA's analysis of risk and probable benefit, the only other treatment

options for chronic refractory primary dystonias are neurodestructive procedures. DBS provides a reversible alternative. The FDA summary of Safety and Probable Benefit states, “Although there are a number of serious adverse events experienced by patients treated with deep brain stimulation, in the absence of therapy, chronic intractable dystonia can be very disabling and in some cases, progress to a life-threatening stage or constitute a major fixed handicap. When the age of onset of dystonia occurs prior to the individual reaching their full adult size, the disease not only can affect normal psychological development but also cause irreparable damage to the skeletal system. As the body of the individual is contorted by the disease, the skeleton may be placed under constant severe stresses that may cause permanent disfigurement. Risks associated with DBS for dystonia appear to be similar to the risk associated with the performance of stereotactic surgery and the implantation of DBS systems for currently approved indications Parkinson’s Disease and Essential Tremor), except when used in either child or adolescent patient groups.”

The FDA HDE approval was based on the results of DBS in 201 patients represented in 34 manuscripts. There were three studies that reported at least ten cases. Clinical improvement ranged from 50 to 88%. A total of twenty-one pediatric patients were studied; 81% were older than seven years. Among these patients there was approximately a 60% improvement in clinical scores.

Since the FDA approval, there have been additional published randomized controlled trials of deep brain stimulation for dystonia, which continue to report positive results.[29-31] These trials included one with a long-term follow-up of five years. Two of the trials reported on the serious adverse effects of DBS, the majority of which were related to the implantation procedure. Dysarthria, involuntary movements and depression were common non-serious adverse events reported.[32]

In 2017, Moro published a systematic review of literature published through November 2015 on primary dystonia (also known as isolated dystonia).[33] Reviewers included studies with at least 10 cases. Fifty-eight articles corresponding to 54 unique studies were identified; most involved bilateral DBS of the GPi. There were only two controlled studies, one RCT (described below) and one study that included a double-blind evaluation with and without stimulation. Twenty-four studies reported data using the Burke-Fahn-Marsden Dystonia Rating Scale (BFMDRS) and were included in a meta-analysis. These studies enrolled a total of 523 patients (mean per study, 22 patients) and had a mean follow-up of 32.3 months (range, 6 to 72 months). In a pooled analysis of BFMDRS motor scores (scale range, 0 to 120) from 24 studies, the mean increase in scores at six months compared with baseline was 23.8 points (95% CI 18.5 to 29.1 points). The mean increase in the motor score at last follow-up compared with baseline was 26.6 points (95% CI 22.4 to 30.9 points). The mean percentage improvement was 59% at six months and 65% at last follow-up. Fourteen studies reported BFMDRS disability scores (scale range, 0 to 30). Compared with baseline, the mean absolute change in the score was 4.8 points (95% CI 3.1 to 6.6 points) at six months and 6.4 points (95% CI 5.0 to 7.8 points) at last follow-up. The mean percentage improvement was 44% at six months and 59% at last follow-up. Rodrigues (2019) performed a Cochrane systematic review of RCTs and identified the same two RCTs.[32]

The remaining literature review below will focus on the use of DBS for the investigational indications in this policy.

TARDIVE DYSKINESIA AND TARDIVE DYSTONIA

Systematic Review

Grabel (2023) published a meta-analysis of clinical outcomes of DBS to treat tardive dystonia.[34] Fourteen studies were included that involved 134 patients. Studies were either single case reports or multiple case series. Using a random effects model on the summary mean data for each study yielded an estimated 70.56% overall mean improvement from DBS with high heterogeneity (I^2=93.91%). The authors acknowledge the possibility of positive selection bias due to the inclusion of single case studies. According to the authors no RCTs have been performed that evaluate DBS for TDD.

Tardive dyskinesia and dystonia (TDD) are severe side effects of dopamine-blocking agents, particularly antipsychotics. Little is known about the possible psychiatric complications of DBS in psychiatric patients. The mean improvement of TDD of the combined patients 3 to 76 months after implantation was 77.5% (95% CI 71.4% to 83.3%; p<0.000) on the Burke-Fahn-Marsden Dystonia Rating Scale.[35] The data suggest DBS could be effective and relatively safe for patients with treatment-resistant TDD; however, these results should be interpreted with caution, as most of the data are from case reports and small trials.

Mentzel (2015) performed a systematic review to assess the effects and side-effects of deep brain stimulation (DBS) in patients that have developed a severe debilitating treatment-resistant form of TDD.[36] This review included 19 case-reports and small-scale trials without randomization or blinding (n=52 patients). Using the Burke Fahn Marsden Dystonia Rating Scale (BFMDRS), the Abnormal Involuntary Movement Scale (AIMS) and the Extrapyramidal Symptoms Rating Scale (ESRS), the investigators assessed the average improvement in the patients' condition, reporting that improvement as a result of DBS was statistically significant (p<0.00001) on all scales. However, limited conclusions can be drawn from this review on the efficacy and safety of DBS in this population, since there were no randomized controlled trials identified.

Randomized Controlled Trials

Stimulation of the globus pallidus has been examined as a treatment of tardive dyskinesia in a phase II double-blinded (presence and absence of stimulation) multicenter study.[37] The trial was stopped early due to successful treatment (greater than 40% improvement) in the first 10 patients.

Gruber (2018) assessed dystonia/dyskinesia severity using the Burke-Fahn- Marsden-Dystonia-Rating-Scale, BFMDRS at three months between active versus sham DBS.[38] Twenty-five patients were randomized. In the intention-to-treat analyses, the between group difference of dystonia severity was not significant at three months. Adverse events occurred in 10 of the 25 patients; three of the adverse events were serious. The study was originally powered to include 48 patients but only 25 were randomized and analyses may be underpowered.

Nonrandomized Studies

Pouclet-Courtemanche (2016) reported on a case series of 19 patients with severe pharmaco-resistant tardive dyskinesia treated with DBS.[39] Patients were assessed after 3, 6, and 12 months after bilateral globus pallidus stimulation. At six months, all patients had experienced greater than 40% reduction in symptoms as measured on the Extrapyramidal Symptoms Rating Scale (ESRS). At 12 months, the mean decrease in ESRS score was 58% (range, 21%

to 81%). An additional small (n=9) case series reported improvement in motor and disability scores.[40]

CEREBRAL PALSY

Koy (2022) published a prospective study aimed at assessing motor and nonmotor outcomes, with a focus on the quality of life (QOL) effects of DBS on pediatric patients with pharmacorefractory dyskinetic cerebral palsy. [41] The multi-site study enrolled 16 patients, age 8 to 18 years for the initial single-arm phase of the study, during which they were treated with DBS that targeted the globus pallidus internus for 12 months. After 12 months of DBS, 14 of the participants entered the second phase of the study; a randomized, double-blind crossover to either DBS for 24 hours followed by sham stimulation for 24 hours, or sham stimulation for 24 hours followed by DBS for 24 hours. The primary endpoint was mean change in the Caregiver Priorities & Child Health Index of Life and Disabilities (CPCHILD) questionnaire from baseline to 12 months. At 12 months the mean change in the CPCHILD score was not statistically significant (p=0.125). Of multiple secondary outcomes, significant results were improvement in Canadian Occupational Performance Measure performance scores from baseline to 12 months (change 1.1 +/- 1.2; [95% CI 0.2 – 1.9] points; p=0.02), and improvement in the Short-Form-36 physical health component noted by both patients and caregivers (patients, change 5.1 +/- 6.2 [95% CI 0.7 – 9.6] points; p= 0.028; caregivers, change 4.6 +/- 7.3 [95% CI 0.5 – 8.6] points; p=0.029). The authors state the statistically significant measures indicate improved performance of activities of daily living and physical health-related QOL for patients and caregivers. Seven other secondary outcome measures of physical health and QOL were not statistically significant. At randomization, there was no significant difference between stimulation modes (ON/OFF) in the BFMDRS-movement scores (p=0.141), or DIS (p=0.513). Limitations of the study include its small number of participants.

Koy (2013) reported data on the therapeutic outcomes of DBS in cerebral palsy.[42] Twenty articles comprising 68 patients with cerebral palsy undergoing deep brain stimulation assessed by the Burke-Fahn-Marsden Dystonia Rating Scale were identified. Most articles were case reports reflecting great variability in the score and duration of follow-up. The mean Burke-Fahn-Marsden Dystonia Rating Scale movement score was 64.94 ± 25.40 preoperatively and dropped to 50.5 ± 26.77 postoperatively, with a mean improvement of 23.6% (p<0.001) at a median follow-up of 12 months. The mean Burke-Fahn-Marsden Dystonia Rating Scale disability score was 18.54 ± 6.15 preoperatively and 16.83 ± 6.42 postoperatively, with a mean improvement of 9.2% (p<0.001). There was a significant negative correlation between severity of dystonia and clinical outcome (p<0.05). Authors suggest DBS can be an effective treatment option for dyskinetic cerebral palsy. In view of the heterogeneous data, a prospective study with a large cohort of patients in a standardized setting with a multidisciplinary approach would be helpful in further evaluating the role of deep brain stimulation in cerebral palsy.[43]

EPILEPSY/INTRACTABLE SEIZURES

DBS has been investigated for the treatment of intractable seizures in patients who do not respond to pharmacologic therapy. Approximately one-third of patients with epilepsy do not respond to anti-epileptic drugs and are considered to have drug-resistant epilepsy. Patients with drug-resistant or refractory epilepsy have a higher risk of death as well as a high burden of epilepsy-related disabilities and limitations. To date studies show promise but these early reports of therapeutic success are not confirmed by controlled clinical trials. Questions

regarding the best structures to stimulate, the most effective stimuli, and the contrasting effects of high-frequency and low-frequency stimulation remain unanswered.

Systematic Review

Haneef (2023) published a systematic review and meta-analysis comparing DBS to vagus nerve stimulation (VNS) and responsive neurostimulation (RNS) for generalized drug-resistant epilepsy.[44] Twenty studies, including eight using DBS were included. Mean follow-up time for DBS was 23.1 months and 39.1 months for VNS. RNS data were insufficient for analysis. Seizure reduction was greater for DBS (64.8%) than VNS (48.3%) (p=0.02). Studies addressing both treatments were deemed of moderate heterogeneity. Limitations include that only one DBS study was an RCT.

Skrehot (2023) also published a systematic review and meta-analysis comparing DBS to VNS and RNS for focal epilepsy.[45] The analysis included 24 studies, of which 11 were of DBS. This study also found that DBS was associated with greater seizure reduction than VNS (p<0.01) and that RNS and DBS had similar efficacy at one year follow-up. However, differences in efficacy narrowed by three-year follow-up to non-significant (p = 0.75).

Touma (2022) in collaboration with The International League Against Epilepsy (ILAE) Surgical Therapies Commission published a systematic review and meta-analysis to summarize the available evidence on DBS, vagus nerve stimulation (VNS), and responsive neurostimulation (RNS) in the treatment of drug-resistant epilepsy (DRE).[46] The analysis focused on the efficacy and tolerability of the three therapies for adults. The primary outcome measure was mean percentage decrease in seizure frequency. Thirty studies were included in the review. The majority were VNS studies. DBS was the intervention in only three studies. No study offered a head-to-head comparison of the treatments. Of the three studies involving DBS, one was an RCT, and the other two reported outcomes for the same cohort. The RCT found a significant difference in seizure frequency at 3 months between the intervention group and the control arm (p=0.0017), but the difference in seizure freedom was not statistically significant (relative risk [RR] = 0.3; 95% CI: 0.0, 8.2). Adverse events reported in the RCT include increased risk for depression (p=0.02) and memory impairment (p=0.03) in the intervention arm. However, long-term data showed mean seizure reduction of 69% at five years and 70% at seven years. There was also improvement in quality-of-life scores (QOLIE-31) at five years (p=0.001).

Rheims (2022) published a systematic review and meta-analysis of 28 studies investigating the impact of surgery and neuromodulation for drug-resistant epilepsy on mortality.[47] The authors note that the higher mortality rate in people with drug-resistant epilepsy is primarily due to epilepsy-related deaths. DBS procedure-related deaths specifically in people with drug-resistant epilepsy were not documented. The study cites an overall 0.2% postoperative in-hospital death rate from DBS for movement disorders. The rate of sudden unexpected death in epilepsy (SUDEP) was similar between DBS (2.9/1000 patient years [PY]) and RNS (2.8/1000 PY). The authors were unable to address whether DBS has a protective effect on SUDEP. When seizure freedom is established after surgery, the data suggest reduced mortality and decreased incidence of SUDEP. The available evidence on the potential impact of DBS on mortality from drug-resistant epilepsy is limited so definitive conclusions could not be drawn.

A 2022 systematic review by Vetkas evaluated the effectiveness of DBS of the anterior thalamic nucleus, the centromedian thalamic nucleus, and the hippocampus.[48] A total of 48 articles with 527 patients (sample sizes between 3 and 81) met inclusion criteria. For the

anterior thalamic nucleus, centromedian thalamic nucleus, and hippocampus there were two, two, and three RCTs (including the SANTE trial described below) and 23, 8, and 13 total studies, respectively. There was moderate to high heterogeneity (I^2 69 to 90%) for the anterior thalamic nucleus and the hippocampus and low heterogeneity for the centromedian thalamic nucleus. According to the meta-analysis, the mean seizure reduction after stimulation of the anterior thalamic nucleus, centromedian thalamic nucleus, and hippocampus was 60.8% (95% CI 55.72 to 65.89), 73.4% (95% CI 68.83 to 77.87), and 67.8% (58.14 to 77.46), respectively.

Two systematic reviews published in 2018 on the use of DBS for drug-resistant epilepsy assessed many of the same studies. The larger review, by Li (2018), identified 10 RCTs and 48 uncontrolled studies.[49] The literature search date was not reported. Meta-analyses were not performed. Summaries of the studies were discussed by area of the brain targeted by DBS. A review of the studies showed that DBS might be effective in reducing seizures when DBS targets the anterior nucleus of the thalamus or the hippocampus. Across studies, more than 70% of patients experienced a reduction in seizures by 50% or more. However, there were very few RCTs and the observational studies had small sample sizes. Individual responses varied, depending on seizure syndrome, presence or absence of structural abnormalities, and electrode position. Results were inconclusive when DBS targeted the centromedian nucleus of the thalamus, the cerebellum, and the subthalamic nuclei. Safety data on DBS was limited due to the small population sizes. The RCT in which DBS targeted the anterior nucleus of the thalamus (Fisher [2010] described below) reported paresthesias (23%), implant site pain (21%), and implant site infection (13%). Reviewers concluded that more robust clinical trials would be needed.

In a 2014 Cochrane review, updated in 2017, the safety, efficacy and tolerability of DBS and cortical stimulation were assessed in patients with refractory epilepsy.[50, 51] The reviews included RCTs comparing DPS to sham stimulation, resective surgery or further treatment with antiepileptic drugs. Of the 10 RCTs identified for inclusion in the 2014 review, three trials were specific to DBS (one anterior thalamic DBS trial, n=109 treatment periods; two centromedian thalamic DBS trials, n=20, 40 treatment periods). The studies added in the 2017 update were a cross-over RCT of bilateral anterior thalamic stimulation (n=4) and a double blind RCT of hippocampal stimulation (n=6) that was not included in the meta-analysis due to missing detailed methodology. The primary outcome measures included the proportion of patients who were disease free and a 50% or greater reduction in seizure frequency after one to three months. The evidence was rated as moderate quality and no statistical or clinically significant differences were reported based upon the primary outcome measures. Authors concluded that there is insufficient evidence upon which to draw conclusions regarding the efficacy and safety of hippocampal DBS or centromedian DBS as a treatment for epilepsy.

Randomized Controlled Trials

Fisher (2010) reported results of a multicenter, RCT of bilateral stimulation of the anterior nuclei of the thalamus for epilepsy (SANTE).[52] Fisher randomized patients who had failed at least three antiepileptic drugs to one of two groups, stimulation on or stimulation off. This was a 3-month double blind phase. After this phase, all patients received unblinded stimulation. During the first and second months of the blinded phase, the difference in seizure reduction between stimulation on and stimulation off was not significantly different (-42.1% vs. -28.7%, respectively). In the last month of the blinded phase, the stimulated group had a significantly greater reduction in seizures compared with the control group (-40.4% vs. -14.5%, respectively p=0.0017). During the blinded phase, the stimulation group experienced significantly fewer

seizure-related injuries than patients in the control group (7.4% vs. 25.5%, respectively p=0.01). Cognition and mood showed no group differences, but participants in the stimulated group were more likely to report depression (8 vs. 1, respectively) or memory problems (7 vs. 1, respectively) as adverse events. Depression symptoms resolved in four of the eight stimulated patients over an average of 76 days (range 14 to 145). There was a progressive reduction in seizure frequency over long-term follow-up. On intention-to-treat analysis, the median change in seizure frequency was -44% at 13 months and -57% at 25 months. By two years, 54% of patients had a seizure reduction of at least 50%, and 14 patients (13%) were seizure-free for at least six months. The most common device-related adverse events were paresthesias in 18.2% of participants, implant site pain in 10.9%, and implant site infection in 9.1%. Eighteen participants (16.4%) withdrew from the study after the implantation because of adverse events. There were five deaths, none of which were considered to be device-related. Although some patients appeared to have benefited from treatment during the extended follow-up phase, the difference between groups in the blinded portion of the study, while significant, was modest.

Troster (2017) assessed neuropsychological adverse events from the SANTE trial during the three-month blinded phase, and at seven-year follow-up during the open-label noncomparative phase.[53] At baseline, there were no differences in depression history between groups. During the three-month blinded phase of the trial, depression was reported in eight (15%) patients from the stimulation group and in one (2%) patient from the no stimulation group (p=0.02). Memory adverse events also occurred at significantly different rates between the treatment groups during the blinded phase (seven in the active group, one in the control group; p=0.03). At seven-year follow-up, after the treatment groups had been combined, there was no statistically significant difference in Profile of Mood State depression score compared with baseline and most cognitive function tests did not improve over baseline measurements.

A seven-year follow-up of SANTE was reported in the FDA SSED.[54] Seventy-three (66% of implanted) patients completed the year seven visit. Reasons for withdrawals from the study after implantation were: death (6), withdrawal of consent (5), investigator decision (3), therapeutic product ineffective (13), implant site infection or pain (6), other adverse event (7) and elective device removal (1). Fifty patients were included in the year 7 analysis of responder rate. Seventy-four percent of the 50 patients were responders (50% or greater reduction in seizure frequency). QOLIE-31 scores (n=67) improved by a mean of 4.9 (SD=11) points at year 7. LSSS scores (n=67) improved by a mean of 18 points (SD=23) at year 7. As the FDA documentation notes, interpretation of the long-term follow-up is limited by several factors: patients were aware they were receiving DBS, only 66% of implanted patients completed the year 7 visit and those who did not do well may be more likely to leave the study, and changes in anti-epileptic drugs were allowed in long-term follow-up.

Cukiert (2017) conducted a double-blind, placebo-controlled randomized trial evaluating outcomes of hippocampal stimulation in 16 patients with refractory temporal lobe epilepsy.[55] Prior to treatment, all patients had focal impaired awareness seizures (FIAS, complex partial seizures), and 87% had focal aware seizures (FAS, simple partial seizures). All patients underwent DBS device implantation, and were followed for six months. Patients were seen weekly to receive the treatment or placebo. To maintain double-blind status, programming was performed by a nontreating assistant. Patients kept a seizure diary during the study period. Patients were considered seizure-free if no seizures occurred during the last 2 months of the trial. Responders were defined as patients experiencing a reduction of 50% or more in frequency reduction. There was a significant difference in FIAS frequency from the first month

of full stimulation until the end of the blinded phase (p<0.001) and FAS frequency for the same period except for the third month of the blinded phase.

Nonrandomized Studies

Peltola (2023) published long-term follow-up data on anterior nucleus of the thalamus (ANT) DBS therapy for 170 adults with drug resistant epilepsy from the Medtronic Registry for Epilepsy (MORE) registry.[56] MORE is an observational registry that collects prospective and retrospective data on adults with drug-resistant epilepsy being treated in 25 centers across 13 countries. After two years, the median monthly seizure frequency decreased by 33.1% (p<0.0001). A subgroup of 47 patients were followed for five years and had a 55% reduction in median seizure activity. Quality of Life in Epilepsy scores were improved by 2-points overall (p< 0.05), but data were available for only 78 people. Importantly, the most frequently observed adverse events were increased seizure frequency/severity in 16% of participants. Other adverse events were self-reported memory impairment (15%), self-reported depressive mood (15%). Limitations include reliability of self-reported data, non-protocolized visit windows, optional questionnaires and the use of retrospective data.

Kim (2017) conducted a retrospective chart review of 29 patients with refractory epilepsy treated with DBS.[57] Patients' mean age was 31 years, they had had epilepsy for a mean of 19 years, and had a mean preoperative frequency of tonic-clonic seizures of 27 per month. Mean follow-up was 6.3 years. Median seizure reduction from baseline was 71% at year one, 74% at year two and ranged from 62% to 80% through 11 years of follow-up. Complications included one symptomatic intracranial hemorrhage, one infection requiring removal and reimplantation, and two lead disconnections.

Long-term outcomes of the SANTE trial, described above, were reported by Salanova in 2015.[58] The uncontrolled open-label portion of the trial began after three months and, beginning at 13 months, stimulation parameters could be adjusted at the clinician's discretion. Of the 110 implanted patients, 105 (95%) completed the 13-month follow-up, 98 (89%) completed the three-year follow-up, and 83 (75%) completed five years. Among patients with at least 70 days of diary entries, the median change in seizure frequency from baseline was 41% at one year and 69% at five years (p<0.001 for both). During the study, 39 (35%) of 110 patients had a device-related serious adverse event, most of which occurred in the first several months after implantation. The most frequently reported serious adverse events were implant site infection (10% of patients) and lead(s) not within target (8.2% of patients). Seven deaths occurred during the study and none were considered to be device-related. Depression was reported in 41 (37%) patients over the study; in three cases, this was considered device-related. Memory impairment (nonserious) was reported in 30 (27%) patients during the study, half of which had a history of the condition. Although some patients appear to have benefited from treatment during the extended follow-up phase, the difference between groups in the blinded portion of the study, while significant, was overall modest.

TRAUMATIC BRAIN INJURY

Central thalamic deep brain stimulation (CT-DBS) has been investigated as a therapeutic option to improve behavioral functioning in patients with severe traumatic brain injury (TBI)[43]; however, there are no RCTs for this indication.

NEUROPSYCHIATRIC APPLICATIONS

In addition to the areas of research discussed above, DBS is being investigated for the treatment of Tourette syndrome, depression, addiction, alcohol addiction, anorexia, and obsessive compulsive disorder. Evidence remains insufficient to evaluate the efficacy of DBS for these disorders due to small sample sizes and other limitations in the available studies.[59]

Tourette Syndrome

Systematic Reviews

Wehmeyer (2021) conducted a pooled analysis of DBS for treatment-refractory Tourette syndrome.[60] A total of 65 studies with 376 patients were included. The primary outcome was Yale Global Tic Severity Scale (YGTSS) scores, which were significantly reduced at maximum follow-up of median 25 months ($p<0.001$). The median scores decreased from 79.92 points (interquartile range [IQR], 13.25) to 34.69 points (IQR, 20.93) post-surgery, which represented a reduction rate of 56.59%. A majority of patients (69.4%) also experienced symptom reduction of more than 50% at maximum follow-up. In addition, other tic-related outcome measures (modified Rush video-based tic rating scale, YGTSS total tic score) and comorbidities (Yale-Brown Obsessive Compulsive Scale, Becks Depression Inventory), were also significantly reduced after deep brain stimulation.

Baldermann conducted a systematic review that included 57 studies on DBS for Tourette syndrome, four of which were randomized crossover studies. The studies included a total of 156 cases.[61] Twenty-four studies included a single patient each and four had sample sizes of 10 or more (maximum, 18). Half of the patients (n=78) were stimulated in the thalamus and the next most common areas of stimulation were the global pallidus internus anteromedial part (n=44) and postventrolateral part (n=20). Two of the RCTs used thalamic stimulation, one used bilateral globus pallidus stimulation, and one used both. The primary outcome was YGTSS scores. In a pooled analysis of within subject pre-post data, there was a median improvement of 53% in the YGTSS, a decline from a median score of 83 to 35 at last follow-up. Moreover, 81% of patients showed at least a 25% reduction in the YGTSS and 54% and more than a 50% improvement. In addition, data were pooled from the four crossover RCTs; there were a total of 27 patients receiving DBS and 27 receiving a control intervention. Targets included the thalamus and the globus pallidus. In the pooled analysis, there was a statistically significant between-group difference, favoring DBS (SMD=0.96; 95% CI 0.36 to 1.56). The authors noted that the effect size of 0.96 is considered to be a large effect.

A 2012 systematic review by Pansaon identified 25 published studies, representing data from 69 patients that reported on the efficacy of DBS in the treatment of Tourette syndrome.[62] However, only three studies with methodological quality ratings of fair to poor met the inclusion criteria for evidence-based analysis. The authors recommend that DBS continues to be considered an experimental treatment for severe, medically refractory tics.

Randomized Controlled Trials

Kefalopoulou (2015) reported on double-blind crossover trial that included 15 patients with severe medically refractory Tourette syndrome.[63] They received surgery for bilateral globus pallidus internus DBS and were randomized to the off-position first or the on-position first for three months followed by the opposite position for the next three months. Fifteen patients underwent surgery 14 were randomized and 13 completed assessments after both on- and off-phases. For the 13 study completers, the mean YGTSS scores were 80.7 (SD=12.0) in the off-stimulation phase and 68.3 (SD=18.6) in the on-stimulation phase. Mean difference n

YGTSS scores was 12.4 (95% CI 0.1 to 24.7) which was statistically significant (p=0.048) after Bonferroni correction. There was no between-group difference in YGTSS scores in patients who were randomized to the on-phase first or second. Three serious adverse events were reported, two related to surgery and one related to stimulation. The authors noted that the most effective target for DBS in Tourette syndrome patients needs additional study.

Piedad (2012) analyzed patient and target selection for DBS of Tourette syndrome. The majority of clinical trials for DBS in Tourette syndrome have targeted the medial thalamus at the crosspoint of the centromedian nucleus, substantia periventricularis, and nucleus ventro-oralis internus.[64] Other targets that have been investigated include the subthalamic nucleus, caudate nucleus, globus pallidus internus, and the anterior limb of the internal capsule and nucleus accumbens. The review found no clear consensus in the literature for the best target or for which patients should be treated. Additional study is needed to clarify these issues.

In 2011, Ackermans reported preliminary results of a double-blind crossover trial of thalamic stimulation in six patients with refractory Tourette syndrome.[65] Tic severity during three months of stimulation was significantly lower than during the three months with the stimulator turned off, with a 37% improvement on the Yale Global Tic Severity Scale (mean 25.6 vs. 41.1) and a decrease in tic severity of 49% at one year after surgery compared to preoperative assessments (mean 21.5 vs. 42.2 – both respectively).Secondary outcomes (change in associated behavioral disorder and mood) were not altered by the stimulation. Serious adverse events included one small hemorrhage ventral to the tip of the electrode, one infection of the pulse generator, subjective gaze disturbances, and reduction of energy levels in all patients. The interim analysis led to the termination of the trial. The authors commented that further RCTs on other targets are urgently needed since the search for the optimal one is still ongoing.

Depression

The role of deep brain stimulation in treatment of other treatment-resistant depression, is also being investigated. Standard treatment modalities for treatment-resistant depression include psychotherapy, medication, and electroconvulsive therapy (ECT). However, even with a number of therapies being available, many patients can still remain symptomatic despite treatment. As an alternative therapy option, there have been multiple trials exploring deep brain stimulation in various cerebral targets for treatment-resistant depression.

Systematic Reviews

Sobstyl (2022) published a systematic review of studies that evaluated deep brain stimulation to the subcallosal cingulate cortex in patients with treatment resistant depression.[66] All study designs were considered but at least five patients were required and follow-up had to be a minimum of 6 months. Among the 14 studies included in the analysis (N=230), mean follow-up was 14 months (range, 6 to 24). Outcomes of interest included response and remission rates at the last follow-up visit. Using raw scores, the response rate at last follow-up was 0.57 (95% CI, 0.44 to 0.69; p=.299; I^2=60.76%) and remission rate was 0.399 (95% CI, 0.2923 to 0.5158; p=.09; I^2=42.80%).

Wu (2021) conducted a meta-analysis of blinded studies that compared deep brain stimulation to control (placebo or sham stimulation).[67] There were 17 studies included, with a total of 233 patients, however, the majority were open-label studies (n=15). Anatomic targets included subcallosal cingulate gyrus (n=8), ventral capsule/ventral striatum (n=2), epidural

prefrontal cortical (n=2), nucleus accumbens (n=1), superior lateral branch of the medial forebrain bundle(n=2), posterior gyrus rectus (n=1) and ventral anterior limb of the interna capsule (n=1). The pooled response rate estimate for the two RCTs was 1.45 (95% CI 0.50 to 4.21) and for the open-label studies it was 0.56 (95% CI 0.43 to 0.69); there was significant heterogeneity (I^2 = 73.6%; p<0.0001). The pooled estimate for remission rate in the open-label studies was 0.32 (95% CI 0.25 to 0.39) with no statistical heterogeneity (I^2 = 30.3%; p=0.127); the pooled estimate for adverse events in the open-label studies was 0.67 (95% CI 0.54 to 0.80) with significant heterogeneity (I^2 =76.8%; p<0.0001).

Hitti (2020) conducted a meta-analysis and meta-regression of blinded studies that compared active deep brain stimulation to sham stimulation (12 trials, 186 patients).[68] Anatomic targets included the ventral anterior limb of the internal capsule, ventral capsule/ventral striatum, subcallosal cingulate, inferior thalamic peduncle, medial forebrain bundle, and lateral habenula. The most common target was the subcallosal cingulate. Meta-analysis showed a modest reduction in depression rating scales (standardized mean difference =-0.75; 95% CI -1.13 to -0.36; p<0.001) with moderate heterogeneity across studies (I^2=59%). Meta-regression did not identify a significant difference between target areas. Adverse events included headache (26% of patients), visual disturbances (21%), worsening depression (16%), sleep disturbance (16%) and anxiety (14%).

In a recent systematic review, the literature was identified and reviewed for research findings related to treatment-resistant BD.[69] Therapeutic trials for treatment-resistant bipolar mania are uncommon and provide few promising leads other than the use of clozapine. Far more pressing challenges are the depressive-dysthymic-dysphoric-mixed phases of BD and long-term prophylaxis. Therapeutic trials for treatment-resistant bipolar depression have assessed various pharmacotherapies, behavioral therapies, and more invasive therapies including electroconvulsive therapy (ECT), transcranial magnetic stimulation, and deep brain stimulation-all of which are promising but limited in effectiveness. Most studies identified in the review were small, involved supplementation of typically complex ongoing treatments, varied in controls, randomization, and blinding, usually involved brief follow-up, and lacked replication. Clearer criteria for defining and predicting treatment resistance in BD are needed, as well as improved trial design with better controls, assessment of specific clinical subgroups, and longer follow-up. Due to significant limitations within literature the effectiveness of DBS for bipolar treatment is not known at this time.

