

## Group Health Pre-Authorization requirements:

Group Health requires pre-authorization for most services to be covered. The information below outlines pre-authorization requirements at a high level. Some requests for pre-authorization will be reviewed by a clinician for medical necessity. The criteria used to determine medical necessity is also outlined below.

For questions regarding pre-authorization requirements for specific services, please consult your Certificate of Coverage or contact Customer Service at 1-888-901-4636.

Public Employees Benefit Board – Core/Group Health					
Service	Is pre-authorization required?	How do I get pre-authorization?	What criteria must be met for coverage?	Notes	Which providers can I see?
Transplants –organ and stem cell transplants	Yes	Your physician will request authorization for all stages including pre-transplant care, transplant, and post-transplant care		Please check your Certificate of Coverage for benefit and cost share information.	You must see a network provider for services to be covered. Please review the Provider Directory to see who is in your network.

## Clinical Review Criteria

### 4Kscore Test: Predicting the Risk of Aggressive Prostate Cancer

- 4KRK
- Four Kallikrein Markers
- Kallikrien Panel

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
GH Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, GHC has chosen to use their own Medical Policy - 4Kscore Test: Predicting the Risk of Aggressive Prostate Cancer

#### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Prostate Specific Antigen (PSA) is the most widespread test for prostate cancer (PCa) screening. However, it is associated with a high risk of overdiagnosis and overtreatment. Since its introduction into practice in the late 1980s, PSA testing has led to a significant increase in the incidence of prostate cancer and migration to an earlier stage at diagnosis. Most men with an elevated PSA either do not have prostate cancer or have a low-risk disease that is unlikely to affect the quality or length of life if left untreated. Between 17% and 50% of men with prostate cancer detected by PSA test have indolent tumors that would not have led to clinical disease. In addition PSA levels may be elevated by conditions other than cancer such as benign prostatic hyperplasia, and prostatitis. The specificity and sensitivity of the PSA test used alone in detecting prostate cancer range from 20-40% and 70-90% respectively, with an AUC (area under the receiver operating characteristic [ROC] curve) of 0.55-0.71 (depending on the cutoff value used), and a positive predictive value (PPV) of only 25-40%. The low specificity of the PSA test, results in performance of a large number of unnecessary biopsy procedures with the associated anxiety and complications. It is estimated that more than one million men undergo prostate biopsy every year in the USA, the majority of which are potentially avoidable (Vickers 2010, Bratt 2012, Voigt 2014, Parekh 2015).

Continuous efforts are being made to improve the accuracy of the PSA test and/or develop new biomarkers for prostate cancer screening. PSA density and PSA velocity have been used, but were found to only slightly improve the predictive value of PSA, to a level that is insufficient to distinguish between aggressive and indolent forms of prostate cancer. PCA3 and TMPRSS2-ERG fusion biomarkers measured in the urine immediately after a vigorous prostate massage, were also evaluated, but each has its limitations (Punnen 2015, Ferro 2016).

Currently the prediction tools used to preoperatively distinguish between an aggressive and a pathologically insignificant disease incorporate PSA level, clinical stage, as well as biopsy variables such as transrectal ultrasound prostate volume, Gleason grade, number of positive biopsy cores, percentage of cancer in any core sample, total cancer length, and noncancer tissue in biopsy cores. The AUC for the accuracy of these prediction tools ranges from 0.70-0.80 (Carlsson 2013).

The 4Kscore® (4KRK) test (OPKO Lab, Nashville, TN) is a new blood test that has been introduced and evaluated for its ability to accurately predict the risk of aggressive prostate cancer. The test incorporates a panel of four kallikrein protein biomarkers (total PSA [tPSA], free PSA [fPSA], intact PSA [iPSA], and human kallikrein-related peptide 2 [hK2]), together with clinical information (age, and optionally the results of a DRE), in an algorithm that, according to some investigators, provides a percent risk for a high grade cancer (Gleason score  $\geq 7$ ). Tissue kallikrein or kallikrein-related enzymes are a family of 15 secreted serine proteases, the regulatory functions of which are linked to the development of malignancy, neurodegeneration, inflammation and other disorders. Messenger RNA expression of all kallikreins can be detected in the prostate tissue, but KLK2 (also known as human kallikrein2 [hK2]), and KLK3 (also known as PSA) are the most dominant. Some researchers found that in prostate cancer there is a dysregulation and overexpression of both PSA and hK2 and that their levels increase as the prostate cancer becomes more undifferentiated. They also indicate that these kallikreins directly and indirectly contribute to prostate cancer progression and metastasis (Konety 2015, Punnen 2015, McDonald 2016).

Several European studies evaluated the ability of the 4Kscore to distinguish between a pathologically insignificant and an aggressive disease. Based on their analyses, several investigators suggest that 4Kscore test would play an important clinical role as a reflex test before performing an initial prostate biopsy in men with elevated PSA, abnormal DRE results, or after a negative biopsy and persistently higher PSA levels (Punnen 2015). According to the manufacturer, the 4Kscore Test does not provide a diagnosis of prostate cancer; it is designed to help clarify the decision on whether or not to perform a biopsy based on the probability of a patient having aggressive prostate cancer. The test should not be used in isolation to make the decision on the need for biopsy. Other factors such as health status, PSA history medical history, family history of prostate cancer, etc., should all be considered with the 4Kscore risk level into a shared decision-making with the patient.

## Medical Technology Assessment Committee (MTAC)

### 4Kscore Test for Prostate Cancer

#### 03/21/2016: MTAC REVIEW

**Evidence Conclusion:** *Clinical validity (Predictive accuracy) of the 4Kscore test* The four kallikrein markers were initially validated in Europe using retrospective data from multiple European cohorts that participated in European Randomized Study of Prostate Cancer Screening (ERSPC). These were followed by a study in the UK using retrospective data from ProtecT study cohort, and a prospective study conducted in the USA. All 4Kscore validation studies compared its predictive accuracy versus the base model using total PSA and reported the results in the area under the receiver operating characteristic curve (AUC). AUC only focuses on the predictive accuracy of a model. It does not account for potential harms, benefits or cost, and may not capture the tradeoffs that the physician and patient face in making a decision about interventions that can carry both benefits and harms (Baker, 2012). Voigt and colleagues' meta-analysis (Evidence Table 1) pooled data from seven separate trials participating in the ERSPC. The results of the meta-analysis as well as the results of the individual studies it included, suggest that an algorithm using a panel of tPSA, fPSA, iPSA, and hK2 measured in the serum, together with age and optional DRE, is more accurate than measuring total PSA (tPSA) alone in predicting high grade cancer among men with a PSA levels  $\geq 3$  ng/mL. The pooled mean difference in AUC between the Kallikrein clinical model vs. base clinical model was 0.10 (95% CI, 0.08- 0.12),  $p < 0.00001$ , for predicting any cancer and 0.08 (95% CI, 0.05-0.11),  $p < 0.00001$  for predicting high-grade cancer. Bryant and colleagues (2015, Evidence Table 2) validated a statistical model based the four kallikrein markers using retrospective data from the Prostate Testing for Cancer and Treatment (ProtecT study) conducted in the UK. In that study, men with PSA  $\geq 3$  ng/mL underwent an extended 10-core biopsy (sextant biopsy in ERSPC). The kallikrein markers were retrospectively measured in cryopreserved blood, mainly plasma rather than serum. Because of these differences from the ERSPC, the investigators generated new prediction models modified from those developed from the ERSPC cohorts. Similar to the other European studies, the results of the UK study showed that the statistical model including the panel of four kallikrein markers significantly improved the prediction of high grade cancer vs. the use of total PSA plus age. The incremental increase in the AUC with using age + a panel of 4K markers versus age + tPSA was 0.085 for any grade prostate cancer and 0.082 for high-grade cancer. It is to be noted however, that these studies used retrospective data from earlier cohorts from European studies conducted among Caucasian men 50 years of age or older. Plasma or serum samples have been stored for several years and may have been previously thawed and refrozen, which would degrade the kallikrein markers. The trials participating in the ERSPC

used sextant biopsy and the ProtecT study used 10-core biopsy. [Parekh et al, 2015 \(Evidence Table 3\)](#) prospectively validated the 4Kscore test in the USA. The study enrolled 1,300 men referred to biopsy (regardless of their PSA level or clinical findings) in 26 urology centers in the USA. 300 men were used for calibrating the algorithm and 1,012 for its validation. The primary outcome was Gleason score  $\geq 7$  prostate cancer (PCa) on prostate biopsy. Accuracy of the 4Kscore test was assessed by the AUC, calibration plots, and decision curve analysis. The great majority of the participants (86%) were white men, which may limit generalization of the results. The authors compared the predictive accuracy of the 4Kscore vs. a modified Prostate Cancer Prevention Trial Risk Calculator (PCPTRC) 2.0. The results showed that the 4Kscore had a significantly higher discrimination in detecting Gleason  $\geq 7$  cancer compared to modified PCPTRC 2.0 (AUC 0.82 versus 0.74,  $p < 0.0001$ ).

The results of validation studies on the predictive accuracy of the 4Kscore may be summarized in the following table: *The AUC for discriminating /predicting Gleason  $\geq 7$  cancer using the full panel 4Kscore\**

	N participants	AUC (95% CI)
USA validation study (Parekh, 2015)*	1,012	0.82 (95% CI, 0.79 to 0.85)
UK study (Bryant, 2015)**	6,129	0.82 (95% CI, 0.80 to 0.84)
European trials participating in ERSPC study		
Unscreened cohorts	262	0.87
France (Benchikh, 2010)	740	0.83-0.84
Goteborg (Vickers, 2008)	2,914	0.76-0.78
Rotterdam (Vickers, 2010)		
Screened cohorts	1,241	0.83
Goteborg (Vickers, 2008)	1,501	0.80
Rotterdam (Vickers, 2010)		

\*Compared to AUC 0.74 with modified Prostate Cancer Prevention Trial Risk Calculator (PCPTRC) 2.0 ( $P < 0.0001$ )

\*\* Compared to AUC of 0.63 (95% CI, 0.62-0.65), for total PSA +age ( $p < 0.001$ ).

- AUC for total PSA models ranged between the European studies from 0.51 to 0.77.
- Mean difference in AUC between 4K model and the base model (consisting of age total PSA, and DRE) in predicting high grade cancer varied between 0.10 (95% CI, 0.06-0.16) to 0.13 (95% CI, 0.11-0.15) depending on whether DRE results were or were not included with the 4K panel and age.

**Clinical utility of the 4Kscore test** Clinical utility of a test implies that high-level evidence shows that the use of the marker improves patient outcome sufficiently to justify its incorporation into routine clinical care (NCCN Task Force [Febbo 2011]). There are no published RCTs or prospective controlled studies, to date, that examined the clinical utility of the 4Kscore test or its therapeutic impact, i.e. whether its results would have an effect on the treatment decision-making and improve patient outcomes. The published studies examined and validated the predictive ability of the 4Kscore test, but did not directly examine its impact on the clinical outcomes. In order to investigate the potential clinical effect of the four kallikrein markers in the blood, the investigators used decision analyses to simulate outcomes if biopsy decisions have been based on various cut-points from the models. Decision analyses methods are based on simulations using estimates of the probability and sequelae of events in a hypothetical cohort of patients (Vickers, 2006). Bryant and colleagues' 2015 (Evidence Table 2), decision curve analysis based on various cutpoints showed that a model using a threshold representing a 6% risk of Gleason score  $\geq 7$  in men with PSA  $\geq 3$  ng/ml, would reduce the biopsy rate by 42.8%, but at the expense of missing 14 of 133 (10.5%) high grade cancers. The analysis of the US prospective study (Parekh et al, 2015, Evidence Table 3) suggests that the use 4Kscore test among men with PSA  $\geq 3$  ng/ml, may potentially reduce the number of prostate biopsies, but may also fail to detect a small number of significant cancers depending on the cutoff value used. Using 6% risk as a cutoff would reduce 30% of the biopsies, and delay the diagnosis of 1.3% of high grade cancers. A  $\geq 9\%$  cutoff would reduce 43% biopsies and delay diagnosis of 2.4% Gleason  $\geq 7$  cancers. Konety and colleagues, 2015 (Evidence Table 4), retrospectively examined the impact of the 4Kscore Test on the urologist-patient decisions about performing a biopsy in men with abnormal PSA and/or DRE results. The study retrospectively collected data from participating urologists who ordered the 4Kscore Test as part of their assessment of men referred their practice for abnormal PSA and or DRE. The results of the analysis suggest that performing the 4Kscore Test resulted in 64.6% reduction in prostate biopsies among the 611 patients seen by the participating urologists. Due to its design and limitations, the study does not provide sufficient evidence to determine the clinical utility of the test. Conclusion: There is fair evidence from a number of validation studies that 4Kscore test may improve the predictive accuracy of total PSA when used among mainly white men with PSA level  $\geq 3$  ng/mL. As indicated earlier the predictive accuracy of a marker or test does not account for potential harms, and benefits, and may not capture the tradeoffs that the physician and patient face in making a decision about interventions that can carry both benefits and harms. There is insufficient evidence on the clinical utility of

the 4Kscore test. There is insufficient evidence to determine the therapeutic impact of the 4Kscore test or the effect of the treatment decision based on the results of the test on the patient outcomes.

**Articles:** The search for studies on the accuracy of the 4Kallikrein panel in predicting high grade prostate cancer, revealed one study that prospectively evaluated the test among men in the USA, and a number of European studies that used retrospective data from several cohorts of screened and unscreened men participating in European Randomized Study of Prostate Cancer (ERSPC) and one cohort from the British ProtecT study. A meta-analysis that pooled the results of seven studies using the ERSPC cohorts was also identified. The search did not reveal any randomized controlled trial that examined the clinical utility of the 4Kscore test, only an observational study that analyzed retrospective data for men receiving the test. The following studies were selected for critical appraisal: Voigt JD, Zappala SM, Vaughan ED, et al. The Kallikrein Panel for prostate cancer screening: its economic impact. *Prostate*. 2014 Feb; 74(3):250-259 [See Evidence Table 1](#). Bryant RJ, Sjoberg DD, Vickers AJ, et al. Predicting high-grade cancer at ten-core prostate. [See Evidence Table 2](#). Parekh DJ, Punnen S, Sjoberg DD, et al. A multi-institutional prospective trial in the USA confirms that the 4Kscore accurately identifies men with high-grade prostate cancer. *Eur Urol*. 2015 Sep; 68(3):464-470. [See Evidence Table 3](#). biopsy using four kallikrein markers measured in blood in the ProtecT study. *J Natl Cancer Inst*. 2015 Apr 11; 107. Konety B, Zappala SM, Parekh DJ, et al. The 4Kscore test reduces prostate biopsy rates in community and academic urology practices. *Rev Urol*. 2015; 17 (4):231-240. [See Evidence Table 4](#).

The use of 4Kscore Test for Prostate Cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

  - [click here to view the current criteria](#).
- **For those with a Microsoft contract,** [click here to view the criteria](#).
- **For plans without a benefit,** the service is not covered at this time.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Autism is a neurodevelopmental disorder in the category of pervasive developmental disorders (PDD), which is a group of conditions that also include Rhett's disorder, childhood disintegrative disorder, Asperger's disorder, and pervasive developmental disorder not otherwise specified (PDD NOS). Autism is characterized by a triad of deficits involving impaired language development, reciprocal social interaction, and stereotyped repetitive patterns of behaviors and interests. The prevalence estimates released by the CDC based on 2002 data show that approximately one in fifty children in the US is autistic. These estimates indicate a dramatic increase in the recent years, which may be due to an actual increase in the occurrence of the disorder as well as the increased awareness of the disorder among the clinicians. There are no definitive medical tests to indicate the presence of any form of autism spectrum disorders (ASD). Diagnostic assessment includes use of ICD and DSM-IV diagnostic criteria and standardized methods to assess core and co-morbid conditions. Parents usually become aware of developmental problems in their child starting around the age of 18 months, but diagnosis is often not made until 2 years after the expression of parents' concerns. It may sometimes be delayed until close to the age of six (Ospina 2008, Granpeesheh 2009, Levy 2009, Spreckley 2009).

Autism is a lifelong condition with variable clinical course throughout childhood and adolescence. Many adults with autism may still require full-time care. While there is no known cure, the general agreement is that early diagnosis followed by appropriate treatment may improve outcomes in later years for most individuals. Over the past twenty years, a variety of therapies have been proposed to improve the symptoms associated with ASD, many of which have not been validated scientifically. These include pharmacological therapies, complementary therapies as diet modifications and vitamin therapy, speech and language therapy, and psychosocial treatments.