Controlled Trials

Crowell (2019) reported long-term follow-up of a within-subject trial with 28 participants with TRD or bi-polar II disorder who were treated with DBS of the subcallosal cingulate.[70] Patients were included who had depression for at least 12 months with non-response to at least three antidepressant medications, a psychotherapy trial, and electroconvulsive therapy (lifetime). Seventeen of the patients had a one-month sham-controlled period and 11 patients had a one-month open label period before the stimulation was turned on. Eight-year follow-up was available for 14 of the 28 participants. The primary outcome measure was the Illinois Density Index, which assesses the longitudinal area under the curve for behavioral measures; in this study these included response (>50% decrease from baseline) and remission (score <7) on the HAM-D. More than 50% of patients maintained a response and 30% in remission, over the eight years of follow-up. The physician-rated Clinical Global Impressions severity score improved from 6.1 (severely ill) at baseline to less than 3 (mildly ill or better) in this open label trial.

Obsessive-compulsive Disorder

The role of deep brain stimulation in treatment of OCD is also being investigated. This condition can be very debilitating and cause significantly reduced quality of life for patients. Conventional management strategies include cognitive-behavioral therapy, medications, and surgical intervention, however response to treatment may take months, and significant improvement with these therapies is not guaranteed. Deep brain stimulation may be an alternative therapy option for patients with treatment-refractory OCD, and some trials have explored safety and efficacy of this treatment for people with OCD.

Systematic Reviews

Gadot (2022) published a systematic review of the efficacy of deep brain stimulation for treatment-resistant OCD and comorbid depressive symptoms.[71] Studies were included if they reported patient-level data on the effect of deep brain stimulation on the Yale-Brown Obsessive-Compulsive Scale. Thirty-four studies (N=352) were included in the analysis (9 RCTs, 25 nonrandomized trials) and both study types had a low risk of bias. Median follow-up in the included studies was 24 months (IQR, 12 to 32). Outcomes of interest included mean difference and percent reduction in the scale, and responder rate (defined as ≥35% reduction in Yale-Brown Obsessive-Compulsive Scale score). Random effects modeling found that Yale-Brown Obsessive-Compulsive Scale scores decreased by a mean of 47% (14.3 points; p<.01). The response rate at last follow-up was 66% (95% CI, 57% to 74%).

Cruz (2022) conducted a systematic review and meta-analysis of 25 studies published between 2003 and 2020 that assessed the efficacy of DBS for severe and treatment-resistant OCD.[72] Severe OCD was defined as a score of between 24 and 31 on the Yale-Brown Obsessive Compulsive Scale (YBOCS). Treatment resistance was defined as resistance after at least 12 weeks of high-dose selective serotonin reuptake inhibitors (SSRI) therapy and augmentation strategies. Of the 25 studies analyzed, 8 were double-blinded clinical trials, all of which were included in the Raviv (2020) systematic review.[73] The analysis included 303 patients and mean follow-up was 36.98 months. Nearly 45% of the participants were female. Funnel plot was used to assess risk of bias. The meta-analysis found significant improvement in YBOCS scores after DBS (25 studies; SMD=2.39; 95% confidence interval [CI] 1.91-2.87; p<0.0001; $I^{2=}$72%). Analysis restricted to the eight RCTs also demonstrated significant improvement in YBOCS scores but heterogeneity was similar (8 studies; SMD=2.51; 95% CI, 1.80-3.22; p<0.0001; I^2=66%). Subgroup analysis found improved YBOCS scores after DBS with different targets, but could not assess all possible targets. Ventral capsule/ventral striatum (VC/VS) and nucleus accumbens (NAc) were the most frequently used targets (VC/BS, 5 studies; SMD=3.72; 95% CI, 1.25-6.18; p<0.0001; I^2=64%); Nucleus accumbens (NAc) (NAc, 3 studies; SMD=2.14; 95% CI, 1.46-2.81; P=0.003; I^2=89%). The analysis found DBS resulted in improvement in affective symptoms and functioning. Hamilton Depression Rating scores (HAM-D) significantly decreased, indicating clinical improvement (9 studies; SMD=1.19; 95% CI, 0.84-1.54; p<0.0001; I^2=17%). Hamilton Anxiety Rating scores (HAM-A) showed significant improvement (5 studies; SMD=1.00; 95% CI 0.32-1.69; p=0.004; I^2=59%). Global Assessment of Functioning scores also significantly improved after DBS (7 studies; SMD=-3.51; 95% CI, -5.00 - -2.02; p=0.005; I^2=90%). The study strengths include that it independently analyzed the four manifestations of OCD; YBOCS scores, and scores related to affective symptoms and functioning. Limitations include that there was high heterogeneity in most analyses and it was not possible to assess the effectiveness of all of the various DBS targets and modes of delivery. Safety of DBS was not addressed.

Mar-Barrutia (2021) evaluated both the short-term and long-term effects of deep brain stimulation for OCD, and included 29 studies (n=230) for short-term response and 11 studies (n=155) for long-term responses assessment; there were 7 total RCTs included.[74] Mean follow-up duration for the short-term and long-term studies was 1.5 years and 5.3 years, respectively. The authors noted that few studies were graded as low risk of bias, and there was marked heterogeneity among the studies reviewed which makes it difficult for comparison. The primary outcome measured was the YBOCS and the mean changes in scores from pre- to post-treatment were similar in the short-term studies (change from 33.0 to 17.2) and the long-term studies (change from 34.4 to 18.0); however, significantly more patients met criteria for response in the long-term group (70.7%) versus the short-term group (60.6%). There were 26.6% of patients in the long-term group who were classified as non-responders.

A systematic review by Raviv (2020) identified 28 studies that met their criteria on deep brain stimulation for OCD, including nine RCTs, one cohort study, one case-control study, one cross-sectional study, and 16 case series with more than two patients.[73] Only four studies were graded as low risk of bias, and the authors noted that there is no consensus on the optimal target. Striatal targets were the most common and included the anterior limb of the internal capsule, ventral striatum, nucleus accumbens, and caudate nucleus, but there was some discrepancy in nomenclature and overlap in stereotaxic coordinates. Additional targets included the subthalamic nucleus, bed nucleus of stria terminalis, inferior thalamic peduncle, and globus pallidus internus. The majority of studies utilized the Yale-Brown Obsessive Compulsive Scale; a score of 24 or more (of a possible 40) indicates severe illness. Responders were defined as at least 35% reduction in Yale-Brown Obsessive Compulsive Scale score and partial responders as a reduction between 25% and 35%. There was substantial variability in response for each target area, which may be related to the phenotypic diversity within the psychiatric diagnosis.

Vicheva (2020) conducted a systematic review and meta-analysis of the use of DBS for treatment-resistant OCD.[75] Eight studies including 80 patients total met inclusion criteria. There was significant heterogeneity across studies. A meta-analysis of Yale-Brown Obsessive Compulsive Scale (Y-BOCS) scores found a 38.68% pooled mean reduction. There were five severe surgery-related adverse events (intracerebral hemorrhage in three patients and infection in two patients) and eight severe mood-related serious adverse events (one completed suicide, three suicide attempts in two patients, and suicidal thoughts and depression in four). There were additional mild and transient adverse events.

Kisely conducted a systematic review and meta-analyses pooling study findings evaluating DBS for OCD, including only double-blind RCTs of active versus sham DBS.[76] Five trials (total N=50 patients) met eligibility criteria and data on 44 patients were available for meta-analysis. Three were parallel group RCTs with or without a crossover phase and two were only crossover trials. The site of stimulation was the anterior limb of the internal capsule (three studies), the nucleus accumbens (one study) and the subthalamic nucleus (one study). Duration of treatment ranged from 2 to 12 weeks. All studies reported scores on the Y-BOCS. This is a 10-item scale in which higher scores reflect more intense symptoms, and a score of 24 or more (of a possible 40) is considered severe illness. Most studies designate a therapeutic response as a Y-BOCS reduction of 35% or more from the pretreatment baseline, with a reduction of 25 to 35% or more considered a partial response. Only one of the five studies reported proportion of responders Y-BOCS as an outcome measure and that study did not find a statistically significant difference between active and sham stimulation groups. All studies reported the outcome measure, mean reduction in Y-BOCS. When data from the

five studies were pooled, there was a statistically significantly greater reduction in the mean Y-BOCS in the active versus sham group (mean difference, -8.49; 95% CI 12.18 to -4.80). The outcome measure, however, does not allow conclusions on whether the difference between groups is clinically meaningful. Trial authors reported 16 serious adverse events including one cerebral hemorrhage and two infections requiring electrode removal. Additionally, nonserious transient adverse events were reported including 13 reports of hypomania, five of increase in depressive or anxious symptoms and six of headaches.

Anorexia Nervosa

Anorexia nervosa is an eating disorder characterized by a chronic course that is refractory to treatment in many patients and has one of the highest mortality rates of any psychiatric disorder. Two systematic reviews and meta-analysis were published in 2022 to evaluate the efficacy of DBS in the treatment of anorexia nervosa. Neither review included RCTs. Karaszewska (2022) sought to estimate the overall effect of DBS in anorexia nervosa by evaluating the evidence of benefit in weight restoration, QOL, and reduction of psychiatric symptoms.[77] The primary outcome was body mass index (BMI) change after DBS. The secondary outcome was combined effect on psychiatric symptoms at the last observation. The meta-analysis included four studies with 56 participants. Only one participant was male. Follow-up periods ranged from 6 to 24 months. Random effects meta-analysis found improvement in BMI after DBS (Hedges's g=1.13; 95% CI=0.80-1.46; Z-value=6.75; p<0.001) without heterogeneity(I^2 =0.00, p=0.901). Meta-analysis also found improvement in combined psychiatric symptom severity at last observation (Hedges's g=0.89; 95% CI=0.57-1.21; Z-value=5.47; p<0.001, I^2=4.29,p=0.371). The most common adverse effect (AE) was pain at the incision site. Less common reported AE's were cutaneous complications, hypomanic symptoms, auto-intoxication, and seizure. The risk of bias was deemed moderate for the primary study outcome of change in BMI, but serious for the secondary outcome measurements. The authors conclude that additional research on DBS therapy for anorexia nervosa is needed, but DBS may be considered an effective "last resort" treatment option for severe treatment-refractory anorexia nervosa.

The goals of the meta-analysis performed by Shaffer (2023) were to assess the efficacy of DBS on longitudinal BMI changes and compare DBS targets with anorexia nervosa.[78] The primary outcome measures were percentage BMI change at 6 and 9-12 months. Eleven studies with 36 participants were included, of whom 94.4% were female. Two of the studies were included in the Karaszewska (2022) review and five were single case studies. The overall mean percentage improvement in BMI was 12.63% at six months (SD 26.72%, n=34; 1.51 [3.28] kg/m^2) and 23.62% at 9-12 months (SD 32.62%, n=25; 2.62 [3.89] kg/m^2]. P-score rankings were calculated for DBS targets based on percentage BMI change at six and 9-12 months. The subcallosal cingulate cortex (SCC) (n=11) had the highest P-score at both time points (6-month: 0.9449, 9-12 month: 0.9771), and the ventral anterior limb of the internal capsule (VALC) (n=4) had the lowest (6-month: 0.0279, 9-12 month: 0.1179). Reported AEs that were considered most likely due to DBS included surgical site infection, pain or headache, seizure, skin ulceration, wound dehiscence or need for revision. Risk of bias in the six studies that included two or more subjects was determined to be small in five studies and fair in one. The authors concluded that there is insufficient evidence that supports DBS as clearly beneficial compared to standard therapy for anorexia nervosa.

In a systematic review by McClelland (2013), two case series and two case reports that applied DBS to anorexic patients were identified and reviewed with mixed results.[79] There are no RCTs investigating DBS for this indication.

Alcohol Addiction

Alcohol dependency can be considered as a chronic mental disorder characterized by frequent relapses even when treated with appropriate medical or psychotherapeutic interventions.

Bach (2023) published an RCT that compared DBS to sham stimulation in 12 male participants with at least a 10-year history of alcohol abuse disorder (AUD) that was treatment resistant.[80] All participants had DBS electrodes surgically placed and then were randomized to have either DBS or sham treatment for six months. Then the study was unblinded and all participants had 12 months of DBS therapy. Nine participants completed the study. The primary outcome measure was time to first alcohol use within six months after randomization. Secondary outcomes were alcohol consumption during the 18-month period after randomization, six subjective measures at 6 and 12 months after randomization, and safety outcomes. The difference between the groups in time to first alcohol use, the primary outcome measure, was not statistically significant (HR = 0.73; 95% CI 0.20-2.62; p=0.625). However, the participants randomized to DBS in the first six months had significantly more abstinent days at six months (p=0.048), a higher mean proportion of abstinent days (p=0.032), and fewer heavy drinking days (p=0.041). The DBS group also reported lower alcohol cravings after six months (p=0.020), but analysis across both groups showed lower alcohol cravings at six months (p=0.014) compared to baseline. Both groups also had significantly higher proportion of abstinent days after 18 months (p=0.004). Further research with larger, more representative groups is needed to understand whether DBS is an effective therapy for alcohol addiction.

A 2012 systematic review by Herremans and Baeken investigated several neuromodulation techniques including deep brain stimulation in the treatment of alcohol addiction.[81] Previous studies investigating these neuromodulation techniques in alcohol addiction remain to date rather limited. Overall, the clinical effects on alcohol addiction were modest. Neuromodulation techniques have only recently been subject to investigation in alcohol addiction and methodological differences between the few studies restrict clear conclusions. Nevertheless, the scarce results encourage further investigation in alcohol addiction.

Alzheimer’s Disease

A 2022 systematic review and meta-analysis by Cheyuo analyzed invasive and non-invasive neuromodulation therapies in the treatment of Alzheimer’s Disease (AD).[82] Six studies were included in the meta-analysis, and of those, four involved DBS. The majority of the participants were in the two studies on non-invasive neuromodulation techniques. Of 242 total participants, 36 were from the four DBS studies. DBS was associated with improved cognitive outcome in people aged 65 years and older (p=0.004), but people younger than 65 years did not report better cognitive outcomes (p=0.65). Non-invasive neuromodulation techniques did not show improved cognitive outcome but were limited by lack of follow-up data. Further research is needed to understand the effect of DBS on cognitive function in people with AD.

OTHER APPLICATIONS

There is interest in applications of DBS beyond that for essential tremors, primary dystonia and Parkinson's disease. Clinical trials are being pursued; however, at this time, FDA approval is limited to the above indications and severe obsessive-compulsive disorder. The following discussion focuses on randomized controlled trials (RCTs) for the investigational indications noted in Policy Guidelines above.

Chronic Pain, Pain Syndromes, and Cluster Headaches

DBS for the treatment of chronic pain was investigated and largely abandoned in the 1980's due to poor results in two trials. With improved technology and surgical techniques there has been a resurgence of interest in DBS for intractable pain. DBS of the posterior hypothalamus for the treatment of chronic cluster headaches has also been investigated as functional studies have suggested cluster headaches have a central hypothalamic pathogenesis. Outcomes and treatment protocols have been heterogenous.

Membrilla (2023) published a systematic review (SR) and meta-analysis of interventions for preventative treatment of refractory chronic cluster headache.[83] Forty-five studies involving 106 participants were included. Of those, ten studies were on DBS, but only one was an RCT. The RCT was the same study included in the Deer (2020) SR described below. The other nine studies were observational and described a variety of DBS stimulation targets. The meta-analysis of the seven studies that reported response data found a pooled response rate of 77.0% (OR 0.770, 95% CI 0.594-0.947, I^2=78.9%, p<0.001). Adverse events included two deaths. One was directly due to the lead implantation procedure that led to cerebral hemorrhage. The authors note the studies showed high heterogeneity, and further research is needed on the safety and efficacy of DBS for chronic cluster headache.

Deer (2020) conducted a systematic review of deep brain stimulation for chronic pain.[84] They identified one RCT from 2017 with 10 patients with post-stroke pain syndrome and one RCT from 2010 with 11 patients who had chronic cluster headaches (described above). Three early case series (1990 to 2017, n=12 to 48) included patients with a variety pain conditions, including phantom limb pain, cancer, brachial plexus injury, failed back surgery, and spinal cord injury. The location of the stimulation was variable. Publication bias was not assessed.

Due to the limited RCTs and small sample sizes, conclusions cannot be reached on the effectiveness of DBS as a treatment of any type of pain, including but not limited to cluster headaches, chronic spinal pain, failed back surgery syndrome, phantom limb pain, facial deafferentation pain, and central or peripheral neuropathic pain.

Morbid Obesity

The study of DBS of the hypothalamus and nucleus accumbens for cluster headache and obsessive-compulsive disorder (OCD) has prompted interest in DBS for obesity and addiction, which are thought to be associated with those brain regions. However, patients with unilateral subthalamic nucleus or globus pallidus internus DBS for PD were found to have gained a mean 4.86 pounds following initiation of DBS.[85] Contreras (2022) performed a systematic review of the literature on DBS for the treatment of refractory obesity.[86] A total of seven studies including 12 patients met inclusion criteria. The incidence of moderate side effects was 33%. Statistical was not possible due to the limited amount of data available in the articles and the small study populations do not permit conclusions on efficacy of DBS for obesity.

Multiple Sclerosis

No randomized controlled trials were found for DBS in the treatment of multiple sclerosis (MS) tremors. Brandmeir (2020) reported a meta-analysis of 13 studies of deep brain stimulation for multiple sclerosis tremor (129 patients received deep brain stimulation and 132 received medical management).[87] Results were compared for tremor severity after deep brain stimulation versus tremor severity at baseline, and were combined across different target areas (ventral intermediate nucleus of the thalamus, ventral oralis nucleus of the thalamus, ventral caudal nucleus of the thalamus, zona incerta) and different levels of evidence. Four studies were rated as level II evidence, but the studies were not randomized and the number of subjects in these studies was small, ranging from 4 to 12. Meta-analysis showed an improvement in the mean tremor score of 2.86 (95% CI 2.03 to 3.70, p<0.001). However, heterogeneity was high, suggesting that meta-analysis is not appropriate, and no distinction was made for the different anatomical targets. There was also evidence of publication bias. The small study populations do not permit conclusions on efficacy of DBS for MS tremors.

PRACTICE GUIDELINE SUMMARY

AMERICAN ACADEMY OF NEUROLOGY

The 2019 guidelines from American Academy of Neurology (AAN) provide recommendations on the assessment for and use of deep brain stimulation in adults with severe, treatment-refractory tics.[88] AAN notes that patients with severe Tourette syndrome resistant to medical and behavioral therapy may benefit from DBS, but there is no consensus on the optimal brain target. Brain regions that have been stimulated in patients with Tourette Syndrome include the centromedian thalamus, the globus pallidus internus (ventral and dorsal), the globus pallidus externus, the subthalamic nucleus, and the ventral striatum/ventral capsular nucleus accumbens region. AAN concludes that DBS of the anteromedial globus pallidus is possibly more likely than sham stimulation to reduce tic severity.

In the 2013 AAN guidelines on the treatment for tardive syndromes (TDS), indicated there is insufficient evidence to support or refute DBS for TDS.[89] This recommendation is based on Level U evidence (evidence is insufficient to support or refute the use of any other treatment over another). The 2011 AAN guideline regarding essential tremor was reaffirmed in 2014 indicating that, “no high quality, long-term studies exist regarding the efficacy and safety of (DBS) for ET.”[90]

The AAN updated its guidelines on the treatment of essential tremor (ET) in 2011.[90] This update did not change the conclusions and recommendations of AAN 2005 practice parameters on DBS for ET.[91] The guidelines stated that bilateral DBS of the thalamic nucleus may be used to treat medically refractory limb tremor in both upper limbs (level C, possibly effective), but that there were insufficient data on the risk/benefit ratio of bilateral vs unilateral DBS in the treatment of limb tremor. There was insufficient evidence to make recommendations on the use of thalamic DBS for head or voice tremor (level U, treatment is unproven).

The 2010 guidelines from AAN on the treatment of nonmotor symptoms of PD found insufficient evidence for the treatment of urinary incontinence with DBS of the STN.[92] AAN found that DBS of the STN possibly improves sleep quality in patients with advanced PD. However, none of the studies performed DBS to treat insomnia as a primary symptom, and DBS of the STN is not currently used to treat sleep disorders.

AMERICAN PSYCHIATRIC ASSOCIATION

In a 2007 the American Psychiatric Association (APA) published an evidence-based guideline, which was reaffirmed in 2012, on the treatment of patients with obsessive-compulsive disorder.[93] The APA gave their lowest level recommendation for DBS, among a list of other therapies with limited published evidence, for OCD that remains refractory “after first- and second-line treatment and well-supported augmentation strategies have been exhausted.” In the 2010 APA guideline for the treatment of major depression, DBS is listed as a search term in the literature review; however, no recommendations for DBS are mentioned.[94]

CONGRESS OF NEUROLOGICAL SURGEONS

In 2020 the Congress of Neurological Surgeons (CNS) updated the guidelines on DBS for obsessive-compulsive disorder, but the guideline is essentially unchanged since 2014:[95]

1. It is recommended that clinicians utilize bilateral subthalamic nucleus DBS over best medical management for the treatment of patients with medically refractory OCD. (Level I)
2. Clinicians may use bilateral nucleus accumbens or bed nucleus of stria terminalis DBS for the treatment of patients with medically refractory OCD. (Level II)

2018 evidence-based guidelines from the Congress of Neurological Surgeons (CNS) compared the efficacy of bi-lateral deep brain stimulation of the subthalamic nucleus and globus pallidus internus for the treatment of patients with Parkinson disease.[96]

Table 1. Recommendations of the Congress of Neurological Surgeons for DBS for Parkinson Disease

Goal	Most Effective Area of Stimulation (subthalamic nucleus or globus pallidus internus)	Level of Evidence
Improving motor symptoms	subthalamic nucleus or globus pallidus internus are similarly effective	I
Reduction of dopaminergic medication	subthalamic nucleus	I
Treatment of "on" medication dyskinesias	globus pallidus internus if reduction of medication is not anticipated	I
Quality of life	no evidence to recommend one over the other	I
Lessen impact of DBS on cognitive decline	globus pallidus internus	I
Reduce risk of depression	globus pallidus internus	I
Reduce adverse effects	insufficient evidence to recommend one over the other	Insufficient

SUMMARY

There is enough research to show that deep brain stimulation (DBS) improves health outcomes in select patients with symptoms related to Parkinson's disease, essential tremor, or primary dystonias. DBS has become a standard of care for these patients. Therefore, DBS, including revision(s) or replacement(s), may be considered medically necessary when policy criteria are met.

Deep brain stimulation (DBS) is not clinically appropriate in patients with symptoms related to Parkinson's disease, essential tremor, or primary dystonias when criteria are not met. Therefore, DBS is considered not medically necessary for these indications when criteria are not met.

There is not enough research to determine the safety and effectiveness of deep brain stimulation (DBS) for other conditions. Current practice guidelines do not recommend the use of deep brain stimulation for the treatment of various neurologic and psychiatric disorders. Therefore, DBS is considered investigational for all other indications when policy criteria are not met.

CODES

Codes	Number	Description
CPT	61850	Twist or burr hole(s) for implantation of neurostimulator electrode(s), cortical
	61860	Craniectomy or craniotomy for implantation of neurostimulator electrodes, cerebral, cortical
	61863	Twist drill, burr hole, craniotomy, or craniectomy for stereotactic implantation of neurostimulator array in subcortical site (e.g., thalamus, globus pallidus, subthalamic nucleus, periventricular, periaqueductal gray), without use of intraoperative microelectrode recording; first array
	61864	Twist drill, burr hole, craniotomy, or craniectomy for stereotactic implantation of neurostimulator array in subcortical site (e.g., thalamus, globus pallidus, subthalamic nucleus, periventricular, periaqueductal gray), without use of intraoperative microelectrode recording; each additional array (List separately in addition to primary procedure).
	61867	Twist drill, burr hole, craniotomy, or craniectomy for stereotactic implantation of neurostimulator array in subcortical site (e.g., thalamus, globus pallidus, subthalamic nucleus, periventricular, periaqueductal gray), with use of intraoperative microelectrode recording; first array
	61868	Twist drill, burr hole, craniotomy, or craniectomy for stereotactic implantation of neurostimulator array in subcortical site (e.g., thalamus, globus pallidus, subthalamic nucleus, periventricular, periaqueductal gray), with use of intraoperative microelectrode recording; each additional array (List separately in addition to primary procedure)
	61885	Insertion or replacement of cranial neurostimulator pulse generator or receiver, direct or inductive coupling; with connection to a single electrode array
	61886	;with connection to two or more electrode arrays
	61888	Revision or removal of cranial neurostimulator pulse generator or receiver
	95970	Electronic analysis of implanted neurostimulator pulse generator/transmitter (eg, contact group[s], interleaving, amplitude, pulsewidth, frequency [Hz], on/off cycling, burst, magnet mode, dose lockout, patient selectable parameters, responsive neurostimulation, detection algorithms, closed loop parameters, and passive parameters) by physician or other qualified health care professional; with brain, cranial nerve, spinal cord, peripheral nerve, or sacral nerve, neurostimulator pulse generator/transmitter, without programming

Codes	Number	Description
	95983	Electronic analysis of implanted neurostimulator pulse generator/transmitter (eg, contact group[s], interleaving, amplitude, pulse width, frequency [Hz], on/off cycling, burst, magnet mode, dose lockout, patient selectable parameters, responsive neurostimulation, detection algorithms, closed loop parameters, and passive parameters) by physician or other qualified health care professional; with brain neurostimulator pulse generator/transmitter programming, first 15 minutes face-to-face time with physician or other qualified health care professional
	95984	;with brain neurostimulator pulse generator/transmitter programming, each additional 15 minutes face-to-face time with physician or other qualified health care professional (List separately in addition to code for primary procedure)
HCPCS	C1820	Generator, neurostimulator (implantable), with rechargeable battery and charging system
	L8678	Electrical stimulator supplies (external) for use with implantable neurostimulator, per month
	L8679	Implantable neurostimulator, pulse generator, any type
	L8680	Implantable neurostimulator electrode, each
	L8681	Patient programmer (external) for use with implantable programmable neurostimulator pulse generator, replacement only
	L8682	Implantable neurostimulator radiofrequency receiver
	L8683	Radiofrequency transmitter (external) for use with implantable neurostimulator radiofrequency receiver
	L8685	Implantable neurostimulator pulse generator, single array, rechargeable, includes extension
	L8686	Implantable neurostimulator pulse generator, single array, nonrechargeable, includes extension
	L8687	Implantable neurostimulator pulse generator, dual array, rechargeable, includes extension
	L8688	Implantable neurostimulator pulse generator, dual array, nonrechargeable, includes extension
	L8689	External recharging system for battery (internal) for use with implantable neurostimulator

Medical Policy Manual Surgery, Policy No. 92

Radiofrequency Ablation (RFA) of Tumors Other than Liver

Effective: January 1, 2024

Next Review: November 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Radiofrequency ablation kills cells using the heat produced by radiofrequency energy delivered into the tumor via a probe.

MEDICAL POLICY CRITERIA

Note: This policy does not address liver tumors (primary or metastatic). See Cross References.

I. Radiofrequency ablation may be considered **medically necessary** to treat tumors when one or more of the following criteria are met:

   A. Localized renal cell carcinoma that is no more than 4 cm in size when one or both of the following criteria are met:

      1. Preservation of kidney function is necessary (i.e., the patient has one kidney or renal insufficiency defined by a glomerular filtration rate (GFR) of less than 60 mL/min per m^2) and standard surgical approach (i.e., resection of renal tissue) is likely to substantially worsen kidney function; or

      2. Patient is not considered a surgical candidate.

B. Osteoid osteomas that are unresponsive to initial medical treatment.

C. To palliate pain in patients with osteolytic bone metastases who have failed or are poor candidates for standard treatments (e.g., radiation).

D. Isolated peripheral non-small cell lung cancer (NSCLC) lesion that is no more than 3 cm in size when both of the following criteria are met:

1. Surgical resection or radiation treatment with curative intent is considered appropriate based on stage of disease, however, medical co-morbidity renders the individual unfit for those interventions; and
2. Tumor is located at least 1 cm from the trachea, main bronchi, esophagus, aorta, aortic arch branches, pulmonary artery and the heart.

E. Malignant non-pulmonary tumor(s) metastatic to the lung that are no more than 3 cm in size when all of the following criteria (1. – 3.) are met:

1. In order to preserve lung function when surgical resection or radiation treatment is likely to substantially worsen pulmonary status, or the patient is not considered a surgical candidate; and
2. There is no evidence of extrapulmonary metastases; and
3. The tumor is located at least 1 cm from the trachea, main bronchi, esophagus, aorta, aortic arch branches, pulmonary artery and the heart.

F. Renal angiomyolipomas when one or more of the following criteria are met:

1. Symptomatic lesion (e.g., hemorrhage), or
2. Asymptomatic lesion larger than 4 cm.

G. Benign thyroid nodules when the following criteria are met (1. – 2.):

1. Nodule is symptomatic; and
2. Nodule is confirmed as benign using fine needle aspiration (FNA)

II. Ultrasound-guided radiofrequency ablation (e.g., Acessa™, Sonata®) may be considered **medically necessary** for the treatment of symptomatic uterine fibroids when there are significant clinical manifestations or findings attributable to fibroids, including one or more of the following:

A. Abnormal uterine bleeding

B. Iron-deficiency anemia

C. Dyspareunia

D. Pelvic pain or pressure

E. Urinary or bowel dysfunction

III. Radiofrequency ablation is considered **investigational** as a technique for ablating all other benign or malignant tumors other than liver tumors that do not meet the policy criteria above including but not limited to breast tumors, initial treatment of osteoid osteomas and painful bony metastases, and all primary or metastatic lung (pulmonary) tumors that do not meet medical necessity.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

REQUIRED DOCUMENTATION

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

1. Specific description of the tumor(s) targeted for treatment including the following:
    - Tumor type (primary vs. metastatic; primary tumor type)
    - The location of tumor(s)
    - The number and size(s) of lesion(s) being treated
2. For requests for ultrasound-guided radiofrequency ablation for the treatment of symptomatic uterine fibroids, documentation of significant clinical manifestations or findings attributable to fibroids
3. Rationale for the determination that the patient is not a surgical candidate or the tumor is unresectable
4. Whether the goal of treatment is curative or palliative
5. Comorbidities and any contraindicated treatments (e.g., surgery; radiation therapy)
6. Prior treatments, if any, and tumor response
7. Documentation of whether this treatment is to preserve organ function

BACKGROUND

Radiofrequency ablation (RFA) was initially developed to treat inoperable tumors of the liver (see Cross References). Recently, studies have reported on the use of RFA to treat other tumors. For some of these, RFA is being investigated as an alternative to surgery for operable tumors. Well-established local or systemic treatment alternatives are available for each of these malignancies. The hypothesized advantages of RFA for these cancers include improved local control and those common to any minimally invasive procedure (eg, preserving normal organ tissue, decreasing morbidity, decreasing length of hospitalization).

Goals of RFA may include 1) controlling local tumor growth and preventing recurrence; 2) palliating symptoms; and 3) extending survival duration for patients with certain cancerous tumors. The effective volume of RFA depends on the frequency and duration of applied current, local tissue characteristics, and probe configuration (eg, single vs multiple tips). RFA can be performed as an open surgical procedure, laparoscopically or percutaneously, with ultrasound or computed tomography guidance.

Potential complications associated with RFA include those caused by heat damage to normal tissue adjacent to the tumor (e.g., intestinal damage during RFA of kidney), structural damage along the probe track (e.g., pneumothorax as a consequence of procedures on the lung), and secondary tumors (if cells seed during probe removal).