The well-researched treatment programs are based on the principles of applied behavioral analysis (ABA), sometimes called behavioral therapy or behavioral modification. The approach has been outlined by Lovaas and colleagues in the 1980s and, as originally described, involves teaching appropriate behaviors by breaking tasks down

into small discrete steps and training in a systematic and precise way called discrete trial training. It is delivered on a 1:1 basis, for 40 hours a week over a three-year period.

The approach of ABA is based on the concept that children with ASD have significant difficulties with learning, being unable to learn through imitation, and listening as normal children do. Its overall goal is to motivate the child to want to be successful. ABA is founded on behavioral principles of learning and motivation, consisting of reinforcement, extinction, stimulus control, and generalization. The basic learning principle at the core of ABA is the idea that the consequences of a behavior can either strengthen or weaken it; behavior that is followed by the presentation of desirable consequences will be strengthened (reinforcement), whereas behavior that is followed by aversive consequences or the removal of desirable consequences will be weakened.

A defining feature of ABA programs is that they are applied consistently. This is accomplished by the use of explicitly written programs for each skill to be taught or maladaptive behavior to be treated, and by having the behavioral analyst train everyone who works with the child to implement it. To increase the likelihood of the generalization of the treatment efforts, it is critical for the therapists and parents to be trained to implement the programs across situations, settings, and people. Typically, teaching trials are repeated until they are mastered. Maladaptive behaviors such as aggression and self-injury are not reinforced, whereas specific, appropriate alternative behaviors are either taught or maintained through positive reinforcement. Each child's program is unique to his/her needs that evolve with the child's progress. Accurate records are kept so that progress can be assessed and programmatic changes made (Spreckley 2009, Granpeesheh 2009).

Treatment based on APA represents a wide range of early intervention strategies for children with autism. As indicated earlier, the first types of behavioral treatment programs developed, the discrete trial training, were very intensive and structured. Investigators found that children may have difficulty generalizing the information from these very structured sessions to group and community settings. One comprehensive intervention program reviewed by the National Research Council (NRC) was early intensive behavioral intervention (EIBI) based on the UCLA Young Autism Project Model. This is an intensive home-based program using the manual published by Lovaas, and involves up to 40 hours of therapy per week for at least 2 years. Other EIBI programs were developed by other researchers (Howlin 2009, Reichow 2009).

Less structured more naturalistic behavior programs e.g. incidental teaching and pivot response training (PRT) have been developed but were not researched in a randomized controlled fashion. Currently, even structured sessions include naturalistic methods for increasing generalization and maintenance. Parent mediated interventions have been reported to be an important aspect of intervention. Overall, structured programs share a common core of set features including: 1. starting the intervention at the earliest possible age (3-4 years), 2. Intervention is intensive (20-40 hours per week), 3. Intervention is individualized, comprehensive, and targeting a wide range of skills, 4. Multiple behavior analytic procedures are used to develop adaptive repertoires, 5. Treatment is delivered in one-to-one format with gradual transition to group activities and natural contexts, 6. Treatment goals are guided by normal developmental sequence, and 7. Parents are, to different extents, trained and become active co-therapists (Levy 2009, Virues-Ortega 2010).

**Authorization Process:** Requests for ABA services need to be reviewed to determine whether they meet Clinical Review Criteria. Preauthorization is needed for ABA treatment. Also ABA treatment can only be delivered by providers who are contracted with Group Health and meet Group Health Credentialing Criteria. The authorization process is as follows:

- There is an initial review of a referral to determine whether an enrollee meets eligibility criteria for ABA services (i.e. diagnosis, coverage, presence of autistic behaviors that are having clinically significant impact on functioning, in home, school, and and/or community).
- If enrollee meets criteria for ABA services, then initial authorization is for development of an individualized treatment plan (ITP).
- Once the ITP is completed, it is reviewed and if it meets Group Health Clinical Review Criteria, authorization is typically given for six months of ABA therapy.
- After six months, a progress report needs to be submitted to determine whether enrollee continues to meet criteria for ABA therapy and if so, an additional six months of ABA therapy is authorized.

- Initial Treatment and Progress Plans should be sent to: Review Services, FAX: 1-800-377-8853
- Group Health criteria for ABA therapy, copies of group health ITP and progress reports are available using information in above criteria links

### **Completing the ITP:**

1. The ITP must be based on a diagnostic assessment within no more than 12 months of initiating treatment.

A diagnostic assessment is a child's performance on standardized developmental assessment, checklists or rating scales. Examples of assessments are as follows:

- a. Self – Help Skills: Vineland Adaptive Behavior Scales
- b. Communication Skills: Preschool Language Scale-5 (PLS-5), Clinical Evaluation of Language Fundamentals-5 (CELF-5)
- c. Social Skills: Social Skills Rating Scales (SSRS), Assessment of Basic Language and Learning Skills (ABLLS), Achenbach System of Empirically Based Assessment (ASEBA),
- d. Behavior Rating Scales: ASEBA, Behavior Assessment System for Children Second Edition (BASC-2)

It is recommended that the goals in the ITP be based upon where there is the most significant developmental and/or standardized gap in the diagnostic assessment.

The ITP should address autistic symptoms in one or more of the following areas:

- a. Communication
- b. Social interaction
- c. Behavior (to include restricted, repetitive, and/or stereotypical patterns of behavior, interests, and/or activities)

When the member contract includes coverage of ABA services it is for behaviors and/or symptoms related to the core symptoms of Autism as noted above.

ABA treatment is not covered for symptoms and/or behaviors that are not part of core symptoms of autism (i.e. impulsivity due to ADHD, reading difficulty due to learning disability, excessive worry due to anxiety disorder)

If academic or adaptive deficits are included in the ITP, then the focus should be on addressing autistic symptoms that are the impeding success in home environment (i.e. reduce frequency of self-stimulatory behavior to allow child to be able to complete mathematics sorting task and/or following through on toilet training instruction) rather than the academic and/or adaptive skill targets (i.e. child will read paragraph level information at grade level or be able to dress self independently)

- a. Objective, baseline measurement levels for each target behavior/symptoms in terms of frequency, intensity and duration, including use of standardized autism measures; and
- b. A comprehensive description of treatment interventions and techniques specific to each of the targeted behaviors/symptoms, including documentation of the number of service hours, in terms of frequency and duration for each intervention; and
- c. Establishment of treatment goals and objective measures of progress for each intervention specified

Functional, objective and measurable goals should be established. As noted above each goal should include baseline performance, desired performance (imitate, label, list); quality of performance (with assistance, independently); criteria for meeting objective (frequency, duration, accuracy, speed, and intensity) and conditions of performance (location, prompts, audience). Again, goals should be related to areas of deficit/delay identified in developmental assessment. Group Health will include coverage assessment of baseline performance in targeted goals when the contract includes coverage of ABA therapy. Target for goals should be what child is expected to achieve within six months.

### **EXAMPLE**

*Target Behavior:* Improve receptive language as noted by standard score of 75 which is greater than 1.5 standard deviations from mean on receptive factor of preschool language scale. Child's performance indicates they are unable to follow 2-step directions.

*Baseline:* 20% accuracy following 2-step directions

*Goal:* In order to improve receptive language skills due to a diagnosis of autism spectrum disorder, patient will follow simple 2-step directions when provided with gesture cues across 80% of opportunities when presented with age appropriate instructional material across 3 treatment sessions.

- a. Strategies for generalized learning skills; and
- b. A description of parental education, goals, training, and support services;

Strategies for generalization of learning skills (for example having child respond to 2-step direction given by parents) should also have specific measurable goals and objectives.

Parent education should include the following:

- a. Role of parent for each target established in the ITP
- b. How the parent will integrate goals to promote generalization in home and other environments.
- c. Parent training goals need to be functional, objective, measurable and specific.

#### EXAMPLE

*Target Behavior:* Improve receptive language

*Parent Goal:* In order to promote generalization of receptive language skills, parents will provide simple 2-step directions, with gesture cue during structured homework activities.

*Target:* Patient is able to follow 2-step directions with gesture cue with 80% accuracy across one week.

- a. Strategies for coordinating treatment with school-based special education programs and other treatment programs

Targets should be developed in coordination with other services (SLP, BHS, IEP team). There should be awareness of what specific goals is being worked by Speech and Language Pathologist and the school (i.e. IEP) with treatment goals identified that can help facilitate generalization of skills learned in school based and/or therapy services to the home environment. While group health only covers ABA services that are provided in the home or clinic, Group Health will cover:

- a. Time needed to review IEP and/or other specialty service goals to incorporate these goals into the ITP and/or
- b. Meeting with school and/or other treatment providers to both coordinate care and to facilitate incorporation of school and/or treatment provider goals into the ITP.
- c. Measurable discharge criteria and a discharge plan.

As part of the ITP, there should be description of what needs to occur in order for the individual to be able to be discharged from ABA treatment. Typically individuals no longer need ABA services if a) their behaviors and/or symptoms do not prevent them from adequately participating in home, school, or community activities and/or no longer present a safety risk to self or others b) their behaviors and/or symptoms can be adequately addressed through alternative methods (i.e. school, developmental disability services, parent training) or c) functional and measurable progress toward treatment goals is not occurring and there is no reasonable expectation of further progress, then continued ABA services are not considered medically necessary.

For continued ABA coverage, at least every six months, providers need to submit a progress report that documents the following:

- Progress towards goals identified in the ITP.
- A description of parent/caregiver goals and participation in implementing the ITP.
- If the member has reached the previously defined goals, the re-evaluation should identify new goals toward progress or transition the member to less intensive interventions.
- If the member has not achieved the defined goals, there should be a re-evaluation that identifies the reasons for not meeting the goals and a revised ITP that addresses revised interventions to help the member meet defined goals.
- If functional and measurable progress toward treatment goals is not occurring and there is no reasonable expectation of further progress, then continued ABA services are not considered medically necessary.

As previously noted, it is expected that goals identified on the ITP should be achieved within six months. It is recognized that there needs to be some experience in working with a child to determine rate of progress and thus there will be some children where a number of goals identified in the ITP are not met after six months. If the goals

are not met, it is important to develop a functional analysis to determine the reason for lack of progress (i.e. child continuing to have difficulty maintaining eye contact, child continues to engage in self-stimulatory behaviors that prevent follow through with discrete learning) as well as then how intervention will be modified to address lack of progress.

If a child is unable to demonstrate progress towards meeting majority of goals after two six month periods of ABA treatment, then consideration will be made as to whether there is a reasonable expectation that child is capable of making progress with ABA therapy. If so, then enrollee no longer meets criteria for continued ABA therapy.

## Medical Technology Assessment Committee (MTAC)

### ABA Therapy

#### 04/19/2010: MTAC REVIEW

**Evidence Conclusion:** There is lack of published well-conducted randomized controlled trials on behavioral interventions for young children with autism. The published trials had their limitations; they had small sample sizes, the majority were not randomized, the participants were frequently diagnosed without using standardized tools, the studies examined different treatments, with different delivery approaches and intensities, over different time spans (ranging from 12 weeks to 2 years), and had different measurement approaches for assessing outcomes. IQ was a major outcome for the majority of studies, and it might not be possible to determine whether an improved IQ results from true improvement of cognitive skills, or better test taking ability. In addition, IQ is not necessarily the main problem in autistic functioning. Autism treatment needs to address every developmental area, all areas of adaptive behavior, and then a whole set of aberrant behavioral responses, involving both positive and negative symptoms (Rogers 2008). A number of systematic reviews and meta-analyses of the published studies were conducted by several authors. The methodology of the analyses were valid in general, however even a well conducted meta-analysis is only as good as the studies it includes. The studies on intensive behavioral intervention, as indicated earlier, had their limitations and biases and varied widely in the treatments intensity, duration, mode of delivery, and outcome measures; all of which limits generalization of the pooled results. The meta-analyses either pooled the results of controlled studies only or all studies with or without comparison groups. Their results were conflicting, while, Virues-Ortega (2010), Eldevik (2009), Reichow (2009), Howlin (2009) and others show that that ABA /EIBI interventions were associated with improved outcome (primarily measured by IQ) among some children with autism, Ospina (2008) and Spreckley et al (2009) showed no statistically significant additional benefit of APA/EIBI intervention vs. other interventions applied to young children with ASD.

Dawson and colleagues' study (2010), a more recently published randomized controlled trial with valid methodology, can be considered the most rigorous RCT on comprehensive development behavioral intervention. The authors randomized 48 young children to receive Early Start Denver Model (ESDM), a comprehensive behavioral intervention, or to be referred to community providers for intervention commonly available in the community. They were followed up for 2 years and the primary outcome was change in Mullen Scales of Early learning (MSEL) and the Vineland Adaptive Behavior Scales (VABS) composite standard scores. The results of the trial suggest that very young children with autistic disorders may achieve higher cognitive and adaptive scores and improvement in diagnosis after a 2-year comprehensive intervention strategy that includes parental involvement. The study however does not allow determining if the benefits gained would be sustained over time.

Conclusions: There is insufficient evidence from well-conducted large randomized comparative trials with long term follow-up to determine which comprehensive treatment approach is best for young children with autism, and in particular the most effective treatment for teaching specific skills given certain profiles and characteristics of the child.

**Articles:** The literature search revealed around 100 articles on ABA/ EIBI for young children with autism. The majority were reviews or articles not related to the current review. There were at least 6 systematic reviews with or without meta-analyses on ABA /EIBI intervention for young children with autism. A small more recent RCT (N=48) on the Early Start Denver Model for toddlers with autism was identified. The search also revealed a systematic review by Clinical Evidence on all interventions for autism including early multidisciplinary interventions based on APA and including home-based, school based, community based or multisite interventions.

Three of the meta-analyses on ABA/EIBI for young children were selected for critical appraisal as well as the recently published randomized trial. Dawson G, Rogers S, Munson J, et al. Randomized controlled trial of an intervention for toddlers with autism: The Early Start Denver Model, *Pediatrics* 2010;125:1:e17-e23 See [Evidence](#)

[Table](#) Eldevik S, Hastings RP, Hughes JC, et al. Meta-analysis of early intensive behavioral intervention for children with autism J Clin Child Adolesc Psych 2008;38:439-450 See [Evidence Table](#)  
 Spreckley M, Boyd R. Efficacy of applied behavioral intervention in preschool children with autism for improving cognitive, language, and adaptive behavior: A systematic review and meta-analysis. J Pediatr 2009;154:338-344. See [Evidence Table](#)  
 Virues-Ortega J. Applied behavioral analytic intervention for autism in early childhood: Meta-analysis, meta-regression and dose-response meta-analysis of multiple outcomes. Clinical Psychology Review. 2010 , doi:10.1016/j.cpr.2010.01.008 See [Evidence Table](#)

The use of applied behavioral analysis therapy (ABA), early intensive behavior interventions (EIBI) for the treatment of young children with autism does not meet the *Group Health Medical Technology Assessment Criteria*.

## Applied Behavioral Analysis Therapy (ABA)

For all Group Health plans with a benefit (except Microsoft)

ABA requires preauthorization for initial and continued therapy. Specific coverage may be defined in the individual member contract.