REGULATORY ISSUES

The U.S. Food and Drug Administration (FDA) issued the following statement September 24, 2008 concerning the regulatory status of radiofrequency ablation.[1] "The FDA has cleared RF ablation devices for the general indication of soft tissue cutting, coagulation, and ablation by thermal coagulation necrosis. Some RF ablation devices have been cleared for additional specific treatment indications, including partial or complete ablation of nonresectable liver lesions and palliation of pain associated with metastatic lesions involving bone. The FDA has not cleared any RF ablation devices for the specific treatment indication of partial or complete ablation of lung tumors, citing lack of sufficient clinical data to establish safety and effectiveness for this purpose. The FDA has received reports of death and serious injuries associated with the use of RF ablation devices in the treatment of lung tumors."

In 2012, the Acessa™ System (Acessa Health, formerly Halt Medical) was cleared for marketing by the U.S. Food and Drug Administration (FDA) through the 510(k) process for percutaneous laparoscopic coagulation and ablation of soft tissue and treatment of symptomatic uterine fibroids under laparoscopic ultrasound guidance (K121858). The technology was previously approved in 2010, at which time it was called the Halt 2000GI™ Electrosurgical Radiofrequency Ablation System. In 2014, the ultrasound guidance system received marketing clearance from the FDA (K132744). FDA product code: GEI. In 2018, the third-generation Acessa™ ProVu System® was cleared for marketing by the FDA through the 510(k) process for use in percutaneous, laparoscopic coagulation and ablation of soft tissue, including treatment of symptomatic uterine fibroids under laparoscopic ultrasound guidance. (K181124). FDA product code: HFG.

In 2018, the Sonata® Sonography-Guided Transcervical Fibroid Ablation System (Gynsonics) was cleared for marketing by the FDA through the 510(k) process for diagnostic intrauterine imaging and transcervical treatment of symptomatic uterine fibroids (K173703). The Sonata system was previously known as Vizablate. FDA product codes: KNF, ITX, and IYO.

EVIDENCE SUMMARY

RENAL CELL CARCINOMA

BACKGROUND

Radical nephrectomy, partial nephrectomy, or nephron-sparing surgery remains the principal treatments of renal cell carcinoma (RCC).

RFA may be considered a treatment option when surgical excision is not an option such as the following:

- When preservation of renal function is necessary (e.g., in patients with marginal renal function, a solitary kidney, bilateral tumors)
- In patients with comorbidities that would render them unfit for surgery.

- In patients at high risk of developing additional renal cancers (as in von Hippel-Lindau disease).

SYSTEMATIC REVIEWS

Green (2023) published a systematic review that evaluated metastasis-directed ablative therapies in extracranial metastatic renal cell carcinoma.[2] 18 prospective and matched-pair case control studies of RFA, cryotherapy, microwave ablation, and stereotactic body radiotherapy (SBRT) in metastatic renal cell carcinoma were included. Most were single-arm studies (n=17), and one study was an RCT. Overall, 570 patients were treated across studies: 56 were treated with cryotherapy (n=2 studies), 90 were treated with RFA (n=2 studies), and 424 (n=14 studies) were treated with SBRT. Study sample sizes ranged from 12 to 69 participants, and mean follow-up occurred at 17.3 months. A median overall survival of 22.7 months was reported in eight studies (five SBRT, two cryotherapy, and one RFA). Median progression-free survival was reported in seven studies (five SBRT, one cryotherapy, and one RFA); the median was 9.3 months (range 3.0 to 22.7 months). The toxicity grade greater than or equal to three ranged from 1.7% to 10%. Due to low sample size, direct comparison of SBRT to ablative studies was not feasible.

Li (2022) conducted a systematic review and meta-analysis to compare the long-term outcomes of RFA to partial nephrectomy for cT1 renal cancer.[3] Seven studies (n=1,635 patients) were included; reviews and case reports were excluded from the review and meta-analysis. Treatment efficacy of RFA was not different than partial nephrectomy in terms of cancer recurrence (OR=1.22, 95% CI, 0.45 to 3.28), progression-free survival (HR=1.26, 95% CI, 0.75 to 2.11), and cancer-specific survival (HR=1.27, 95% CI, 0.41 to 3.95) as well as major complications (OR=1.31, 95% CI, 0.55 to 3.14) ($p>0.05$ for all). RFA was a potential significant risk factor for overall survival (HR=1.76, 95% CI, 1.32 to 2.34, $p<0.001$). The authors did not identify significant heterogeneity or publication bias and concluded that RFA has comparable therapeutic efficacy to partial nephrectomy.

Yanagisawa (2022) published a systematic review (SR) with meta-analysis comparing differential clinical outcomes of partial nephrectomy (PN) versus ablation techniques, including RFA, cryoablation, and microwave ablation, for cT1b and cT1a renal tumors.[4] The review included 27 studies with 13,996 total patients who received either PN or ablation for treatment of their tumors. There were no differences in the percent decline of estimated glomerular filtration rates (eGFR) or in the overall complication rates between PN and ablation therapy for either tumor type. There was no difference in cancer mortality rates between PN and ablation in patients with either cT1a or cT1b tumors. However, compared to ablation, PN was associated with a lower risk of local recurrence in patients with either tumor type (cT1a: pooled risk ratio [RR]; 0.43, 95% confidence intervals [CI]; 0.28-0.66, cT1b: pooled RR; 0.41, 95%CI; 0.23-0.75). A majority of the included studies were retrospective with a significant heterogeneity in methodology.

In their systematic review and meta-analysis, Uhlig (2019) compared oncologic, perioperative, and functional outcomes for PNwith outcomes for various ablative techniques, including RFA and others, for small renal masses (mean diameter=2.53 to 2.84 cm).[5] They identified 47 moderate-quality studies, mostly retrospective, published from 2005 to 2017, including one RCT. A total of 24,077 patients were included, of whom 15,238 received PN and 1,877 received RFA. The network meta-analysis used PN as the reference point. Cancer-specific mortality and local recurrence were calculated as incidence rate ratio. According to the meta-

analysis, for RFA and PN, respectively, cancer-specific mortality was 2.03 and 1.00 (95% CI 0.81 to 5.08), local recurrence was 1.79 and 1.00 (95% CI 1.16 to 2.76), complications OR was 0.89 and 1.00 (95% CI 0.59 to 1.33), and renal function decline (mean difference in glomerular filtration rate) was 6.49 and 0.00 (95% CI 2.87 to 10.10). The overall results indicated that PN had better overall survival (OS) and local control over ablative techniques, but it was not significantly better for cancer-related mortality. In addition, ablation had fewer complications and better renal function outcomes. Across the studies included, patients treated by PN tended to be younger with less comorbidity compared with patients receiving thermal ablation—a consideration when assessing the outcomes for survival and local control.

A 2019 systematic review reported by Favi included a descriptive summary of ablative therapy for renal allograft tumors.[6] The 28 studies that met inclusion criteria assessed RFA (n=78), cryoablation (n=15), MWA (n=3), HIFU (n=3), and irreversible electroporation (n=1) for mainly papillary renal cell carcinoma (RCC) and clear cell RCC. All but two neoplasms were stage T1a N0 M0. In this population, three cases of primary treatment failure, a single case of recurrence, and no cancer-related deaths were reported. Complication rate was mostly below 10% and graft function remained stable in the majority of patients. No meta-analyses were performed and due to the limited sample size the authors were not able to determine a clear benefit of one procedure over the others.

An AHRQ Evidence Report, most recently amended in 2016, included thermal ablation (RFA or cryoablation; surgical or image-guided) as an available management strategies for stage I or II RCC.[7] The report noted that better oncologic outcomes were believed to be achieved with partial or radical nephrectomy; however, these procedures were associated with significantly higher complication rates than thermal ablation or active surveillance.

In 2014 Wang published a meta-analysis of 145 studies published through July 2013 comparing effectiveness and complications of radiofrequency ablation and partial nephrectomy (PN) for treatment of stage T1 renal tumors.[8] The rate of local progression was greater with RFA than laparoscopic/robotic or open partial nephrectomy (4.6%, 1.2%, 1.9%, respectively; $p<0.001$.) RFA had more frequent minor complications than laparoscopic/robotic or open partial nephrectomy (13.8%, 7.5%, 9.5%, respectively; $p<0.001$). However, the rate of major complications was greater with open partial nephrectomy than laparoscopic/robotic partial nephrectomy or RFA (7.9%, 7.9%, 3.1%, respectively, $p<0.001$). Several limitations to this meta-analysis were discussed in the article. These included the limited follow-up duration of the included studies and the unavailability of the original study data. Despite the limitations, the data was sufficient for the authors to conclude that both RFA and PN were viable in terms of short-term outcomes and low complication rates. RFA showed a higher risk of local tumor progression but lower complication rates.

RANDOMIZED CONTROLLED TRIALS

Since the systematic reviews reported above, no additional randomized controlled trials evaluating RFA as a treatment for renal cell carcinoma were identified.

NONRANDOMIZED STUDIES

Published studies have consistently reported fairly high success rates at up to six years follow-up; two to five re-ablation sessions were often necessary to achieve 95% tumor necrosis.[9-32] Numerous case series, while unreliable, consistently suggest that the benefits of RFA outweigh the risks in patients for whom nephrectomy is not possible. Current studies suggest

that physician specialty (i.e., interventional radiology, urology) and experience, and procedure approach (i.e., percutaneous, open, laparoscopic) may impact tumor recurrence and patient survival outcomes, and authors have recommended further study on these variables.

ADVERSE EVENTS

Reported complication rates have been low.[9-31, 33] Complications reported in the literature to date have included the following:

- Perinephric hematomas
- Hemorrhage
- Ureteral strictures
- Percutaneous urinary fistula
- Appendiceal perforation

BREAST TUMORS

BACKGROUND

The standard treatment for breast cancer is surgical excision by lumpectomy or mastectomy. Adjuvant radiation therapy, chemotherapy, and/or hormone therapy may also be used. If treated, fibroadenomas, benign tumors of the breast, are typically surgically excised.

SYSTEMATIC REVIEWS

Xia (2021) conducted a SR and meta-analysis of studies assessing RFA in patients with breast cancer and tumors that were 2 cm or smaller.[34] The primary endpoints of interest were technical success rate, complete ablation rate, and rate of complications. A total of 17 studies were identified, which accounted for 399 patients (401 lesions). Technical success rate ranged from 86.67% to 100% in the included studies; the pooled technical success rate was 99% (95% CI 98% to 100%). After RFA, the majority of patients underwent surgical tumor excision (65.74%, 261/397). The pooled complete ablation rate was 98% (95% CI 97% to 100%). The complication rate in the entire cohort was 6.8%; the most common complications were skin burn (2%), breast inflammation (1.5%), and infections (1%). The pooled complications rate was 2% (95% CI 1% to 4%). Local recurrence was reported in 10 studies (232 cases); there was no local recurrence reported after a median follow-up of 27 months in these patients. The authors noted that prospective studies evaluating the use of RFA alone are needed to validate the place in therapy.

In 2016, Chen reported results from a meta-analysis of clinical trials assessing the effect of RFA for breast cancer.[35] The authors pooled data from fifteen nonrandomized studies that were published between 2001 and 2012. Of the 15 studies, eight studies reported that the tumor size was <2 cm, five studies reported <3 cm, and the remaining two studies reported <5 cm; eleven studies reported complete ablation rate, from which pooled estimates were 89% (95% CI 85 to 93%) of patients receiving RFA achieved a complete ablation. Five studies reported recurrence rate, from which pooled data suggest no local recurrence at a maximum follow-up of 76 months. A statistical test of publication bias showed no potential publication bias (Z=0.78, p=0.436). The analyses were limited by small sample size of the included studies, and heterogeneity in patient selection; the authors conclude large, well-designed studies are necessary.

In 2010, Zhao conducted a systematic review of 38 studies on ablation techniques for breast cancer treatment published from 1994 to 2009.[36] Nine of the studies reviewed focused on RFA for small breast tumors ranging in size from 0.5 – 7 cm. Tumor resection was performed immediately after ablation or up to four weeks after RFA. Complete coagulation necrosis rates of 76% to 100% were reported. These studies were limited to feasibility or pilot studies that were difficult to compare due to heterogeneous patient and tumor characteristics and energy sources. In addition, the studies were conducted in the research setting rather than in clinical practice. The authors concluded that RFA for breast cancer tumors was feasible but further studies with longer follow-up on survival, tumor recurrence and cosmetic outcomes are needed.

Similarly, another 2010 review of 17 studies by Soukup reported that RFA for the treatment of breast tumors was feasible and promising.[37] However, while minimal adverse effects and complications occurred with breast RFA, the authors noted that incomplete tumor ablation remained a concern. Additional studies of health outcomes and refinement of the procedure were recommended.

RANDOMIZED CONTROLLED TRIALS

No randomized controlled trials of RFA as a treatment for breast tumors were identified.

NONRANDOMIZED STUDIES

Ito (2018) retrospectively studied the safety and efficacy of percutaneous RFA of breast carcinomas in 386 patients from 10 institutions treated with RFA between 2003 and 2009.[38] Patients were followed for a median of 50 months and ipsilateral breast tumor recurrence was more frequent in patients with initial tumor sizes of 2 cm or more (10% [3/30]) than those with initial tumors 2 cm or less (2.3% [8/355]; p=0.015). Ipsilateral breast tumor recurrence rates five years after RFA were 97%, 94%, and 87% in patients with initial tumor sizes of 1 cm or less, 1.1 to 2.0 cm, and greater than 2 cm, respectively. The authors concluded that RFA was safe for tumors of 2 cm or less. The retrospective design and lack of data on ipsilateral breast tumor recurrence for different types of chemotherapy and endocrine therapy and analyses to ascertain whether adjuvant chemotherapy or endocrine therapy influenced outcomes are the limitations of this study.

The efficacy and safety of using ultrasound-guided RFA for multiple breast fibroadenoma as an alternative to surgical resection were retrospectively analyzed by Li (2016).[39] From 2014 to 2016, 65 patients with 256 nodules were treated with ultrasound-guided RFA and complete ablation was achieved for 251 nodules (98.04%) after the first month of treatment; after the first and third months, tumor volume overall was reduced by 39.06% and 75.99%, respectively. The study reported minimal to no complications such as skin burns, hematoma, or nipple discharge. The retrospective design and short follow-up time limited the conclusions drawn from this study.

The remainder of the published evidence is primarily limited to nonrandomized studies with small numbers of patients.[40-51] These studies preclude conclusions due to methodologic limitations such as non-random allocation of treatment and a lack of appropriate comparison groups.

Systematic reviews, retrospective studies, and observational studies have reported varied and incomplete ablation rates as well as concerns about postablation tumor cell viability. Long-term

improvements in health outcomes have not been demonstrated. Additionally, available studies have not compared RFA with conventional breast-conserving procedures. For small breast tumors, further prospective study, with long-term follow-up, is needed to determine whether RFA can provide local control and survival rates compared with conventional breast-conserving treatment.

LUNG (PULMONARY) TUMORS

BACKGROUND

Surgery is the preferred treatment for primary non-small cell lung carcinoma (NSCLC). Patients with early-stage NSCLC who are not surgical candidates may be candidates for radiation treatment with curative intent. RFA is being investigated as a treatment of small primary lung cancers or lung metastases in patients who are not surgical candidates.

SYSTEMATIC REVIEWS

Laeseke (2023) conducted a systematic review and meta-analysis that compared the efficacy of image guided thermal ablation, including RFA, to SBRT in patients with stage IA NSCLC among studies with at least 40 patients.[52] Comparative and single-arm studies, as well as single treatments from comparative studies were included in the meta-analysis. Studies that enrolled patients with recurrent NSCLC, or that used interventions as salvage treatments, were excluded. Key outcomes of interest were local tumor progression, overall survival, and disease-free survival. 40 image-guided thermal ablation study-arms (n=2,691 patients) and 215 SBRT study-arms (n=54,789 patients) were identified. Local tumor progression was lowest after SBRT at years one and two in single-arm pooled analyses (4% and 9% versus 11% and 18%) and at one year in meta–regressions when compared to ablative therapies (odds ratio [OR]=0.2, 95% CI = 0.07 to 0.63). Microwave ablation patients had the highest disease-free survival of all treatments in single-arm pooled analyses. In meta–regressions at two and three years, disease-free survival was significantly lower for RFA compared to microwave ablation (OR=0.26, 95% CI = 0.12 to 0.58; OR=0.33, 95% CI = 0.16 to 0.66, respectively). Overall survival was similar across treatment types and time points. Older age, male patients, larger tumors, retrospective studies, and non-Asian study region were predictors of worse clinical outcomes. Among high quality studies, stage IA microwave ablation patients had lower local tumor progression, higher overall survival, and generally lower disease-free survival, compared to the main analysis of all NSCLC patients.

Sultan (2023) published a systematic review conducted by the Department of Veterans Affairs to compare the effectiveness of surgery to SBRT, stereotactic ablative radiotherapy (SABR), RFA, cryoablation, microwave ablation, laser ablation, and brachytherapy in patients with early-stage lung cancer.[53] The review authors did not identify any RCTs that examined ablation therapies for stage I lung cancer. RFA, cryoablation, microwave ablation, and laser ablation were assessed in non-randomized comparative studies. RFA was most often studied (k=11). Three retrospective studies compared any type of ablation with SBRT/SABR, and three retrospective studies compared RFA to SBRT/SABR. Ten retrospective studies reported on ablation compared to surgery (n=4 microwave ablation, n=4 RFA, n=2 combined ablation of any type, n=2 SBRT/SABR versus RFA versus surgery). Most of these studies (n=12) had 300 or fewer participants, except for six studies of the National Cancer Database and the Surveillance, Epidemiology and End-Results Database datasets which included 2,000-30,000 participants. All studies included older adults, and most studies did not report on whether participants were medically operable or inoperable. Two studies reported on only medically operable individuals. Due to heterogeneity of patient populations, interventions, and study designs, review authors did not pool data across studies to compare ablative therapies to surgery.

Chan (2021) published a SR and meta-analysis of CT-guided percutaneous ablation for stage I NSCLC.[54] A total of eight studies with 792 patients met inclusion criteria. Statistically significant differences were identified for one- and two-year disease-free survival, favoring surgery OR 2.22, 95% CI 1.14 to 4.34; OR 2.60, 95% CI 1.21 to 5.57 respectively). No statistically significant differences between groups were identified for one- to five-year OS or cancer-specific survival or three- to five-year disease-free survival. According to the subgroup analysis, there was no statistically significant difference in OS between lobectomy and microwave ablation but patients treated with sublobar resection (wedge resection or segmentectomy) had significantly longer one- and two-year OS versus RFA (OR 2.85, 95% CI 1.33 to 6.10; OR 4.54, 95% CI 2.51 to 8.21, respectively).

In a 2013 Agency for Healthcare Research and Quality (AHRQ) Comparative Effectiveness Review on local nonsurgical therapies for stage I non–small-cell lung cancer (NSCLC), no comparative RFA studies were identified.[55] The AHRQ report found available evidence is insufficient to draw conclusions on the comparative effectiveness of local nonsurgical therapies for NSCLC including RFA.

In a 2013 SR of RFA, surgical excision and stereotactic radiotherapy (SBRT) for colorectal cancer lung metastases, no randomized trials were identified and evidence was also insufficient to draw conclusions on the comparative effectiveness of these therapies.[56]

A 2011 SR also reported low quality evidence consisting of nonrandomized observational case series with no control group. The review included 46 studies with a total of 2,905 ablations in 1,584 patients.[57] The mean tumor size of 2.8 ± 1.0 cm. Local recurrence occurred in 282 cases (12.2%) and ranged from 0% to 64% as reported in 24 studies. Overall survival rates ranged from 25% to 100% with a mean of 59.4% as reported in 21 studies with a mean of 17.7 ± 12.4 months follow-up. The mean cancer-specific survival rate was 82.6% as reported in 24 studies with a range of 55% to 100% with a mean of 17.4 ± 14.1 months follow-up. Mean overall morbidity was 24.6% and most commonly included pneumothorax, pleural effusion and pain. Mortality related to the RFA procedure was 0.21% overall. The authors concluded RFA for the treatment of lung tumors demonstrated promise but that higher quality studies comparing RFA to other local treatment options “are urgently needed.”

In a 2012 review of evidence from 16 studies, Bilal compared RFA to SABR in patients with inoperable early stage non-small cell lung cancer (NSCLC).[58] The authors found overall survival rates for RFA and SABR were similar in patients at one year (68.2 to 95% vs. 81 to 85.7%) and three years (36 to 87.5% vs. 42.7 to 56%). However, survival rates at five years were lower with RFA (20.1 to 27%) than with SABR (47%). Caution must be used in interpreting these findings drawn from comparisons of results from uncontrolled, case series and retrospective reviews.

RANDOMIZED CONTROLLED TRIALS

No randomized controlled trials of RFA as a treatment for pulmonary tumors were identified.

NONRANDOMIZED STUDIES

Current studies consist of small case series, retrospective reviews, or uncontrolled cohort studies which focused primarily on technical feasibility and initial tumor response.[59-91]

One larger nonrandomized case series was published in 2011. Huang prospectively followed 329 consecutive patients treated with RFA for lung tumors.[92] Complications were experienced

by 34.3% (113) patients and was most commonly pneumothorax (19.1%). Overall survival at two and five years was 35.3% and 20.1%, respectively. The risk of local progression was not significantly different in tumors < 4 cm but became significant in tumors > 4 cm.

In 2015 de Baere review of a database from two cancer centers that included all consecutive patients (n=566) with lung metastases treated with RFA.[93] Median follow-up was 35.5 months (range 20 to 53 months) with 235 patients followed for more than two years. During follow-up, 176 patients died, of which 112 had progression of their lung tumor disease. Disease progression was also found in 227 of the 390 patients who were alive at last follow-up. Four-year local efficacy was 89% and lung disease control was 44.1%. Median overall survival was 62 months. Limitations of this study included the lack of a control group, and the lack of consideration of the impact of adjuvant chemotherapy.

Study quality concerns include lack of long-term follow-up, significant interstudy heterogeneity in terms of study design, patient populations and RFA methods used, and non-uniformity of reporting and efficacy scoring criteria. Prospective comparison in an RCT would permit greater certainty for this finding but the studies are consistent with some effect of RFA on lung tumors.

ADVERSE EVENTS

Acute, delayed or recurrent pneumothorax is the most commonly reported complication of lung RFA for primary or metastatic tumors (30 to 56% of treatment sessions).[84, 92, 94-97] Most cases resolved without chest tube placement. Other complications reported in the literature to date are considered uncommon and include, but are not limited to:[96-101] pleural effusion, intrathoracic hemorrhage with or without hemothorax, hemoptysis, pneumonia, pneumonitis, stellate ganglion injury, and brachial plexus injury.

OSTEOID OSTEOMAS

BACKGROUND

Osteiod osteomas (OO) usually heal spontaneously in three to four years and standard initial treatment includes medical management with NSAIDs. Invasive procedures including open surgery, laser photocoagulation, radiofrequency ablation, or core drill excision may be necessary if symptoms cannot be managed with NSAIDs.

SYSTEMATIC REVIEWS

Sangiorgio (2022) published a SR with meta-analysis to evaluate the safety and efficacy of radiofrequency ablation (RFA) versus surgical excision (SE) for the treatment of spinal OO. A total of 31 studies (n=749 patients) were included.[102] The main outcomes were pain before and after intervention, treatments success rate (complete pain relief with no recurrence until the last follow-up) and the number and type of complications. The reported mean treatment success rate was 85.6% (19 studies) for the SE group and 88.6% for the RFA group (18 studies). At last follow-up, the pooled mean difference in pain scores from baseline on a 0–10 scale was 5.8 points in the SE group and 6.7 points in the RFA group. Recurrences were observed in 5.6% of the patients who underwent SE and in 6.7% of the patients treated with RFA. The complication rate was 7.8% in the SE group and 4.4% in the RFA group. The authors conclude that the complication rate was low for both treatments and that RFA is a less invasive procedure which is as a safe and effective option for the treatment of spinal OO.

Lindquester (2020) reported a SR of various thermal ablation techniques for the treatment of OOs.[103] Of the total of 36 studies that met inclusion criteria (n=1798 patients), 32 evaluated RFA, three evaluated cryoablation, and one evaluated microwave ablation. The overall success rate, defined as all ablations minus technical failures, clinical failures, and recurrences, was 91.9% (95% CI 91 to 93%). The rates of technical failure, clinical failure, and recurrence were 0.3%, 2.1%, and 5.6%, respectively. Complications occurred in 2.5% (95% CI 1.9 to 3.3%) of patients.

RANDOMIZED CONTROLLED TRIALS

No randomized controlled trials of RFA as a treatment for osteoid osteomas were identified.

NONRANDOMIZED STUDIES

Numerous nonrandomized uncontrolled case series have consistently suggested that the benefits of RFA outweigh the risks in patients who require treatment due to failed response to nonsurgical treatments.[104-111]

SECTION SUMMARY

Despite the weaknesses in the published clinical evidence, RFA of osteomas has become a standard of care for osteomas that have failed standard treatments. This was based on the lower morbidity and quicker recovery time associated with the procedure compared with open surgery. The risk of osteoma recurrence with RFA is 5 to 10%; recurrent tumors can be retreated with RFA. There are minimal clinical trial data on the risks and benefits of RFA as initial treatment of osteoid tumors. Since most of these tumors heal spontaneously with medical treatment, the necessity of surgical intervention as initial treatment is unclear.

PALLIATION OF PAIN FROM BONE METASTASES

BACKGROUND

External beam irradiation is often the initial palliative therapy for osteolytic bone metastases. However, pain from bone metastases is refractory to radiation therapy in 20% to 30% of patients, while recurrent pain at previously irradiated sites may be ineligible for additional radiation due to risks of normal tissue damage. Other alternatives include hormonal therapy, radiopharmaceuticals such as strontium-89, and bisphosphonates. Less often, surgery or chemotherapy may be used for palliation and intractable pain may require opioid medications. RFA may be considered another alternative for palliating pain from bone metastases.

SYSTEMATIC REVIEWS

Mehta (2020) published a systematic review and meta-analysis of RFA for painful osseous metastases.[112] A total of 14 studies with 426 patients met inclusion criteria. The median pain reduction at a median follow-up of 24 weeks post-RFA was 67% (R^2=-0.66, 95% CI -0.76 to -0.55, I^2=71.24%). Pain scores were not significantly affected by primary tumor type or tumor size.

A systematic review reported by Gennaro (2019) assessed four percutaneous thermal ablation techniques for pain reduction in patients with bone metastases.[113] A total of eleven studies addressing RFA (n=3), MWA (n=1), cryoablation (n=2), and MRgFUS (n=5) were included (total n=364 patients). Mean pain reduction for all techniques combined ranged from 25 to 91%

at four weeks and from 16 to 95% at 12 weeks. There were no complications in the MWA group while the MRgFUS group had the highest complication rate. Overall, the number of minor complications reported ranged from 0 to 59 and the number of significant adverse events ranged from 0 to 4.

RANDOMIZED CONTROLLED TRIALS

No randomized controlled trials of RFA as a treatment for palliation of pain from bone metastases were identified.

NONRANDOMIZED STUDIES

Levy (2020) conducted a global, multicenter, nonrandomized, prospective postmarketing study to evaluate the effectiveness of RFA in patients with painful osteolytic bone metastases.[114] Between October 2017 and March 2019, 134 ablations were performed in 100 patients (68% vs. 32% of the cohort had a single vs. multiple sites treated, respectively). The most common tumor location was thoracic (44%) followed by lumbar (33%). Patient outcomes including pain, pain interference, and quality of life were collected. Forty percent of the cohort did not participate through the six-month follow-up, with two additional discontinuations after six months. The most common reason for discontinuation was death (30 patients), which were all classified as related to the underlying malignancy. The primary endpoint evaluated was pain improvement, from baseline to three months. At baseline, the mean score for worst pain (measured by Brief Pain Inventory) for the entire cohort was 8.2. After RFA, worst pain significantly improved, with mean scores decreasing to 5.6, 4.7, 3.9, 3.7, and 3.5 at three days, one week, one month, three months, and six months, respectively ($p<0.0001$ for all visits). Immediate improvement in pain (≥ 2-point change in worst pain at the treatment site(s) three days after RFA) was achieved by 59% of patients. Four adverse events were reported, of which two resulted in hospitalization for pneumonia and respiratory failure, respectively.

Additional nonrandomized evidence is limited to data from small, poorly designed case series.[115-119] However, though small and uncontrolled, available studies consistently reported significant improvement in pain following RFA in patients who failed or were poor candidates for standard treatments. Clinical trial data is lacking for use of RFA as an alternative to conventional techniques for initial treatment of painful bony metastases.

ANGIOMYOLIPOMA

BACKGROUND

Angiomyolipomas (AMLs) or angiomyolipomata are rare benign tumors that contain blood vessels, smooth muscle, and fat. They are usually associated with the kidneys but may also be in the liver or other locations. They are more frequently seen in patients with tuberous sclerosis complex (TSC). These lesions are usually asymptomatic but may hemorrhage, particularly if large (4 cm or larger). Treatment consists of surveillance as long as the lesion remains small and asymptomatic. Treatment or prevention of hemorrhage may include surgical resection, arterial embolization, or laparoscopic or percutaneous ablation.

PUBLISHED STUDIES

Due to the rare nature of these tumors, there is limited published evidence on the tumor management.[120-125] The current studies have significant methodological limitations including retrospective records review, small size (n=4 to 32), heterogeneity of patients and treatment

modalities, and short-term follow-up. However, the available studies consistently reported low rates of complications and high rates of successful ablation, generally without recurrence at mean follow-up ranging between 9 and 45 months. Some larger tumors (>3.5 cm) required two RFA sessions. Minor complications included transient perinephric hematoma, intercostal nerve transection. A patient in one early study developed a small skin metastasis at the electrode insertion site which was resected and did not recur.

SECTION SUMMARY

Because this is a rare tumor that is often identified incidentally and may not require treatment, it is unlikely that large randomized controlled trials or comparative studies will become available. Due to the risk of potentially life-threatening hemorrhage in large (≥4 cm) AMLs and the low rate of adverse effects, treatment of symptomatic or large lesions may be warranted.

HEAD AND NECK TUMORS

BACKGROUND

Tumors of the head and neck arise in the lip, oral cavity, pharynx, larynx, paranasal sinuses and salivary glands. Treatment depends on the location and extent of the disease.[126] Standard treatment for patients with early-stage disease (stage I or II) is single-modality with surgery or radiation therapy. The two modalities result in similar survival. Combined modality therapy is required for locally advanced disease. In patients with recurrent head and neck cancer, surgical salvage attempts are poor in terms of local control, survival and quality of life, and these recurrent tumors are often untreatable with standard salvage therapies. Palliative chemotherapy or comfort measures may be offered.

SYSTEMATIC REVIEWS RANDOMIZED CONTROLLED TRIALS

No systematic reviews or randomized trials evaluating the safety and effectiveness of RFA for treatment of head and neck tumors were identified.

NONRANDOMIZED STUDIES

Current published evidence is limited to poorly designed case series, feasibility, and retrospective studies that are considered unreliable due to lack of a control group for comparison and lack of randomization to control for bias.[127-131]

In addition to these methodological limitations, prospective case series included small numbers of patients. Small study populations limit the ability to rule out the role of chance as an explanation of study findings.

ADVERSE EVENTS

Complications and adverse events are reported to be uncommon, but are often severe. They are generally related to burning of local soft tissue (e.g., fistula formation).[127-130]

THYROID CANCER

BACKGROUND

Thyroid carcinoma is uncommon, with a lifetime risk of being diagnosed with thyroid carcinoma less than 1%. Thyroid carcinoma occurs two to three times more often in women than men.