Additionally, all criteria below must be met:

1. The member has a diagnosis of an Autism Spectrum Disorder (DSM-V-TR299.00) by a neurologist, pediatric neurologist, developmental pediatrician, psychologist, psychiatrist experienced in the diagnosis and treatment of autism
2. A documented diagnostic assessment:
  - Documented routine developmental surveillance by providers at every well child visit
  - Audiology assessment results
  - Screening questionnaire
  - Documentation of formal diagnostic procedures by experienced clinician
  - Specific evaluations to determine developmental profile using standard tools for such evaluation
  - Expanded laboratory, only if indicated
3. The member's behaviors are having an impact on development, communication or adjustment such that:
  - The member cannot adequately participate in home, school or community activities; and/ or
  - The member presents a safety risk to self or others.
4. Less intrusive and/or less intensive behavioral interventions have been tried and have not been successful and/or there is no equally effective alternative strategy available to address member's behaviors
5. A documented individualized treatment plan (ITP) that includes:
  - A time-limited ITP that has been developed based on a diagnostic assessment within no more than 12 months of initiating treatment
  - ITP is multidisciplinary in nature, member-centered, family focused, community based, culturally competent and least intrusive
  - Treatment plans that are templates or generic to a particular program are not acceptable
  - The ITP must address behaviors and symptoms that prevents the member from adequately participating home, school or community activities and/or presents a safety risk to self or others with a focus on parent training
  - The ITP should take to account all school or other community resources available to the patient and provide evidence that the requested services are not redundant to other services already being provided
  - Coverage of ABA therapy in public or private schools is only provided under the following circumstances:
    - i. Observation and assessment of behavior may take place in the school as part of the ITP assessment with their permission of school personnel
    - ii. ABA may be provided on school property before and after regular school hours with the permission of school personnel
    - iii. ABA may be provided during regular school hours for children up to the age of 6 years in a day care or preschool setting except when a child is eligible to receive services under an Individual Education Plan (IEP)
  - The ITP must include:
    - i. Identification and detailed description of targeted autistic behaviors and symptoms; and
    - ii. Objective, baseline measurement levels for each target behaviors and symptoms; and

- iii. A comprehensive description of treatment interventions and techniques specific to each of the targeted behavioral/symptoms, including documentation of the number of service hours, in terms of frequency and duration for each intervention; and **(not new)**
  - iv. Establishment of treatment goals and objective measures of progress for each intervention specified; and
  - v. Strategies of generalized learning skills; and
  - vi. A description of parental education, goals, training and support services to include specific detailed description of interventions with parents including plan for transferring interventions with the patient to parents; and **(modified)**
  - vii. Strategies for communication and coordinating treatment with other providers and agencies including school-based special education programs, day care and other health care providers; and (modified)
  - viii. Plans for transition through a continuum of treatments, services and settings; and
  - ix. Measurable discharge criteria for completing treatment and plans for continued care after a discharge plan from ABA **(modified)**
6. Evaluation of progress: At least every six months document a summary outlining the member's progress based on the establish ITP measures of progress.
- If the member has reached the previously defined goals the re-evaluation should identify new goals toward progress or transition to less intensive interventions
  - If the member has not achieved the defined goals, there should be a re-evaluation that identified what are the reasons for not meeting the goals and a revised ITP that addresses revised interventions to meet goals
  - If functional and measurable progress toward treatment goals is not occurring and there is not reasonable expectation of further progress, then continued ABA services are not considered medically necessary.

#### **Guidelines for Application of Group Health ABA Benefit**

- **The ITP must be based on a diagnostic assessment within no more than 12 months of initiating treatment.** A diagnostic assessment is a child's performance on standardized developmental assessment, checklists or rating scales. ITP goals should be based upon where there is the most significant developmental and/or standardized gap in the diagnostic assessment.
- **The ITP should address autistic symptoms in one or more of the following areas:**
  - Communication
  - Social interaction
  - Behavior (to include restricted, repetitive, and/or stereotypical patterns of behavior, interests, and/or activities)
- **All ABA visits with patient and/or family should be documented to include targeted behavior, interventions, response, modifications in techniques and plan for next visit with behavior tracking sheets that record and graph data collected for each visit.**
- Coverage of ABA treatment is for behaviors and/or symptoms related to the core symptoms of autism as noted above.
- ABA treatment is not covered for symptoms and/or behaviors that are not part of core symptoms of autism (i.e. impulsivity due to ADHD, reading difficulty due to learning disability, excessive worry due to anxiety disorder).
- If academic or adaptive deficits are included in the ITP, then the focus should be on addressing autistic symptoms that are impeding these deficits in the home environment (i.e. reduce frequency of self-stimulatory behavior to allow child to be able to complete mathematics sorting task and/or following through on toilet training instruction), rather than on the academic and/or adaptive skill targets (i.e. child will read paragraph level information at grade level or be able to dress self independently).

- Functional, objective, and measurable goals should be established. As noted above each goal should include baseline performance, desired performance (imitate, label, list); quality of performance (with assistance, independently); criteria for meeting objective (frequency, duration, accuracy, speed, and intensity) and conditions of performance (location, prompts, audience). Again, goals should be related to areas of deficit/delay identified in developmental assessment. Group Health will cover for assessment of baseline performance in targeted goals. Target for goals should be what child is expected to achieve within six months.
- Targets should be developed in coordination with other services (SLP, BHS, IEP team). There should be awareness of what specific goals is being worked by Speech and Language Pathologist and the school (i.e. IEP) with treatment goals identified that can help facilitate generalization of skills learned in school based and/or therapy services to the home environment. Group Health will cover:
  - a. Time needed to review IEP and/or other specialty service goals to incorporate these goals into the ITP and/or
  - b. Meeting with school and/or other treatment providers to both coordinate care and to facilitate incorporation of school and/or treatment provider goals into the ITP
- Development of the six month progress report to include data review, development of new goals and written preparation of the report is covered.
- If an individual is unable to demonstrate progress towards meeting the majority of goals after two six month periods of ABA treatment **or longer**, then consideration will be made as to whether there is a reasonable expectation that child is capable of making progress with ABA therapy. If so, then the individual no longer meets criteria for continued ABA therapy.
- Coverage of development of ITP does include time to do baseline assessments, review of past treatment (including IEPs) and development of plan that includes parent training and coordination with other treatment providers. Six to ten hours is usually sufficient for the development of the ITP. However, more complex cases, or cases in which a complete functional analysis is needed, may require up to 15-20 hours for the initial assessment and treatment planning.
- Following the initial evaluation/assessment, 20-40 hours total per week is the usual range of services for early intervention intensive ABA when deficits are across a broad range of autistic behaviors (language, social, and behavioral deficits). These services can include direct services to member/identified patient and/or parents by program manager/lead behavioral therapist and/or therapy assistants/behavioral technicians/paraprofessionals, program development, treatment plan development, case review, and supervision.
- Supervision hours are typically 1-2 hours for every 10 hours of service.
- Fewer hours may be required (5- 15 hours per week) for Focused ABA when primary difficulty is in one targeted area (i.e. social skills deficits).
- Direct services to the member/identified patient are generally provided one-on-one or with parents present, most often in the home setting but also in community settings depending on the member/identified patient's needs and the settings where significant difficulties occur.
- Social skills groups may be appropriate as a component of a member's overall ABA program.

The following are not considered to be medically necessary ABA services:

- More than one program manager/lead behavioral therapist for a member/identified patient at any one time.
- More than one agency/organization providing ABA services for a member/identified patient at any one time.
- If the school has determined that a child is eligible to receive services under an IEP which would overlap with ABA services and the school services are declined or discontinued by the parent.
- Activities and therapy modalities that do not constitute application of applied behavioral analysis techniques for treatment of autism. Examples include (but not limited to):
  1. Taking the member/identified patient to appointments or activities outside of the home (e.g. recreational activities, eating out, shopping, play activities, medical appointments), except when the member/identified patient has demonstrated a pattern of significant behavioral difficulties during specific activities.
  2. Assisting the member/identified patient with academic work or functioning as a tutor, educational or other aide for the member/identified patient in school

3. Provision of services that are part of an IEP and therefore should be provided by school personnel, or other services that schools are obligated to provide
4. Doing house work or chores, or assisting the member/identified patient with house work or chores, except when the member has demonstrated a pattern of significant behavioral difficulties during specific house work or chores, or acquiring the skills to do specific house work or chores is part of the ABA treatment plan for the member/identified patient
5. Travel time
6. Residing in the member's home and functioning as live-in help (e.g. in an au-pair role)

### **ABA Provider Qualifications and Procedure Codes**

1. Providers delivering ABA must meet the following qualifications:
    - At a minimum, the lead behavioral therapist, providing treatment and clinical supervision of treatment program must demonstrate that she/he is a board certified behavior analyst (BCBA) or must demonstrate that she/he has at least 240 hours of coursework related to behavior analysis and/or 750 hours of supervised experience or 2 years of practical experience in designing and implementing comprehensive behavioral analytic therapies for children with autism; **and**
      - a. **Either:**
        - ii. Individually satisfy the following requirements:
          1. Be a licensed health provider under Title 18, Revised Code of Washington, including but not limited to: speech therapist, occupational therapist, psychologist, pediatrician, neurologist, psychiatrist, mental health counselor, social worker; and
          2. Be licensed to practice independently; and
          3. Be credentialed and contracted by the Plan; **or**
        - iii. Be employed by a Healthcare Delivery Organization that meets the following requirements:
          1. Be a hospital, mental health facility, home health agency or in-home agency licensed to provide home health services, **or** other mental health agency licensed by the Washington Department of Health; **or** a community mental health agency or home health agency licensed by the Washington Department of Social and Health Services; and
          2. Be credentialed and contracted by the Plan.
      - b. Clinical supervision for unlicensed staff providing services must be provided by a lead behavioral therapist as indicated above. Such supervision must:
        - i. Include bimonthly (once every 60 days) approval and review of the ITP and case review of every member receiving clinical health services; and
        - ii. Include at least one hour of on-site supervision, with on-site observation for at least one hour for every 40 hours of service to the member.
2. Providers must use the following codes to obtain reimbursement for ABA and ABA-related services

<b>HCPCS</b>		
<b>Codes</b>	<b>Number</b>	<b>Description</b>
	H2017	Provision of ABA services by lead behavioral therapist to patient to include direct one to one services, face to face parent training as well as supervision of unlicensed provider per 15 minutes
	H2014	Provision of ABA services face to face with patient one to one by unlicensed provider as well as providing face to face parent training per 15 minutes
	H2019	Covers assessment of patient by lead behavior therapist (which includes administration of assessment instruments, scoring interpretation of assessment instruments as well as write of initial individualized treatment plan) as well as completion of 6 month progress reports per 15 minutes
	H2012	ABA Group Therapy services maximum of 2 hours per session

## Applied Behavioral Analysis Therapy (ABA)

### Microsoft Criteria

Applied Behavioral Analysis (ABA) requires preauthorization for initial and continued therapy. Specific coverage may be defined in the individual member contract.

Additionally all criteria below must be met:

1. The member is over the age of 2 and has a diagnosis by the treating physician, neurologist, pediatric neurologist, developmental pediatrician, psychologist, or psychiatrist experienced in the diagnosis and treatment of Autism Spectrum Disorder (DSM-V code 299.00) which includes:
  - a. Childhood Disintegration Disorder
  - b. Asperger's Disorder
  - c. Rett's Disorder and Pervasive Development Disorder Not otherwise Specified/Atypical Autism
  - d. Pervasive Developmental Disorder
2. This benefit is not provided for rehabilitation services (which may be covered under the rehabilitation services benefit) or mental health services (which may be covered under the mental health, substance abuse and alcoholism treatment benefit).
3. ABA services are not covered for the following:
  - a. Babysitting or doing household chores
  - b. Time spent under the care of any other professional
  - c. Travel time
  - d. Home schooling in academics or other academic tutoring
4. A documented individualized treatment plan (ITP) is developed by a certified ABA provider and is submitted for the initial 6 months of treatment includes:
  - a. A time-limited ITP that has been developed based on a diagnostic assessment within no more than 12 months of initiating treatment
  - b. ITP is multidisciplinary in nature, member-centered, family focused, community based, culturally competent and least intrusive.
  - c. Treatment plans that are templates or generic to a particular program are not acceptable.
  - d. The ITP must address behaviors and symptoms that prevents the member from adequately participating home, school or community activities and/or presents a safety risk to self or others with a focus on parent training.
  - e. The ITP must include:
    - i. Identification and detailed description of targeted behaviors and symptoms; and
    - ii. Objective, baseline measurement levels for each target behavior/symptoms in terms of frequency, intensity, and duration, including use of standardized autism measures; and
    - iii. A comprehensive description of treatment interventions and techniques specific to each of the targeted behaviors/symptoms, including documentation of the number of service hours, in terms of frequency and duration for each intervention.; and
    - iv. Establishment of treatment goals and objective measures of progress for each intervention specified; and
    - v. Strategies for generalized learning skills; and
    - vi. A description of parental education, goals, training and support services; and
    - vii. Strategies for coordinating treatment with school-based special education programs; and
    - viii. Plans for transition through a continuum of treatments, services and settings; and
    - ix. The approved certified provider must determine that the treatment plan and services being provided are in accordance with ABA guideline.
    - x. Measurable discharge criteria and a discharge plan

- xi. If any substantial change in the frequency or type of program is necessary during the six month treatment time, a revised Treatment Plan should be submitted to Group Health Cooperative for notification of the revision of the treatment plan.
5. Evaluation of progress: At least every 6 months document a summary outlining the member's progress based on the establish ITP measures of progress for further coverage of therapy.
    - a. If the member has reached the previously defined goals the re-evaluation should identify new goals toward progress or transition to less intensive interventions.
    - b. If the member has not achieved the defined goals, there should be a reevaluation that identifies what are the reasons for not meeting the goals and a revised ITP that addresses revised interventions to meet goals.
    - c. If functional and measurable progress toward treatment goals is not occurring and there is no reasonable expectation of further progress, then continued ABA services are not considered medically necessary.
    - d. Progress reports should be created at least monthly by the certified provider to include documentation of the therapy assistant interventions and/or their own interventions with the Participant and a written summary of the child's progress. If the child has not made progress in the last 6 months, the updated treatment plan should reflect a change in approach. Progress reports should be available to Group Health Cooperative upon request.

## Current MS SPD language

### Autism/Applied Behavior Analysis (ABA) therapy

Plan pays 90%

This benefit covers behavioral interventions based on the principles of Applied Behavioral Analysis (ABA) through eligible providers.

### Who is eligible

This benefit will be available to dependent children age two and older covered by Group Health, whose primary diagnosis is the following:

- Autistic Disorder (International Classification of Diseases, 9th Revision, Clinical Modification (DSM-V code 299.0)
- Childhood Disintegrative Disorder (DSM-V code 299.10)
- Asperger's Disorder (DSM-V code 299.80)
- Rett's Disorder and Pervasive Development Disorder Not Otherwise Specified/Atypical Autism (ICDA-9-CM code 299.10)
- Pervasive Developmental Disorder (DSM-V code 299.80)

### Eligible providers

The benefit covers services through providers who have met established qualifications for certification (known as certified providers) and who perform services in consultation with a certified provider (known as therapy assistants).

- Call 206-901-4636 or 888-901-4636 or visit Group Health Cooperative online for a list of approved Certified Autism Providers (not including Therapy Assistants) eligible for reimbursement under this benefit, to receive a copy of the certification criteria, or for an application for providers not currently on the list.

For the purpose of this benefit only, services of a certified provider will be covered even if the provider does not meet the plan's requirements as an eligible provider under the rehabilitative services or mental health and substance abuse benefit.

### Covered services

Services must be ordered by the dependent's treating physician to be covered. An approved certified provider acts as the program manager for the member. Benefits are available for time used to evaluate the member and document findings and progress reports, and to create and update treatment plans; and time used to train and evaluate the work of the therapy assistants working directly with the member to implement the treatment plan. Therapy Assistant services that are provided by a Program Manager will be paid at the Therapy Assistant rate.

In most cases, therapy assistants will provide the implementation portion of the treatment plan. Therapy assistant time is eligible for face-to-face time with the member to perform the tasks described in the treatment plan and to document outcomes; and time to meet with the program manager for training and to discuss treatment plan issues. Therapy Assistant services that are provided by a Program Manager will be paid at the Therapy Assistant rate. Claims for ABA services should clearly list the level of service (certified provider/program manager; or therapy assistant, the date the service was provided, the time the service started and ended, the hourly charge for the service, and the total charge for that service).

ABA services are not covered for the following:

- Babysitting or doing household chores
- Time spent under the care of any other professional
- Travel time
- Home schooling in academics or other academic tutoring

### **Benefit coverage above the allowable amount**

You may be billed for charges assessed above the allowable amount from providers who have not agreed to offer discounts to members covered by this plan. Any amounts you pay for charges in excess of allowable charges will not count towards satisfying any deductible requirements, or out-of-pocket maximums that may apply to other benefits provided through this plan.

An **allowable charge** is the level of benefits that are payable by Group Health when expenses are incurred from a community provider. Expenses are considered an allowed amount if the charges are consistent with those normally charged to others by the provider or organization for the same services or supplies; and the charges are within the general range of charges made by other providers in the same geographical area for the same services or supplies. Members shall be required to pay any difference between the community provider's charge for services and the allowed amount.

---

### **Prior Authorization**

Prior authorization, also referred to as a pre-service review, is recommended to determine coverage is available before the service occurs. Either the member or the provider may contact Group Health for prior authorization.

**Prior authorization** is an advance determination by Group Health that the service is medically necessary and that the member's plan has benefits available for the service being requested. This determination is offered in certain situations where medical records must be provided to establish medical necessity before the plan will pay for the service. Services are subject to eligibility and benefits at the time of service.

---

**Prior authorization confirms that the treatment plan submitted by the treating provider is medically necessary for the condition based on national, evidence-based guidelines. Group Health and Microsoft reserve the right to have appropriate medical professionals review current treatment at any time to determine if medical necessity criteria continue to be met.**

For ABA/Autism benefits, the prior authorization requires the following documents:

- The dependent's treating physician's order for ABA services
- The clinical documentation of the qualifying diagnosis
- The Plan of Treatment created by the approved Program Manager

Group Health will issue a prior authorization that will provide services for a six-month period of time. The prior authorization process and subsequent clinical review includes the following steps:

The following is the process for a prior authorization for the autism/ABA therapy benefit and subsequent clinical review:

1. The dependent's treating physician or specialist diagnoses the child with an Autism Spectrum Disorder (Autistic Disorder, Childhood Disintegrative Disorder, Rett's Disorder, Pervasive Developmental Disorder Not otherwise Specified, and Asperger's Disorder) and refers the child for ABA treatment.
2. An initial evaluation is performed by the approved certified provider to determine if the child is a candidate for an ABA and/or related structured behavioral program. If the child is determined to be a candidate by the evaluating approved certified provider, the approved certified provider would create and submit a treatment plan including type and frequency of services planned for the immediate six-month period. The approved certified provider must send the treatment plan to Group Health so that eligibility for services can be determined.
3. Every six months, the approved certified provider who is overseeing the treatment must submit an updated treatment plan to Group Health. The approved certified provider must determine that the treatment plan and services being provided are in accordance with ABA guidelines. If any substantial change in the frequency or type of program is necessary during the six-month treatment time, a revised Treatment Plan should be submitted to Group Health for notification of the revision of the treatment plan.
4. Progress reports should be created at least monthly by the certified provider to include documentation of the therapy assistant interventions and/or their own interventions with the member and a written summary of the child's progress. If the child has not made progress in the last six months, the updated treatment plan should reflect a change in approach. Progress reports should be available to Group Health upon request.

Services for this treatment that do not meet criteria described in the program are subject to retrospective denial of benefits. Claims for these services must be accompanied by a completed Autism/ABA Therapy Services Billing Summary signed by the certified provider and the child's parent.

#### **Additional exclusions and limitations for autism/ABA therapy**

In addition to the plan's Exclusions and limitations, the following services and supplies are excluded from this benefit:

- This benefit is not provided for rehabilitative services (which apply under the rehabilitation services benefit) or mental health services (which apply under the mental health and substance abuse benefit).
- Benefits for services provided by volunteers, childcare providers, or family members, and benefits paid for by state, local, and Federal agencies will not be covered. Volunteer services or services provided by a family member of the child receiving the services by or through a school, books, and other training aids will also not be covered.
- Other unspecified developmental disorders or delays, or any other delay or disorder in a child's motor, speech, cognitive, or social development are not covered under this benefit
- This benefit covers only the allowable fees for eligible services performed by the approved certified provider and those providing interventions based on principles of ABA and/or related structured behavioral programs under the supervision of the approved certified provider. Other expenses associated with providing the treatment, such as the tuition, program fees, travel, meals, and lodging of the approved certified provider and expenses of those working under the approved certified provider's supervision, the dependent, and his or her family members will not be covered.

## Applied Behavioral Analysis Therapy (ABA)

For all Group Health plans with a benefit (except Microsoft)

ABA requires preauthorization for initial and continued therapy. Specific coverage may be defined in the individual member contract.

The following criteria must be met:

1. The member has a diagnosis of an Autism Spectrum Disorder (DSM-V-code including severity levels) by a neurologist, pediatric neurologist, developmental pediatrician, psychologist, psychiatrist experienced in the diagnosis and treatment of autism
2. The diagnostic assessment must include **All of the following** elements:
  - a. Documentation of formal diagnostic procedures by experienced clinician (i.e. autism diagnostic interview-revised, autism diagnostic observation scale, diagnostic interview using DSM 5 criteria)
  - b. Description of how patient's behaviors are having an impact on development, communication or adjustment such that;
    - i. The member cannot adequately participate in home, school or community activities; and/or the member presents a safety risk to self or others and
    - ii. Less intrusive and/or less intensive behavioral interventions have been tried and have not been successful and/or there is no equally effective alternative strategy available to address member's behaviors
  - c. Specific evaluations to determine developmental profile using **ONE or more of the following** standard tools
    - i. Adaptive/Functional skills: Vineland Adaptive Behavior Scales
    - ii. Communication skills: Preschool Language Scale-5 (PLS-5), Clinical Evaluation of Language Fundamentals-5 (CELF-5), Verbal Behavior Milestones Assessment and Placement Program (VB-MAPP)
    - iii. Cognitive Assessment (Wechsler scales, Kaufman scales)
    - iv. Social Skills Rating Scales (SSRS), Assessment of Basic Language and Learning Skills (ABBL), Achenbach System of Empirically Based Assessment (ASEBA)
    - v. Behavior rating scales: ASEBA, Behavior Assessment System for Children Second Edition (BASC-2), Gilliam Autism Rating Scale
  - d. Expanded laboratory, documented routine developmental surveillance by providers at every well child visit, screening questionnaire, audiology assessment results, only if indicated.
3. A documented individualized treatment plan (ITP) that includes:
  - a) A time-limited ITP that has been developed based on a diagnostic assessment within no more than 12 months of initiating treatment
  - b) ITP is multidisciplinary in nature, member-centered, family focused, community based, culturally competent and least intrusive
  - c) Treatment plans that are templates or generic to a particular program are not acceptable
  - d) The ITP must address behaviors and symptoms that prevents the member from adequately participating home, school or community activities and/or presents a safety risk to self or others with a focus on parent training
  - e) The ITP should take into account all school or other community resources available to the patient and provide evidence that the requested services are not redundant to other services already being provided. The ITP should include review of school based IEP if present and how ITP does not duplicate what is on IEP. ITP should also include review of other treatment if present (i.e. outpatient mental health, speech therapy) and how ITP does not duplicate these community based resources
  - f) Coverage of ABA therapy in public or private schools is only provided under the following circumstances:

- i. Observation and assessment of behavior may take place in the school as part of the ITP assessment with the permission of school personnel
  - ii. ABA may be provided on school property before and after regular school hours with the permission of school personnel
  - iii. ABA may be provided during regular school hours for children up to the age of 6 years in a day care or preschool setting except when a child is eligible to receive services under an Individual Education Plan (IEP)
- 4. The ITP must include **All of the following**:
  - a. Description of autistic behaviors that are targets for treatment. The targets for treatment should be based on where there is the most significant gap in functioning as measured by developmental and behavioral assessment including **ONE or more of the following**:
    - i. Adaptive/Functional skills: Vineland Adaptive Behavior Scales
    - ii. Communication skills: Preschool Language Scale-5 (PLS-5), Clinical Evaluation of Language Fundamentals-5 (CELF-5), Verbal Behavior Milestones Assessment and Placement Program (VB-MAPP)
    - iii. Cognitive Assessment (Wechsler scales, Kaufman scales)
    - iv. Social Skills Rating Scales (SSRS), Assessment of Basic Language and Learning Skills (ABBLs), Achenbach System of Empirically Based Assessment (ASEBA)
    - v. Behavior rating scales: ASEBA, Behavior Assessment System for Children Second Edition (BASC-2)
  - b. A comprehensive description of treatment interventions and techniques specific to each of the targeted behavioral/symptoms
  - c. Establishment of treatment goals and objective measures of progress for each intervention specified (including baseline and targeted goals); and
  - d. Strategies of generalized learning skills; and
  - e. A description of parental education, goals, training and support services to include specific detailed description of interventions with parents to support their active participation in ABA treatment including plan for transferring interventions with the patient to parents; and
  - f. Strategies for communication and coordinating treatment with other providers and agencies including school-based special education programs, day care and other health care providers; and (modified)
  - g. Hours requested for each treatment modality (i.e. parent training, paraprofessional time, lead behavior therapist, supervision, social skills group, completion of six month progress report)
  - h. Measurable discharge criteria for completing treatment and plans for continued care after a discharge plan from ABA which include **All of the following**:
    - i. Plans for transition through a continuum of less intensive treatments such that patient's symptoms can be effectively managed at a lower level of care.
    - ii. Specific behavior goals that when reached will indicate the patient is adequately participating in home, school, or community activities and/or is no longer present a safety risk to self or others
- 5. Discharge Criteria - Typically individuals' no longer need ABA services if **ONE of the following** is met:
  - a. Their behaviors and/or symptoms do not prevent them from adequately participating in home, school, or community activities and/or no longer present a safety risk to self or others
  - b. Their behaviors and/or symptoms can be adequately addressed through alternative methods (i.e. school, developmental disability services, parent training), or
  - c. Functional and measurable progress toward treatment goals is not occurring (majority of goals are not being met, there is not significant progress on behaviors and/or symptoms that prevent them from adequately participating in home, school, or community activities and/or no longer present a safety risk to self or others), improvement is not durable over time, and generalizable outside the treatment setting, and there is no reasonable expectation of further progress.
  - d. Parents have not been active participants in ABA treatment.
- 6. Coverage of development of ITP does include time to do baseline assessments, review of past treatment (including IEPs) and development of plan that includes parent training and coordination with other treatment providers. Six to ten hours is usually sufficient for the development of the ITP. However, more complex cases, or cases in which a complete functional analysis is needed, may require up to 15-20 hours for the initial assessment and treatment planning.

7. As noted in the 2014 Agency for Healthcare Research and Quality update on A Review of Research of Therapies for Children with Autism Spectrum Disorder, early intervention programs (i.e. for children typically under the age of six), programs are provided for up to 25 hours a week and can last as long as 12 weeks to 3 years. These services can include direct services to member/identified patient and/or parents by program manager/lead behavioral therapist and/or therapy assistants/behavioral technicians/paraprofessionals, supervision, and development of six month progress report.
8. Fewer hours may be required (5- 15 hours per week) for Focused ABA when primary difficulty is in one targeted area (i.e. social skills deficits).
9. Evaluation of progress: At least every six months document a summary outlining the member's progress based on the establish ITP measures of progress including the following information:
  - a) How patient is progressing towards goals (i.e. what percentage of goals patient has achieved and how these goals have led to functional progress as it pertains to increasing patient's ability to adequately participate in home, school, or community activities, and /or decrease safety risk to self or others
  - b) Progress towards parent goals (how parents have been active participants in the treatment, what percentage of parent goals have been passed and progress towards transferring interventions with the patient to the parents)
  - c) For goals that have not been met, describe reason for not meeting goals, how goals are being adjusted and how interventions are being revised to meet goals
  - d) Any new goals that have been identified (if new goals are identified, include baseline and targeted performance). New goals should be geared towards progress or transition to less intensive interventions
  - e) How the patient is progressing towards discharge and/or plans for discharging from care and/or reducing intensity of intervention based upon patient progress and/or the implementation of less intensive behavioral interventions
  - f) A brief description of what was done during past six months to coordinate treatment with school and/or health care providers (i.e. phone call was made to speech therapist to make sure there is common picture communication system, conference held with school to coordinate behavioral intervention for self-injurious behavior)
  - g) If functional progress is not occurring (i.e. every six months patient is not meeting majority of goals and not making significant progress towards increased participation, home school, or community activities and/or is not less of a safety risk to self or others) and there is not a reasonable expectation of further progress, then continued ABA services are not considered to be medically necessary
10. Every 12 months, developmental assessment should be re-administered to assess whether patient continues to be making functional and measurable progress.
11. The following are not considered to be medically necessary ABA services:
  - a. More than one program manager/lead behavioral therapist for a member/identified patient at any one time.
  - b. More than one agency/organization providing ABA services for a member/identified patient at any one time.
  - c. If the school has determined that a child is eligible to receive services under an IEP which would overlap with ABA services and the school services are declined or discontinued by the parent.
  - d. Activities and therapy modalities that do not constitute application of applied behavioral analysis techniques for treatment of autism. Examples include (but not limited to):
    - i. Taking the member/identified patient to appointments or activities outside of the home (e.g. recreational activities, eating out, shopping, play activities, medical appointments), except when the member/identified patient has demonstrated a pattern of significant behavioral difficulties during specific activities
    - ii. Assisting the member/identified patient with academic work or functioning as a tutor, educational or other aide for the member/identified patient in school
    - iii. Provision of services that are part of an IEP and therefore should be provided by school personnel, or other services that schools are obligated to provide
    - iv. Doing house work or chores, or assisting the member/identified patient with house work or chores, except when the member has demonstrated a pattern of significant behavioral

- difficulties during specific house work or chores, or acquiring the skills to do specific house work or chores is part of the ABA treatment plan for the member/identified patient
- v. travel time
- vi. residing in the member's home and functioning as live-in help (e.g. in an au-pair role)

12. All ABA visits with patient and/or family should be documented to include:

- a. Who was present at the visit
- b. Duration of the visit
- c. What was the targeted behavior during the visit
- d. What was procedure/activity/intervention during visit
- e. What was response to procedure/activity/intervention.
- f. Intervention format (individual, group, supervision, parent training)
- g. Graphical or numerical data to track progress/participation.
- h. Signature title, credentials of person completing documentation;
- i. Include targeted behavior, interventions, response, modifications in techniques and plan for next visit with behavior tracking sheets that record and graph data collected for each visit.

### ABA Provider Qualifications and Procedure Codes

Providers delivering ABA must meet **ALL of the following** qualifications:

- a) At a minimum, the lead behavioral therapist, providing treatment and clinical supervision of treatment program must demonstrate that she/he is a board certified behavior analyst (BCBA) or must demonstrate that the she/he has at least 240 hours of coursework related to behavior analysis and/or 750 hours of supervised experience or 2 years of practical experience in designing and implementing comprehensive behavioral analytic therapies for children with autism; **and**
- b) **Either:**
  - i) Individually satisfy **ALL of the following** requirements:
    - 1. Be a licensed health provider under Title 18, Revised Code of Washington, including but not limited to: speech therapist, occupational therapist, psychologist, pediatrician, neurologist, psychiatrist, mental health counselor, social worker; and
    - 2. Be licensed to practice independently; and
    - 3. Be credentialed and contracted by the Plan; **or**
  - ii) Be employed by a Healthcare Delivery Organization that meets **All of the following** requirements:
    - 1. Be a hospital, mental health facility, home health agency or in-home agency licensed to provide home health services, or other mental health agency licensed by the Washington Department of Health; **or** a community mental health agency or home health agency licensed by the Washington Department of Social and Health Services; and
    - 2. Be credentialed and contracted by the Plan.
- c) Clinical supervision for unlicensed staff providing services must be provided by a lead behavioral therapist as indicated above. Such supervision must:
  - i) Include bimonthly (once every 60 days) approval and review of the ITP and case review of every member receiving clinical health services; and
  - ii) Include at least one hour of on-site supervision, with on-site observation for at least one hour for every 40 hours of service to the member.

Providers must use the following codes to obtain reimbursement for ABA and ABA-related services

HCPCS		
Codes	Number	Description
	H2017	Provision of ABA services by lead behavioral therapist to patient to include direct one to one services, face to face parent training as well as supervision of unlicensed provider per 15 minutes
	H2014	Provision of ABA services face to face with patient one to one by unlicensed provider as well as providing face to

H2019	face parent training per 15 minutes Covers assessment of patient by lead behavior therapist (which includes administration of assessment instruments, scoring interpretation of assessment instruments as well as write of initial individualized treatment plan) as well as completion of 6 month progress reports per 15 minutes
H2012	ABA Group Therapy services maximum of 2 hours per session

Providers may also use the Behavior Identification and Follow-up Assessment T codes (0359-0363T) and the Adaptive Behavior Treatment T codes (0364-0374T)

GroupHealth®

## Clinical Review Criteria

### Autologous Chondrocyte (Carticel®) Implantation for Treatment of Defects in Articular Cartilage of the Knee

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Covered without review.

##### For Non-Medicare Members

Group Health has elected to use the Autologous Chondrocyte Implantation (A-0415) MCG\* for medical necessity determinations.

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Articular hyaline cartilage is a highly specialized connective tissue that covers the surface of bone in synovial joints. It is a 2-4mm thick hyaline cartilage that provides smooth low friction movement and shock absorption. Unlike most tissues, articular cartilage does not have blood vessels, nerves, or lymphatics. It is composed of a dense extracellular matrix (ECM) with a sparse distribution of highly specialized cells called chondrocytes. The ECM is principally composed of water, collagen, and proteoglycans, with other non-collagenous proteins and glycoproteins present in lesser amounts. These components help to retain water within the ECM, which is critical to maintain the unique mechanical properties of the cartilage (Fox 2009, Negrin 2013, Oussedik 2015).