The main histological types of thyroid carcinoma include: 1) differentiated (including papillary, follicular, and Hürthle); 2) medullary; 3) anaplastic (aggressive undifferentiated tumor). All anaplastic thyroid carcinomas are considered stage IV and are almost uniformly lethal, however most deaths are from papillary, follicular, and Hürthle cell carcinomas, which account for nearly 95% of thyroid carcinoma cases. The treatment of choice for differentiated thyroid carcinoma is surgery followed by radioiodine in selected patients and thyroxine therapy in most patients. There is no effective therapy for anaplastic thyroid carcinoma; most are unresectable, but EBRT may improve local control and provide palliation. Surgical resection is the primary treatment choice for medically unresponsive, symptomatic benign thyroid tumors and thyroid carcinomas. However, techniques for ablation of thyroid tumors (eg, RFA, microwave ablation) are being investigated.

SYSTEMATIC REVIEW

Sun (2022) published a SR to evaluate tumor progression and complications between RFA and thyroidectomy for patients with Papillary thyroid cancer (PTC) or papillary thyroid microcarcinoma (PTMC).[132] Six retrospective, single -center non randomized studies (1708 patients) were included in their analysis (two for PTC and 4 for PTMC). The tumor progression of the RFA group was similar to the surgical groups [odds ratio, 1.31; 95% CI, 0.52-3.29; heterogeneity (I2 statistic), 0%, p = 0.85]. The risk of complication rates was significantly lower in the RFA group than that in the surgical group [odds ratio, 0.18; 95% CI, 0.09-0.35; heterogeneity (I2 statistic), 40%, p = 0.14]. The authors conclude that RFA can achieve a good efficacy and has a lower risk of major complications. The authors indicate that multi-center, large-scale studies with sufficient follow-up (minimum 5 years) analysis are needed.

Cho (2021) reported a systematic review and meta-analysis of five-year outcomes of thermal ablation for papillary thyroid microcarcinoma.[133] A total of three studies (including 207 patients) met inclusion criteria. No local tumor recurrence, lymph node metastasis, distant metastasis or delayed surgery were reported during a mean pooled 67.8-month follow-up. The pooled mean major complication rate was 1.2%, with no reported life-threatening or delayed complications. New tumors in the remaining thyroid gland were successfully treated by repeat thermal ablation in four patients.

Choi (2020) reported a systematic review of thermal ablation techniques for the treatment of primary papillary thyroid microcarcinoma.[134] A total of 11 studies of radiofrequency-, laser-, and microwave-ablation met inclusion criteria. The included 715 patients were pooled for analysis. There was significant between-study heterogeneity for complete disappearance ($p<0.001$, I^2 99%), mean volume reduction ($p<0.001$, I^2 93%), and volume reduction rate ($p <0.001$, I^2 86%). A subgroup analysis showed heterogeneity of the complete disappearance proportion among the treatment modality (I^2 range 95 to 100%). The pooled estimates of complete disappearance, mean volume reduction, and volume reduction rate were 57.6% (95% CI 35.4 to 79.8), 73.5 mm3 (52.4 to 94.6 mm3), and 98.1% (95% CI 96.7 to 99.5), respectively. RFA showed the highest mean volume reduction rate (99.3%), followed by MWA (95.3%) and LA (88.6%; $p<0.001$). The pooled proportions of overall and major complications were 3.2% (95% CI 1.1 to 5.2) and 0.7% (95% CI 0 to 1.5), respectively.

RANDOMIZED CONTROLLED TRIALS

No new RCTs were published since those included in the systematic reviews summarized above.

NONRANDOMIZED STUDIES

Xiao (2021) published a retrospective study of RFA for solitary T1aN0M0 and T1bN0M0 papillary thyroid carcinoma.[135] The overall local tumor progression (LTP) rate was 3.82%. LTP and LTP-free survival rates were not significantly different between those with T1a and T1b disease. One patient with T1b disease developed transient recurrent laryngeal nerve injury. There was an 81.7% rate tumor disappearance in those with T1a disease and 52.7% in those with T1b disease (p<0.001).

Cao (2021) reported a multicenter retrospective study of thermal ablation for the treatment of solitary T1N0M0 papillary thyroid carcinoma.[136] A total of 847 patients were included, of whom 645 underwent MWA and 202 underwent RFA. Statistically significant reductions in tumor size were reported at six, nine, and twelve months (p<0.001). There was complete disappearance of tumors in 68% of T1a patients and 64% of T1b patients (p<0.001). Postablation disease progression occurred in 1.1% of T1a patients and 1.7% of T1b patients (p=0.54). The overall complication rate was 3.4%.

In 2016, Kim reported on a comparative review of 73 patients with recurrent thyroid cancer smaller than 2 cm who had been treated with RFA (n=27) or repeat surgery (n=46).[137] RFA was performed in cases of patient refusal to undergo surgery or poor medical condition. Data were weighted to minimize potential confounders. The three-year recurrence-free survival rates were similar for RFA (92.6%) and surgery (92.2%, p=0.681). Posttreatment hoarseness rate did not differ between the RFA (7.3%) and surgery (9.0%) groups. Posttreatment hypocalcemia occurred only in the surgery group (11.6%).

ADVERSE EVENTS

In 2017, Chung reported results of a systematic review and meta-analysis evaluating the safety of RFA for benign thyroid nodules and recurrent thyroid cancers.[138] Twenty-four studies were included, totalling 2,421 participants and 2,786 thyroid nodules. Overall, 41 major complications and 48 minor complications (as defined by the Society of Interventional Radiology) of RFA were reported, giving a pooled proportion of 2.38% for overall RFA complications (95% CI 1.42% to 3.34%) and 1.35% for major RFA complications (95% CI 0.89% to 1.81%). Subgroup analysis found major complication rates were significantly higher for malignant thyroid nodules than for benign. Major complications included voice change, nodule rupture, permanent hypothyroidism, and brachial plexus injury. Minor complications included pain, hematoma, vomiting, skin burns, and transient thyroiditis.

BENIGN THYROID TUMORS (NODULES)

Thyroid nodules (including multinodal goiter) that have been verified as benign using fine needle aspiration (FNA) may require treatment when they cause symptoms, such as obstruction or compression.

SYSTEMATIC REVIEWS

In 2021, Monpeyssen published a systematic review of RFA for the treatment of benign thyroid nodules.[139] The 17 included studies addressed RFA for the treatment of benign solid (nonfunctioning or autonomous) thyroid nodules with at least 18 months of follow-up. At 12-monhts post-procedure, the volume reduction rate was 67% to 75% from a single procedure

and 93.6% for nodules that received multiple ablations. The 12-month regrowth rate was reported between 0% and 34%.

Cho (2020) reported a systematic review of the efficacy of thermal ablation (RFA and laser ablation) for the treatment of benign thyroid nodules.[140] The analysis demonstrated long-term maintenance (up to 36 months) of volume reduction. Further, RFA was found to be superior to laser ablation. The volume reduction rate for RFA at last follow up was 92.2%, whereas in the laser ablation group, the volume reduction rate peaked at 12 months (52.3%) and was at 43.3% at last follow up.

A 2019 systematic review and meta-analysis was reported by Trimboli on the efficacy of thermal ablation for benign non-functioning solid thyroid nodules.[141] Twelve studies per therapy were identified addressing RFA and laser ablation, with three RCTs on RFA and four on laser ablation. The remainder were prospective and retrospective cohort studies. Overall there was high heterogeneity. Only studies with six months or longer follow-up were included and median follow-up was 12 months. The primary outcome was the volume reduction rate at 6, 12, 24, and 36 months. The volume reduction rate for the RFA group was 68%, 75%, and 87%, respectively, with insufficient 36-month reporting for analysis. The volume reduction rate for the laser ablation group was 48%, 52%, 45%, and 44%, respectively.

In 2014 Fuller reported on a systematic review and meta-analysis of studies on RFA for benign thyroid tumors.[142] Included in the review were nine studies (five observational studies[143-147], four randomized studies[148-151]) totaling 306 treatments. After RFA, statistically significant improvements were reported in nodule size reduction (29.77 mL; 95% CI -13.83 to -5.72), combined symptom improvement and cosmetic scores on the 0 to 6 scale (mean, -2.96; 95% CI -2.66 to -3.25) and withdrawal from methimazole (odds ratio, 40.34; 95% CI 7.78 to 209.09). Twelve adverse events were reported, two of which were considered significant but did not require hospitalization.

RANDOMIZED CONTROLLED TRIALS

No new RCTs were published since those included in the systematic reviews summarized above.

NONRANDOMIZED STUDIES

Kandil (2022) published a prospective, cohort study of benign thyroid nodules (n=233) treated with RFA at two institutions.[152] The median and interquartile range of volume reduction rate (VRR) at 1, 3, 6, and 12 months were 54% [interquartile range (IQR): 36%-73%], 58% (IQR: 37%-80%), 73% (IQR: 51%-90%), and 76% (IQR: 52%-90%), respectively ($p<0.001$). Four patients presented with toxic adenomas and two patients developed temporary hoarseness of voice, but no hematoma or nodular rupture occurred postprocedure. All patients were confirmed euthyroid at 3-month postprocedure follow-up. The authors also report that VRR was significantly related with elastography with stiff and mixed elasticity more likely to have lower VRR than soft nodules. The authors conclude that RFA is a safe and effect treatment option that allows preservation of thyroid function with minimal risk of procedural complications.

ADVERSE EVENTS

See the systematic review above by Chung (2017) that addressed the safety of RFA for benign thyroid nodules and recurrent thyroid cancers and reported significantly higher major complication rates for malignant thyroid nodules than for benign nodules.

CHOLANGIOCARCINOMAS

BACKGROUND

Cholangiocarcinomas are tumors that originate in the bile duct epithelium; 90% are adenocarcinomas. Intrahepatic cholangiocarcinomas (ICC) are located within the hepatic parenchyma and are reviewed under Ablation of Primary and Metastatic Liver Tumors, Surgery, Policy No. 204 (see Cross References for a link to the policy). They may also be referred to as peripheral cholangiocarcinomas. Extrahepatic cholangiocarcinomas (ECC) are more common than intrahepatic cholangiocarcinoma and are located within the extrahepatic bile duct. Complete resection with negative margin is potential curative, though recurrence is common and most cases are unresectable due to advanced disease when diagnosed. For unresectable or metastatic cholangiocarcinomas at any location, the primary treatment may include chemotherapy, treatment within a clinical trial, or best supportive care. RFA and other locoregional therapies may be an option. Biliary drainage with biliary stenting may be warranted for unresectable or metastatic extrahepatic disease. Liver transplantation is potentially curative in carefully selected patients with lymph node negative, nondisseminated locally advanced hilar cholangiocarcinomas and otherwise normal biliary and hepatic function or underlying liver disease precluding surgery.

SYSTEMATIC REVIEWS AND RANDOMIZED CONTROLLED TRIALS

No systematic reviews or randomized controlled trials regarding radiofrequency ablation for the treatment of extrahepatic cholangiocarcinomas were identified.

NONRANDOMIZED STUDIES

The evidence for ECC consists of a single short-term case series.[153] This study included 11 patients with hilar ECC. At one-month follow-up after RFA, the reduction in tumor size was 30% in six tumors, 20% in two tumors, and size was unchanged in three tumors. At six months following RFA, the overall size reduction was 35%, with the largest reduction 60%. Overall survival ranged from 10-30 months.

UTERINE FIBROIDS (LEIOMYOMAS OR MYOMAS)

BACKGROUND

Uterine fibroids, also known as leiomyomas or myomas, are benign smooth muscle tumors of the uterus occurring in women during their reproductive years. They frequently occur in multiples, and the tumor location within the uterus is often used to describe the fibroids (intramural, submucosal, subserosal, or cervical myomas). Surgery, including hysterectomy and various myomectomy procedures, is considered the criterion standard treatment for symptom resolution. There has been long-standing research interest in developing minimally invasive alternatives for treating uterine fibroids, including procedures that retain the uterus and allow for future childbearing. Various techniques to induce myolysis have also been studied including Nd:YAG lasers, bipolar electrodes, cryomyolysis, and radiofrequency

ablation. With these techniques, an energy source is used to create areas of necrosis within uterine fibroids, reducing their volume and thus relieving symptoms.

SYSTEMATIC REVIEWS

Polin (2022) published a SR of pregnancy outcomes after radiofrequency ablation (RFA) of uterine myomas.[154] Ten publications were included in the review. There were 50 pregnancies reported among 923 RFA patients: 40 pregnancies after 559 laparoscopic RFAs and 10 pregnancies after 364 transcervical RFAs. Most patients had between 1 and 3 myomas ablated, and myomas size ranged from <2 cm to 12.5 cm. The authors reported two complications of the 44 deliveries (placenta previa and delayed postpartum hemorrhage). There were no cases of uterine rupture, uterine window, or invasive placentation and no fetal complications. The spontaneous abortion rate (12%) was comparable with the general obstetric population. The authors conclude that hat radiofrequency myoma ablation may offer a safe and effective alternative to existing treatments for women who desire future fertility.

Morris (2022) completed a SR evaluating the associations between minimally invasive approaches to fibroid treatment and quality of life (QoL) or fibroid-associated symptoms.[155] A total of 37 studies were included (26 evaluating individual approaches and 11 comparative studies of minimally invasive approaches and surgical interventions). Radiofrequency ablation and ultrasound-guided sclerotherapy (USGS) significantly improved overall QoL. The authors conclude that outcomes among minimally invasive approaches were similar, presenting patients with numerous non-surgical options for fibroid treatment.

Zhang (2022) published a SR evaluating the efficacy of uterine-preserving, minimally invasive treatment modalities in reducing fibroid-related bleeding.[156] Eighty-four studies were included in the review (10 RCTs and 74 observational studies). Fifteen studies demonstrated significantly reduced bleeding severity after radiofrequency ablation (RFA). The authors conclude that additional research is needed to determine best practices and that long-term evidence is limited in current literature.

Arnreiter and Oppelt reported on the safety and efficacy of transcervical ultrasound-guided RFA using the Sonata system in a 2021 systematic review.[157] A total of 10 studies met inclusion criteria, all of which were rated as fair quality on the Newcastle Ottawa Scale (NOS). The reported reduction in total and perfused myoma volume was 63.2% and 64.5%. Clinically meaningful reduction in menstrual blood loss after 12 months was achieved in 87.2% of patients. Symptom Severity Scores dropped by 28.8 ± 19.3, 23.3 ± 23.7, and 23.7 ± 19.4 points at three, six, and twelve months and Health-Related Quality of Life Scores increased to 77.5 ± 22.0, 82.8 ± 19.0, and 83.3 ± 20.5 points. The reintervention rate at an average of 64 months post-ablation was 11.8%. Time to return to activities of daily life was 2.9 ± 2.5 days. There were three reported pregnancies following ablation, all of which were without complications.

Berman (2020) conducted a retrospective review of pregnancy delivery and safety after laparoscopic RFA of uterine fibroids.[158] The review included results from two RCTs, six cohort studies, and commercial cases (total N=28) that evaluated rates of spontaneous abortion, preterm delivery, postpartum hemorrhage, placental abnormalities, intrauterine growth restriction, and rates of cesarean delivery. Thirty pregnancies resulted in 26 full-term births (86.7%), with an equal distribution of vaginal and cesarean deliveries, and the spontaneous abortion rate (13.3%) was within the range for the general population. There were no cases of preterm delivery, uterine rupture, placental abruption, placenta accreta, or intrauterine growth

restriction. One patient experienced severe postpartum hemorrhage. More rigorous prospective studies evaluating pregnancy outcomes after laparoscopic RFA are needed.

Bradley (2019) published a systematic review and meta-analysis of RFA for the treatment of uterine fibroids.[159] A total of 32 articles representing 20 studies of percutaneous laparoscopic (19 articles; Accessa device; n=461 patients), transvaginal (8 articles; n=579 patients), and transcervical RFA (5 articles; Sonata device; n=214 patients) met inclusion criteria. The number of patients ranged from 11 to 153 and the mean follow-up ranged from in-hospital to 64 months. Study quality was rated as good or fair for 19 of 20 studies. A meta-analysis was conducted of 1,283 patients at the 12-month follow-up. The weighted mean time to discharge was 8.2 hours (95% CI 6.3 to 10.0 hours) and the weighted mean time to normal activities was 5.2 days (95% CI 3.3 to 7.1 days). There was a decrease in fibroid volume of 66%, an increase in health-related quality of life by 39 points, and a decrease in symptom severity score of 42 points (all $p<0.001$ versus baseline). The annual cumulative rates of reintervention due to fibroid-related symptoms were 4.2%, 8.2%, and 11.5% at one, two, and three years, respectively. Complication reporting within the included studies was highly inconsistent and inadequate and therefore was not reported in this systematic review. However, the authors noted that no serious procedural complications such as death or iatrogenic injury to the bowel, bladder, or ureter were reported in any study. There were no statistically significant differences across RFA approaches for reintervention rates or fibroid volume reduction, but procedure time was significantly different (all pairwise comparisons $p\leq0.002$), with laparoscopic being longest (73 minutes) followed by transcervical (44 minutes) and transvaginal (24 minutes).

A systematic review and meta-analysis by Sandberg (2018) evaluated the risk of reintervention for hysterectomy and QOL after uterine-sparing interventions for fibroids.[160] Risk of reintervention at 12 months was 0.3% for radiofrequency volumetric thermal ablation (RFVTA) compared with 3.6% for UAE and 1.1% for myomectomy. Symptom severity and QOL scores were similar for the three treatments. Only one RFVTA study was identified on reintervention risk at 36 months; none was identified on reintervention risk at 60 months.

A systematic review by Havryliuk (2017) that did not separate outcomes by the length of follow-up found a reintervention rate of 5.2% after RFVTA (four studies, 12- to 36-month follow-up) compared to 4.2% after myomectomy (six studies, 12- to 52-month follow-up).[161] There was no significant difference in complication rates between RFVTA (6.3%) and myomectomy (7.9%). The length of stay after myomectomy was two days (range 0.5 to 6.0). No data were provided on length of stay after RFVTA.

Lin (2018) conducted a meta-analysis of improvement in symptom severity, QOL, and reintervention after laparoscopic radiofrequency ablation.[162] The review included one RCT and seven non-comparative trials. The recurrence risk at a weighted mean follow-up of 24.65 months (range, 3 to 36 months) was 4.4%. Improvements in symptoms and QOL were maintained out to 24 months in three studies and out to 36 months in one study. No studies were identified that had follow-up longer than 36 months.

RANDOMIZED CONTROLLED TRIALS

Rattray (2018) and Yu (2022) published three- and 12-month outcomes of a RCT comparing laparoscopic radiofrequency ablation (Lap-RFA) and myomectomy for patients with symptomatic uterine leiomyomas (ULs).[163, 164] Patients (n=57) were randomized to either laparoscopic RFA (n=30) or myomectomy (n=27). There was a significant improvement in UL symptoms at 3 and 12 months after the procedure within each treatment group, and these

improvements were similar between treatment groups. At 3 and 12 months after the procedure, the percentages of patients who were hospitalized in the LAP-RFA group were 74% and 49% lower than those of patients in the laparoscopic myomectomy group, respectively, with the 3-month difference being statistically significant. The authors conclude that LAP-RFA has lower healthcare resource use overall, including lower postprocedure hospitalization rate and shorter length of stay. Both studies reported 1 (<1%) serious adverse event within 30 days of the procedure. No efficacy outcomes were reported. The authors conclude that the results suggest that LAP-RFA is a safe, effective, uterine-sparing alternative to laparoscopic myomectomy in the treatment of ULs.

In Germany in 2014, Brucker published a single-center manufacturer-sponsored randomized controlled trial (RCT) comparing radiofrequency volumetric thermal ablation (RFVTA) with the Acessa system to laparoscopic myomectomy.[165] The trial included 51 premenopausal women at least 18 years old with symptomatic uterine fibroids less than 10 cm in any diameter and a uterine size of less than 17 weeks of gestation. Pregnancy and lactation were exclusion criteria. Prior to randomization, all women underwent laparoscopic ultrasound mapping. Data on 50 of the 51 women were analyzed. The primary study outcome, mean (SD) time to hospital discharge, was 10.0 (5.5) hours in the RFVTA group and 29.9 (14.2) hours in the myomectomy group. The criterion for noninferiority (no more than 10% longer hospital stay with RFVTA than laparoscopic myomectomy) was met at a significance level of $p<0.001$. All patients in the myomectomy group were hospitalized overnight; although not explicitly stated, this appeared to be the standard procedure at the study hospital. In the Acessa group, there was one unplanned hospitalization due to unexplained vertigo and four hospitalizations as standard procedure because the patients also underwent adhesiolysis.

Secondary outcomes of the RCT were reported in a 2015 publication by Hahn [166] (12-month outcomes) and a 2016 publication by Kramer [167] (24-month outcomes). Analysis was per protocol and 43 (84%) of 51 randomized participants were available for both the 12- and 24-month analyses. Each publication reported on 12 symptoms: heavy menstrual bleeding, increased abdominal gait, dyspareunia, pelvic discomfort/pain, dysmenorrhea, urinary frequency, urinary retention, sleep disturbance, backache, localized pain, and “other symptoms” (not specified). At 12 months, no participants reported four of the symptoms (dyspareunia, urinary retention, sleep disturbance, uterine pain) and there were no statistically significant between-group differences in the frequency of any of the remaining eight symptoms (at the $p<0.05$ level). The most commonly reported symptom at 12 months (heavy menstrual bleeding) occurred in seven (33%) of women in the RFVTA group and two (9%) of women in the laparoscopic myomectomy group ($p=0.069$) after controlling for baseline bleeding. At 24 months, no participants reported urinary retention or “other” symptoms, and there were no statistically significant between-group differences in any of the 10 reported symptoms. The most commonly reported symptom at 24 months (dysmenorrhea) occurred in eight (38%) in the RFVTA group and in seven (32%) in the laparoscopic myomectomy group ($p=0.67$). Patients were also assessed using several validated questionnaires (eg, the Uterine Fibroid Symptom and Quality of Life). There were no statistically significant between-group differences at 12 or 24 months on these validated questionnaires. In addition, the authors described pregnancy outcomes. Three patients in the RFVTA group conceived and all delivered a healthy neonate; the number of women who desired to become pregnant was not reported. Limitations of the 12- and 24-month analyses included lack of intention-to-treat analysis and failure to describe secondary study hypotheses and statistical analyses clearly. The RCT was relatively small in size and thus may have been underpowered to detect clinically meaningful

differences in secondary outcomes, so these results do not rule out potential differences between treatments.

NONRANDOMIZED STUDIES

Shifrin (2021) conducted a subgroup analysis of patients with submucous (type 1, 2, or 2-5) or large fibroids (> 5 cm) from patients in the FAST-EU and SONATA clinical trials.[168] In total, 72.5% of the 534 treated fibroids were not amenable to hysteroscopic resection because they were intramural, transmural, or subserous. At 3 month follow-up, 86% of women with only submucous fibroids and 81% of women with large fibroids experienced bleeding reduction. At 12 month follow-up, a reduction in menstrual bleeding was found in 92% to 96% of women with submucous fibroids and 86% to 100% of women with large fibroids (although fibroids >5 cm was an exclusion in SONATA, 2.5% (n=11) of patients were in this category). Improvement in the SSS, HR-QoL, and EQ-5D were also noted in these subgroups. Rates of surgical reintervention for women with submucous fibroids was less than 3.7%.

Yüce (2020) reported on 35 patients treated with percutaneous RFA.[169] The fibroid volume was reduced significantly compared to baseline at 3, 6, and 12 months ($p<0.001$), and Visual Analogue Scores were significantly reduced at 6 and 12 months ($p<0.01$).

A prospective observational study by Rey (2019) assessed the effectiveness of transvaginal ultrasound-guided RFA of myomas (TRFAM) in reducing tumor volume and eliminating metrorrhagia associated with myomas.[170] The study included 205 women with symptomatic type II/III uterine submucosal or intramural cavity-distorting myomas undergoing RFA. The preoperative mean standard deviation (SD) volume of the myomas was 122.4 (182.5) cm3 (95% CI 82.1 to 162.8). Mean myoma volume decreased significantly at one (85.2 [147.9] cm3; p=0.001), three (67.3 [138.0] cm3; p=0.001), six (59.3 [135.3] cm3; p=0.001, and 12 months (49.6 [121.4] cm3; p=0.001). At 12 months, the mean volume reduction was 60% compared with preoperative volume. All patients returned to normal menstruation at a mean follow-up of three months and 12 months. Of the 205 patients, 201 (98.04%) were satisfied with the procedure. The investigators conceded that a larger population with a longer follow-up is needed, but their study suggests that transvaginal ultrasound-guided RFA of myomas TRFAM is effective and safe for treating select patients with metrorrhagia secondary to myomas.

A large retrospective case series was published by Yin in 2015.[171] The study was conducted in China and used Chinese gynecologic radiofrequency ablation devices. It included 1216 consecutive patients treated at a single hospital over a 10-year period. All fibroids were less than 6 cm in size and mean diameter was 4.5 cm (range, 3.1 to 6.0 cm). Mean follow-up time was 36.5 months. Among the 476 premenopausal women, the mean reduction in myoma diameter was 2.7 cm at six months, 2.4 cm at 12 months, and 2.2 cm at 24 months. Among the 740 peri- or postmenopausal women, mean reduction was 3.3 cm at six months, 2.3 cm at 12 months, and 2.3 cm at 24 months. Myoma diameter was significantly lower at each of these time-points posttreatment compared with pretreatment. In the premenopausal subgroup, the proportion of women with dysmenorrhea decreased from 43.7% at baseline to 7.6% at 12 months and to 6.7% at 24 months; rates were significantly lower after treatment.

In 2013, Chudnoff published a prospective industry-funded multicenter study.[172] It included 135 premenopausal women at least 25 years old with symptomatic uterine fibroids, a uterine size of 14 weeks of gestation or less, and six or fewer treatable fibroids, with no single fibroid larger than 7 cm. In addition, women desired to preserve their uteri but not to have children in the future. RFVTA was conducted using the Acessa system. According to the study protocol,

most fibroids less than 1 cm in diameter were not treated. The primary efficacy outcomes were change in the volume of menstrual bleeding and the surgical reintervention rate after 12 months. A total of 127 (94%) of 135 women completed the study. From baseline to 12 months, 53 (42%) of 127 women (95% confidence interval, 32% to 49%) experienced at least a 50% reduction in the volume of menstrual bleeding. Most women (104/127 [82%]) experienced a decrease in menstrual bleeding at 12 months. Only one woman underwent a surgical reintervention through 12 months (this woman had been lost to follow-up and was not included in the other efficacy analyses). Three-year outcomes were reported by Berman in 2014.[173] A total of 104 (77%) of the 135 women who participated in the study were evaluable at three years. Fourteen underwent reintervention over the three years to treat uterine fibroid symptoms. Eleven women had hysterectomies, two had myomectomies, and one had uterine artery embolization. Bleeding outcomes were not reported at three years, but the authors stated that quality-of-life variables improved from baseline to 36 months and that most of the improvement in quality of life occurred within three months of the procedure.

MISCELLANEOUS TUMORS

BACKGROUND

The standard treatment of miscellaneous tumors depends on the type, location, and extent of the cancer. A large number of phase II or III clinical trials involving the use of RFA in the treatment of primary or metastatic cancers are underway.[174]

SYSTEMATIC REVIEWS

Tang (2022) published a SR evaluating the safety and efficacy of RFA, microwave ablation (MWA), and laser ablation (LA) for the treatment of cervical metastatic lymph nodes (CMLNs) of papillary thyroid carcinoma (PTC). A total of 17 studies were included (312 patients and 559 CMLNs).[175] The pooled proportions of VRR, complete disappearance and recurrence of CMLNs were 91.28% [95% confidence interval (CI): 86.60-95.97%], 67.9% [95% CI: 53.1-81.1%] and 7.8% [95%CI: 3.0-14.1%], respectively. The pooled proportions of overall and major complications were 2.9% [95%CI: 0.3-7.1%] and 0.3% [95%CI: 0-1.9%], respectively. The VRR of MWA was the highest (97.97%), followed by RFA (95.57%) and LA (84.46%) ($p<0.001$).The authors conclude that thermal ablations were safe and effective for the treatment of CMLNs of PTC. Each treatment had significant heterogeneity in VRR.

Nadeem (2021) published a SR of RFA for adrenal tumors. A total of 15 studies including 292 patients were included. No comparative results were reported. Overall, cumulative technical success, primary technique efficacy, and secondary technique efficacy rates were 99%, 95.1% and 100%, respectively. Local progression rates at three, six, and 12 months were 20.3%, 26.3%, and 29.3%, respectively, and overall survival rates at six, 12, and 18 months were 81.8%, 59.6%, and 62.9%. The intraprocedural complication rate was 30.2%.

Imperatore (2020) and Dhaliwal (2020) performed SR of RFA of pancreatic neuroendocrine tumors and unresectable pancreatic ductal adenocarcinoma (PDAC), respectively.[176, 177] Zhang (2020) published a systematic review of various ultrasound-guided ablation techniques for the treatment of solid pancreatic tumors.[178] Additionally, a systematic review by Rombouts (2015) examined studies of ablative therapies, including RFA, in patients with locally advanced pancreatic cancer.[179] No RCTs were identified in any of these systematic reviews, and conclusions are limited by the sparse evidence available on RFA in this setting.

Thomson (2019) published a SR on non-surgical treatments for Morton's neuroma.[180] A total of 22 studies, addressing nine non-operative treatment modalities, met inclusion criteria. In addition to RFA, treatment modalities included corticosteroid injection, alcohol injection, extra-corporeal shockwave therapy (ESWT), cryoablation, capsaicin injection, Botulinum toxin, orthosis and YAG laser therapy. All showed statistically significant improvements, but the pain-relieving results for alcohol injection were only short-term and orthotics, capsaicin injections, cryoablation, Botulinum toxin, RFA and ESWT had limitations to their application.

The remainder of the current published evidence on RFA for other tumors is limited to unreliable data from small case series and retrospective reviews. Evidence from these studies is considered unreliable due to methodological limitations such as non-random allocation of treatment and a lack of appropriate comparison groups.[127, 143, 144, 181-196]

PRACTICE GUIDELINE SUMMARY

NATIONAL COMPREHENSIVE CANCER NETWORK

The National Comprehensive Cancer Network (NCCN) guidelines for thyroid carcinoma (v..2023) indicate that local therapies such as RFA may be considered for locoregional recurrence of thyroid carcinoma-papillary carcinoma in select individuals with limited burden nodal disease. Additionally, local therapies, including RFA, can be considered in those with metastatic disease.[197]

NCCN guidelines for colon cancer (v.3.2023) indicate that for metastases, "ablative techniques may be considered alone or in conjunction with resection. All original sites of disease need to be amenable to ablation or resection."[198] The guidelines also state that "ablative techniques can also be considered [in patients whose primary colon tumor was resected for cure when metastatic lung tumors are] unresectable and amenable to complete ablation" (category 2A)."

NCCN guidelines for kidney cancer (v.1.2024) indicate "thermal ablation (e.g., cryosurgery, radiofrequency ablation) is an option for the management of individuals with clinical stage T1 renal lesions." Thermal ablation is an option for masses <3 cm, but it may also be an option for larger masses in select individuals. Ablation in masses >3 cm is associated with higher rates of local recurrence/persistence and complications.[199] RFA is also an option for relapse or Stage IV and in select patients (e.g., elderly patients, others) with competing health risks.