The articular cartilage is prone to damage from acute high energy trauma and from repetitive shear and torsional forces applied to the surface. Lesions to the articular cartilage are often associated with pain and compromised joint function, and may lead to the development and progression of osteoarthritis. The damaged cartilage has very limited capacity for self-repair due to its avascular and hypocellular nature. Surgery has thus been the standard approach for repairing articular cartilage damage. Surgical techniques intended for restoring the articular surface are classified into 3 categories: 1. Marrow stimulation procedures such as microfracture, 2. Cell-based implantation, and 3. Osteochondral grafting. Surgical interventions have also been categorized as 1. Reparative, which includes marrow stimulation such as microfracture; drilling; and abrasion arthroplasty, and 2. Reconstructive that includes allograft transplantation; osteochondral autograft transplantation (OAT); and autologous chondrocyte implantation (ACI). Investigators suggest that microfracture surgeries is more effective than reconstructive surgeries for the repair of smaller cartilage defects (<100mm<sup>2</sup>) while reconstructive surgeries are more effective for larger defects (>100mm<sup>2</sup>) (Crawford 2012, Perera 2012, Negrin 2013, Mundi 2015, Li 2015).

Currently, marrow stimulation through microfracture is the standard first-line surgical treatment for articular cartilage lesions of the knee. The microfracture technique was developed by Steadman in the early 1980s. It is a single-stage arthroscopic procedure that involves penetrating the subchondral bone plate after removing the damaged hyaline cartilage. Bleeding from the subchondral bone forms a clot that attracts bone marrow cells to migrate into the cartilage defect and create a 'super clot' that eventually matures into a firm repair tissue consisting of a combination of fibrous and hyaline-like cartilage. The technique is minimally invasive, technically simple, and is associated with low morbidity. However, the repair is composed of fibrocartilaginous tissue, which is mechanically inferior to the native hyaline cartilage; it has less ability to withstand shock and shearing forces leading to deterioration in function over time. In addition, the bone marrow stem cells and growth factors are released into the joint rather than being contained in the site of the defect. Some researchers suggest that microfracture is more effective in reducing pain and improving joint function when performed for new injuries,

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

small focal injuries, and in younger individuals with lower body mass index (Crawford 2012, Negrin 2013, Lee 2014, Mundi 2015).

Osteochondral autograft transfer (OAT), also known as osteochondral cylinder transplantation or mosaicplasty, is a whole tissue transplantation procedure that was developed in the 1990s for hyaline cartilage repair. It is a surgical technique that uses osteochondral grafts taken from the lighter-load bearing areas of the patient's own joint to fill the focal defects. There is a concern however, with the donor site morbidity, and thus the technique may not be recommended for lesions larger than 400mm<sup>2</sup> (Li 2015, Mundi 2015).

Autologous chondrocyte implantation (ACI), also known as autologous chondrocyte transplantation is a cell-based method that was introduced in the late 1980s for the treatment of symptomatic full thickness cartilage defects of the knee. The first generation of ACI (ACI-P) is a two-stage procedure. First, a cartilage biopsy is harvested from healthy cartilage of the affected knee during an arthroscopic biopsy procedure. The specimen of live articular cartilage is sent to a cell expansion laboratory for chondrocyte culture. The cells are separated from the cartilage under a strictly controlled environment, and then multiplied using a cell-culture technique for 3-6 weeks. The cultured chondrocytes are then implanted into the cartilage defect in an open arthrotomy procedure. This procedure involves removing a periosteal flap from the proximal medial tibia, suturing it to the surrounding rim of normal tissue, and implanting the expanded chondrocytes beneath the flap to start filling the defect by producing a matrix. Unlike the MS techniques, it is reported that ACI has the ability of repairing the defect by a hyaline-like cartilage with a hybrid of fibrocartilage and hyaline like tissue, or with fibrocartilaginous material containing type-I and type II collagen. ACI-P is an invasive, technically complicated procedure that involves two operations, has a long recovery time, and requires extensive post-surgical rehabilitation. The technique has variable success rate and may be associated with periosteal hypertrophy and overgrowth that would require additional surgeries (Crawford 2012, Niemeyer 2014, Mundi 2015).

Several modifications to the first generation ACI-P have been made to reduce the procedural technical demands associated with the tissue harvest and the use of periosteal flap in order to decrease the surgical morbidity and prevent periosteal hypertrophy and overgrowth. These modifications were described as second and third generations. The second generation ACI (ACI-C) uses bioengineered bilayer collagen covers to substitute for the periosteal flap and avoid the spill over and asymmetric distribution of chondrocytes following implantation. The third generation ACI explores the use of biomaterials to construct a 3-dimensional scaffold for chondrocyte implantation; the all-in-one grafts do not need a periosteal cover or fixing stitches and can be trimmed to fit the cartilage defect with fibrin glue. It has been reported that implantation of third generation ACI can be performed arthroscopically or with a small incision (Vasiliadis 2010, Kuroda 2011, Crawford 2012, Negrin 2013, Mundi 2015, Samsudin 2015).

## Medical Technology Assessment Committee (MTAC)

### **Autologous Chondrocyte Implantation**

#### **02/14/2001: MTAC REVIEW**

**Evidence Conclusion:** The existing evidence is not sufficient to determine the effect of ACI on health outcomes. The only data available are from case series reports that have compromised validity and are not considered to provide high quality data. Each of the two case series articles evaluated had additional limitations beyond study type including providing little information about possible adverse effects. Peterson and colleagues are involved with a prospective randomized trial of autologous chondrocyte transplantation compared to periosteum alone or subchondral drilling for the treatment of primary chondral lesions of the femoral condyle. Results of this study will provide higher-quality data.

**Articles:** Fourteen articles were identified. Eleven articles were not directly relevant, did not include clinical outcomes or were review articles; three articles presented empirical data on clinical outcomes. Articles were selected based on study type. There were no meta-analyses or randomized controlled trials. The three empirical articles were all case series. Sample sizes were 8 patients, 44 patients and 94 patients. An evidence table was created for the two case series reports with the largest number of patients: Peterson L, Minas T, Brittberg M, Nilsson A, Sjogren-Jansson E, Lindahl, A. Two-to-9 year outcome after autologous chondrocyte transplantation of the knee. *Clin Orthop* 2000; 374: 212-234. See [Evidence Table](#). Minas T. Chondrocyte implantation in the repair of chondral lesions of the knee: Economics and quality of life. *Am J Orthop* 1998; 27: 739-44. See [Evidence Table](#).

The use of Autologous Chondrocyte (Carticel®) Implantation for Treatment of Defects in Articular Cartilage of the Knee does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **04/17/2003: MTAC REVIEW**

## **Autologous Chondrocyte Implantation**

**Evidence Conclusion:** There were two small randomized controlled trials (Bentley et al, n=100.; Horas et al., n=40). Neither provided strong evidence that autologous chondrocyte implantation is superior to an alternate procedure for repairing osteochondral defects in the knee. The Bentley study was larger and had stronger methodology. The authors found that the overall clinical results did not differ significantly between groups (autologous chondrocyte implantation compared to mosaicplasty), but that, among the 51 patients with medial femoral defects, the autologous chondrocyte group had better post-operative knee function. The one-year arthroscopic data in the Bentley study was compromised because 40% of patients were missing from the analysis. The Horas study had inadequate randomization and several additional threats to validity. They found worse post-operative knee instability in the autologous chondrocyte transplantation group compared to a group receiving autologous osteochondral cylinder transplantation and no significant differences between groups on the two other primary measures.

**Articles:** Bentley G, Biant LC, Carrington RWJ et al. A prospective, randomized comparison of autologous chondrocyte implantation versus mosaicplasty for osteochondral defects in the knee. *J Bone Joint Surg (Br)* 2003; 85-B: 223-230. See [Evidence Table](#). Horas U, Pelinkovic D, Aigne T, Schnettler R. Autologous chondrocyte implantation and osteochondral cylinder transplantation in cartilage repair of the knee joint. *J Bone Joint Surg (Br)* 2003; 85-A: 185-192. See [Evidence Table](#).

The use of Autologous Chondrocyte (Carticel®) Implantation for Treatment of Defects in Articular Cartilage of the Knee does not meet the *Group Health Medical Technology Assessment Criteria*.

### **07/14/2004: MTAC REVIEW**

#### **Autologous Chondrocyte Implantation**

**Evidence Conclusion:** The evidence consists of three controlled trials (2 randomized, 1 pseudo-randomized), all comparing autologous chondrocyte implantation to other surgical procedures to restore articular cartilage. There are no sham controlled studies. None of the studies found significantly better clinical outcomes with ACI compared to the alternative intervention 1-2 years post-surgery; some may have been underpowered. Knutsen et al, the strongest study methodologically, found better results for the group receiving microfracture on one key outcome, the physical component score of the SF-36. The Bentley study found better histological results in the ACI group, but this analysis included only 60% of the randomized patients. In summary, ACI does not provide a clear clinical advantage over other surgical procedures to heal cartilage injuries and may be inferior to microfracture.

**Articles:** The Medline search yielded 42 articles, many of which were on technical aspects of the procedure or on related technologies. There were three randomized controlled trials and all three were critically appraised. References are as follows: Knutsen G, Engebretsen L, Ludvigsen TC. Autologous chondrocyte implantation compared with microfracture in the knee. *J Bone Joint Surg* 2004; 86-A: 455-464. See [Evidence Table](#).

The use of Autologous Chondrocyte (Carticel®) Implantation for Treatment of Defects in Articular Cartilage of the Knee does not meet the *Group Health Medical Technology Assessment Criteria*.

### **06/05/2006: MTAC REVIEW**

#### **Autologous Chondrocyte Implantation**

**Evidence Conclusion:** One new RCT compared autologous chondrocyte implantation to an alternative procedure. The study (Dozin et al., 2005) did not find a significant difference in the clinical success rate of patients who received ACI or mosaicplasty. The study was underpowered to detect a clinically meaningful difference between groups due to low compliance rate. Only 12/22 (54%) in the ACI group and 11/22 (50%) in the mosaicplasty group actually received the surgery, which occurred 6 months after an initial debridement. The best evidence on ACI for treatment of defects in articular cartilage of the knee remains the randomized controlled trials reviewed in 2004. The conclusion from the previous MTAC report was: The evidence consists of three controlled trials (2 randomized, 1 pseudo-randomized), all comparing autologous chondrocyte implantation to other surgical procedures to restore articular cartilage. There are no sham controlled studies. None of the studies found significantly better clinical outcomes with ACI compared to the alternative intervention 1-2 years post-surgery; some may have been underpowered. Knutsen et al, the strongest study methodologically, found better results for the group receiving microfracture on one key outcome, the physical component score of the SF-36. The Bentley study found better histological results in the ACI group, but this analysis included only 60% of the randomized patients. In summary, ACI does not provide a clear clinical advantage over other surgical procedures to heal cartilage injuries and may be inferior to microfracture. A 2005 technology assessment conducted by the National Institute for Health and Clinical Effectiveness (NICE) in England concluded that there is inconsistent evidence on the clinical effectiveness of ACI and did not recommend ACI except in the context of ongoing clinical trials.

**Articles:** Three new randomized controlled trials were identified. Two trials, one by Bartlett and colleagues and the other by Gooding and colleagues, were not evaluated further because they compared two types of autologous

chondrocyte replacement and did not include a control group that received an intervention other than ACI. (In addition, the Gooding study was only available as an abstract). The other trial compared ACI and mosaicplasty and was critically appraised: Dozin B, Malpeli M, Cancedda R et al. Comparative evaluation of autologous chondrocyte implantation and mosaicplasty. Clin J Sport Med 2005; 15: 220-226. [See Evidence Table.](#)

The use of Autologous Chondrocyte (Carticel®) Implantation for Treatment of Defects in Articular Cartilage of the Knee does not meet the *Group Health Medical Technology Assessment Criteria*.

### 03/21/2016: MTAC REVIEW

#### **Autologous Chondrocyte Implantation (Autologous Chondrocyte Transplantation) For the Treatment of Chondral Defects in the Knee**

**Evidence Conclusion:** Autologous chondrocyte Implantation (Carticel, the first generation) was previously reviewed by MTAC, four times between 1998 and 2006. At the time the best published evidence consisted of four controlled trials (three randomized and one pseudo-randomized), none of which found significantly better clinical outcomes with ACI compared to the alternative interventions at 1-2 years post-surgery. Knutsen, et al (2004), the strongest study methodologically, at the time, found better results for the group receiving microfracture on one key outcome (the physical component score of the SF-36). The Bentley et al's study (2003) found better histological results in the ACI group, but the analysis included only 60% of the randomized patients. In summary the 2006 report concluded that ACI does not provide a clear clinical advantage over other surgical procedures to heal cartilage injuries and may be inferior to microfracture. The updated literature search for the current re-review of ACI, identified a number of published comparative and non-comparative studies evaluating the effectiveness of ACI, marrow stimulation (MS, mainly with MF techniques), and OAT, in improving the clinical outcomes of patients with cartilage lesions in the knee. Different ACI generations and techniques were evaluated and /or compared to other interventions used for restoring knee function. The published studies were relatively small, and in addition to the variations in the surgical techniques and approaches used for ACI and other procedures, there were differences between the studies in the criteria for patient selection, lesion sizes, outcomes, duration of follow-up, and measures used to evaluate histological and/or functional outcomes. In addition none of the trials was blinded and pain and function measures mainly relied on subjective evaluation, which may bias the results. Few studies showed minimal differences between ACI compared to MF, or OAT, and many others found no significant differences in outcomes with the different surgical techniques. The majority of the studies were underpowered to detect statistical differences, and a lack of significant differences between procedures does not necessarily indicate that they are equivalent or have similar effects. Combining the studies into meta-analyses increases the power, but the significant heterogeneity between the published studies on the treatment of chondral lesions in the knee precluded pooling the results of the individual studies in many cases, and/or performing subgroup analyses to determine the optimal procedure to the patient according to the lesion size, type of activity, comorbidity, and other characteristics. Few authors cautiously pooled the results of studies into meta-analyses, but these have to be interpreted with caution as the results of a meta-analysis are as good as the quality of the studies it includes.

**ACI versus microfracture (MF):** Mundi and colleagues (2015) (Evidence Table 1), performed a systematic review and meta-analysis of RCTs to compared ACI, MF, and OAT. The authors could only pool the results of the studies comparing ACI versus marrow stimulation (MS), mainly using the microfracture (MF) technique. The meta-analysis had valid methodology and analysis, but the included studies had their limitations, and were significantly heterogeneous. The overall pooled results showed no significant difference between ACI and MF in improving knee function and pain at intermediate-term follow-up. [Oussedik and colleagues \(2015\)](#) performed a systematic review to compare the outcomes of MF and ACI in patients with articular cartilage lesions of the knee. The review included 34 articles only 9 of which were comparative studies, the rest were observational with no control groups, and 2 were animal model studies. The authors could not pool the results of the comparative studies into a meta-analysis due to the significant heterogeneity between the studies. They concluded that low quality (grade IV) evidence suggests that MF may be effective in smaller lesions and is usually associated with a greater proportion of fibrocartilage production which may affect its durability. They also suggested that the multiple lesions treated with MF have poorer outcomes compared with single lesions. ACI was an effective treatment that may result in a greater proportion of hyaline-like tissue at the repair site, appears to be effective for larger lesions. The authors noted however, that the variation in techniques and modifications used for repairing chondral lesions of the knee, together with the different outcomes and measures used, and lack of long-term follow up make it hard to compare techniques and /or determine the optimal procedure for the different patient groups. [Negrin and colleagues \(2013\)](#) (Evidence Table 2), conducted a systematic review and meta-analysis to compare the clinical outcomes of MF and ACI after equal follow-up periods. The review included 7 RCTs and 2 observational studies with at least one year follow-up. The meta-analysis had some disadvantages which may limit generalization of its results. It included a small number of studies with relatively small population sizes, and the authors pooled the results of the RCTs together with the observational studies that used different scores and values for assessing the outcomes. They performed two meta-analyses: the first included all three ACI generations, and the second only included the second and third generations. The first analysis showed a small statistically insignificant difference between MF

and all three ACI generations combined after 1 year, and the second meta-analysis showed a significant improvement with ACI after the first generation study (Knutsen et al, 2007) was excluded. The authors noted however, that the observed statistically significant difference was clinically irrelevant. They indicated that the two procedures are complementary, and that large RCTs with long-term follow-up are needed to determine which groups of patients would benefit more from each procedure. Vanlauwe J, and colleagues (2011) published 5-year follow up results of an earlier study (Saris et al, 2008) that compared ACI using characterized chondrocyte implantation (CCI) (ChondroCelect, Belgium) vs. MF in 118 patients with a single symptomatic cartilage defect in the knee. The study had 90% power to detect a significant difference in the success rate between the two techniques. The first article reporting the results of one-year follow up showed significant clinical improvement with the two techniques when compared to baseline. There were no significant differences between the two procedures in the short-term clinical outcomes or complication rates, but the tissue regenerate was superior with ACI. The published 5-year results showed that the clinical improvements reported at 12 months and 24 months were maintained for the duration of follow-up. There were no significant differences between the two groups in clinical outcomes, radiological outcomes, or treatment failures. However, the latter tended to occur earlier with MF (in those treated in less than 3 years from onset of symptoms). Subgroup analyses showed no significant differences by age (at 35 years cutoff), and that females had more treatment failures irrespective of the procedure they underwent. Knutsen and colleagues' (2007) long-term follow-up results of the RCT that compared first generation of ACI vs. MF (published in 2004 and reviewed earlier by MTAC) showed no significant difference between the two techniques in the clinical or radiological outcomes at 5 years posttreatment. There was a 23% failure rate (need for a reoperation due to lack of healing) in each of the treatment groups at 5 years compared to only 2.5% failures in the MF and 5% with ACI at 2 years. Younger patients (<30 years of age) had better outcomes than older patients irrespective of the treatment group. One third of the patients had radiographic evidence of early osteoarthritis at 5 years. The authors noted that the study was limited by only including patients with chronic symptomatic cartilage defect of the knee, and by the lack of a control group that did not undergo surgical treatment or who were simply treated with arthroscopic lavage. The authors concluded that further long-term follow-up is needed to determine if one method is superior to the other, and to study the progression of osteoarthritis. ***ACI versus Osteochondral autograft transplantation (OAT)*** Li et al, 2015 (Evidence Table 3) performed a systematic review and meta-analysis of RCTs to compare the efficacy of OAT versus ACI in the treatment of large cartilage defects of the knee. The analysis included 5 relatively small trials two of which evaluated the same cohort at different time periods. There were differences between the studies in the surgical techniques and scoring of outcomes. The authors quantified the results into crude grades for comparisons. The overall pooled results of the trials, after performing a sensitivity analysis suggest that there were no significant differences between OAT and ACI results in the short-term, but ACI has superior outcomes on the long-term. Patients undergoing OAT were more likely to have worse conditions on the long-term when compared to those receiving ACI. The authors explained that the injuries for autografts in OAT, the absence of fill and difference in orientation may influence the patient outcomes and limit further OAT procedures. On the other hand ACI can be performed repeatedly in the same patient using tissue engineered material. Clave, et al (2016), randomized 55 patients with isolated symptomatic femoral osteochondral defects 2.5-7.5 cm<sup>2</sup> to receive Cartipatch (third generation ACI) or mosaicplasty (OAT). Patients were followed-up or 2 years, and the primary outcome measure was the change in the functional outcome from baseline to month 24 postoperatively. This was subjectively measured by International Knee Documentation Committee (IKDC) score. The investigators could only recruit 55 of the 76 (72%) patients needed to provide sufficient power, 15% of those randomized were lost to follow-up, and only 54% were included in the analysis. The authors indicated that contrary to the hypothesis of the study, the results showed that mosaicplasty was superior to Cartipatch in improving IKDC score 2 years after surgery. The significant difference between the two procedures was observed for defects measuring ≥ 3.5 cm<sup>2</sup>. No significant difference was observed for smaller lesions. The trial was randomized and controlled, but had several disadvantages that would limit generalization of its results. It was small in size, the patients were not blinded to the procedure they underwent, only 55% of those randomized were included in the analysis, the outcome was subjective, and the follow-up duration was insufficient to determine the long-term outcomes of the interventions. Bentley and colleagues, 2012 (included in Li et al's 2015 meta-analysis discussed earlier) published 10-year results of an earlier RCT that compared ACI to mosaicplasty among 100 patients with chronic lesions. The mean articular cartilage lesion size was 440.9 mm<sup>2</sup> (range 100-1050 mm<sup>2</sup>) in the ACI group, and 399.6 mm<sup>2</sup> (100-2000 mm<sup>2</sup>) in the mosaicplasty group. The early results of the trial showed significantly better outcome with ACI at 18 months post-surgery. This has been sustained over the years. At ten years, the functional outcome was significantly better with ACI vs. mosaicplasty when measured by the Cincinnati score, but insignificant with Stanmore-Bentley score. It is to be noted however, that only 15 of 48 patients randomized to OAT were included in the 10-year assessment of function. The failure rate (needed revision operations) was significantly higher in the mosaicplasty group vs. the ACI group (55% and 17% respectively). The pattern of failure was different; the ACI showed a low steady failure rate across 10 years, while the mosaicplasty group remained relatively satisfactory for the first 2 years then experienced a steep failure rate over the next 2 years. ***ACI versus any other treatment for articular cartilage lesions*** Vasiliadis and colleagues, 2010 conducted a systematic review of RCTs and quasi-randomized trials to compare ACI with any other type of

treatment (including no treatment or placebo). The authors could not pool the results into a meta-analysis due to the clinical and methodological heterogeneity between the studies. They concluded that the studies show that ACI is an effective treatment for full thickness chondral defects and associated with improvement in clinical outcomes compared to baseline. The published evidence however, does not suggest any superiority of ACI over other treatments; complications rates were comparable between the different interventions except with an increased graft hypertrophy with ACI-P (the first generation ACI). [Mundi and colleagues \(2015\)](#) ([Evidence Table 1](#)), systematic review and meta-analysis of RCTs (discussed earlier) compared ACI, marrow stimulation (MS mainly using MF), and OAT to determine whether a single technique has superior outcomes at an intermediate follow-up period. The review included 11 RCTs (published through April 2014) with a total of 765 patients. 5 trials compared ACI vs MS, 3 compared ACI vs. OAT, and 3 evaluated different generations of ACI. The authors could only pool the results of the RCTs comparing ACI versus MS and found no significant difference between the two procedures in improving function or reducing pain at intermediate term follow-up. They indicated that ACI, MS, and OAT are all generally efficacious in improving symptoms in patients with focal knee cartilage defects, The authors pointed to the limitations and heterogeneity of the published studies and noted that the current best evidence does not show that any of the three techniques is superior to the others in improving the intermediate-term pain and function. They concluded that high quality studies with sufficient power and long-term outcomes are needed before any specific intervention is recommended over others. [Samsudin and Kamural \(2015\)](#) conducted a systematic review to compare different generations of ACI to other treatment modalities. Like many other researchers, they could not pool the results of the trials into a meta-analysis due to the heterogeneity between the studies. They concluded that the literature shows a trend towards similar outcomes when comparing ACI generations with other repair techniques, and that there is insufficient evidence to conclude that that ACI and its newer generations are more effective than other techniques in repairing articular cartilage defects of the knee. Conclusion: There is insufficient published evidence from adequately powered large RCTs with valid methodology and long-term follow-up duration to determine that ACI and its newer generations are superior to other surgical techniques in repairing articular defects of the knee. The variations between the published studies make it difficult to accurately compare one intervention versus another or to determine the optimal procedure and technique for the individual patient. The literature suggests, but does not provide sufficient evidence that the newer generations of ACI may be associated with better long-term outcomes compared to microfracture in patients with larger full thickness, focal chondral defects in the knee.

**Articles:** The literature search revealed a large number of experimental and observational studies on autologous chondrocyte implantation. Several small randomized controlled studies compared one or more generation ACI with MF, with OAT, or versus another ACI generation. The search also identified a number of systematic reviews with or without meta-analyses on ACI compared to one or more of the other treatment modalities. The more recent meta-analysis comparing ACI with microfracture (Negrin, 2013), a meta-analysis comparing ACI to OAT (Li, 2015), an analysis comparing all three procedures (Mundi, 2015) were selected for critical appraisal. Studies comparing one generation ACI to another generation were excluded from the review. ## Clinical Review Criteria

### Actigraphy Testing for the Evaluation of Sleep Disorders

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

See the [NCD for Sleep Testing for Obstructive Sleep Apnea \(OSA\) \(240.4.1\)](#)

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

A sleep disorder (somniphathy) is a medical disorder of the sleep patterns. The international classification of sleep disorders (ICSD)-2 lists over 80 sleep disorders under eight major categories including insomnia, sleep-related breathing disorders, hypersomnia, circadian rhythm sleep disorders, parasomnia, sleep-related movement disorders, and others. It is estimated that 30-40% of Americans have a sleep complaint at any one time and that 10-15% suffer from chronic insomnia (Quan 2006).

The proper diagnosis and management of patients with sleep disorders depends on an accurate clinical history. There is a variety of sleep history questionnaires including the Epworth Sleepiness Scale (ESS) and the Pittsburgh Sleep Quality Index (PSQI). Keeping a sleep-wake diary is a standard procedure used for the subjective assessment of sleep, and may give a more complete picture of the individual's sleep patterns and variability from day to day. Sleep diaries are useful for evaluating sleep over extended periods of time in the patient's home environment; they represent an important clinical tool and are often used in behavioral treatment of sleep disorders such as insomnia. However, self-documentation of sleep frequency and duration is prone to bias. The fully attended traditional polysomnography (PSG) is the basic diagnostic procedure and is considered the standard for evaluating sleep disorders. It is an overnight test performed in a sleep laboratory and comprises continuous recording of several physiological variables including airflow, chest/abdominal movements, arterial oxygen saturation, electroencephalography (EEG), electrocardiogram [ECG], electromyography (EMG), and electrooculography (to measure eye movement). The EEG activity, eye movements, and muscle tone reveal the differences between wakefulness and sleep. Some investigators indicate that while the full PSG is widely considered the standard in clinical practice, it is not a true gold standard as it had not been validated. The use of PSG is limited by its high cost, time consumption, complexity, and considerable utilization of hospital resources. It may be impractical in some cases among whom sleep patterns must be assessed over extended periods of time. Moreover, PSG assesses sleep in an abnormal environment, which can alter its structure. These disadvantages of PSG have led to the search for alternative tools to diagnose and/or monitor sleep disorders in a natural environment (Bar 2003, Buysse 2005 Broughton 1996, Zou 2006, To 2009, Sunwoo 2010, Martin 2011).

Actigraphs, also called actometers or actimeters, were first used to record sleep and wakefulness based on movement in the early 1970s. The term actigraphy refers to methods utilizing miniaturized sensors that translate physical motion into a numeric presentation. Actigraphy simply measures movement, and is one dimensional, whereas polysomnography comprises at least three distinct types of data (EEG, EOG, and EMG), which jointly determine if a patient is asleep or awake. The actigraphy device may be placed on the wrist, ankle, or trunk. The best placement site for the actigraph to obtain the most reliable data is still controversial. In most studies it is worn on the nondominant wrist based on observations that wrist may detect more movements compared with the ankle and trunk, and that placement on the dominant arm detects more movement than the nondominant arm. The actigraphy device includes a

small accelerometer that monitors and records the occurrence and degree of motion. It can collect data continuously over an extended period of one week or longer. Actigraphic data can be displayed and scored manually or downloaded to a computer for display and analysis by software and algorithms that give estimates of sleep-wake and circadian rhythm parameters. The collected data are translated into epochs (typically 30 seconds or 1 minute) of activity. Using validated algorithms, the epochs are scored as sleep or awake. The device interprets the presence of movement as time awake, and absence of movement as sleep time. Some investigators treat PSG and actigraphy measures as equally valid or alternative measures that provide an estimation of the time an individual spends sleeping and awake. However, actigraphy only measures movement; and electrographic sleep-wake status and motor activity/inactivity are not equivalent. Despite the sophisticated algorithms for actigraphy that may potentially estimate the time an individual spent sleeping and awake based on movement, actigraphy just provides an indirect estimate of sleep-wake as it is commonly defined (Broughton 1996, Lotjonen 2003, Ancoli 2003, Flemons 2003, Kuna 2010, Sanchez-Ortuno 2010, Calogiuri 2013).

Actigraphs vary widely in sizes and features, and can be expanded to include sensors which monitor light, sound, temperature, and parkinsonian tremors. Some devices are programmable and allow the selection of specific modes of operation while others have only one fixed mode. New devices, scoring algorithms and operating procedures are continuously being developed and updated. Newer devices have the advantage of the small size and light weight making them more convenient for all patients. Different devices have different measuring mechanisms and scoring algorithms, but their results are usually interpreted equally between studies, despite the fact that research found that their accuracy in estimating sleep varies between population groups and from one device to the other (Broughton 1996, Lotjonen 2003, Ancoli 2003, Flemons 2003, Kuna 2010, Meltzer 2012, Blackwell 2011).

Actigraphy was reviewed by MTAC in 2007 and 2011 for detecting obstructive sleep apnea (OSA), and in 2008 for the assessment of sleep disorders, and did not meet the Committee's evaluation criteria. The technology is being re-reviewed for its use for the evaluation of insomnia and circadian rhythm disorders.

## Medical Technology Assessment Committee (MTAC)

### *Actigraphy in the Treatment of Sleep Disorders*

#### **12/03/2007: MTAC REVIEW**

**Evidence Conclusion:** The studies that evaluated the use of actigraphy for the assessment of sleep apnea did not use the technology alone but embedded/ or combined it with other devices as peripheral arterial tonometers (PAT), or respiratory polygraphs. Watch-PAT 100 was the device most commonly used in the published studies. The actometer estimated the total sleep time while the tests of respiratory function were used to calculate the apnea severity, and apnea hypopnea index (AHI). To date, there are no published controlled trials that would determine whether actigraphy can replace PSG or provide incremental information that would impact patient management decisions or improve health outcomes.

The population sizes of the studies varied from <20 patients to just over 200, and the majority assessed the portable monitors simultaneously with PSG in sleeping laboratories in the presence of sleep clinicians, and not in unattended settings. This would be ideal for testing the ability of the monitors to work, but does not assess its performance in the patient's home where it is intended, which in turn may limit extrapolation of the results. Moreover, the studies mainly included patients referred to sleep laboratories for suspected OSA. The high prevalence of the disorder among these patients would affect the sensitivity, specificity and likelihood ratios of the test that would also limit generalization of the results.

Diagnostic accuracy: Different algorithms were used for the evaluation of data. The investigators examined multiple respiratory disturbance index (RDI) thresholds for determining abnormal apnea hypopnea index (AHI) and define a positive result. The cutoff for used for AHI was arbitrary and varied between studies. Some investigators question the use of AHI as the correct reference standard. The Watch-PAT does not measure airflow and thus cannot differentiate hypopneas from apneas. Overall the results of the studies show that using PSG as the gold standards, the sensitivity of actigraphs embedded in peripheral arterial tonometers ranged from 82-90%, and specificity ranged from 68-90% depending on severity of the obstructive sleep apnea. The sensitivity tended to be lower, and specificity higher with increasing severity the disorder. The area under the curve (AUC) also varied between studies with severity of sleep apnea, and its measures. It ranged from 0.82 for patients with RDI.>10 in Bar's study, to 0.98 for AHI >30 in Garcia-Diaz study. This latter study also compared the respiratory polygraph (RP) performed in the hospital versus that at home, either with or without the addition of actigraphy. Its results showed that RP performed at the laboratory was more accurate than that done at home, and that the addition of actigraphy did not result in significant improvement but tended to overestimate sleep time. The agreement rate between actigraphy devices and PSG was reported in some studies and ranged from 80% to 93%, also depending on the severity of the obstructive sleep apnea.

Diagnostic impact: There is insufficient evidence to determine that actigraphy can provide information that may influence the management decisions for patients diagnosed with obstructive sleep apnea. Therapeutic impact:

There is insufficient evidence to determine that using actigraphy for the diagnosis of obstructive sleep apnea would improve health outcomes.