NCCN guidelines for the treatment of non-small cell lung cancer (v.4.2023) state: "For medically operable disease, resection is the preferred local treatment modality (other modalities include SABR, thermal ablation such as radiofrequency ablation and cryotherapy. Image-guided thermal ablation (cryotherapy, microwave, radiofrequency) may be an option for selected patients who will not be receiving SABR or definitive RT"[200]

AMERICAN COLLEGE OF RADIOLOGY

The American College of Radiology (ACR) Appropriateness Criteria® (updated in 2021) consider RFA to be an alternative to partial nephrectomy for small (<4 cm) RCC tumors.[201]

The 2014 ACR Appropriateness Criteria on early-stage NSCLC that current evidence from a number of retrospective series involving varied patient populations reported a wide range of responses to RFA, ranging from 38% to 93%.[202] Primary tumor relapse rate after RFA ranged from 8% to 43% and two-year cancer-specific survival after RFA ranged from 57% to 93%,

with three-year OS of 15% to 46%. Predictors of complete response included smaller tumor size metastases, and ablation zone four times the tumor diameter. The document quoted the 2012 ACCP/STS guidelines[203] summarized below.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The American College of Chest Physicians (ACCP) guidelines on the treatment of stage I and II NSCLC indicate RFA has been used effectively in clinical stage 1 NSCLC. Therefore, in medically inoperable patients, peripheral NSCLC tumors less than 3 cm may be treated with RFA.[204]

The ACCP also joined with the Society of Thoracic Surgeons (STS) to develop consensus guidelines on the treatment of high-risk patients with stage I NSCLC.[203] These consensus guidelines indicate RFA is an alternative treatment option in patients who are not surgical candidates due to severe medical comorbidity.

AMERICAN THYROID ASSOCIATION

The 2021 American Thyroid Association (ATA) Guidelines for Management of Patients With Anaplastic Thyroid Cancer state that local therapy (including RFA) is a reasonable option for oligo-progressive metastases “to postpone the need to change otherwise beneficial systemic therapy.”[205]

AMERICAN UROLOGICAL ASSOCIATION

The 2017 American Urological Association (AUA) Guidelines state that “Physicians should consider TA [thermal ablation] as an alternate approach for the management of cT1a renal masses <3 cm in size.” and “Both radiofrequency ablation and cryoablation are options for patients who elect thermal ablation.” Both are rated as “Conditional Recommendation; Evidence Level Grade C.”[206] The guidelines were updated in 2021 and recommendations are generally consistent with the 2017 guideline.[207] The 2021 AUA guideline explicitly states that RFA and cryoablation may be offered as options to patients who elect thermal ablation.

AMERICAN COLLEGE OF OBSTETRICIANS AND GYNECOLOGISTS

The American College of Obstetricians and Gynecologists (ACOG) Practice Bulletin #96 (now #228), *Management of Symptomatic Uterine Leiomyomas* states “Laparoscopic radiofrequency ablation can be considered as a minimally invasive treatment option for the management of symptomatic leiomyomas in patients who desire uterine preservation and are counseled about the limited available data on reproductive outcomes.”[208]

AMERICAN ASSOCIATION OF CLINICAL ENDOCRINOLOGISTS

The American Association of Clinical Endocrinologists, American College of Endocrinology, and Associazione Medici Endocrinologi Medical published clinical practice guidelines (updated in 2016)for the diagnosis and management of thyroid nodules provides the following recommendations:[209] “Consider laser or radiofrequency ablation for the treatment of solid or complex thyroid nodules that progressively enlarge, are symptomatic or cause cosmetic concern [BEL 2, GRADE C]. Repeat FNA for cytologic confirmation before thermal ablation treatment [BEL 3, GRADE B].” BEL2 indicates a level of evidence that includes RCTs with limited body of data and well-conducted prospective cohort studies and meta-analyses of

cohort studies and BEL3 indicates a level of evidence that includes methodologically flawed clinical trials and observational studies.

SOCIETY OF INTERVENTIONAL RADIOLOGY

The Society of Interventional Radiology (2020) published a position statement on the role of percutaneous ablation in renal cell carcinoma.[210] The relevant recommendations are as follows: In patients with small renal tumors (stage T1a), percutaneous thermal ablation is a safe and effective treatment with fewer complications than nephrectomy and acceptable long-term oncological and survival outcomes. In selected patients with suspected T1a renal cell carcinoma, percutaneous thermal ablation should be offered over active surveillance. (Level of Evidence: C; Strength of Recommendation: Moderate)"

In high-risk patients with T1b renal cell carcinoma who are not surgical candidates, percutaneous thermal ablation may be an appropriate treatment option; however, further research in this area is required. (Level of Evidence: D; Strength of Recommendation: Weak)"

Radiofrequency ablation, cryoablation, and microwave ablation are all appropriate modalities for thermal ablation, and method of ablation should be left to the discretion of the operating physician. (Level of Evidence: D; Strength of Recommendation: Weak)"

SUMMARY

RENAL CELL CARCINOMA

Although there are currently no high-quality studies of radiofrequency ablation (RFA) of renal cell carcinoma (RCC), the overall body of published evidence suggests RFA may be beneficial in the short- to mid-term for small (4 cm or smaller), localized RCCs in patients who are not considered candidates for partial or complete surgical removal of the kidney. Therefore, RFA may be medically necessary for small RCCs in patients who are not surgical candidates or when preservation of kidney function is necessary, such as in patients with only one kidney.

Surgical excision is the preferred treatment for renal cell carcinoma (RCC) in patients who are considered to be healthy enough for surgery. There is insufficient evidence to determine whether radiofrequency ablation (RFA) is effective as surgical excision for treatment of RCC tumors. Therefore, RFA is considered investigational for treatment of RCC tumors for which surgical resection is an option.

BREAST TUMORS

There is insufficient evidence to determine the effectiveness of radiofrequency ablation for treatment of benign or malignant breast masses. Therefore, this treatment is considered investigational for the treatment of these tumors.

LUNG TUMORS

Surgical resection is the treatment of choice for primary non-small cell lung cancer (NSCLC) or metastatic tumors in the lung. For those patients who are unable to tolerate surgery, radiofrequency ablation (RFA) may be a treatment option in certain cases. While available studies are limited by study design, accumulating evidence suggests that RFA may be

similar to surgery in survival rates, and rates of procedure-related complications and mortality. Therefore, in patients with NSCLC or metastatic tumors in the lung who are ineligible for surgical treatment, RFA may be medically necessary when the policy criteria are met. There is not enough evidence to show that radiofrequency ablation (RFA) is effective as alternative treatments when criteria are not met. Therefore, RFA is considered investigational when the policy criteria are not met.

OSTEOID OSTEOMAS

Although the published evidence is limited to studies of lower methodological quality, radiofrequency ablation (RFA) of osteomas has become a standard of care based on expert opinion that the potential benefits of RFA outweigh risks in patients with osteoid tumors who have failed nonsurgical treatments. Therefore, RFA may be medically necessary for select patients when policy criteria are met.

The current preferred treatment of osteoid osteomas is non-surgical medical treatment. There is insufficient evidence to determine the effectiveness of radiofrequency ablation (RFA) for initial (first-line) treatment of osteoid tumors. RFA is, therefore, considered investigational as initial treatment of these tumors in patients who have not undergone standard medical management.

ANGIOMYOLIPOMAS

The current published evidence on radiofrequency ablation (RFA) of angiomyolipomas (AMLs) is limited to studies of lower methodological quality. However, because these tumors are rare, it is unlikely that evidence from large comparative studies will become available. Given the potential for life-threatening hemorrhage from large AMLs (4 cm or larger), and the consistent reports that the potential benefits of treatment outweigh any risks, RFA may be medical necessary to treat symptomatic or large asymptomatic AMLs. There is not enough evidence to show that radiofrequency ablation (RFA) is effective as alternative treatments when criteria are not met. Therefore, RFA of asymptomatic AMLs smaller than 4 cm is considered investigational.

PALLIATION OF PAIN FOR BONE METASTASES

The current evidence for radiofrequency ablation (RFA) for treatment of painful metastatic tumors in the bone is limited to studies of lower methodological quality; however, these studies have consistently reported significant improvement in pain following RFA in patients who have failed or are poor candidates for standard treatments. In light of this evidence, the unlikelihood of randomized controlled trials in these patients, and the lack of treatment options, the potential benefits of RFA appear to outweigh risks. Therefore, RFA may be medically necessary in patients with painful metastatic bone lesions who have failed or are poor candidates for standard treatments.

Because of the lack of data on the effectiveness of radiofrequency ablation (RFA) for initial (first-line) treatment of painful bony metastases, this indication is considered investigational.

HEAD AND NECK CANCERS

There is insufficient evidence to determine whether radiofrequency ablation (RFA) is effective for treatment of tumors of the head and neck. Therefore, RFA is considered investigational for the treatment of head and neck cancers.

THYROID TUMORS

Radiofrequency ablation (RFA) appears to be a safe alternative to more invasive surgical treatment for benign thyroid tumors. In addition, clinical guidelines based on evidence recommend this treatment. Therefore, RFA may be considered medically necessary for the treatment of benign thyroid tumors (nodules) when criteria are met.

There is not enough evidence to show that radiofrequency ablation (RFA) is safe and effective for benign thyroid tumors that do not meet the criteria. Therefore, RFA is considered investigational for the treatment of benign thyroid tumors (nodules) when criteria are not met.

While radiofrequency ablation (RFA) has been shown to reduce the size of malignant thyroid tumors and improve clinical symptoms, complications can be common. The available evidence is insufficient to determine whether any beneficial effects of RFA outweigh the risks. Therefore, RFA for the treatment of malignant thyroid tumors is considered investigational.

UTERINE FIBROIDS

There is enough research to show that radiofrequency ablation (RFA) may improve health outcomes for people with uterine fibroids. Additionally, clinical guidelines based on evidence from the American College of Obstetricians and Gynecologists (ACOG) recommend this treatment option. Therefore, RFA may be considered medically necessary for treating uterine fibroids when criteria are met.

There is not enough research to show that radiofrequency ablation (RFA) improves health outcomes for people with uterine fibroids when policy criteria are not met. Therefore, RFA is considered investigational for the treatment of uterine fibroids when policy criteria are not met.

MISCELLANEOUS TUMORS

There is insufficient evidence to determine whether radiofrequency ablation (RFA) is effective for treatment of other tumors. Therefore, RFA is considered investigational for all other tumors.

Medical Policy Manual Surgery, Policy No. 104

Varicose Vein Treatment

Effective: December 1, 2023

Next Review: March 2024
Last Review: November 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Varicose veins are dilated, tortuous veins that may cause pain or skin ulcers; however, the majority of treatment is done for cosmetic reasons. Invasive treatment may include surgical removal and/or destruction using lasers, heat, or injection of sclerosing solution.

MEDICAL POLICY CRITERIA

Notes:

- Member contracts for covered services vary. Member contract language takes precedence over medical policy. In addition, when there is a contract denial for treatment of varicose veins, the denial not only includes treatment but also the associated venous imaging studies (i.e. CPT 93970 or 93971) for treatment planning.
- This policy addresses treatment of the superficial system veins of the lower extremity (e.g., great and small saphenous veins, saphenous tributaries, varicose veins and associated lower extremity perforator veins), upper extremity varices, and vulvar varices.
- Embolization, ablation, and sclerotherapy of the ovarian, internal iliac, or gonadal veins for treatment of pelvic congestion syndrome or varicoceles are addressed separately (see Cross References below).

- This policy uses the nomenclature great saphenous vein and small saphenous vein. Great saphenous veins are also known as long saphenous veins (CPT nomenclature) or greater saphenous veins. Small saphenous veins are also known as short saphenous veins (CPT nomenclature) or lesser saphenous veins.

I. **ALL** of the following **general criteria** (see List of Information Needed for Review) must be met for varicose vein treatment to be considered for coverage:

A. One or more of the following indications must be documented:

1. Functional impairment, attributed to varicose veins, which limits performance of instrumental activities of daily living (ADLs). Instrumental ADLs are defined as feeding, bathing, dressing, grooming, meal preparation, household chores, and occupational tasks that are required as a daily part of job functioning. Clinical records **must specifically document** ALL of the following:

a. The specific instrumental ADL that is impaired; and

b. A description of how performance of the instrumental ADL is limited; and

c. Progress notes must document patient compliance with medically supervised conservative therapy, including the current use for a minimum of 3 months of compression (minimum 15 mmHg) stockings and the patient's response; or

2. Venous imaging study documented recurrent attacks of superficial phlebitis; or

3. Recurrent or persistent hemorrhage from ruptured varix, which does not include bleeding caused by scratching or shaving; or

4. Documentation of ulceration from venous stasis where incompetent varices are a significant contributing factor; and

B. A complete venous imaging study in the superficial system veins (e.g., great and small saphenous veins, perforator veins, and saphenous tributaries) is performed including documentation of the diameter of the vein and the reflux in seconds measured at multiple levels in the thigh and calf.

II. Procedures

A. Endovenous ablation

1. Endovenous radiofrequency, laser ablation, or endovenous glue or adhesive of incompetent great or small saphenous veins may be considered **medically necessary** when ALL of the following Criteria (a.-d.) are met:

a. Criterion I. above is met.

b. Documentation by venous imaging study of minimum vein diameter measurements for:

i. Great saphenous vein diameter 5.5 mm or greater (not at or closely adjacent to the saphenofemoral junction)

ii. Small saphenous vein diameter is 4 mm or greater (not at or closely adjacent to the saphenopopliteal junction); and

c. Incompetence exceeding 0.5 seconds; and

d. Clinical documentation that all incompetent segments of the same vein will be treated in the same session and with the same modality.

B. Ligation/stripping and phlebectomy (i.e., stab, hook, transilluminated powered)

1. Ligation/stripping and phlebectomy of incompetent superficial system veins (including the great and small saphenous veins and saphenous tributaries including accessory saphenous veins) and varicose veins may be considered **medically necessary** when ALL of the following Criteria (a.-d.) are met:

a. Criterion I. above is met; and

b. The incompetent superficial veins proximal to the vein to be treated either have been treated or are being treated concurrently; and

c. Documentation by venous imaging study of minimum vein diameter of 4mm or greater (not at or closely adjacent to the saphenofemoral junction or saphenopopliteal junction); and

d. Incompetence exceeding 0.5 seconds.

C. Sclerotherapy

1. Sclerotherapy (liquid, foam, or microfoam) of the following superficial system veins: great saphenous vein below the knee, small saphenous vein, and saphenous tributaries including accessory saphenous veins, and other varicose veins may be considered **medically necessary** when ALL of the following Criteria (a.-c.) are met:

a. Criterion I. above is met; and

b. Documentation by venous imaging study of minimum vein diameter of 4mm or greater (not at or closely adjacent to the saphenofemoral junction or saphenopopliteal junction); and

c. The incompetent superficial veins proximal to the vein to be treated either have been treated or are being treated concurrently.

2. Venous imaging study guidance (see Policy Guidelines) may be considered **medically necessary** for liquid, foam, or microfoam sclerotherapy of the great saphenous vein below the knee, small saphenous vein, accessory saphenous veins and saphenous tributaries**.**

III. Treatment sessions (see List of Information Needed for Review): When applicable medical necessity criteria detailed above are met, either initial or subsequent treatment may be considered **medically necessary** when performed within either of the following numbers of treatment sessions:

A. One treatment session; or

B. Two treatment sessions of bilateral veins (a separate session for each of the right and left legs).

IV. Varicose vein treatment is considered **not medically necessary** when Criterion I. is not met.

V. If Criterion II.A.1. is not met, endovenous radiofrequency, laser ablation, or endovenous glue or adhesive of incompetent great or small saphenous veins is considered **not medically necessary.**

VI. Endovenous ablation is considered **investigational** for ALL of the following:

A. Cryoablation of any vein; and

B. Radiofrequency, endovenous glue or adhesive, or laser ablation of veins other than the great or small saphenous veins, including but not limited to the following:

1. accessory saphenous veins
2. branch tributaries
3. perforator veins; and

C. Ablation of any other veins (e.g., vulvar varices); and

D. Mechanochemical ablation of any vein; and

E. Microwave ablation of any vein; and

F. Steam injection ablation of any vein.

VII. If Criterion II.B.1. is not met, ligation/stripping or phlebectomy (including perforator veins) is considered **not medically necessary.**

VIII. If Criterion II.C.1. is not met, sclerotherapy is considered **not medically necessary.**

IX. Sclerotherapy is considered **investigational** for ALL of the following:

A. Vulvar, including labial and buttock varices; and

B. Upper extremity varices; and

C. Great saphenous vein from the saphenous femoral junction (SFJ) to knee; and

D. Perforator veins

X. Sclerotherapy of small (less than 4 mm in diameter) superficial veins, including but not limited to reticular veins and/or telangiectasias (spider veins) is considered **cosmetic.**

XI. Venous imaging study guidance is considered **not medically necessary** for sclerotherapy of all other superficial system veins**.**

XII. Separate sessions for ablation of segments of a continuous vein are considered **not medically necessary** (See Policy Guidelines).

XIII. Treatment sessions not meeting Criterion III. above are considered **not medically necessary**.

XIV. Follow-up venous imaging studies performed within 6 months following the most recent ipsilateral treatment, in the absence of complications, are considered **not medically necessary**, including but not limited to routine confirmation studies

following endovenous ablation. Focused venous imaging studies to confirm ablation or rule out deep vein thrombosis or endovenous heat-induced thrombosis are considered a component of and incidental to the procedure or follow-up evaluation.

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History of present illness and physical examination.
- Impact on activities of daily living (including the specific ADL) impaired, how it impacts performance, and what is done to alleviate it. Conservative therapy treatment plan (including units of compression stocking strength documented in mmHg and timeframe) with documented results and evidence of medical supervision.
    - Note: Impact on ADLs and conservative therapy plan are not required when there are documented recurrent attacks of superficial phlebitis, recurrent or persistent hemorrhage from ruptured varix, which does not include bleeding caused by scratching or shaving, and/or ulceration from venous stasis where incompetent varices are a significant contributing factor)
- Complete venous imaging studies including vein names with measurements of seconds of reflux and average vein diameters not including focal dilations (i.e. valve).
    - Not at or closely adjacent to the saphenofemoral junction refers to the **measurement in the mid to distal thigh** where the ablation most commonly is being done.
    - Not at or closely adjacent to the saphenofemoral junction refers to the **measurement in the mid-calf** where the ablation most commonly is being done.
- Documentation of ulceration from venous stasis where incompetent varices are a significant contributing factor which may include photographs.
- Procedures requested:
    - Specific procedures to be performed
    - Specific veins to be treated
    - Number of treatment session(s) being requested
    - If bilateral endovenous ablation is requested, document whether a bilateral or two unilateral sessions are being requested
    - Specify the veins to be treated in each session
    - For ablations, specify how all incompetent segments of the same vein are to be treated

ADDITIONAL INFORMATION

- Additional Venous Imaging Studies
    - For additional treatment sessions after previous varicose vein procedures, additional imaging is only required when the previous imaging did not identify the veins requested in the additional treatment session(s). Additional imaging is not required when an initial request was denied (for criteria not related to imaging)

and the member is seeking subsequent approval. Initial imaging will be considered adequate unless there is a relevant intervening venous procedure(s), in which case new imaging studies may be requested.

- Conservative Therapy
  - Compression stockings should be worn daily while the patient is out of bed. *Unna boot* or *compression wrap* may be utilized in lieu of compression stockings when there is documentation of an open venous stasis ulcer of the leg to be treated. For additional treatment requests after initial treatment, there must have been 3 months of conservative therapy after the most recent varicose vein procedure which has not successfully treated the patient's symptoms.
- Treatment Sessions
  - Each treatment session should address as much abnormality as is appropriate and reasonable and may include more than one vein and/or modality.
  - Endovenous laser or radiofrequency ablation of the entire incompetent saphenous vein usually can be accomplished in a single treatment session. Although additional procedures, including ligation or sclerotherapy, performed in the same treatment session on the same ablated saphenous vein are considered included components of the ablation procedure, procedures on other saphenous venous systems may be distinct procedural services.

BACKGROUND

The venous system of the lower extremities consists of the superficial system (e.g., great and small saphenous veins and accessory or tributary veins that travel in parallel with the great and small saphenous veins) and the deep system (e.g., popliteal and femoral veins). These two parallel systems are interconnected via perforator veins and at the saphenofemoral and the saphenopopliteal junctions.

One-way valves are present within all veins to direct the return of blood up the lower limb. Larger varicose veins, many protruding above the surface of the skin, typically are related to valve incompetence. As the venous pressure in the deep system is generally greater than that of the superficial system, valve incompetence leads to increased hydrostatic pressure transmitted to the unsupported superficial vein system. Backflow (venous reflux) with pooling of blood ultimately results in varicosities. In addition, clusters of varicosities may appear related to incompetent perforating veins, such as Hunter and Dodd, located in the mid- and distal thigh, respectively and/or associated with incompetence at the saphenofemoral junction. In some instances, the valvular incompetence may be isolated to a perforator vein, such as the Boyd perforating vein located in the anteromedial calf. These varicosities are often not associated with saphenous vein incompetence since the perforating veins in the lower part of the leg do not communicate directly with the saphenous vein.

Although many varicose veins are asymptomatic, when present, symptoms include itching, burning, heaviness, fatigue, and pain. In addition, chronic venous insufficiency secondary to venous reflux can lead to peripheral edema, hemorrhage, thrombophlebitis, venous ulceration, and chronic skin changes. In an effort to improve the consistency in diagnosing chronic venous

disorders, particularly for patient selection in clinical trials, an international consensus committee developed CEAP classification.[1] In this system, classification is based on clinical manifestations (C), etiology (E), anatomical distribution (A), and underlying pathophysiology (P). (See Appendix 1)

Note: The term "varicose veins" does not apply to the telangiectatic dermal veins, which may be described as "spider veins" or "broken blood vessels." While abnormal in appearance, these veins typically are not associated with any symptoms, such as pain or heaviness, and their treatment is considered cosmetic.

TREATMENT OF SUPERFICIAL VARICOSE VEINS

Conservative Therapy

Treatment of venous reflux/venous insufficiency is aimed at reducing abnormal pressure transmission from the deep to the superficial veins. Varicose veins can usually be treated with non-surgical measures. Symptoms often decrease when the legs are elevated periodically, when prolonged standing is avoided, and when elastic compression stockings are worn.

Operative Therapy

If conservative treatment measures fail, additional treatment options typically focus first on identifying and correcting the site of reflux, and second on redirecting venous flow through veins with intact valves. Thus, conventional surgical treatment of varicosities is based on the following three principles:

- Control of the most proximal point of reflux, typically at the saphenofemoral junction, as identified by preoperative Doppler ultrasonography. Surgical ligation and division of the saphenofemoral or saphenopopliteal junction is performed to treat the valvular incompetence.
- Removal or occlusion by ablation of the refluxing great and/or small saphenous vein from the circulation. The classic strategy for isolation is vein stripping in conjunction with vein ligation and division.
- Removal or occlusion of the refluxing varicose tributaries. Strategies for removal include phlebectomy (i.e., ligation/division/stripping, powered phlebectomy, or stab avulsion) or occlusion by injection sclerotherapy; either at the time of the initial treatment, or subsequently. Over the years various minimally invasive alternatives to ligation and stripping have been investigated, including sclerotherapy and thermal ablation using radiofrequency energy (high frequency radiowaves), laser energy, or cryoablation (also called cryotherapy).

Endovenous Ablation

The objective of endovenous ablation techniques is to cause injury to the vessel, causing retraction and subsequent fibrotic occlusion of the vein.

<u>Thermal Ablation</u>

Three endovenous thermal ablation techniques have been investigated as minimally invasive alternatives to vein ligation and stripping.

- Radiofrequency (RF) ablation is performed by means of a specially designed catheter inserted through a small incision in the distal medial thigh to within 1-2 cm of the saphenofemoral junction. High frequency radio waves (200-300 kHz) are delivered through the catheter electrode and cause direct heating of the vessel wall, causing the vein to collapse. The catheter is slowly withdrawn, closing the vein.

- Laser ablation is performed similarly; a laser fiber is introduced into the saphenous vein under ultrasound guidance; the laser is activated and slowly removed along the course of the saphenous vein. Laser ablation may be referred to as endovenous laser ablation (EVLA) or endovenous laser treatment (EVLT).

- Cryoablation uses extreme cold to cause injury to the vessel. Technical developments since thermal ablation procedures were initially introduced include the use of perivenous tumescent anesthesia which allows treatment of veins larger than 12 mm in diameter and helps to protect adjacent tissue from thermal damage during treatment of the lesser saphenous vein.

- There are two technologies that are not available in the United States:

    - Microwave ablation is performed via endovenous catheter using microwave energy to heat the vessel walls.

    - Steam ablation is catheter-based endovenous thermal ablation that uses high pressure pulses of steam to heat the vein to 120°C.

Mechanochemical Ablation

Endovenous mechanochemical ablation (MOCA) utilizes both sclerotherapy and mechanical damage to the lumen. Following ultrasound imaging, a disposable catheter with a motor drive is inserted into the distal end of the target vein and advanced to the saphenofemoral junction. As the catheter is pulled back, a wire rotates at 3500 rpm within the lumen of the vein, abrading the lumen. At the same time, a liquid sclerosant (sodium tetradecyl sulphate) is infused near the rotating wire. It is proposed that mechanical ablation allows for better efficacy of the sclerosant, without the need for the tumescent anesthesia used in thermal ablation.

Cyanoacrylate Adhesive

Cyanoacrylate adhesive is a clear, free-flowing liquate that polymerizes in the vessel via an anionic mechanism (i.e. polymerizes into a solid material upon contact with body fluids or tissues). The adhesive is gradually injected along the length of the vein in conjunction with ultrasound and manual compression. The acute coaptation halts blood flow through the vein until the implanted adhesive becomes fibrotically encapsulated and establishes chronic occlusion of the treated vein. Cyanoacrylate glue has been used as a surgical adhesive and sealant for a variety of indications, including gastrointestinal bleeding, embolization of brain arteriovenous malformations, and to seal surgical incisions or other skin wounds.

Sclerotherapy

The objective of sclerotherapy is to destroy the endothelium of the target vessel by injecting an irritant solution (either a detergent, osmotic solution, or a chemical irritant), ultimately resulting in the complete obliteration of the vessel. The success of the treatment depends on accurate injection of the vessel, an adequate injectant volume and concentration of sclerosant, and

post-procedure compression. Compression theoretically results in direct apposition of the treated vein walls to provide more effective fibrosis and may decrease the extent of the thrombosis formation.

Sclerotherapy is an accepted and effective treatment of telangiectatic vessels. Historically, larger veins and very tortuous veins were not considered to be good candidates for sclerotherapy. Technical improvements in sclerotherapy, including the routine use of Duplex ultrasound to target refluxing vessels, luminal compression of the vein with anesthetics, and foam sclerosant in place of liquid sclerosant, have improved its effectiveness in these veins. Other concerns have arisen with these expanded uses of sclerotherapy. For example, use of sclerotherapy in the treatment of varicose tributaries without prior ligation, with or without vein stripping creates issues regarding its effectiveness in the absence of the control of the point of reflux and isolation of the refluxing saphenous vein. Sclerotherapy of the great saphenous vein raises issues regarding appropriate volume and concentration of the sclerosant and the ability to provide adequate post-procedure compression. Moreover, the use of sclerotherapy, as opposed to the physical removal of the vein with stripping, raises the issue of recurrence due to recanalization.

TREATMENT OF PERFORATOR VEINS

Perforator veins cross through the fascia and connect the deep and superficial venous systems. Incompetent perforating veins were originally addressed with an open surgical procedure, called the Linton procedure, which involved a long medial calf incision to expose all posterior, medial, and paramedial perforators. While this procedure was associated with healing of ulcers, it was largely abandoned due to a high incidence of wound complications. The Linton procedure was subsequently modified by using a series of perpendicular skin flaps instead of a longitudinal skin flap to provide access to incompetent perforator veins in the lower part of the leg. The modified Linton procedure may be occasionally utilized for the closure of incompetent perforator veins that cannot be reached by less invasive procedures. Subfascial endoscopic perforator surgery (SEPS) is a less-invasive surgical procedure for treatment of incompetent perforators and has been reported since the mid-1980s. Guided by Duplex ultrasound scanning, small incisions are made in the skin and the perforating veins are clipped or divided by endoscopic scissors. The operation can be performed as an outpatient procedure. Endovenous ablation of incompetent perforator veins with sclerotherapy and radiofrequency has also been reported.

OTHER

Deep vein valve repair or reconstruction and replacement are being investigated.

Venous “glue” or “superglue” is not cleared for use in the United States for this indication. This is an adhesive delivered via endovenous catheter as a method for sealing the vein.

REGULATORY STATUS

Devices that have received specific U.S. Food and Drug Administration (FDA) marketing clearance for the endovenous treatment of superficial vein reflux include:

- The VenClose® radiofrequency system received FDA approval in 2016 and is approved for endovascular coagulation for superficial vein reflux.

- The Alma 810 nm diode tabletop laser received FDA approval in 2016 and is indicated for endoluminal or endovenous laser surgery for incompetent saphenous veins.

- The VenaSeal™ (Medtronic) Closure System was FDA approved in 2015. The system includes a liquid adhesive, catheter, guidewire, dispenser gun and tips, and syringes. The clear liquid adhesive, cyanoacrylate adhesive, is injected into the diseased vein and polymerizes into a solid material to permanently seal the vein.

- The CERMAVEIN Steam Vein Sclerosis (SVS™) system is being studied outside of the United States but does **not** have FDA approval or clearance for marketing.

- The ClariVein® Infusion Catheter (Vascular Insights) received marketing clearance through the 510(k) process in 2008 (K071468). It is used for mechanochemical ablation. Predicate devices were listed as the Trellis® Infusion System (K013635) and the Slip-Cath® Infusion Catheter (K882796). The system includes an infusion catheter, motor drive, stopcock and syringe and is intended for the infusion of physician-specified agents in the peripheral vasculature.

- Polidocanol is an injectable sclerosing agent that may be used for intravenous treatment of varicose veins.

    - Varithena® (Biocompatibles, Inc, a BTG group company), formerly Varisolve®, is a polidocanol sclerosant microfoam made with a proprietary gas mix that is dispersed from a canister with a controlled density and more consistent bubble size. FDA approval in 2013 was for the treatment of incompetent great saphenous veins, accessory saphenous veins, and visible varicosities of the great saphenous vein system above and below the knee.

    - In 2010, Asclera® (Merz North America, Inc) is an injectable solution with FDA approval for the treatment of uncomplicated spider veins (varicose veins $\leq$ 1mm in diameter) and reticular veins (varicose veins 1-3 mm in diameter) in the lower extremities.

- A modified Erbe Erbokryo® cryosurgical unit (Erbe USA) received FDA clearance for marketing in 2005. A variety of clinical indications are listed, including cryostripping of varicose veins of the lower limbs.

- The Trivex system is a device for transilluminated powered phlebectomy that received FDA clearance through the 510(k) process in October 2003. According to the label, the intended use is for “ambulatory phlebectomy procedures for the resection and ablation of varicose veins.”

- In 2002, the Diomed 810 nm surgical laser and EVLT ™ (endovenous laser therapy) procedure kit received FDA clearance through the 510(k) process, "… for use in the endovascular coagulation of the greater saphenous vein of the thigh in patients with superficial vein reflux."

- In 1999, the VNUS® Closure™ system (a radiofrequency device) received FDA clearance through the 510(k) process for "endovascular coagulation of blood vessels in patients with superficial vein reflux." The VNUS RFS and RFS*Flex* devices received FDA clearance in 2005 for “use in vessel and tissue coagulation including: treatment of

incompetent (i.e., refluxing) perforator and tributary veins. The modified VNUS® ClosureFAST™ Intravascular Catheter received FDA clearance through the 510(k) process in 2008.