**Articles:** The literature search revealed over 500 articles on actigraphy. The majority of the published studies used the technology to investigate patients with insomnia, circadian rhythm sleep disorders, and as an outcome measure to determine response of therapy, mainly melatonin 1. Diagnostic accuracy There were no randomized or nonrandomized trials that compared the results of actigraphy used alone, to polysomnography to determine if it can be used as an alternative to PSG in the diagnosis of obstructive sleep apnea. There were several studies that focused on the accuracy and usefulness of actigraphy in evaluating patients with obstructive sleep apnea. These studies however, did not use actigraphs alone, but combined it with tests of respiratory function in order to calculate the apnea hypopnea index which measures the severity of apnea in these patients. The studies that compared the wrist worn devices with embedded actigraphs used PSG as the gold standard, and reported sensitivity, specificity, likelihood ratios or areas under the receiver operator curves were selected for critical appraisal. 2. Diagnostic impact The literature search did not reveal any study that would determine the influence of the technology on management decisions. 3. Therapeutic impact No studies on the impact of technology on patient outcomes were identified by the search. *The following studies were critically appraised:*

Ayas NT, Pittman S, MacDonald M, et al. Assessment of a wrist-worn device in the detection of obstructive sleep apnea. *Sleep Medicine* 2003;4:435-442 See [Evidence Table](#). Bar A, Pillar G, Dvir I, et al. Evaluation of a portable device based on peripheral arterial tone for unattended sleep studies. *Chest* 2003;123:695-703 See [Evidence Table](#). Garcia-Diaz E, Quintana-Gallego E, Ruiz A, et al. Respiratory polygraphy with actigraphy in the diagnosis of sleep apnea-hypopnea syndrome. *Chest* 2007;131:725-732. See [Evidence Table](#). Hedner J, Pillar G, Pittman SD, et al. A novel adaptive wrist actigraphy algorithm for sleep-wake assessment in sleep apnea patients. *Sleep* 2004;27:1560-1566. See [Evidence Table](#). Zou D, Grote L, Peker Y, et al. Validation a portable monitoring device for sleep apnea diagnosis in a population based cohort using synchronized home polysomnography. *Sleep* 2006;29:367-374. See [Evidence Table](#).

The use of actigraphy in the treatment of obstructive sleep apnea does not meet the *Group Health Medical Technology Assessment Criteria*.

## 02/04/2008: MTAC REVIEW

### Actigraphy in the Treatment of Sleep Disorders

**Evidence Conclusion:** The published studies that evaluated actigraphy for the assessment of insomnia were conducted on selected groups of patients and used different actigraph models, software, and scoring algorithms. Most studies were conducted in sleep laboratories where recording conditions are standardized and the artifacts controlled. These controls would be lost when the actigraphy devices are used in the home environment, where it is intended for use. Also the algorithms that were validated for a specific model, mode of operation, or in a selected population may by not be equally accurate when used with a different brand of device, different gender or age group. The studies reviewed compared actigraphy to PSG, but the authors did not indicate whether the investigators interpreting the results of one test were blinded to the results of the other. The overall results of the studies reviewed, indicate that compared to polysomnography, actigraphy had a high sensitivity (92-98%) but very low specificity (28-48%) in detecting insomnia. It was also found to overestimate the total sleep time and sleep efficiency. Actigraphy tends to overestimate sleep in people with insomnia when they are lying quietly as quiet wakefulness could be miscoded as sleep. Insomnia patients can remain inactive for a period of time attempting to fall asleep. On the other hand actigraphy may underestimate the amount of sleep and overestimate the duration awake among those who are asleep but are restless or have large amounts of movements during sleep. The use of actigraphy for the assessment of periodic leg movements in sleep was evaluated in only a few small studies with methodological limitations. It was compared with polysomnography with bilateral anterior tibialis electromyography (BATEMG). However EMG and leg actigraphy are not interchangeable, and each measures a different event. One records electrical activity of a certain muscle and the other records leg acceleration. Leg activity may be due to movement artifacts produced by obstructive sleep apnea. Kemlink et al (2007) did not exclude patients with suspicious sleep apnea and did not adjust for it in the analysis. In conclusion there is insufficient evidence to determine that actigraphy would replace PSG or add to its value in the diagnosis and management of patients with sleep disorders.

**Articles:** The following questions were considered in screening the published articles:

- 1) What is the diagnostic accuracy of actigraphy in the evaluation of patients with sleep disorders?
- 2) Does the use of actigraphy influence management decisions?
- 3) Does actigraphy lead to better treatment outcomes?

The literature search revealed over 500 articles on actigraphy. Due to the continuing development in the actigraphic devices, operating procedures, software, and scoring algorithms, the literature was screened to identify the more recent studies. Many of these used actigraphy to assess treatment effects or compared results from one actigraphy scoring algorithm to another. Others reported on the use of actigraphy in specific groups as very young infants, children with ADHD, patients with depression, dementia, Parkinson's disease, and others. There were a

number of nonrandomized studies that compared actigraphy with other tools for the evaluation of patients with insomnia, periodic leg movement, narcolepsy and other medical disorders other than sleep disorders. The literature search did not reveal any study that would determine the influence of the technology on management decisions or its impact on patient outcome. *The following studies that compared actigraphy with the gold standard of polysomnography were critically appraised:* Kushida CA, Chang A, Gadkary C, et al. comparison of actigraphic, polysomnographic, and subjective assessment of sleep parameters in sleep-disordered patients. *Sleep Medicine* 2001;2:389-396. [See Evidence Table 3](#) and [see Evidence Table 4](#). Sivertsen B, Omvik S, Havik OE, et al. A comparison of actigraphy, polysomnography in older adults treated for chronic primary insomnia. *Sleep* 2006;29:1353-1358. [See Evidence Table](#). Lichstein K, Stone KC, Donaldson J, et al. Actigraphy validation with insomnia. *Sleep* 2006;29:232-239. [See Evidence Table](#). Kemlink D, Pretl M, Sonka K, et al. A comparison of polysomnographic and actigraphic evaluation of periodic limb movement in sleep. *Neurol Res* 2007;000:1-5. [See Evidence Table](#). King MA, Jaffre MR, Morrish E, et al. The validation of a new actigraphy system for the measurement of periodic leg movement in sleep. *Sleep Medicine* 2005;6:507-513. [See Evidence Table](#).

The use of actigraphy in the treatment of sleep disorders does not meet the *Group Health Medical Technology Assessment Criteria*.

**02/04/2011**

### **Actigraphy in the Treatment of Sleep Disorders**

**Evidence Conclusion:** Accuracy of actigraphs/portable monitors for the detection of OSA. There were no published studies that compared portable monitors head-to-head. The accuracy of one device cannot be extrapolated to others even from the same class due to the differences in the number and types of signals recorded, sensors used, and the processing of signals. It is unknown which sensors or combinations have the highest sensitivity and specificity. Moreover, differences in scoring, testing environment, and night to night variability in the apnea hypopnea index (AHI) make generalization of results difficult. The studies that evaluated the use of actigraphy for the assessment of sleep apnea did not use the technology alone but embedded or combined it with other devices such as peripheral arterial tonometers (PAT), or respiratory polygraphs. Watch-PAT 100 was the device most commonly used in published studies. The actometer estimated the total sleep time while the tests of respiratory function were used to calculate the apnea severity, and apnea hypopnea index. As indicated in the 2007 review of the technology, the overall results of the studies reviewed showed that using PSG as the gold standards, the sensitivity of actigraphs embedded in peripheral arterial tonometers ranged from 82-90%, and specificity ranged from 68-90% depending on severity of the obstructive sleep apnea. The sensitivity tended to be lower, and specificity higher with increasing severity of the disorder. The agreement rate between actigraphy devices and PSG was reported in some studies and ranged from 80% to 93%, also depending on the severity of the obstructive sleep apnea. Therapeutic impact of actigraphs/ portable home monitors: In a randomized controlled trial that included 106 subjects with a high likelihood of OSA, Berry and colleagues (Evidence table 1) compared a clinical pathway with the watch-PAT 100 for the diagnosis and unattended autotitrating continuous positive airway pressure (CPAP) for those with an respiratory disturbance index (RDI) > 5 events /hour) to select an effective CPAP, versus standard in-laboratory PSG for diagnosis of OSA and CPAP titration. Using a similar approach, Skomro and colleagues' trial (Evidence table 2) randomized 102 subjects with high a probability of OSA to either home-based diagnosis (using Embletta device that incorporates an actigraph) and auto-CPAP (APAP) or in-laboratory PSG. The in-home study was considered positive if the respiratory disturbance index (RDI) was > 5, and patients were offered auto-CPAP therapy for 1 week followed by fixed-pressure CPAP based on the auto-CPAP P95 results. An earlier trial (Mulgrew 2007) compared a type IV portable monitor and APAP titration to in-laboratory PSG in 68 patients (22% of the eligible population) with moderate to severe OSA, and followed the patients for 3 months. All three trials showed no statistically significant differences in the Epworth Sleepiness Scale scores, quality of life scores, and other outcome studied between patients in the in-home diagnosis and auto CPAP titration group versus those in-laboratory PSG diagnosis and CPAP titration. These results however, should be interpreted with caution, and may not be generalized to the population at large due to several factors including but not limited to: participants in the studies were highly selected, had high pre-test probability of OSA, were mainly men, those with co-morbidities were excluded, short duration of follow-up, patients and/or providers were not blinded, and most of the participants in the PSG group had split-night PSG, which may lead to different outcomes of CPAP therapy than those derived from a full-night of CPAP titration. In addition, the studies were powered as superiority and not equivalence trials, and lack of significant differences does not necessarily indicate equivalence. Berry and colleagues powered their trial as noninferiority, but only for the compliance outcome. More high quality randomized trials are needed to compare clinical outcomes of laboratory PSG versus home monitoring for sleep disorders among diverse population groups e.g. ethnic groups, women, the elderly, and patients with cardiopulmonary and neurological diseases as COPD, asthma, heart failure, neuromuscular diseases, and other sleep disorders.

**Articles:** The literature search revealed over 400 articles on actigraphy. The great majority were unrelated to the current review. The technology was frequently used to determine response of therapies for insomnia, mainly

melatonin. There were few small validation studies on different portable monitor devices for diagnosing obstructive sleep apnea. There were no head-to-head comparisons between the devices for accuracy in detecting OSA. The search identified two published trials that compared the outcomes of in-laboratory diagnosis and treatment of OSA versus home-based diagnosis and treatment using portable monitoring devices that incorporated an actigraph. Both were critically appraised. Berry RB, Hill G, Thompson L, et al. Portable monitoring and autotitration versus polysomnography for the diagnosis and treatment of sleep apnea. *Sleep* 2008;31:1423-1431. [See Evidence Table.](#) Skormo RP, Gjevra J, Reid J, et al. Outcomes of home-based diagnosis and treatment of obstructive sleep apnea. *Chest* 2010;138:257-263. [See Evidence Table.](#)

The use of actigraphy in the treatment of sleep disorders does not meet the *Group Health Medical Technology Assessment Criteria*.

## 08/19/2013: MTAC REVIEW

### **Actigraphy in the Treatment of Sleep Disorders**

**Evidence Conclusion:** The published studies that evaluated actigraphy for the assessment of insomnia as a primary outcome or in a secondary analysis were conducted on selected groups of patients and used different actigraph models, software, and scoring algorithms. The majority of sleep studies were conducted in sleep laboratories where the recording conditions are standardized and the artifacts controlled. These controls would be lost when the actigraphy devices are used in the home environment, which is the primary intention for their use. In addition, the authors of the studies that compared actigraphy to PSG did not indicate whether interpretation of the results of one test was blinded to the results of the other. According to Sadeh (2011), a point that deserves attention is that actigraphic validation studies against PSG are all based on "time in bed" period whereas the main advantage of actigraphy is documenting sleep wake patterns continuously over 24-hour periods across days. Generalization of the results of the published studies may be limited to similar devices and population groups as the algorithms that were validated for a specific model, mode of operation, or in a selected population may not be equally accurate when used with a different brand of device, different gender, or age group. The results of the studies previously reviewed for MTAC showed that compared to polysomnography, actigraphy had a high sensitivity (92-98%) but very low specificity (28-48%) in detecting insomnia. These older as well as the more recent studies showed that actigraphy in general underestimates wake and overestimates the total sleep time and sleep efficiency. Individuals with insomnia can remain inactive for a period of time attempting to fall asleep, and actigraphy tends to overestimate sleep in these people as quiet wakefulness could be miscoded as sleep. On the other hand, actigraphy may underestimate the amount of sleep and overestimate the duration awake among those who are asleep but are restless or have large amounts of movements during sleep. A number of studies measured the correlation of actigraphy and PSG sleep outcomes as a measure of validity of actigraphy. These ranged between studies from 0.51-0.93 for total sleep time (TST), 0.48-0.85 for wake time after sleep onset (WASO), 0.36-0.81 for sleep efficiency (SE), and 0.30-0.95 for sleep onset latency (SOL). The MrOS Sleep Study (Blackwell et al, 2011), (Evidence Table 1) was embedded in the Osteoporotic Fractures in Men (MrOS) study and examined whether there was a difference between in-home-PSG and actigraphy (using the Sleepwatch-O device) in estimating the total sleep time (TST). The authors used 3 modes for collecting actigraphic data to determine the one that corresponds highest with PSG. These modes were the proportional integration mode (PIM), time above threshold (TAT), and zero crossings mode (ZCM). PIM mode is a measure of the activity level or vigor of motion, the TAT mode measures time spent in motion or time spent in active state, and the ZCM measures the frequency of movement. The study had the advantage of including a large population size of community dwelling individuals and the use of in-home PSG as a gold standard. It however, only included men >60 years of age; and the PSG data were collected in 30 minute epochs while the actigraphy data were collected in 1-minute epochs with no synchronization in the clock time. This did not allow direct comparisons for each epoch. In addition, the authors did not explain whether the study participants were asked to complete sleep diaries. The results of the analysis showed that the three actigraphy modes either over-estimated or underestimated sleep and wake compared to PSG. The PIM mode of actigraphy corresponded more closely with PSG estimation of total sleep time (TST) than the TAT or ZCM modes, yet the correlation was weak to moderate. These results however, may not be generalized to populations in different age groups or to other actigraphy devices. Van Den Berg and colleagues, 2008 (Evidence Table 2) measured the disagreement among actigraphy and sleep diary in estimating the total sleep time (TST) among 969 community dwelling elderly men and women participating in a cohort study that primarily investigated the incidence and risk factors of disabling disease. The participants in this substudy wore an actigraph (Actiwatch model AW4) and kept a sleep diary over a period of 5-7 consecutive days and nights. PSG was not used as the gold standard, but the authors only used the Actiwatch algorithm that was validated against polysomnography. The results of the analysis showed that, the estimated TST in the sleep diaries deviated more than one hour from that measured by actigraphy among 34% of the participants. The level of this disagreement decreased with subjective and actigraphic measures of sleep quality and increased with male gender, poor cognitive function, and functional disability. In a smaller study, Levenson and colleagues 2013 (Evidence Table 3) also compared the accuracy of actigraphy versus sleep diary among a group of older

insomniac patients participating in a larger study that examined the effect of behavioral therapy on insomnia in older adults. The study included 119 participants with a mean age of 71.7 years (79 with insomnia confirmed with PSG, and 40 controls who did not undergo a PSG). The participants completed at least 7 nights of sleep diary and actigraphy (using the Minimitter Actiwatch). The results of the analyses indicate that the sleep diary parameters discriminated individuals with insomnia from good sleepers more accurately than actigraphy. The AUC of actigraphy was in the low to moderate range (0.58 for sleep efficiency, and 0.61 for total sleep time, the 95% CI contained the value of 0.5 for many of the parameters). Johnson and colleagues, 2007 (Evidence Table 4) examined the level of agreement between actigraphy and polysomnography among 181 adolescents 12-16 years of age. All participants completed an overnight PSG in a clinical research center. The week prior to the PSG and during the overnight PSG study, they wore a wrist actigraph (Octagonal Sleep watch 2.01) and completed daily sleep logs. Data were digitized in 1-minute epochs and the activity count was calculated and stored based on 1 of 3 data modes: PIM, TAT, and ZCM. The results of the analysis showed significant differences between the assessments of total sleep time by actigraphy vs. PSG. The differences were more pronounced for boys vs. girls and for those with sleep disturbed breathing. In conclusion there is insufficient evidence to determine that actigraphy would replace PSG or add to its value in the diagnosis and management of patients with insomnia or circadian rhythm disorders.