EVIDENCE SUMMARY

Outcomes of interest for venous interventions include symptom control, healing and recurrence, recanalization of the vein, and neovascularization. Recanalization is the restoration of the lumen of a vein after it has been occluded; this occurs more frequently following treatment with endovenous techniques. Neovascularization is the proliferation of new blood vessels in tissue, and occurs more frequently following vein stripping. Direct comparisons of durability for endovenous and surgical procedures are complicated by these different mechanisms of recurrence. Relevant safety outcomes include the incidence of paresthesia, thermal skin injury, thrombus formation, thrombophlebitis, wound infection, and transient neurologic effects.

VARICOSE VEIN TREATMENT

Systematic Reviews

Kheirelseid (2017) published a systematic review (SR) of nine randomized control trials (RCTs) that evaluated long-term outcomes (five years or more) of endovenous laser therapy, radiofrequency ablation, or ultrasound guided foam sclerotherapy for great saphenous vein-related varicose veins.[2] No difference in recurrence rate was seen for endovenous laser therapy or radiofrequency ablation versus conventional surgery. The authors concluded this study was too small to make a definitive determination on long-term effectiveness for varied varicose vein procedures.

Hamann (2017) published a SR of RCTs evaluating the long-term (≥ five years) impact on health outcomes for different types of treatment for the great saphenous vein, including ligation and stripping, endovenous thermal ablation and ultrasound guided foam sclerotherapy, for great saphenous vein incompetence.[3] Three RCTs and 10 follow-up reports on RCTs were included, of which one could not be included in the meta-analysis. At five years, endovenous thermal ablation and ligation stripping were more successful than ultrasound guided foam sclerotherapy. The reoccurrence of reflux was lower for ligation and stripping, than for endovenous thermal ablation and ultrasound guided foam sclerotherapy. Venous clinical severity scores were similar for ligation and stripping and endovenous thermal ablation. The authors stated the included studies had methodological limitations including unknown or high risk of bias and that more long-term RCTs are needed to compare success rates and clinical outcomes.

Vemulapalli (2017) published a SR that evaluated treatments for lower extremity varicose veins and/or venous insufficiency, reflux, or incompetence.[4] Included in the review were 53 RCTs (10, 034 patients), which were poor to good quality and four additional studies. Various therapy comparisons could not be made because of heterogeneity in therapies, populations and outcomes. Long-term symptom scores were no different between high ligation/stripping and endovascular laser ablation. There were no short-term bleeding differences between high ligation/stripping and radiofrequency ablation. The authors stated there is lack of high quality evidence on the safety and effectiveness of treatments for chronic lower extremity venous disease. Additional studies must compare effectiveness and provide practice parameters.

Boersma (2016) published results from a SR and meta-analysis that compared the anatomical success rates and complication rates of six treatment modalities for small saphenous vein incompetence: surgery (n=9), endovenous laser ablation (EVLA) (n=28), radiofrequency ablation (RFA) (n=9), ultrasound-guided foam sclerotherapy (UGFS) (n=6), and mechanochemical endovenous ablation (MOCA) (n=1).[5] Although the review included 49 articles (five RCTs and 44 cohort studies), nine were specific to RFA and were cohort studies. The pooled anatomical success rate for RFA in 386 incompetent small saphenous veins was 97.1% (95% CI 94.3% to 99.9%). RFA had a relatively low neurological complication rate (mean 9.7%) when compared to the overall neurological complication rate (mean 19.6%). The pooled anatomical success rate for UGFS in 494 incompetent small saphenous veins was 63.6% (95% CI 47.1% to 80.1%); however, more research is needed to determine these effects. The 28 articles specific to EVLA included both RCT's and cohort studies. The pooled anatomical success rate for EVLA in 2,950 incompetent small saphenous veins was 98.5% (95% CI 97.7% to 99.2%). EVLA had a low neurological complication rate (mean 4.8%) when compared to the overall neurological complication rate (mean 19.6%). There was one study on mechanochemical ablation (MOCA) and although the authors reported an anatomical success rate of 94%, more research is needed to determine these effects. The authors concluded that EVLA/RFA should be a preferred treatment over surgery and foam sclerotherapy in small saphenous vein incompetence. An updated Cochrane review from 2014 compared RFA, EVLA, and foam sclerotherapy versus ligation/stripping for saphenous vein varices.[6] Included in the review were 13 randomized studies with a combined total of 3081 patients. The overall quality of the evidence was moderate. For EVLA versus surgery, there were no significant differences between the treatment groups for clinician noted or symptomatic recurrence, or for recanalization. Neovascularization and technical failure were reduced in the laser group (OR=0.05, p<0.001; and OR=0.29, p<0.001, respectively). For RFA versus surgery, there were no significant differences between the groups in clinician noted recurrence, recanalization, neovascularization, or technical failure. The authors concluded that sclerotherapy, EVLA, and RFA were at least as effective as surgery in the treatment of long saphenous vein varicose veins.

In 2012, a SR of RCTs and meta-analysis was published that compared the clinical outcomes of EVLA, RFA, UGFS, and surgery.[7] The review included 28 RCTs and reported no significant difference in primary failure and clinical recurrence with EVLA and RFA compared with surgery. The advantages of the endovenous ablation techniques over surgery were a lower rate of wound infections and hematoma, and a shorter recovery period.

RANDOMIZED CONTROL TRIALS

Lawaetz (2017) published a five-year follow-up on an RCT in which 500 patients (580 legs) received either endovenous radiofrequency ablation, endovenous laser ablation, ultrasound guided foam sclerotherapy or high ligation and stripping for great saphenous vein reflux.[8] Recanalization occurred more often after ultrasound guided foam sclerotherapy, but there was no difference in technical efficacy between the procedures. There was a higher unknown reason for reoccurrence after endovenous laser ablation and high ligation and stripping.

van der Velden (2015) published results from a five-year follow-up comparing conventional surgery, endovenous laser ablation, and ultrasound-guided foam sclerotherapy in patients with great saphenous varicose veins.[9] A total of 224 legs were included (69 conventional surgery, 78 EVLA, and 77 UGFS), and 193 were evaluated at final follow up (86.2%). At the five-year follow-up, the Kaplan-Meier analysis showed obliteration or absence of the great saphenous

vein in 85% of patients who underwent conventional surgery and 77% of patients who underwent EVLA (not significantly different). Grade I neovascularization was higher in the conventional surgery group (27% vs 3%, p<0.001), while grade II neovascularization was similar in the two groups (17% vs 13%).

Brittenden (2014) reported a multicenter randomized trial that compared foam sclerotherapy, EVLA, and surgical treatment in 798 patients.[10] The study was funded by U.K.'s Health Technology Assessment Programme of the National Institute for Health Research.[11] Veins greater than 15 mm were excluded from the study. At the six-week follow-up visit, patients who were assigned to treatment with foam or laser had the option of treatment with foam for any residual varicosities; this was performed in 38% of patients in the foam group and 31% of patients in the EVLA group. Six months after treatment, mean disease-specific quality of life was slightly worse after sclerotherapy than after surgery (p=0.006), and there were more residual varicose veins, although the differences were small. Disease-specific quality of life was similar for the laser and surgery groups. The frequency of procedural complications was similar for the foam sclerotherapy (6%) and surgery (7%) groups, but was lower in the laser group (1%). The rate of complications at 6 months (primarily lumpiness and skin staining), was highest for the sclerotherapy group.

Five-year follow-up data from the Brittenden trial was published in 2019 on disease-specific and generic quality of life.[12] Disease-specific quality of life after five years was significantly better for those who received laser ablation or surgery compared to foam sclerotherapy.

Biemans (2013) published results from the MAGNA trial, which randomized 223 consecutive patients (240 legs) with long saphenous vein reflux to EVLA, ligation and stripping, or physician compounded foam sclerotherapy (1 ml aethoxysclerol 3#: 3ml air).[13] At one-year follow-up, the anatomic success rates were similar between EVLA and stripping (88.5% and 88.2%, respectively), which were superior to foam sclerotherapy (72.2%). Ten percent of the stripping group showed neovascularization. Health-related quality of life improved in all groups. The CEAP classification improved in all groups with no significant difference between the groups. Transient adverse events were reported in 11 patients after stripping, seven after EVLA, and five after sclerotherapy.

ENDOVENOUS ABLATION

Endovenous ablation of varicose veins has been proposed as an alternative to ligation and/or stripping. Outcomes of interest include short- and long-term functional improvement and recurrence rates related either to recanalization of the saphenous vein or neovascularization. In terms of safety, relevant outcomes include the incidence of paresthesias, thermal skin or nerve injuries, thrombus formation, thrombophlebitis, and wound infection.

Vein Diameter

There is currently no standardized range for saphenous vein diameter most likely to be associated with severe symptoms or for which endovenous ablation is recommended. In studies of the correlation between great saphenous vein diameter and the presence or absence of reflux, the best cutoff measurement to predict reflux varied between studies from 5.05 mm to 7.3 mm.[14-17] Sensitivity and specificity ranged from 76% to 87% and 60% to 87%, respectively. It is important to note that there is heterogeneity among the populations included in the studies. In addition, there was heterogeneity between studies in measurement techniques (e.g., location, position).

Endovenous Laser and Radiofrequency Ablation

Systematic Reviews

He (2017) conducted a SR which evaluated the effectiveness and safety of endovenous laser ablation compared to radiofrequency ablation for the treatment of varicose veins.[18] The SR included a total of 12 studies (N=1,577) (10 RCTs and 2 nonrandomized studies).The meta-analysis of the combined studies concluded that there were no significant differences in effectiveness and safety outcomes between the two groups.

Woźniak (2016) also evaluated laser ablation compared to radiofrequency ablation.[19] The study included 510 adults with five year follow-up and reported similar conclusions to He (2017) summarized above. A SR of EVLA versus surgery was published in 2009.[20] Fifty-nine studies were included, with seven studies that directly compared EVLA and surgery. Randomized and nonrandomized studies directly comparing outcomes for EVLA or surgery were included for the assessment of safety or effectiveness, while case series with a minimum patient population of 100 were included for the assessment of safety alone. For all studies, it was calculated that 5,759 patients (6,702 limbs) were treated with EVLA and 6,395 patients (7,727 limbs) underwent surgery. Few differences were apparent between treatments with respect to clinical effectiveness outcomes, although long-term follow-up was lacking. Nonclinical effectiveness outcomes generally favored EVLA over surgery in the first two months after treatment. The authors concluded that while EVLA offers short-term benefits and appears to be as clinically effective as surgery up to 12 months after treatment, clinical trials with a minimum of three years of follow-up are required to establish the enduring effectiveness of EVLA.

A number of SRs of RCTs comparing various types of ablation to surgical treatment have been published. These reviews consistently reported moderate quality of evidence. Most of the reviews compared EVLA, RFA, and surgical treatment of varicose veins. Overall, these techniques had similar, statistically significant improvement in function and in pain relief compared to preoperative scores. RFA and EVLA had low rates of technical procedure failure rates, and short-term recannulization rates. Adverse effects were generally minor for all techniques. Though intraoperative pain was not reported, EVLA consistently resulted in significantly greater pain and bruising when compared to RFA for one to two weeks following the procedure. RFA had significantly more occurrences of superficial phlebitis. Recanalization was similar for EVLA and RFA at one-year follow-up.

The primary limitation of the current evidence is the lack of long-term data on recanalization rates for ablation techniques and neovascularization rates for ligation and stripping. In addition, many of the available studies used first-generation technology and, therefore, do not provide data on newer devices. For example, newer laser technology may result in decreased pain during and after the procedure. Newer RFA technology (e.g., ClosureFast RF catheter) may result in higher rates of vein occlusion.

Randomized Controlled Trials

The ongoing, and largest randomized study on EVLA, comparing endovenous laser ablation with costectomy and stripping of the great saphenous vein (RELACS), schedule to follow patients for five years, randomized 400 patients to EVLA performed by a surgeon at one site or to ligation and stripping performed by a different surgeon at a second location.[21] Fifty-four patients withdrew from the study after receiving the randomization result (from an independent

site), due primarily to preference for the other treatment. At the two-year follow-up there was no significant difference between the groups for clinically recurrent varicose veins, medical condition on the Homburg Varicose Vein Severity Score, or disease-related quality of life. Saphenofemoral reflux was detected by ultrasonography more frequently after EVLA (17.8% vs 1.3%). At 5-year follow-up, Kaplan-Meier analysis showed obliteration or absence of the great saphenous vein in 85% of patients who underwent conventional surgery and 77% of patients who underwent EVLA (not significantly different).15 Grade I neovascularization was higher in the conventional surgery group (27% vs 3%, p<0.001), while grade II neovascularization was similar in the 2 groups (17% vs 13%).

Rasmussen (2012) reported the five-year follow-up data comparing EVLA (n=121) with ligation and stripping (n=68).[22] Data was available on 98% of the patients. There was no significant difference between the two groups for clinical recurrence (EVLA 36%, stripping 35%) or in the percentage of reoperations (EVLA 38.6%, stripping 37.7%).

Literature on isolated treatment of the anterior accessory saphenous vein is limited. In a 2009 study, outcomes from a cohort of 33 patients who underwent EVLA of the anterior accessory saphenous vein were compared with 33 matched controls undergoing EVLA of the greater saphenous vein.[23] In 21 of the patients (64%) in the accessory saphenous vein group there had been no previous treatment of the greater saphenous vein. At 12-month follow-up there was no evidence of reflux in these patients, and the treated accessory saphenous vein was not visible with ultrasound. The Aberdeen Varicose Vein Symptom Severity Score had improved in both groups, with no significant difference between the two groups. Patient satisfaction scores were also similar.

Nonrandomized Trials

Several case series have reported on endoluminal radiofrequency ablation.[24-27] The largest was reported by Merchant and colleagues, who analyzed the four-year data collected in the ongoing Closure Study Group registry focusing on the treatment of reflux of the long saphenous vein.[24] Data were available on 890 patients and 1,078 limbs treated at 32 centers. Clinical and duplex ultrasound follow-up was performed at one-week, six-months, and yearly for four-years. The vein occlusion rates were 91% at one week and 88.8% at four-years, although only 98 limbs had been followed up to the four-year mark. These results suggest that radiofrequency ablation results in durable occlusion. Radiofrequency ablation has typically been limited to vessels less than 12 mm in diameter. The rationale behind this patient selection criterion is that the electrodes must remain in direct contact with the vein wall during treatment and the largest diameter of the deployed radiofrequency electrodes is 12 mm. The authors noted that exsanguinations, perivenous tumescent infiltration, and external compression may promote electrode and vessel wall contact such that larger veins can be treated. However, in this large case series, there were only 58 limbs with vein sizes larger than 12 mm, and only 29 available for follow-up at six-months or one-year. While the occlusion rate was similar to that seen in smaller vessels, long-term data are inadequate to determine if this effect is durable.

Merchant and Pichot (2005) also reported the 5-year Closure Study Group registry data.[28] There were 1222 limbs in 1006 patients treated at 34 centers with radiofrequency ablation of various levels of the long saphenous vein, the short saphenous vein, and the accessory saphenous vein. At five-year follow-up using duplex ultrasound examination, 185 limbs were considered failures due to nonocclusion (12.4%), recanalization of a previously occluded vein (69.7%), or groin reflux of a vein with occluded trunk (17.8%). In the latter group, the groin

reflux often involved an accessory vein. Logistic regression analysis of risk factors of gender, age, body mass index [BMI], vein diameter, and catheter pullback speed showed that each unit increase in BMI over 25 was associated with increasing risk of long-term failure. In addition, a catheter pull-back speed over the standard speed of 3 cm/min was associated with failure to occlude or recanalization. The authors pointed out that this anatomical failure did not necessarily result in clinical failure; most patients experienced initial symptom relief that was maintained over 5 years.

Many other clinical trials on laser ablation of varicose veins are case series[29-33] and registry data[28]. Using historical controls for comparison is difficult since treatment outcomes are variably reported. There are no consistent definitions of success versus failure, either based on patient or clinical assessment. In general, recurrence rates after ligation and stripping are estimated at around 20%. Doppler or Duplex ultrasound are perhaps the most objective form of assessment of recurrence, but many of the reports of the long-term outcomes of ligation and stripping did not use ultrasound studies for postoperative assessment. Only two studies have reported objective results of ligation and stripping at 12 and 24 months. Jones and colleagues reported on the results of a study that randomized 100 patients with varicose veins to undergo either ligation alone or ligation in conjunction with stripping.[34] The results of the ligation and stripping group are relevant to this discussion. At one year, reflux was detected in 9% of patients, rising to 26% at two years. Rutgers and Kitslaar reported on the results of a trial that randomized 181 limbs to undergo either ligation and stripping or ligation combined with sclerotherapy.[35] At two years, Doppler ultrasound demonstrated reflux in approximately 10% of patients, increasing to 15% at three years. Therefore, based on this crude assessment, the reflux rate of 13% for radiofrequency ablation at one year[36] and 6% for laser ablation at two years[29] is roughly comparable to the reflux rate of 9-10% reported by Jones et al and Rutgers and Kitslaar.

Cryoablation

Disselhoff (2008, 2011) reported two and five-year outcomes from a randomized trial that compared cryostripping with EVLA.[37, 38] One hundred and twenty patients were included with symptomatic uncomplicated varicose veins (CEAP C2) with saphenofemoral incompetence and greater saphenous vein reflux. At 10 days after treatment, EVLA had better results than cryostripping with respect to pain score over the first 10 days (2.9 vs. 4.4), resumption of normal activity (75% vs. 45%) and induration (15% vs. 52%). At the two-year follow-up, freedom from recurrent incompetence was observed in 77% of patients after EVLA and 66% of patients after cryostripping (not significantly different). At five years, 36.7% of patients were lost to follow-up; freedom from incompetence and neovascularization was found in 62% of patients treated with EVLA and 51% of patients treated with cryostripping (not significantly different). Neovascularization was more common after cryostripping, but incompetent tributaries were more common after EVLA. There was no significant difference between groups in the Venous Clinical Severity Score or Aberdeen Varicose Vein Severity Score at either two or five years.

Klem (2009) published results from a randomized trial that found endovenous cryoablation (n=249) to be inferior to conventional stripping (n=245) for treating patients with symptomatic varicose veins.[39] The percentage of patients with greater saphenous vein remaining was 44% in the endovenous cryoablation group and 15% in the conventional stripping group. The Aberdeen Varicose Vein Questionnaire also showed better results for conventional stripping (score of 11.7) in comparison with cryoablation (score of 8.0). There were no differences

between the groups in SF-36 subscores, and neural damage was the same (12%) in both groups.

Cyanoacrylate Ablation

Amshar (2022) published a systematic review comparing cyanoacrylate embolization (CAE) and laser ablation (EVLA) in the treatment of saphenous vein insufficiency which included 1432 ablation procedures.[40] Venous closure rates and VCSS did not differ significantly between CAE group and EVLA group. Pooled data showed that CAE group was associated with less periprocedural pain score (P < 0.001), lower skin pigmentation rates (0.60% vs. 4.46%; P = 0.008), and lower nerve damage rates (0% vs. 3.94%; P = 0.007). Rates of phlebitis, deep vein thrombosis, and ecchymosis did not differ significantly between the groups. In addition, intervention time was significantly faster in CAE group compared to EVLA group. The authors concluded that CAE has similar efficacy compared to EVLA.

Garcia-Carpintero (2020) published a systematic review of endovenous cyanoacrylate adhesive treatment compared to radiofrequency ablation or endovenous laser ablation in 1057 participants.[41] The authors concluded that all three treatment types reduced disease severity and there was no significant difference across the three treatment options. There were fewer adverse events with participants who received cyanoacrylate adhesive treatment compared to the other ablation techniques.

Morrison (2017) published a report on the 12-month outcomes of the VeClose trial that compared endovenous cyanoacrylate closure to radiofrequency ablation for great saphenous vein incompetence.[42] Ninety-five patients who underwent endovenous cyanoacrylate closure and ninety-seven patients who underwent radiofrequency ablation presented at the one-year follow-up evaluation. The authors concluded that although endovenous cyanoacrylate closure showed faster closer rates and fewer reopening episodes, quality of life was the same for both procedures. The study was not blinded, but may not have been possible because of the differences in the way the procedures are performed.

Morrison (2018) published thirty-six month follow-up data to the VeClose trial with follow-up on 146 (66%) patients (72 from CAC and 74 from RFA)[43]. Loss to follow-up was similar in the two groups. The complete closure rates for CAC and RFA were 94.4% and 91.9% (p=0.005 for non-inferiority), respectively. Recanalization-free survival through 36 months was not statistically different for the two groups. No significant device- or procedure-related adverse events were reported for either group.

Morrison (2020) reported five year outcomes from the VeClose trial. 89 patients of the 220 patients enrolled in the original study completed the 60-month follow-up.[44] At five years, Kaplan-Meier estimates for freedom from recanalization in the randomized CAC and RFA groups were 91.4% and 85.2%. Noninferiority of CAC compared with RFA was demonstrated. Sustained improvements in EQ-5D and quality of life measures through 60 months were demonstrated in both groups. Whereas patients assigned to C0 or C1 clinical class were excluded from the original study, more than half of all returning patients (64% [57/89]) were now assigned to C0 or C1, suggesting an improved clinical class from baseline. 41.1% of returning CAC patients and 39.4% of returning RFA patients were shown to be at least two CEAP classes lower than their baseline class. No adverse events were reported in either group between 36- and 60-month follow-up.

Yasmin (2017) published a retrospective review on results of VariClose (n-butyl cyanoacrylate) treatment for varicose veins.[45] One hundred and eighty patients with great saphenous vein diameter > 5.5mm and small saphenous vein diameter > 4mm and reflux > 5 s were treated and followed up at between three and seven months. No recanalization was observed and the venous clinical severity scores dropped to an average of 3.9 three months after the procedure versus 10.2 before. No long-term results were reported.

Bozkurt (2016) conducted a one year prospective comparative study (n=310) evaluating cyanoacrylate glue compared to endovenous laser ablation for venous insufficiency.[46] The authors concluded that periprocedural pain, ecchymosis, permanent paresthesia were less in the cyanoacrylate ablation group. There were no significant differences in closure rates at 12 months follow-up. In addition, there were no significant differences in severity scores nor the Aberdeen Varicose Vein Questionnaire. Additional studies are needed to evaluate the effectiveness and safety of this technique.

Mechanochemical Ablation

Systematic Review

Witte (2017) published a SR of 13 studies evaluating the anatomic, technical, and clinical success of mechanochemical endovenous ablation (MOCA) using ClariVein® for the great and small saphenous veins.[47] Studies were of “moderate to good quality”. Two-three year pooled anatomic outcomes for the great saphenous vein and small saphenous vein reported were 91% and 87% respectively. The authors stated MOCA using the ClariVein® and liquid sclerosant is associated with an anatomic success rate of 87%-92% and the risk of complications is low, but no RCTs were available to compare MOCA to endothermal ablation.

Vos (2017) published a SR of 15 prospective studies evaluating the anatomic and technical success of MOCA and cyanoacrylate vein ablation (CAVA) for great saphenous vein incompetence.[48] MOCA and CAVA pooled anatomic success were 94.8% and 94.1% at six months and 94.1% and 89% at one year. The authors stated additional RCTs of high quality comparing MOCA and CAVA to conventional procedures are needed. These will assist in establishing clinical outcomes and practice parameters.

Randomized Controlled Trials

Belramman (2022) published a comparison of pain outcomes between mechanochemical ablation and cyanoacrylate adhesive in the treatment of varicose veins.[49] A total of 167 patients were randomized to treatment groups and the primary outcome measure was pain score immediately after ablation. There were no differences between groups in improvement in clinical severity, generic and disease-specific QoL scores, and complete occlusion rates as both groups demonstrated significant, but comparable improvement.

Mohamed (2020) published results of a trial comparing endovenous laser ablation and mechanochemical ablation using ClariVein in the management of superficial venous insufficiency.[50] Patients (n=150) were randomized to MOCA with 1.5% sodium tetradecyl sulfate or to EVLA. Occlusion rates were lower in the MOCA group 77% compared to the EVLA group (91%) with no significant difference between the two treatments in intraprocedural pain scores. Clinical severity and quality of life scores were not significantly different between the groups at one year follow-up. Additional follow-up is continuing to evaluate durability of the treatments.

Holewijn (2019) published a non-inferioty trial examining three percent policocanol in the Mechanochemical endovenous Ablation to RADiOfrequeNcy Ablation (MARADONA).[51] The trial included 213 patients who were randomized before reimbursement for the procedure was suspended. Pain scores in the 14 days after the procedure were slightly lower, but hyperpigmentation was higher. Anatomic failures were significantly greater in the MOCA group at 1 year and approached significance at 2-years. The study was underpowered for anatomic failures because of the early stoppage of the study. At 1 and 2-years follow-up, clinical and quality of life outcomes were similar in the two groups.

Lane (2017) published a multi-center RCT evaluating pain levels for 170 patients undergoing either mechanical occlusion chemically assisted ablation or radiofrequency ablation.[52] Pain, duplex ultrasound results, clinical outcomes and quality of life were evaluated at one and six months after treatment. Pain after mechanical occlusion chemically assisted ablation was lower than with radiofrequency ablation, but other outcomes including quality of life and safety did not differ.

Bootun (2014) published early one month results from an ongoing study comparing 119 patients randomized to mechanochemical ablation (MCA) (n=60) or RFA (n=59).[53] The maximum and average pain scores were significantly lower during MCA compared to RFA ($p<0.001$). At one-month follow-up, both groups showed complete or proximal occlusion rates of 92%, though data were available for only 67% of participants. These preliminary outcomes do not permit conclusions due to methodological limitations including the short-term follow-up and incomplete data. The authors noted that data from longer follow-up is being collected.

Nonrandomized Studies

Thierens (2019) published a prospective cohort study with five year follow up data. Anatomic and clinical follow-ups were performed at 4 weeks, 6 months, and 1, 3, and 5 years after the procedure. Less than half of the study population remained at 5 years, however 79% had freedom from anatomic failure and clinical measures had worsened. Nearly 15% of the recanalizations occurred in the first year, which the authors considered to be due to technical issues when the procedure was initially introduced. It should be noted, however, that the more recent MARADONA trial from the same group of investigators using 3% polidocanol (described above) also saw a rate of recanalization of 16.5% in the first year and 20% in the second year. Without a control condition, it cannot be determined whether the loss of clinical improvement in this cohort study is due to recanalization or the usual progression of venous disease over time.

Tang (2017) published single-center study outcomes for 300 patients who received ClariVein® treatment for varicose veins.[54] Veins treated included great saphenous vein (n=184), bilateral great saphenous veins (n=62), short saphenous vein (n=23), and bilateral short saphenous veins (n=6). Evaluations occurred two months after the procedures. At two months, 13 out of 393 veins or 3.3% had to be retreated with ultrasound-guided foam sclerotherapy. The authors stated there were no adverse findings and results are promising, but these results are from a one surgeon’s experience and RCTs with long-term follow-up are needed.

The remainder of the evidence on MCA of varicose veins is limited to nonrandomized series and cohort studies.[55-60] In the only comparative study, van Eekeren and colleagues compared postoperative pain and early quality of life in 68 patients treated with either RFA or MCA of great saphenous veins.[58] Patients who did not want to be treated with MCA were offered treatment with RFA; this study design could potentially lead to selection bias. There was no significant between-group difference in procedure-related pain. Compared with RFA, patients

treated with MCA had a 14.3 mm reduction in pain measured on a 100 mm visual analog scale (VAS) measured over the first 3 postoperative days (6.2 vs. 20.5) and a 13.8 mm reduction in pain (4.8 vs. 18.6 mm; p<.001) over the first two weeks. MCA patients treated also had a significantly earlier return to normal activities (1.2 vs. 2.4 days) and return to work (3.3 vs. 5.6 days; p=.02). There was a similar improvement in quality of life for the two groups when measured at six weeks. Longer studies are required to determine the durability of these effects.

Microwave Ablation

This technique has not been approved or cleared for marketing by the FDA. Two clinical trial reports were found. The first, a preliminary randomized trial, compared endovenous microwave ablation (EMA) with high ligation and stripping (HLS).[61] At 24-months follow-up, there was no significant difference in outcomes between the two groups. The second, a retrospective comparison between laser (n=163 limbs in 138 patients) and microwave (n=143 limbs in 121 patients) ablation of the greater saphenous vein, found significantly lower ecchymosis, skin burn, and paresthesia in the laser ablation.[62] However, the recanalization rate was significantly higher in the laser ablation group at one week and six months postoperatively (p<0.01). Loss to follow-up at 24-months was about 19% in each group.

Steam Ablation

This technique has not been approved or cleared for marketing by the FDA. There is currently no published clinical trial evidence on this technique.

SCLEROTHERAPY

In general, reported outcomes of uncontrolled studies have varied for sclerotherapy, as have the periods of follow-up. In many studies the outcomes are reported in terms of cure rates, but the criteria for cure or failure are poorly defined. Studies have also reported subjective patient-assessed outcomes or physician assessment, both of which may be poorly defined. More recent studies included results of Doppler or duplex ultrasonography; however, the relationship between finding ultrasonographic evidence of recurrent reflux and clinical symptoms is uncertain. Finally, it should be noted that sclerotherapy of the long saphenous vein is a fundamentally different approach than stripping. With stripping, recurrences are likely related to an incomplete surgical procedure or to revascularization. With sclerotherapy, recurrences may be additionally related to recanalization of an incompletely fibrosed saphenous vein.

Systematic Reviews A SR from 2008 found that foam sclerotherapy of varicose veins is associated with a higher recurrence rate in patients with saphenofemoral incompetence compared to the rates of endovenous laser therapy or radiofrequency obliteration, while a 2009 SR suggested that outcomes from sclerotherapy are worse than those of surgery (ligation and stripping) for saphenous vein reflux.[63, 64]

Randomized Controlled Trials

Yin (2017) reported on a randomized control study for patients who received ultrasound guided foam sclerotherapy combined with great saphenous vein high ligation (n= 73) or stripping and multistab avulsion or transilluminated powered phlebectomy of the great saphenous vein (n=90).[65] Only 73 patients who received ultrasound guided foam sclerotherapy and 74 patients in the control group completed follow-up at one, six, and 12 months following treatment. At 12 months reflux recurrence rate was 13.8% after ultrasound guided foam

sclerotherapy and 13.5% for the control treatment. Minor and major complications, venous filling index, VCSS, and AVVQ scores were similar. Patient satisfaction, operating times, and hospital costs were more favorable for ultrasound guided foam sclerotherapy.

Gibson (2017) reported on a multi-center randomized placebo-controlled trial evaluating the safety and efficacy of Varithena®.[66] Patients with symptomatic varicose veins received Varithena® (n=39) or a placebo (n=38). Assessments took place at baseline and at weeks one, four, eight and 12 after treatment. The authors stated Varithena® improves vein appearance and symptoms in patients with varicose veins. The study had methodological limitations including small sample size and potential author conflicts of interest. In addition, outcomes for appearance and symptoms may be viewed as subjective; thus, additional larger RCTs, with long-term follow-up are needed to validate health outcomes for Varithena®.

Several controlled trials comparing sclerotherapy of varicose tributaries or the saphenous vein, with and without associated ligation and stripping, have reported that the absence of ligation and stripping was associated with an increased frequency of recurrence. These trials are difficult to interpret due to the lack of clarity about which vein– either the varicose tributaries or the saphenous vein itself – have undergone sclerotherapy. Nonetheless, these trials established the importance of control of the site of reflux (ligation) and isolation of the refluxing portion of the saphenous vein (stripping). The following are examples of these studies:

Results from the five year follow up published by van der Velden (2015) examined ultrasound-guided foam sclerotherapy in 77 legs.[9] The authors found obliteration or absence of the greater saphenous vein was observed in only 23% of patients treated with sclerotherapy compared to 85% of patients who underwent conventional surgery and 77% of patients who underwent EVLA. Thirty-two percent of legs treated initially with sclerotherapy required one or more reinterventions during follow-up compared with 10% in the conventional surgery and EVLA groups. However, clinically relevant grade II neovascularization was higher in the conventional surgery and EVLA groups (17% and 13%, respectively), compared with the sclerotherapy group (4%). EuroQol-5D scores improved equally in all groups.

King (2015) published results from the VANISH-1 study, a manufacturer-funded multicenter placebo RCT undertaken to evaluate the efficacy of relief of symptoms and safety of Varithena (0.5%, 1%, and 2%) compared with 0.125% (control) and placebo.[67] Seven-hundred and eighty patients were screened; 279 patients met the study criteria and were treated with either placebo (n=56), or Varithena 0.125% (n=57), 0.5% (n=51), 1% (n=52), or 2% (n=63). Patients rated the duration and intensity of nine symptoms and activity levels during the previous 24 hours using the VVSymQscore instrument. At week eight VVSymQscores for pool Varithena (0.5% +1%+2%) patients were significantly superior to placebo (p=<.001), and VVSymQscores decreased significantly (p<.001) from baseline at eight weeks for all Varithena individual doses. There were no serious AE's and no PE's; however, patients receiving higher Varithena dose concentrations (1% and 2%) had higher rates of treatment-emergent AE's, which occurred in ≥ 3% of patients. The most common kinds of treatment-emergent AE's included pain, superficial thrombophlebitis, and hematoma at the injection site.

Vasquez and Gasparis (2015) published results from a manufacturer sponsored multicenter randomized placebo-controlled study. The purpose of the study was to determine the efficacy and safety of Varithena (0.5%, 1.0%) and placebo, each administered with endovenous thermal ablation.[68] A total of 234 patients were screened; 117 patients met the study criteria and received treatment (38 placebo, 39 Varithena 0.5%, and 40 Varithena 1%). Patients were

assessed using the Quality of Life/Symptoms (mVEINES-QOL/Sym) questionnaire, Patients Self-Assessment of Visible Varicose Veins (PA-V) and the Independent Photography Review-Visible Varicose Veins (IPR-V) instruments. Efficacy showed baseline scores were greater at week eight for pooled Variethena than for placebo for both IPR-V (−1.2 vs. −0.8 points, $p = 0.001$) and PA-V (−1.8 vs. −1.6 points, $p = 0.16$), however, only IPR-V change score reached statistical significance. The comparison of the individual dose concentrations of Variethena (0.5%, 1.0%) with placebo showed a similar pattern for both IPR-V and PA-V scores. Although no patients presented spontaneously with symptoms of thrombus, six patients were found to have venous thrombi, and all occurred during the first eight weeks post treatment. Through six months of follow-up, there were no reports of visual disturbance or migraine among Varithena recipients, no pulmonary emboli, and no AE-related study withdrawals. There was one serious AE, breast cancer, considered unrelated to the study drug.

Microfoam sclerotherapy was studied in the 2014 VANISH-2 study, an ongoing five year manufacturer-funded pivotal double-blind RCT undertaken to obtain FDA marketing approval for Varithena microfoam (BTG).[69] The study compared 0.5% or 1.0% polidocanol microfoam with subtherapeutic foam dose (0.125%) and endovenous placebo in 232 patients. The authors reported early eight week follow-up data[70] finding elimination of reflux and/or occlusion of the previously incompetent vein in 85.6% of the combined 0.5% and 1.0% groups, 59.6% in the 0.125% “subtherapeutic” group, and 1.8% of the placebo group. The improvement in the venous clinical severity score was significantly greater in the 0.5% and 1.0% groups (-5.10) compared with placebo (-1.52), but was not reported for the 0.125% group. The 1.0% dose of Varithena was selected for the 2013 FDA approval. Adverse events occurred in 60% of patients receiving foam sclerotherapy compared to 39% of placebo; 95% were mild or moderate and transient. The most common adverse events were retained coagulum, leg pain, and superficial thrombophlebitis. Deep vein thrombosis was detected by ultrasound in 2.8% of Varithena-treated patients with 1% having proximal symptomatic thrombi treated with anticoagulants. No pulmonary emboli were detected and no clinically significant cardiac or cardiopulmonary, neurologic, or visual adverse events were reported. In the short-term the rates of occlusion with this microfoam sclerotherapy were similar to those reported for EVLA or stripping. RCTs comparing EVLA or stripping with microfoam sclerotherapy with long-term outcomes are needed to evaluate comparative effectiveness. In 2015, Todd and Wright published an update to the VANISH-2 study and reported on findings at one year.[71] Results at year one showed symptoms improved when compared to week 8 (64% with total VVSymQ scores of 3 or less at week eight vs 85% at year one). Reductions from baseline in the individual symptom scores that compose the VVSymQ score were also demonstrated, with all five HASTI symptoms showing a continued decrease from over time. In addition, improvements from baseline in appearance as assessed by both the patients themselves (PA-V score) and blinded experts reading standardized photographs (IPR-V score) were maintained, with a small trend toward further improvement between week eight and one year. Ten patients of the 232 in the total population had 12 AEs reported during the long-term follow-up period through year one, including one death; however, all were unrelated to treatment. Of the patients who had venous thrombus AEs during the main eight week trial, none had recurrent venous thrombus AEs, and all clots stabilized or resolved completely. No post-thrombotic syndrome or other clinically important sequelae were reported. No patient developed a new venous thrombus AE in the one year follow-up, and no pulmonary emboli were diagnosed at any time through the one year in this study.

A 2012 study was a noninferiority trial of foam sclerotherapy versus ligation and stripping in 430 patients.[72] Analysis was per protocol. Forty patients (17%) had repeat sclerotherapy. At two years, the probability of clinical recurrence was similar in the two groups (11.3% sclerotherapy vs 9.0% ligation and stripping), although reflux was significantly more frequent in the sclerotherapy group (35% vs 21%). Thrombophlebitis occurred in 7.4% of patients after sclerotherapy. There were two serious adverse events in the sclerotherapy group (deep venous thrombosis and pulmonary emboli) that occurred within one week of treatment.

Blaise (2010) reported three-year follow-up from a multicenter double-blind randomized trial (143 patients) that compared treatment of the greater saphenous vein with either 1% or 3% polidocanol foam.[73] Additional treatment with foam sclerotherapy was carried out at six weeks, three and six months if required to abolish persistent venous reflux. There were 49 additional injections in the 1% polidocanol group and 29 additional injections in the 3% group. At the three-year follow-up, venous reflux was observed in 21% of patients in the 1% group and 22% of patients in the 3% polidocanol group.

Neglen (1993) reported on a “partially randomized” trial that compared the outcomes of three different treatment strategies: 1) sclerotherapy alone; 2) ligation and stripping, or 3) ligation combined with sclerotherapy.[74] It was difficult to determine the target of the sclerotherapy. As described in the article, sclerosant was injected into all points of control (presumably at the junction of the perforator veins) and, "if possible, into the main stem of the long saphenous vein." Thus, it seems that the intent of the sclerotherapy was not the obliteration of the long saphenous vein as an alternative to stripping, but as a treatment of the varicose tributaries. Therefore, among those patients who underwent ligation plus sclerotherapy, this trial tested whether or not stripping could be eliminated from the overall approach. In the group who received sclerotherapy alone, almost 70% of patients self-reported a cure immediately postoperatively, which declined to about 30% after five years. This gradual recurrence rate for sclerotherapy alone is similar to that reported in the above studies. For the ligation and sclerotherapy group, 70% reported a cure immediately postoperatively, dropping to 50% after five years. The best long-term results were reported for the ligation and stripping group, which reported an 80% immediate cure rate, dropping to 70% after five years. The physician assessment of treatment outcome showed greater differences among the three groups. For example, based on physician assessment (observation and foot volumetric measurements), only 5% of the sclerotherapy group were considered cured after 5 years, compared to 10% in the ligation and sclerotherapy group and 60% in the ligation and stripping group.

Rutgers (1994) reported on a trial that randomized 156 patients with varicose veins and saphenofemoral incompetence to undergo either ligation and stripping or ligation and sclerotherapy.[35] The site of sclerotherapy was not described. At the three years follow-up, the cosmetic results were better in those limbs that had undergone stripping. Additionally, the clinical and Doppler ultrasound evidence of reflux was significantly less in those undergoing stripping.

Nonrandomized Studies

There has also been interest in injecting sclerosant into the saphenous vein either in conjunction with ligation as an alternative to stripping, as a stand-alone procedure, or as an alternative to both ligation and stripping.

Myers (2007) published results from a three-year follow-up prospective observational study of sclerotherapy in 489 patients with refluxing saphenous veins and related tributaries.[75] Out of

807 veins treated, 56% were associated with the great saphenous vein and 22% with the small saphenous vein; 22% were tributaries alone. Ultrasound at three to five days after each treatment showed successful occlusion in an average of 1.5 sessions for the group as a whole (65% in one session and 26% in two sessions). The Kaplan-Meier analysis showed three-year survival rates of 83% for tributaries, 53% for great saphenous veins, and 36% for small saphenous veins. These results do not support the use of sclerotherapy for refluxing saphenous veins.

Kanter and Thibault (1996) published result from a case series, which included 172 patients with 202 limbs who had varicose veins with associated saphenofemoral incompetence.[76] Using ultrasound guidance, sclerosant was injected into the long saphenous vein 3-4 cm distal to the saphenofemoral junction. Injections were given at 30- to 90-second intervals, proceeding distally as previously injected segments were observed to spasm. Immediately after therapy, a thigh compression stocking was applied. Two weeks after the initial procedure, patients were reevaluated with Duplex ultrasound and were re-treated if found to have persistent reflux. There was a clinical recurrence rate of 22.8% at one year.

Ninja published two case series (1996; 1997) evaluating sclerotherapy for patients with symptomatic vulvar varicosities.[77, 78] The first study included seven women and the second study included five women. Both studies concluded that all patients noticed marked improvements in symptoms after treatment. However, the sample sizes in these two studies were very small and they lacked a comparator group.

Adverse Effects

Although long-term sequelae have not been reported with sclerotherapy, transient adverse effects have been found in up to 8% of patients, including cerebrovascular accidents, transient ischemic attacks, speech and/or visual disturbance, migraine, shortness of breath, dizziness, and numbness.[79, 80] Bubbles appear in the right side of the heart between 9 and 59 seconds after injection and emboli have been detected in the middle cerebral artery following sclerotherapy of saphenous trunks and varices. Deep venous occlusion after ultrasound-guided sclerotherapy has also been reported; risk was found to be greater when treating veins $\geq$5 mm in diameter (odds ratio of 3.7) and injecting 10 mL or more of foamed sclerosant (odds ratio of 3.6).[81] A SR of visual disturbance following sclerotherapy found this adverse effect to be rare and transient; further research was recommended to clarify the mechanism of action of sclerosants.[82]

Other Treatments

FDA approval of the VenaSeal™ Closure System, which uses adhesive, was based on three manufacturer-sponsored clinical studies, one of which was a randomized controlled noninferiority trial. In the VeClose Study, 222 subjects with symptomatic long saphenous vein incompetence were randomized to undergo either the VenaSeal closure (n=108) or RFA (n=114).[83] A three-month follow-up was conducted during which no adjunctive procedures were allowed. There were a number of methodological limitations in this study, which include but are not limited to, a 14% loss of data, which was accounted for using various methods such as imputing missing data. While these analyses supported noninferiority, their reliability is unclear. These results require validation in large RCTs with lower rates of data loss and longer-term follow-up.

PRACTICE GUIDELINE SUMMARY

AMERICAN VEIN AND LYMPHATIC SOCIETY (AVLS)

The AVSL guidelines committee (2016) published a consensus statement on treatment options for incompetent accessory saphenous veins.[84] They performed a SR to evaluate clinical outcomes and treatment options. They stated treatment recommendations for symptomatic great saphenous veins should include endovenous thermal ablation (laser or radiofrequency) and ultrasound-guided foam sclerotherapy (Grade 1C-strong recommendation, low quality evidence).

The AVLS (2014) published a practice guideline for treatment of superficial veins of the lower leg.[85] Recommendations for the treatment of saphenous veins included laser and radiofrequency ablation, for the small and great saphenous veins and the anterior and posterior accessory of the great saphenous vein (Grade 1B-strong recommendation, moderate quality evidence). Mechanical or Chemical ablation could be used for truncal veins (Grade 2B-weak recommendation, moderate quality evidence). Open surgery is not recommended, unless the conditions do not respond to other recommended treatments (Grade 1B evidence). Nonvisible symptomatic tributary veins could be treated with ultrasound-guided foam sclerotherapy or chemical ablation (Grade 1B evidence).

NATIONAL INSTITUTE FOR HEALTH AND CARE EXCELLENCE (NICE)

NICE (2013) published a clinical guideline for the diagnosis and management of varicose veins.[86] No new evidence was found in 2016 that would change the guideline recommendations.

“1.3.2 For people with confirmed varicose veins and truncal reflux:

- Offer endothermal ablation (see radiofrequency ablation of varicose veins [NICE interventional procedures guidance 8] and endovenous laser treatment of the long saphenous vein [NICE interventional procedures guidance 52]).
- If endothermal ablation is unsuitable, offer ultrasound-guided foam sclerotherapy (see ultrasound-guided foam sclerotherapy for varicose veins [NICE interventional procedures guidance 440]).
- If ultrasound-guided foam sclerotherapy is unsuitable, offer surgery.

  If incompetent varicose tributaries are to be treated, consider treating them at the same time.

1.3.3 If offering compression bandaging or hosiery for use after interventional treatment, do not use for more than 7 days.”

INTERSOCIETAL ACCREDITATION COMMISSION

In 2016, the Intersocietal Accreditation Commission (IAC) published standards and guidelines on vascular testing for accreditation.[87] The IAC has recommendations for peripheral venous testing in section 4B. The guideline for documentation of lower extremity venous duplex for reflux states the following (section 4.7.2B):

4.7.2.1B Transverse grayscale images without and with transducer compressions (when anatomically possible or not contraindicated) must be documented as required by the protocol and must include at a minimum: i. common femoral vein;

ii. saphenofemoral junction;
iii. mid femoral vein;
iv. great saphenous vein;
v. popliteal vein;
vi. small saphenous vein.

4.7.2.2B Spectral Doppler waveforms with the extremity(s) in a dependent position, demonstrating baseline flow and response to distal augmentation and if reflux is present, duration of retrograde flow measured with calipers and documented as required by the protocol and must include at a minimum: i. common femoral vein;

ii. saphenofemoral junction;
iii. great saphenous vein;
iv. mid femoral vein;
v. popliteal vein;
vi. small saphenous vein.

4.7.2.3B Transverse grayscale images of *diameter measurement* must be documented as required by the protocol and must include at a minimum:

i. saphenofemoral junction;
ii. great saphenous vein at proximal thigh;
iii. great saphenous vein at knee;
iv. small saphenous vein (at saphenopopliteal junction).

CYANOACRYLATE GLUE

National Institute for Health and Care Excellence (NICE)

NICE (2015) published a guidance on cyanoacrylate glue occlusion for varicose veins.[88] NICE recommendations included using cyanoacrylate glue occlusion for special circumstances. Evidence was limited in quantity and quality.

ENDOVENOUS ABLATION

Society for Vascular Surgery and the American Venous Forum

The 2011 Society for Vascular surgery (SVS) and the American Venous Form (AVF) clinical practice guidelines on varicose veins and chronic venous disease included recommendations for endovenous radiofrequency or laser ablation for the treatment of incompetent long saphenous veins.[89]

- A Grade 1B recommendation was made in favor of endovenous thermal ablation over foam sclerotherapy and high ligation and stripping due to the reduced convalescence, pain, and morbidity. A Grade 1B recommendation was defined as a strong recommendation based on moderate quality evidence.
- A Grade 1B recommendation was made against treatment of incompetent perforator veins with CEAP class C2, but recommend treating these veins if they are located

underneath a healed or active ulcer (Grade 2B recommendation defined as a weak recommendation based on moderate quality evidence.)
- The guideline does not make recommendations for saphenous vein diameter.

The 2014 SVS/AVF guidelines for management of venous ulcers included the following recommendations in favor of standard compressive therapy and ablation of incompetent superficial veins that have axial reflux directed to the bed of the ulcer[90]:

- In a patient with a venous leg ulcer and incompetent superficial veins to 1) improve ulcer healing (Grade 2B recommendation defined as a weak recommendation based on moderate quality evidence), and 2) prevent recurrence (Grade 1C recommendation defined as a strong recommendation based on low- to very low-quality evidence)
- To prevent ulceration in a patient with skin changes at risk for venous leg ulcer, and incompetent superficial veins (Grade 2C recommendation defined as a weak recommendation based on low- to very low- quality evidence)
- To aid in ulcer healing and to prevent recurrence in a patient who also has pathological perforating veins located beneath or associated with the ulcer bed (Grade 2C recommendation defined as a weak recommendation based on low- to very low- quality evidence)
- To prevent ulceration or ulcer recurrence in a patient with skin changes at risk for venous leg ulcer or healed venous ulcer and incompetent superficial veins (Grade 2C recommendation defined as a weak recommendation based on low- to very low-quality evidence).
- If a patient is expected to benefit from pathologic perforator vein ablation, percutaneous ablation with ultrasound-guided sclerotherapy or endovenous RFA or EVLA is recommended over open venous perforator surgery (Grade 1C recommendation defined as a strong recommendation based on low- to very low-quality evidence)

National Institute for Health and Care Excellence (NICE)

NICE (2016) published guidance on endovenous mechanochemical ablation for varicose veins.[91]

“Current evidence on the safety and efficacy of endovenous mechanochemical ablation for varicose veins appears adequate to support the use of this procedure provided that standard arrangements are in place for consent, audit and clinical governance. Clinicians are encouraged to collect longer-term follow-up data.”

NICE published a guidance in 2004 for endovenous laser treatment of the long saphenous vein.[92]

“Current evidence on the safety and efficacy of endovenous laser treatment of the long saphenous vein appears adequate to support the use of this procedure provided that the normal arrangements are in place for consent, audit and clinical governance. Current evidence on the efficacy of this procedure is limited to case series with up to 3 years follow-up. Clinicians are encouraged to collect longer-term follow-up data.”

NICE published a guidance in 2003 for radiofrequency ablation of varicose veins.[93]

"Current evidence on the safety and efficacy of radiofrequency ablation of varicose veins appears adequate to support the use of this procedure as an alternative to saphenofemoral ligation and stripping, provided that the normal arrangements are in place for consent, audit and clinical governance."

American College of Radiology[94]

The 2012 the American College of Radiology (ACR) published appropriateness criteria for the treatment of lower-extremity venous insufficiency considered endovenous radiofrequency or laser ablation at least as effective as surgery. Cryoablation and mechanochemical ablation are not addressed. The criteria do not include patient selection criteria related to vein size. They also stated injection sclerotherapy may be appropriate in specific situations, but has not shown to have long-term effectiveness for the great saphenous veins.

Society of Interventional Radiography, Cardiovascular Interventional Radiological Society of Europe, American College of Phlebology, Canadian Interventional Radiology Association[95]

The 2010 the Society of Interventional Radiography (SIR), Cardiovascular Interventional Radiological Society of Europe (CIRSE), American College of Phlebology (ACP), Canadian Interventional Radiology Association (CIRA) published a joint consensus statement on endovenous thermal ablation using either laser or radiofrequency devices under imaging guidance and monitoring an effective treatment of extremity venous reflux and varicose veins under the following conditions:

I. The endovenous treatment of varicose veins may be medically necessary when one of the following indications (A–E) is present:

   A. Persistent symptoms interfering with activities of daily living in spite of conservative/nonsurgical management. Symptoms include aching, cramping, burning, itching, and/or swelling during activity or after prolonged standing.
   B. Significant recurrent attacks of superficial phlebitis
   C. Hemorrhage from a ruptured varix
   D. Ulceration from venous stasis where incompetent varices are a contributing factor
   E. Symptomatic incompetence of the great or small saphenous veins (symptoms as in A above)

II. A trial of conservative, nonoperative treatment has failed. This would include mild exercise, avoidance of prolonged immobility, periodic elevation of legs, and compressive stockings.

III. The patient's anatomy is amenable to endovenous ablation.

SCLEROTHERAPY

National Institute for Health and Care Excellence (NICE)

NICE published a guidance in 2013 for sclerotherapy.[96]

"1.1 Current evidence on the efficacy of ultrasound-guided foam sclerotherapy for varicose veins is adequate. The evidence on safety is adequate, and provided that patients are warned

of the small but significant risks of foam embolisation (see section 1.2), this procedure may be used with normal arrangements for clinical governance, consent and audit."

"1.2 During the consent process, clinicians should inform patients that there are reports of temporary chest tightness, dry cough, headaches and visual disturbance, and rare but significant complications including myocardial infarction, seizures, transient ischaemic attacks and stroke."

Society for Vascular Surgery and the American Venous Forum

The 2011 Society for Vascular Surgery (SVS) and the American Venous Forum (AVF) published practice guidelines[89] and included the following recommendations concerning sclerotherapy in varicose vein treatment:

- Grade 1B (strong recommendation based on moderate quality evidence) recommendation for the use of sclerotherapy to treat varicose tributaries
- Grade 1B recommendation against selective treatment of perforating vein incompetence in patients with simple varicose veins
- Grade 2B (weak recommendation based on moderate quality evidence) for sclerotherapy to treat pathologic perforating veins (i.e., outward flow of $\geq$ 500 ms duration and a diameter of $\geq$ 3.5 mm) located under healed or active ulcers (CEAP class C5-C6)

The 2014 SVS/AVF guidelines[90] for management of venous ulcers included the following recommendations:

- Grade 1C (Strong recommendation, low quality or very-low quality evidence) For those patients who would benefit from pathologic perforator vein ablation, we recommend treatment by percutaneous techniques that include ultrasound-guided sclerotherapy or endovenous thermal ablation (radiofrequency or laser) over open venous perforator surgery to eliminate the need for incisions in areas of compromise skin.

SUMMARY

There is enough research to determine that treatment of certain symptomatic varicose veins using ligation, phlebectomy, endovenous treatment with radiofrequency or laser ablation, endovenous glue/adhesive, and sclerotherapy may improve short-term clinical outcomes (e.g., pain and return to work). Therefore, these procedures may be considered medically necessary in select patients when the policy criteria are met. Procedures not meeting the policy Criteria are considered not medically necessary. In addition, follow-up venous studies performed within six months following the most recent treatment in the absence of complications is considered not medically necessary.

There is not enough research to show improvement in health outcomes for endovenous ablation or sclerotherapy of the investigational indications listed in the medical policy Criteria. Further, the current evidence has limitations including no comparator groups, small study population, and short-term follow-up.

There is not enough research to show that mechanochemical ablation of varicose veins improves patient outcomes and is safe. Therefore, the use of mechanochemical ablation of any vein is considered investigational.

Appendix 1: CEAP Classification	
Clinical classification (C)	C0: no visible or palpable signs of venous disease C1: telangiectasias or reticular veins C2: varicose veins (≥3 mm diameter) C3: edema C4: skin and subcutaneous tissue changes C4a: pigmentation or eczema C4b: lipodermatosclerosis or atrophie blanche C5: healed venous ulcer C6: active venous ulcer
Each clinical class is further characterized by a subscript for symptomatic (S) or asymptomatic (A), for example, C2A or C5S.	
Etiologic classification (E)	Ec: congenital Ep: primary Es: secondary (postthrombotic) En: no venous cause identified
Anatomic classification (A)	As: superficial veins Ap: perforator veins Ad: deep veins An: no venous location identified
Pathophysiologic classification	
Basic CEAP	Pr: reflux Po: obstruction Pr,o: reflux and obstruction Pn: no venous pathophysiology identifiable
Advanced CEAP includes the addition of any of following 18 venous segments as locators:	
Superficial veins	Telangiectasias or reticular veins Great saphenous vein above knee Great saphenous vein below knee Small saphenous vein Nonsaphenous veins
Deep veins	Inferior vena cava Common iliac vein Internal iliac vein External iliac vein Pelvic: gonadal, broad ligament veins, other Common femoral vein Deep femoral vein Femoral vein Popliteal vein Crural: anterior tibial, posterior tibial, peroneal veins (all paired) Muscular: gastrocnemial, soleal veins, other
Perforating veins	Thigh Calf

96. (NICE) NIfHaCE. Ultrasound-guided foam sclerotherapy for varicose veins. Interventional procedures guidance [IPG440]. [cited 5/13/2023]. 'Available from:' https://www.nice.org.uk/guidance/ipg440.

CODES

NOTES:

- This policy uses the nomenclature great saphenous vein and small saphenous vein, also known as greater or long and lesser or short saphenous veins, respectively. Current CPT nomenclature uses long and short saphenous veins.
- There is no specific CPT code for mechanochemical treatment devices (e.g., the ClariVein® device) which should be reported with an unlisted procedure code such as 37799. Per CPT definitions, it is inappropriate to use codes 37241-37244 or 37475-37479 to report this procedure.
- Varithena is not separately reimbursable using any CPT or HCPCS Code.
- There is no specific CPT code for transilluminated powered phlebectomy. Providers might elect to use CPT codes describing stab phlebectomy (37765 or 37766), excision of varicose vein cluster(s) (37785), or unlisted vascular surgery procedure (37799).
- There is no specific CPT for microfoam sclerotherapy. Providers might elect to use CPT codes describing sclerotherapy (36468-36471) or the unlisted vascular surgery procedure code 37799. Use of codes 36475-36476 would be inappropriate as the procedure is not ablation therapy.

Codes	Number	Description
CPT	0524T	Endovenous catheter directed chemical ablation with balloon isolation of incompetent extremity vein, open or percutaneous, including all vascular access, catheter manipulation, diagnostic imaging, imaging guidance and monitoring
	36465	Injection of non-compounded foam sclerosant with ultrasound compression maneuvers to guide dispersion of the injectate, inclusive of all imaging guidance and monitoring; single incompetent extremity truncal vein (eg, great saphenous vein, accessory saphenous vein)
	36466	Injection of non-compounded foam sclerosant with ultrasound compression maneuvers to guide dispersion of the injectate, inclusive of all imaging guidance and monitoring; multiple incompetent truncal veins (eg, great saphenous vein, accessory saphenous vein), same leg
	36468	Single or multiple injections of sclerosing solutions, spider veins (telangiectasia); limb or trunk
	36470	Injection of sclerosing solution; single incompetent vein
	36471	Injection of sclerosing solution; multiple incompetent veins, same leg
	36473	Endovenous ablation therapy of incompetent vein, extremity, inclusive of all imaging guidance and monitoring, percutaneous, mechanochemical; first vein treated
	36474	;subsequent vein(s) treated in a single extremity, each through separate access sites (List separately in addition to code for primary procedure)
	36475	Endovenous ablation therapy of incompetent vein, extremity, inclusive of all imaging guidance and monitoring, percutaneous, radiofrequency; first vein treated
	36476	;subsequent vein(s) treated in a single extremity, each through separate access sites (List separately in addition to code for primary procedure)
	36478	Endovenous ablation therapy of incompetent vein, extremity, inclusive of all imaging guidance and monitoring, percutaneous, laser; first vein treated
	36479	;subsequent vein(s) treated in a single extremity, each through separate access sites (List separately in addition to code for primary procedure)
	36482	Endovenous ablation therapy of incompetent vein, extremity, by transcatheter delivery of a chemical adhesive (eg, cyanoacrylate) remote from the access site, inclusive of all imaging guidance and monitoring, percutaneous; first vein treated
	36483	;subsequent vein(s) treated in a single extremity, each through separate access sites (list separately in addition to code for primary procedure)
	37700	Ligation and division of long saphenous vein at saphenofemoral junction, or distal interruptions
	37718	Ligation, division, and stripping, short saphenous vein (for bilateral procedure, use modifier 50)
	37722	Ligation, division, and stripping, long (greater) saphenous veins from saphenofemoral junction to knee or below
	37735	Ligation and division and complete stripping of long or short saphenous veins with radical excision of ulcer and skin graft and/or interruption of communicating veins of lower leg, with excision of deep fascia
	37760	Ligation of perforators veins, subfascial, radical (Linton type) including skin graft, when performed, open, 1 leg
	37761	Ligation of perforator vein(s), subfascial, open, including ultrasound guidance, when performed, 1 leg
	37765	Stab phlebectomy of varicose veins, one extremity; 10-20 stab incisions
	37766	Stab phlebectomy of varicose veins, one extremity; more than 20 incisions

Codes	Number	Description
	37780	Ligation and division of short saphenous vein at saphenopopliteal junction
	37785	Ligation, division, and/or excision of varicose vein cluster(s), one leg
		Unlisted procedure, vascular surgery
	93970	Duplex scan of extremity veins including responses to compression and other maneuvers; complete bilateral study
	93971	Duplex scan of extremity veins including responses to compression and other maneuvers; unilateral or limited studies
HCPCS	J3490	Unclassified drugs
	S2202	Echosclerotherapy

Medical Policy Manual Surgery, Policy No. 109

Percutaneous Angioplasty and Stenting of Veins

Effective: February 1, 2024

Next Review: September 2024
Last Review: December 2023

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION

Dilation and/or stent placement in veins is intended to restore blood flow in a narrowed or collapsed vein.

MEDICAL POLICY CRITERIA

Note: This policy addresses percutaneous angioplasty and stenting of **veins** only. This policy does *not* address percutaneous angioplasty and stenting of peripheral arteries, including repair of aneurysms, which may be considered medically necessary. Extracranial carotid angioplasty is addressed in a separate policy (see Cross References section).

I. Percutaneous transluminal angioplasty, with or without stenting, may be considered **medically necessary** for the treatment of venous stenoses in the following instances:

   A. Stenotic lesions of arteriovenous dialysis fistulas and grafts, and ipsilateral venous stenosis in the outflow of a functioning dialysis fistula and graft

   B. Superior or inferior vena cava syndrome with significant symptoms, from either extrinsic compression or intrinsic stenosis/occlusion [when standard treatments (i.e., radiation and/or chemotherapy) have failed]

C. Left iliac vein compression syndrome (May-Thurner Syndrome)

D. As an adjunct to prior or concurrent ipsilateral first rib resection for venous thoracic outlet syndrome due to persistent extrinsic compression (Paget-Schroetter syndrome) documented by pre-procedure imaging (i.e., ultrasound, venography, CT, or MRI)

E. Pulmonary vein stenosis

F. Thrombotic obstruction of major hepatic veins (Budd-Chiari syndrome)

G. Post-operative venous narrowing due to repair of sinus venosus atrial septal defect

H. Pulmonary artery stenosis and/or hypoplasia

I. Venous obstruction of an atrial baffle following Mustard or Senning repair of transposition of the great arteries

J. Symptomatic venous occlusion due to electrical device lead or central line placement

K. Portal vein stenosis in a liver transplant recipient

II. The use of angioplasty and/or endoprostheses for creation of intrahepatic shunt connections between the portal venous system and hepatic vein may be considered **medically necessary**.

III. Percutaneous transluminal angioplasty, with or without stenting, is considered **investigational** when policy criteria are not met and for all other venous indications, including but not limited to:

A. Deep vein thrombosis, venous stenosis, or venous insufficiency that is not related to the medically necessary indications above (I.A.- K.)

B. Chronic cerebrospinal venous insufficiency in multiple sclerosis or other conditions

C. Venous sinus obstruction or occlusion in idiopathic intracranial hypertension

NOTE: A summary of the supporting rationale for the policy criteria is at the end of the policy.

LIST OF INFORMATION NEEDED FOR REVIEW

It is critical that the list of information below is submitted for review to determine if the policy criteria are met. If any of these items are not submitted, it could impact our review and decision outcome.

- History and Physical/Chart Notes
- Documentation of symptoms, associated diagnoses and treatments

CROSS REFERENCES

BACKGROUND

PERCUTANEOUS TRANSLUMINAL ANGIOPLASTY OF THE VEINS

Percutaneous transluminal angioplasty (PTA) of the veins is a procedure that has been used as an alternative to open vascular surgery in order to restore blood flow through narrowed veins. Techniques may include balloon angioplasty, laser angioplasty, and stent placement.

INTRAVASCULAR STENTS

Intravascular stents are used as an adjunct to angioplasty to prevent vessel wall collapse. They can be placed via transluminal catheters or placed with catheters during open vascular procedures. Drug-eluting stents are intended to prevent restenosis by reducing the growth of neointimal tissue. A number of different drugs are being evaluated for this use, including paclitaxel and sirolimus. These stents are coated with a mixture of synthetic polymers blended with the drug. A second coat of drug-free polymers is then added to serve as a diffusion barrier, thus allowing the gradual release of drug to the precise site of interest while avoiding systemic side effects.

ILIAC VEIN COMPRESSION SYNDROME

Iliac vein compression syndrome (IVCS) is deep vein thrombosis (DVT) that occurs as a result of compression of the left common iliac vein between the overlying right common iliac artery and the body of the fifth lumbar vertebra. This syndrome is relatively uncommon. If DVT occurs, it is treated with anticoagulation therapy. However, the underlying mechanical compression must be treated with surgery or stent placement. Left untreated it may result in recurrent DVT or postthrombotic syndrome (PTS) characterized by chronic swelling and pain in the affected extremity. Some patients also develop varicosities and stasis ulcers. This condition may also be referred to by other terms including but not limited to May-Thurner syndrome, non-thrombotic iliac vein lesions (NIVL), and Cockett syndrome.

PROXIMAL UPPER EXTREMITY VENOUS THROMBOSIS

Proximal upper extremity venous thrombosis occurs as a result of mechanical compression of the subclavian vein at the thoracic outlet. The natural history of the disorder is typically one of chronic venous obstruction with development of a painful, swollen extremity.[1, 2] Thrombosis may affect the brachiocephalic, subclavian, and/or axillary veins. Typical management of this condition involves thrombolysis and surgical decompression after a variable interval of oral anticoagulation. Venous stent placement may be helpful in maintaining patency of the vein following thoracic outlet decompression surgery that includes first rib resection. This condition may also be referred to by other terms including but not limited to axillary-subclavian venous thrombosis, effort thrombosis, Paget-Schroetter syndrome, or venous thoracic outlet syndrome.

IDIOPATHIC INTRACRANIAL HYPERTENSION

Idiopathic intracranial hypertension (IIH) is characterized by elevated intracranial pressure (ICP). The most common symptoms are headache and papilledema. Other symptoms include transient visual obscurations, pulsatile tinnitus, diplopia, and sustained visual loss. Initial evaluation of patients presenting with headache and papilledema consists of CT or MRI scan for possible hydrocephalus or tumor. Occlusion of the venous sinus, particularly the transverse sinus, is considered an uncommon cause of increased ICP. There has been some debate as to whether this occlusion is the cause or the effect of ICP. The hypothesis is that obstruction of venous return decreases venous outflow from the brain which also decreases

cerebrospinal fluid (CSF) outflow with subsequent increase in intracranial CSF pressure. Medical treatment includes medications that lower CSF production and/or therapeutic lumbar puncture. Since most patients with IIH are obese, weight loss is commonly recommended. If medical treatment fails to control IIH, surgical treatments include ventriculoperitoneal shunting, optic nerve sheath fenestration (optic nerve decompression), and subtemporal decompression. Angioplasty with stenting has been proposed for maintaining venous sinus patency. IIH may also be referred to as pseudotumor cerebri or benign intracranial hypertension, though these terms are considered inadequate and IIH is the preferred term.

CHRONIC CEREBROSPINAL VENOUS INSUFFICIENCY IN MULTIPLE SCLEROSIS

Multiple sclerosis (MS) is generally considered a chronic inflammatory demyelinating disease of the central nervous system (brain, spinal cord, and optic nerve) believed to be triggered by an autoimmune response to myelin. However, in part due to the periventricular predilection of the lesions of MS, vascular etiologies have also been considered. The core foundation of this vascular theory is that venous drainage from the brain is abnormal due to outflow obstruction in the draining jugular vein and/or azygos veins. This abnormal venous drainage, which is characterized by special ultrasound criteria, is said to cause intracerebral flow disturbance or outflow problems that lead to periventricular deposits. In the chronic cerebrospinal venous insufficiency (CCSVI) theory, these deposits have a similarity to the iron deposits seen around the veins in the legs of patients with chronic deep vein thrombosis. Balloon dilatation, with or without stenting, has been proposed as a means to treat the outflow problems, thereby alleviating CCSVI and MS complaints.

REGULATORY STATUS

While there are several types of stents that are approved by the U.S. Food and Drug Administration (FDA) for improvement of outflow for arteriovenous (A-V) access grafts in hemodialysis patients, and for the creation of intrahepatic shunt connections between the portal venous system and hepatic vein [i.e., transjugular intrahepatic portosystemic shunt (TIPS)], there are currently no stents with FDA approval for use in veins for any other indications.

In March 2017, the FDA issued a safety communication regarding the use of balloon angioplasty devices to treat autonomic dysfunction. This supplemented an earlier warning from the FDA concerning the potential for adverse events following endovascular interventions to treat CCSVI. Reports of adverse events obtained by the FDA included death, stroke, detachment and/or migration of stents, vein damage, thrombosis, cranial nerve damage, and abdominal bleeding. This communication included the caveat that clinical trials of this procedure require FDA approval and an investigational device exemption due to potential for harms.

EVIDENCE SUMMARY

The following discussion focuses on the investigational indications noted in Criterion III above.

DEEP VEIN THROMBOSIS (DVT)

There are several objectives for treatment of venous thromboembolism including:[3, 4]

- Prevention of pulmonary embolism;
- Restoration of unobstructed blood flow through the thrombosed vein;

- Preservation of venous valve function; and
- Prevention of recurrent thrombosis.

The current standard of treatment for achieving these goals is anticoagulant therapy (i.e., intravenous unfractionated heparin) to achieve a therapeutic partial thromboplastin time (PTT). After completion of an initial course of anticoagulation therapy, patients with venous thromboembolism (VTE) require continuing therapy to prevent recurrence. Thus, anticoagulation therapy is the standard against which PTA with or without stenting must be compared in order to evaluate the safety, efficacy, and final health outcomes. In addition, long-term follow-up is needed to determine the rates of restenosis, device failure, reoperation, and VTE recurrence.

The following literature appraisal is focused on the published evidence for DVT that is not related to left iliac vein compression syndrome or proximal upper extremity venous thrombosis.

Systematic Reviews

No systematic reviews were identified.

Randomized Controlled Trials

There are no randomized controlled clinical trials (RCTs) in which PTA with or without stenting was compared to standard medical management of DVT.

Nonrandomized Studies

- The bulk of the current literature investigating thrombolysis followed by angioplasty and stenting is limited to small (n<50), non-randomized, non-comparative retrospective reviews and case series of short- to medium-term duration.[4-9]
- The majority of studies are for DVT related to extrinsic compression (e.g., May-Thurner syndrome), or have heterogeneous patient populations that include both compression-related and non-compression-related DVT.

IDIOPATHIC INTRACRANIAL HYPERTENSION

Studies for the diagnosis and treatment of idiopathic intracranial hypertension (IIH) must answer the following questions:

1. Is venous sinus occlusion the cause or the effect of increased intracranial pressure (ICP)?
2. Is venous PTA with or without stenting safe and effective in reducing ICP compared with conventional treatment?

To assess the effectiveness and safety of intracranial venous stenting as a treatment of IIH, health outcomes must be compared with current standard treatments. The ideal clinical trial design is random allocation of similar patients to active or sham venous angioplasty, and/or conventional medical or surgical treatments.

Systematic Reviews

Kalyvas (2021) published a systematic review of controlled and observational studies on surgical treatments of IIH, including CSF diversion techniques, optic nerve sheath fenestration, bariatric surgery, and venous sinus stenting.[10] One hundred and nine publications were

included in the review, consisting of three prospective observational studies, 74 retrospective case series, and 31 case reports. No randomized controlled trials were identified for inclusion in the review. Of the 2,302 predominately female (84.3%) patients included across studies, 825 underwent venous sinus stenting. Data specific to venous sinus stenting were from 47 studies, of which three were prospective, 29 were retrospective case series, and 14 were single case reports. Improved papilledema, visual fields and headaches following venous sinus stenting was reported as 87.1%, 72.7% and 72.1% of the patients respectively. Restenting or supplementary intervention was needed due to venography-documented restenosis in 3.4% of patents. Adequate data to generate estimates of 12-month failure rate for venous sinus stenting of 13.1% was available from 20 studies. Major complications were reported in 19 patients (2.3%) including subdural hematoma, intracerebral hematoma, subarachnoid hemorrhage, cerebellar hematoma, obstructive hydrocephalus, and death.

A 2015 updated Cochrane review evaluated the evidence for IIH interventions, and included RCTs in which any intervention used to treat IIH had been compared to placebo or another form of treatment.[11] Stenting of the transverse intracerebral venous sinus was assessed as a treatment, however the reviewers found no studies that met their inclusion criteria due to the lack of a control group for comparison. The review excluded five small case series, one retrospective review and two small clinical trials.

A 2014 systematic review of various treatments for IIH found only case series, of which 30 had extractable data.[12] Of the 332 total patients, 88 had venous sinus stenting. However, the studies only reported secondary outcomes related to symptoms of headache, papilledema, and visual acuity. The primary outcome of increased intracranial pressure was not reported. The authors concluded that the evidence was insufficient to recommend for or against any treatment modalities for IIH.

Randomized Controlled Trials

There are no randomized controlled clinical trials in which PTA with or without stenting was compared to standard medical or surgical management of IIH.

Nonrandomized Studies

Current evidence is limited to mainly small retrospective reviews and case series.[13-16] One of the largest studies was a retrospective review of 52 patients at a single center who underwent stenting due to IIH unresponsive to maximum acceptable medical treatment.[17] The follow-up period ranged from two months to nine years. All 52 patients were reported to have immediate elimination of the transverse sinus stenosis gradient and rapid improvement in IIH symptoms including resolution of papilledema. Six patients had relapse of symptoms (headache) and increased venous pressure with recurrent stenosis adjacent to the previous stent. In these patients, an additional stent was placed, with response similar to that following the first stent placement. Another retrospective study, published by Boddu (2019), included 70 consecutive patients who underwent venous sinus stenting for IIH and reported that 13% of the patients had impaired drainage of the vein of Labbé following treatment.[18]

ILIOFEMORAL VENOUS OBSTRUCTIVE DISEASE

Systematic Reviews

Ferreira (2021) published a systematic review of available data on mid-term (30 days to three years) stent patency rates and clinical outcomes of iliac stenting in post-thrombotic

syndrome.[19] Data from 1008 patients reported in 18 publications were included. The pooled technical success rate was 96%. The pooled primary and secondary patency rates were 98.2% and 100% at 30 days, 78.1% and 94.5% at 12 months and 66.3% and 89.4% at 36 months, respectively. Pooled rates of ulcer healing, pain and edema relief were 78.1%, 53.4% and 48.8%, respectively. Intraoperative venous injury was reported in four studies, with a pooled proportion rate of 28.0% (95% CI 14.1 to 44.5, I^2=91.4%). The most common minor complication, postoperative back pain, was reported in three studies at a rate of 57.1% (95% CI 46.3 to 67.6, I^2=73.9%). Two studies reported stent fracture at a rate of 5.9% (95% CI 3.1 to 9.4, I^2=18.6%). Stent migration was reported in one study. Bias at the outcome level was evaluated with the GRADE system in 14 of the studies; serious or very serious risk of bias was found in nine of the 14 studies assessed and the quality of all studies assessed was low or very low.

Nonrandomized Studies

A retrospective analysis of forty-two patients (27 women and 15 men with a mean age of 47.3 years) who underwent venous recanalization, pre-dilatation and stenting of the narrowed or occluded iliac and/or femoral veins to treat chronic femoro-iliac venous obstructive disease was published by Guillen (2020).[20] Severity of post-thrombotic syndrome (PTS) and quality of life were assessed at baseline and three months after the intervention respectively, using Villalta score and Chronic Venous Insufficiency Questionnaire (CIVIQ-20) scale. Results: Immediate technical success was achieved in 41/42 (97.6%) patients, without any major complications. Primary patency, primary assisted patency and secondary patency at the end of the median imaging follow-up of 18.1 months (IQR, 9.7 to 34.4) were achieved in 29/42 (66.7%) patients, 33/42 (78.6%) patients and 37/42 (88.1%) patients, respectively. Median Villalta and CIVIQ-20 scores decreased from 14 (IQR, 10 to 19) and 57 (IQR, 39 to 72) at baseline, respectively, to 5 (IQR, 2 to 9) and 30 (IQR, 24 to 50) three months after the procedure, respectively ($p<0.0001$), indicating significant decrease in the severity of PTS and improvement in quality of life. Of note, early in-stent thrombosis within one month occurred in 9/42 (21.4%) patients. This study is limited by its retrospective design, heterogeneity in the stent used, and lack of long-term outcome data.

Results of the VIRTUS trial (VIRTUS Safety and Efficacy of the Veniti Vici Venous Stent System When Used to Treat Clinically Significant Chronic Non-Malignant Obstruction of the Iliofemoral Venous Segment) were published by Razavi (2019).[21] This prospective, international, single-arm, FDA-IDE pivotal study evaluated the safety and effectiveness of a dedicated endovenous stent for symptomatic iliofemoral venous obstruction. One hundred and seventy patients (127 chronic post-thrombotic, mean age 54 years, 56.4% female) at 22 sites were treated with a self-expanding nitinol stent developed for dedicated use in the venous system (Vici Venous Stent System). Patients included those with ≥50% obstruction on venography and Clinical, Etiology, Anatomic, Pathophysiology clinical classification ≥3, or at least moderate leg pain with a Venous Clinical Severity Score of two or greater. Results: Freedom from a major adverse event through 30 days was 98.8%. Through one year, 54 device or procedure-related serious adverse events were reported in 28 (16.5%) of the patients. The one-year primary patency rate for the entire group was 84.0%. Venographic patency rates for the nonthrombotic and chronic post-thrombotic groups were 96.2% and 79.8%, respectively. At 12 months, 64% (85/132) of patients demonstrated at least a three-point reduction in Venous Clinical Severity Score. Long-term (five-year) outcomes are anticipated. This study was funded by both Veniti, Inc. and Boston Scientific, and at least one study author holds financial interest in the sponsoring company.

CHRONIC CEREBROSPINAL VENOUS INSUFFICIENCY (CCSVI) IN MULTIPLE SCLEROSIS (MS)

Systematic Reviews

A Cochrane review[22] and five systematic reviews[23-27] with critical analyses of the current literature concluded that there is insufficient evidence to verify a relationship between CCSVI and MS. The authors noted the high degree of heterogeneity between study outcomes, sensitivity, and specificity, and marked variability of odds ratios.

Two meta-analyses[28, 29] reported outcomes after exclusion of outlier studies (e.g., studies with a disproportionately high odds ratio (OR) and/or potential bias). Tsivgoulis (2014) reported on the association between CCSVI and MS and included 19 studies with a total of 1,250 MS patients and 899 healthy controls.[28] When data from all 19 studies were pooled, CCSVI was associated with MS with an OR of 8.35 (95% confidence interval [CI] 3.44 to 20.31, p<0.001). However, in additional sensitivity analyses, the OR associating CCSVI and MS decreased. In the most conservative sensitivity analysis, which excluded eight outlier studies, MS was not associated with CCSVI with an OR of 1.35 (95% CI 0.62 to 2.93, p=0.453). The Zwischenberger (2013) meta-analysis of 13 studies with a total of 1141 MS patients and 738 healthy controls reported CCSVI and MS was associated with MS (OR 2.57, p<0.001).[29] In a subsequent analysis of nine studies with four outliers (studies with disproportionately high ORs) removed, the OR decreased, but still associated CCSVI with MS.

A systematic review of the association between CCSVI and MS was published by Laupacis (2011).[26] This review included eight studies that used ultrasound to diagnose CCSVI by the Zamboni criteria and compared the rate of CCSVI in patients with MS to those without MS. These studies were mostly small, with the median number of patients with MS of 50. A large degree of heterogeneity existed across studies in the rate of CCSVI among MS patients. Two smaller studies reported a rate of 0% for CCSVI in a total of 20 and 56 patients with MS. In contrast, the original study by Zamboni (2009a) reported a 100% rate of CCSVI in 109 patients with MS.[30] A small study of 25 patients also reported a very high rate of CCSVI at 84% (21/25). There was no obvious reason identified for this large discrepancy in CCSVI rates; the authors hypothesized that the most likely reason was variability in ultrasound technique and interpretation. The analysis suggested a significant association of CCSVI with MS in combined analysis, with an OR of 13.5 (95% CI, 2.6 to 71.4). A substantial degree of heterogeneity existed in this measure as well, with a reported I2 of 89%. Several sensitivity analyses showed marked variability of the OR from a low of 3.7 to more than 58,000. However, in all cases the association of CCSVI with MS remained significant.

Another systematic review published in 2011 included a smaller number of studies (n=4) but reached conclusions similar to the other analyses.[27] The rate of CCSVI in MS patients ranged from 7% to 100%, and the rate in non-MS patients ranged from 2% to 36%. A significant association was detected between MS and CCSVI but with a high degree of heterogeneity (I^2=96%) and an OR for association that varied widely, from approximately 2 to more than 26,000.

A recently updated Cochrane review evaluated the evidence for PTA to treat CCSVI in patients with MS and included three RCTs, described in greater detail below (total n=238).[31] Two of the studies were judged to be at unclear risk of bias for one item (random sequence generation in one study and blinding in the other), but otherwise at low risk of bias. The authors concluded

that there was moderate-quality evidence that venous PTA did not improve health outcomes for patients with MS and that further study was not necessary.

Randomized Controlled Trials

A randomized wait list study by Napoli (2019) included 66 MS patients with a diagnosis of CCSVI who were randomized to receive venous PTA immediately or after six months.[32] A number of outcomes were assessed, including clinical-functional measures, evoked potentials and upper limb kinematic measures. While there were some statistically significant differences between groups for a composite functional outcome, there were no differences in evoked potential or upper limb kinematic measures.

The following three studies were included in the Cochrane review described above:

Traboulsee (2018) published a double-blind, sham-controlled RCT of balloon venoplasty for MS patients with narrowing of the extracranial jugular and azygos veins.[33] The trial included 104 patients, 49 randomized to venoplasty and 55 to sham treatment, and 103 patients completed the trial with 48 weeks of follow-up. Narrowing of the veins >50% was confirmed by venography prior to randomization. The primary outcome of the trial was change in the MS Quality of Life-54 (MSQOL-54) questionnaire from baseline at 48 weeks. Additional clinical and MRI outcomes were also evaluated. There was no difference found between groups for any of the study's outcomes, and the authors concluded that "for patients with MS, balloon venoplasty of extracranial jugular and azygous veins is not beneficial in improving patient-reported, standardized clinical, or MRI outcomes."

Results from the Brave Dreams trial were published by Zamboni (2018).[34] This was a double-blind, sham-controlled RCT conducted at six MS centers in Italy and included a total of 115 CCSVI patients. These patients were randomized to either venous PTA (n=76) or catheter venography without angioplasty (sham, n=39). There were two primary endpoints assessed at 12 months: the number of new or expanded cerebral lesions by MRI, and a functional measure that included walking control, manual dexterity, balance, postvoid residual urine volume, and visual acuity. There were no significant differences in these endpoints between groups, and no adverse events were reported. The authors concluded that venous PTA was "a safe but largely ineffective technique; the treatment cannot be recommended in patients with MS."

Siddiqui (2014) published results from a prospective, double-blind, sham-controlled RCT of venous angioplasty in MS patients with CCSVI.[35] This trial enrolled nine patients in intervention group and 10 in the sham-controlled group. All patients met the criteria for diagnosis of CCSVI.[36] The primary end points of the trial included safety at 24 hours and 30 days postangioplasty; greater than 75% restoration of venous outflow at 30 days; the presence of new MS lesions; and relapse rate over six months. Secondary end points included changes in disability scores, brain volume, cognitive test scores, and quality-of-life measures. All patients tolerated the procedures well; no operative or postoperative complications were identified. One patient in the angioplasty group experienced an episode of symptomatic bradycardia. No significant differences were observed in venous outflow characteristics between the treated and control groups, nor were any significant improvements observed in clinical disease scores among treated patients compared with controls. The results of this RCT are limited by the small number of patients. However, the failure to show a beneficial effect of venous angioplasty on MS activity supports a lack of efficacy for this treatment.

Nonrandomized Studies

The studies that focused on the potential relationship between CCSVI and MS reported varying and contradictory outcomes. For example, while Zamboni (2009a) and other authors[30, 37-39] reported a strong association between CCSVI and MS, numerous studies have reported insignificant or no difference in the prevalence of CCSVI in MS patients compared to healthy controls, or no association between CCSVI and MS occurrence or symptoms[36, 38, 40-46].

The studies that focused on outcomes of PTA with or without stent placement reported few adverse events, but mixed efficacy outcomes.[47-53] For example, while Zamboni (2009b).[48] reported significant improvement in all measures for patients with relapsing-remitting MS, Kostecki (2011) reported a significant improvement only in heat intolerance and fatigue severity six months post endovascular treatment.[47] No trials were found that compared PTA with concurrent control groups. All authors noted the need for well-designed randomized clinical trials. Many authors asserted that PTA with or without stenting in these patients should not be performed outside the clinical trial setting.

Adverse Events

Burton (2011) described five patients who had undergone venoplasty and presented with complications of the procedure.[54] The complications were internal jugular vein stent thrombosis, cerebral sinovenous thrombosis, stent migration, cranial nerve injury, and injury associated with venous catheterization. There was not a denominator in these studies to determine the rate of these events.

Petrov (2011) reported on the safety profile of 495 venoplasty procedures performed in 461 patients with MS, including 98 stent implantations.[49] There were no deaths, major bleeding events, or acute exacerbations of MS. The most common procedure-related complication was vein dissection, which occurred in 3.0% of cases. Other complications included cardiac arrhythmias (1.2%), groin hematoma (1.0%), vein rupture (0.4%), and acute stent thrombosis (1.6%).

Mandato (2012) reported adverse events within 30 days of endovascular intervention for 240 patients with MS over an 8-month period.[55] Neck pain occurred in 15.6% of patients, most commonly following stent implantation. Headache occurred in 8.2% of patients and was persistent past 30 days in 1 patient (0.4%). Intraprocedural arrhythmias occurred in 1.3%, and one patient was diagnosed with a stress-induced cardiomyopathy following the procedure.

An FDA alert issued in May 2012 reported the potential for adverse events following endovascular interventions for MS.[56] Reports of adverse events obtained by FDA included death, stroke, detachment and/or migration of stents, vein damage, thrombosis, cranial nerve damage, and abdominal bleeding. This alert included the caveat that clinical trials of this procedure require FDA approval and an investigational device exemption because of the potential for harms.

PERCUTANEOUS TRANS-HEPATIC BALLOON AND/OR STENT ANGIOPLASTY

Systematic Reviews

Kyaw (2022) performed a systematic review to determine the efficacy and safety of percutaneous trans-hepatic balloon and/or stent angioplasty in the management of portal vein (PV) stenosis following pediatric liver transplantation.[57] There were 213 pediatric liver recipients who underwent PTA for PV stenosis in 19 included studies published between 1991 and 2019. Balloon angioplasty was the initial treatment in the majority (n=153). Primary stent

placement (n=34) was performed for elastic recoil, intimal tears and PV kinks and rescue stent placement (n=14) for recurrent PV stenosis following primary balloon angioplasty. The technical success was 97.6% to 100% overall, 97.6% to 100% for balloon angioplasty only, and 100% for primary stenting. The clinical success was 50% to 100% overall, 50% to 100% for balloon angioplasty only, and 100% for primary stenting. Long-term PV patency was 50% to 100% overall, 37.5% to 100% for balloon angioplasty only, and 100% for primary stenting. The authors comment that "Stent placement may be a primary option in selected cases and a reliable rescue option for recurrent portal vein stenosis following balloon-angioplasty-only".

PRACTICE GUIDELINE SUMMARY

DEEP VEIN THROMBOSIS

Two consensus-based clinical practice guidelines from the Society of Interventional Radiology and the American Heart Association, respectively, provided evidence appraisals and noted a benefit in venous stenting for DVT.[58, 59] However, the majority of the references listed were related to May-Thurner syndrome which is caused by extrinsic compression for which stenting is considered medically necessary. Both guidelines graded the available evidence as very limited.

The American Society of Hematology

The American Society of Hematology published a 2020 guideline for the treatment of deep vein thrombosis and pulmonary embolism which does not discuss venous angioplasty or venous stenting.[60]

Society of Vascular Surgery / American Venous Forum

In the 2014 joint guidelines published by Society of Vascular Surgery and American Venous Forum on the management of proximal chronic total venous occlusion/severe stenosis.[61] The guideline states the following:

> *In a patient with inferior vena cava or iliac vein chronic total occlusion or severe stenosis, with or without lower extremity deep venous reflux disease, that is associated with skin changes at risk for venous leg ulcer (C4b), healed venous leg ulcer (C5), or active venous leg ulcer (C6), we recommend venous angioplasty and stent recanalization in addition to standard compression therapy to aid in venous ulcer healing and to prevent recurrence.*

This was a grade 1 recommendation (strong) but the evidence was considered low/very low quality which was primarily focused on May-Thurner syndrome.

American College of Radiology (ACR)

ACR Appropriateness Criteria® for radiologic management of lower extremity venous insufficiency recommendation guidelines was updated in 2023 with no change to criterion related to this policy.[62]

The 2012 ACR Appropriateness Criteria® for radiologic management of lower extremity venous insufficiency recommendation did not address angioplasty or stenting for these indications.[62, 63] However, they suggest that patients with venous insufficiency and associated venous occlusion or stenosis of the common iliac vein may require venous recanalization with

angioplasty and stenting as an adjunctive treatment, based on three case reports and one small retrospective analysis.

CHRONIC ILIOFEMORAL VENOUS OBSTRUCTION

Society of Interventional Radiology

A 2023 position statement on the endovascular placement of metallic stents for the management of chronic iliofemoral venous obstruction by the Society of Interventional Radiology (SIR) concluded that "the use of endovascular stent placement for chronic iliofemoral venous obstruction to be likely to help selected patients, but the risks and benefits have not been fully quantified in well-designed randomized studies."[64] They recommended the urgent completion of such studies.

CHRONIC CEREBROSPINAL VENOUS INSUFFICIENCY IN MULTIPLE SCLEROSIS (MS)

Society of Interventional Radiology

In 2010 the SIR published a position statement on the association of CCSVI with MS and the efficacy of endovascular treatments.[65] Their recommendations included the following statements:

- At present, SIR considers the published literature to be inconclusive on whether CCSVI is a clinically important factor in the development and/or progression of MS, and on whether balloon angioplasty and/or stent placement are clinically effective in patients with MS.
- SIR strongly supports the urgent performance of high-quality clinical research to determine the safety and efficacy of interventional MS therapies, and is actively working to promote and expedite the completion.

SUMMARY

There is enough research to show that percutaneous venous angioplasty, with or without stenting, can improve health outcomes for patients with certain types of venous stenosis. Therefore, this angioplasty may be considered medically necessary for patients that meet the policy criteria.

There is not enough research to show that percutaneous venous angioplasty, with or without stenting, can improve health outcomes for patients that do not meet the policy criteria, including patients with deep vein thrombosis that is not related to upper extremity venous compression requiring rib resection or iliac vein compression syndrome, or in patients with chronic cerebrospinal venous insufficiency venous sinus obstruction or occlusion in idiopathic intracranial hypertension. Therefore, this procedure is considered investigational when policy criteria are not met.

CODES

Codes	Number	Description
CPT	36481	Percutaneous portal vein catheterization by any method
	36901	Introduction of needle(s) and/or catheter(s), dialysis circuit, with diagnostic angiography of the dialysis circuit, including all direct puncture(s) and catheter placement(s), injection(s) of contrast, all necessary imaging from the arterial anastomosis and adjacent artery through entire venous outflow including the inferior or superior vena cava, fluoroscopic guidance, radiological supervision and interpretation and image documentation and report
	36902	;with transluminal balloon angioplasty, peripheral dialysis segment, including all imaging and radiological supervision and interpretation necessary to perform the angioplasty
	36903	;with transcatheter placement of intravascular stent(s), peripheral dialysis segment, including all imaging and radiological supervision and interpretation necessary to perform the stenting, and all angioplasty within the peripheral dialysis segment
	36904	Percutaneous transluminal mechanical thrombectomy and/or infusion for thrombolysis, dialysis circuit, any method, including all imaging and radiological supervision and interpretation, diagnostic angiography, fluoroscopic guidance, catheter placement(s), and intraprocedural pharmacological thrombolytic injection(s)
	36905	;with transluminal balloon angioplasty, peripheral dialysis segment, including all imaging and radiological supervision and interpretation necessary to perform the angioplasty
	36906	;with transcatheter placement of intravascular stent(s), peripheral dialysis segment, including all imaging and radiological supervision and interpretation necessary to perform the stenting, and all angioplasty within the peripheral dialysis circuit
	36907	Transluminal balloon angioplasty, central dialysis segment, performed through dialysis circuit, including all imaging and radiological supervision and interpretation required to perform the angioplasty (List separately in addition to code for primary procedure)
	36908	Transcatheter placement of intravascular stent(s), central dialysis segment, performed through dialysis circuit, including all imaging radiological supervision and interpretation required to perform the stenting, and all angioplasty in the central dialysis segment (List separately in addition to code for primary procedure)
	36909	Dialysis circuit permanent vascular embolization or occlusion (including main circuit or any accessory veins), endovascular, including all imaging and radiological supervision and interpretation necessary to complete the intervention (List separately in addition to code for primary procedure)

	37238	Transcatheter placement of an intravascular stent(s), open or percutaneous, including radiological supervision and interpretation and including angioplasty within the same vessel, when performed; initial vein
	37239	; each additional vein (List separately in addition to code for primary procedure)
	37248	Transluminal balloon angioplasty (except dialysis circuit), open or percutaneous, including all imaging and radiological supervision and interpretation necessary to perform the angioplasty within the same vein; initial vein
	37249	;each additional vein (List separately in addition to code for primary procedure)
HCPCS	C2623	Catheter, transluminal angioplasty, drug-coated, non-laser

Date of Origin: *January 1996*

IMPORTANT REMINDER

Medical Policies are developed to provide guidance for members and providers regarding coverage in accordance with contract terms. Benefit determinations are based in all cases on the applicable contract language. To the extent there may be any conflict between the Medical Policy and contract language, the contract language takes precedence.

PLEASE NOTE: Contracts exclude from coverage, among other things, services or procedures that are considered investigational or cosmetic. Providers may bill members for services or procedures that are considered investigational or cosmetic. Providers are encouraged to inform members before rendering such services that the members are likely to be financially responsible for the cost of these services.

DESCRIPTION