**Articles:** The literature search revealed over 800 articles published on actigraphy and sleep in the last 5 years. The great majority was unrelated to the current review; many reported on the use of actigraphy in specific groups as very young infants, children with ADHD, patients with depression, dementia, Parkinson’s disease, and others. There was a lack of published studies on the use of actigraphy in patients with circadian rhythm sleep disorders. The studies that compared the use of actigraphy versus PSG for the evaluation of insomnia were mainly embedded in larger community based studies conducted among specific age groups and for studying different conditions and/or factors that were not necessarily related to sleep. The following studies with more valid methodology, larger population size, and used actigraphy concurrently with PSG and /or sleep diary were selected for critical review. Blackwell T, Ancoli-Israel S, Redline S, Stone KL; Osteoporotic Fractures in Men (MrOS) Study Group. Factors that may influence the classification of sleep-wake by wrist actigraphy: the MrOS Sleep Study. J Clin Sleep Med. 2011;7:357-367 [See Evidence Table](#). Johnson NL, Kirchner HL, Rosen CL, et al. Sleep estimation using wrist actigraphy in adolescents with and without sleep disordered breathing: a comparison of three data modes. Sleep. 2007;30:899-905. [See Evidence Table](#). Levenson JC, Troxel WM, Begley A, et al. A quantitative approach to distinguishing older adults with insomnia from good sleeper controls. J Clin Sleep Med. 2013;9:125-131. [See Evidence Table](#). Van Den Berg JF, Van Rooij FJ, Vos H, et al. Disagreement between subjective and actigraphic measures of sleep duration in a population-based study of elderly persons. J Sleep Res. 2008;17:295-302. [See Evidence Table](#).

The use of actigraphy in the treatment of obstructive sleep apnea does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Acupuncture

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
<b>CMS Coverage Manuals</b>	None
<b>National Coverage Determinations (NCD)</b>	<a href="#">Acupuncture (30.3)</a> <a href="#">Acupuncture for Fibromyalgia (30.3.1)</a> <a href="#">Acupuncture for Osteoarthritis (30.3.2)</a>
<b>Local Coverage Determinations (LCD)</b>	None
<b>Local Coverage Article</b>	None

##### For Non-Medicare Members

Authorizations for covered acupuncture treatments beyond eight visits (per condition that is not specifically excluded by the member contract) require prior approval by the health plan. Clinical review criteria for acupuncture are as follows. The patient must meet **ALL of the following**:

1. The condition has symptoms present on a daily basis resulting in functional limitations (decreased ability to perform activities of daily living) and has not resolved within a typical time frame of a self-limited illness or injury.
2. The patient has an established, documented diagnosis of one of the following:
  - a. Chronic arthritis
  - b. Fibromyalgia (The patient has an established, documented diagnosis of fibromyalgia consistent with the 1990 American College of Rheumatology Criteria.)
  - c. Chronic myofascial pain (Clinical conditions that frequently fall into this category include: cervicalgia, chronic neck and back pain, lumbago, muscular tension headaches, plantar fasciitis, and thoracic outlet syndrome.)
  - d. Chronic neuropathic pain
  - e. Chronic headaches
  - f. Dysmenorrhea
  - g. Hyperemesis with pregnancy
  - h. Nausea and vomiting associated with chemotherapy
  - i. Chronic pain secondary to cancer
  - j. Other medical conditions that have responded to an initial course of acupuncture with expectation of continued functional improvement.
3. There is documentation of the patient's baseline measurable functional limitations related directly to one of the above diagnoses.
4. Continued treatment is part of a defined treatment plan with measurable and progressive functional improvement. Maintenance therapy in the absence of progressive functional improvement is not an indication for coverage.
5. Acupuncture is covered for flares of pain when acupuncture has provided clinical improvement in the past.

Review staff will consider each referral request on a case-by-case basis and will consider requests outside the above criteria based on, among other things, clear documentation of objective improvement by the licensed acupuncturist or the patient's personal physician, as well as a detailed treatment plan.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Acupuncture originated in China about 5000 years ago as part of an organized approach to diagnosis and healing that became known as Traditional Chinese Medicine (TCM). According to TCM principles, disease is caused by imbalances in the flow of energy (qi) through 14 major energy pathways, or meridians. Acupuncture seeks to rebalance the flow of qi by inserting special needles at specific points along the meridians. Needling is commonly combined with heat or electricity.

Licensed acupuncturists in Washington must complete a minimum of three years of training at an accredited school. Training includes basic sciences, needling techniques, and herbal medicine.

## Evidence and Source Documents

There is a small body of literature supporting the efficacy of acupuncture. There is also case documentation that supports the value of acupuncture for treatment of specific clinical conditions, particularly chronic pain.

##### National Coverage Determination (NCD)

[Heart Transplants \(260.9\)](#)

##### For Non-Medicare Members

Group Health has elected to use the Inpatient and Surgical Care Guidelines Clinical Indications for Heart Transplant MCG\*(S- 535) for medical necessity determinations.

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed for heart transplant eligibility, you may request a copy of the by calling the Group Health Clinical Review staff at 1-800-289-1363.)

#### If requesting this service, please send the following documentation to support medical necessity:

- Copy of final summary report from multidisciplinary transplant team

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

A heart may be irreversibly damaged by long-lasting heart disease or viral infection. When the heart can no longer adequately work and a person is at risk of dying, a heart transplant may be appropriate.

Cardiac transplant has become increasingly successful over the past several years. Adult heart transplant recipients have a one-year survival rate of eighty to ninety percent and a five-year survival rate of sixty to seventy percent. Group Health contracts have included coverage for heart transplantation for several years. Members with coverage who meet the selection criteria are considered for transplantation.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Rheumatoid arthritis is a chronic, systemic, inflammatory disorder that affects approximately 0.5–1% of the Western population. If left untreated, this disease can result in permanent joint damage (Binker 2010). Evidence from recent studies suggests that achieving early control of rheumatoid arthritis minimizes joint destruction and increases long-term disease control.

Methotrexate is one of the most effective and commonly prescribed drugs for the treatment of rheumatoid arthritis. Although methotrexate is effective, it is not without side effects. Side effects of methotrexate include: gastrointestinal disturbance, mucositis, fatigue, alopecia, elevated serum transaminase levels, and bone marrow toxicity. Frequent blood tests are required to monitor for the development of these adverse effects. Additionally, patient response to methotrexate, both in terms of efficacy and toxicity is highly variable. It is estimated that approximately 30–40% of patients with rheumatoid arthritis taking methotrexate do not adequately respond to treatment (Danilia 2010, Goodman 2010). Currently, there is no reliable means of predicting patient response to methotrexate.

After administration and absorption, serum methotrexate levels fall rapidly as it is actively transported into a variety of cells. In the cells, up to six additional glutamate residues are added, converting methotrexate into the more stable polyglutamate form. Methotrexate polyglutamate can be converted back to methotrexate to permit efflux from the cell. The therapeutic effect of methotrexate depends on its conversion to methotrexate polyglutamate. It has been suggested that if methotrexate polyglutamate levels were associated with adverse events or therapeutic response then knowledge of these levels could be used to help optimize methotrexate therapy in rheumatoid arthritis (Binker 2010, Danilia 2010, Goodman 2010). The Advise PG test (Cypress Bioscience, San Diego, CA) measures methotrexate polyglutamate levels and was developed to aid in dosage optimization for rheumatoid arthritis patients who have been on methotrexate for at least three months. Results of the Advise PG test are reported as therapeutic (> 60 nmol/L), intermediate (20-60 nmol/L), and subtherapeutic (< 20 nmol/L).

#### Medical Technology Assessment Committee (MTAC)

##### Advise PG Test for Measuring Methotrexate Polyglutamate Levels

06/20/2011: MTAC REVIEW

**Evidence Conclusion:** Analytic validity - There are a variety of rapid, sensitive, and accurate methods for the detection of methotrexate polyglutamate (Dervieux 2003, Li 2007). Clinical validity - Two cross-sectional studies

that examined the association between methotrexate polyglutamate levels and disease activity were selected for review. The first study included 192 subjects with rheumatoid arthritis who had been taking methotrexate for at least 3 months and had a stable dose for at least a month prior to study entry. Before adjusting for confounding factors results suggest that higher disease activity, measured using the swollen joint count (SJC), the physician's global assessment, the physician's assessment of response to methotrexate, the Disease Activity Score in 28 joints (DAS28), the Clinical Disease Activity Index (CDAI), and the Simplified Disease Activity Index (SDAI), was associated with higher MTX PG concentrations (MTX PG<sub>4</sub>, MTX PG<sub>5</sub>, MTX PG<sub>1-5</sub>, and MTX PG<sub>3-5</sub>). After adjusting for confounding factors, patients with higher disease activity measured using TJC, SJC, and DAS28 still had higher MTX PG<sub>5</sub> concentrations. There was no association between methotrexate polyglutamate concentration and adverse events (Stamp 2010). Two other studies also failed to find an association between methotrexate polyglutamate concentration and adverse events (Dervieux 2006, Angelis-Stoforidis 1999). The second study included 226 subjects with rheumatoid arthritis who had been taking methotrexate for at least 3 months. After controlling for confounding factors, low methotrexate polyglutamate levels were associated with poor clinical status (high number of tender and swollen joints, physician's assessment of disease activity, and the modified Health Assessment Questionnaire)(Dervieux 2005). The same group of authors also conducted two other studies that examined the relationship between methotrexate polyglutamate levels and clinical status. Both of these studies along with two other observational studies also found that low methotrexate polyglutamate levels were associated with poor clinical status (Angelis-Stoforidis 1999, Dervieux 2004, Dervieux 2006, Hornung 2008). Clinical utility - No studies were identified that addressed the clinical utility of measuring methotrexate polyglutamate levels to aid in dosage optimization for rheumatoid arthritis patients.

**Conclusion:** Analytic validity: There are a variety of rapid, sensitive, and accurate methods for the detection of methotrexate polyglutamate. Clinical validity: Several observational studies have investigated the association between methotrexate polyglutamate levels and clinical status. While the majority of these studies found that low methotrexate polyglutamate levels were associated with poor clinical response, not all studies have found this association. Clinical utility: There is insufficient evidence to determine the clinical utility of measuring methotrexate polyglutamate levels to aid in dosage optimization for rheumatoid arthritis patients.

**Articles:** Two studies were identified that address analytic validity. Several observational studies were identified that examined the relationship between methotrexate polyglutamate levels and clinical status (clinical validity). Two of the larger studies were selected for review. No studies were identified that addressed the clinical utility of measuring methotrexate polyglutamate to aid in dosage optimization for rheumatoid arthritis patients. The following studies were critically appraised: Stamp LK, O'Donnell JL, Chapman PT, et al. Methotrexate polyglutamate concentrations are not associated with disease control in rheumatoid arthritis patients receiving long-term methotrexate therapy. *Arthritis Rheum* 2010; 62:359-638. See [Evidence Table](#). Dervieux T, Frust D, Lein DO, et al. Pharmacogenetic and metabolite measurements are associated with clinical status in patients rheumatoid arthritis treated with methotrexate: results of a multicentered cross sectional observational study. *Ann Rheum Dis* 2005; 64:1180-1185. See [Evidence Table](#).

The use of Advise PG test for measuring methotrexate polyglutamate levels does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Medicare Members

Allogeneic Meniscal Transplant (CPT code 29868) was removed from the Non-Covered Services LCD on 07/11/2014. This does not imply that the service will always be covered. Please send for Medical Director review.

##### For Non-Medicare Members

Group Health has elected to use the MCG\* (A-0216) for medical necessity determinations. This service is not covered per MCG guidelines.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (Orthopedics/podiatry)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

The knee meniscus is a fibrocartilagenous crescent-shaped structure that plays an important part in the biomechanics of the joint. It functions as load bearing, shock absorption, stabilization of the joint as well as lubrication. Partial or complete loss of the meniscus alters the joint function, and predisposes the articular cartilage to degenerative changes. In the past, total or subtotal meniscectomy was routinely performed for patients with meniscal tears. More recently, repair of the meniscus has become the standard treatment for tears. If un-repairable, arthroscopic partial meniscectomy of only the torn segments is recommended (Yoldas 2003). Subtotal or complete meniscectomy is however performed when the entire meniscus is torn and irreparable. Meniscectomy leads to deterioration of the articular cartilage, and narrowing of the knee joint. Allograft meniscal transplantation, has become an option for these patients, and is believed to prevent progression of degenerative changes of the knee.

The first meniscal allograft was performed in 1984 by Milachowski and Wirth. The technique of the transplantation has evolved over the years, and different graft types were used. These include meniscus prosthesis, scaffolds, genetically engineered tissue, meniscus xenografts, meniscus autografts, and meniscus allografts. The allografts used are fresh, fresh-frozen, lyophilized, or cryopreserved menisci. Fresh menisci are thought to be superior as the architecture is unchanged, and chondrocytes and other cells are still viable. However, fresh grafts are logistically difficult to obtain. Fresh-frozen and cryopreserved menisci are reported to have good results but are associated with storage and availability problems. The Lyophilized and freeze dried menisci can be stored for a long time, but have the disadvantage of the decay of ground substance and destruction of the architecture in the freeze dried menisci, and shrinkage in the lyophilized. Cryopreservation may maintain fibrochondrocytes for 2-4 weeks but is very expensive in cost. The success of the transplantation depends on the revascularization and the cell proliferation for the restitution of the lost ground substance. Sizing of the meniscus before transplantation is also important to have a good geometrical fit in the joint, and a proper function.

The indications of the transplantation are not well defined. Persistent pain after meniscectomy is a common indication. Some authors believe that a knee with minimal or no arthritic changes is the ideal for transplantation, and others indicate it only for knees with degenerative changes. Some investigators in the US (Felix N, and Paulos L 2003), indicate meniscal transplantation for those <40 years old, with pain and swelling not responding to

conservative treatment, minimal degenerative changes, stable knee, and axial alignment. In other countries e.g. Germany (Peters 2003) the indications include total meniscectomy with early arthritis, loss of anterior cruciate ligament, concomitant osteotomy, and prophylactic transplantation. It is contraindicated in patients with severe degenerative changes in the joint, instability, malalignment, and history of infection of the joint.

## Medical Technology Assessment Committee (MTAC)

### Allogenic Meniscal Transplant

#### 07/14/2004: MTAC REVIEW

**Evidence Conclusion:** The results of the studies reviewed are promising but do not provide sufficient evidence, on the effectiveness of the meniscal allograft transplantation in restoring the knee function and preventing degenerative osteoarthritis. The prospective study, the two case series appraised, as well as the other published case series and reports were small, included heterogeneous patients at different ages, and with different indications for the meniscal transplantation. None of the studies used a consistent protocol. The grafts used were fresh, deep-frozen, cryopreserved, or lyophilized allografts. The duration from the meniscectomy to the transplant varied among patients from few months to more than 30 years. In several reports and within studies some patients received an anterior cruciate ligament repair, together with the meniscal transplant. In others, patients underwent different procedures after the transplantation. The rehabilitation programs varied between and within studies, as well as the duration of follow-up. Overall the results of the studies show that meniscal transplantation may alleviate pain and improve the knee function. However, there is insufficient data to determine which patients will benefit most, and if benefits observed would be maintained over time, and whether the transplantation will prevent degenerative changes from occurring within the joint.

**Articles:** The search yielded 75 articles many of which were review articles. There were no meta-analyses or randomized controlled trials. One prospective cohort study and several case series reports with limited number of patients were identified. The prospective cohort study and two case series reports were selected for critical appraisal. Selection for the case series reports for review was based on the population size, duration of follow-up, and/or primary outcomes. *Evidence tables were created for the following studies:*

Wirth CJ, Peters G, Milachowaski KA, et al. Long-term results off meniscal allograft transplantation. *Am J Sports Med* 2002;30:174-181. See [Evidence Table](#) van Arkel ERA, and de Boer HH. Survival analysis of human meniscal transplantations. *J Bone Joint Surg* 2002;84-B:227-31. See [Evidence Table](#) Rath E, Richmond JC, Yassir W et al. Meniscal allograft transplantation. Two-to eight-year results. *Am J Sports Med* 2001;29:174-181. See [Evidence Table](#)

The use of allogeneic meniscal transplant in the treatment of knee pain and swelling does not meet the *Group Health Medical Technology Assessment Criteria*.

Local Coverage Article	<a href="#">AlloMap Billing and Coding Guidelines (A54366)</a>

##### For Non-Medicare Members

Service	Criteria
AlloMap Test	Allomap is covered for heart transplant patients who can no longer undergo biopsy for the detection of allograft rejection.
Heartsbreath Test	There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Approximately 3,500 people worldwide now undergo heart transplantation every year with at least 40% of recipients experiencing at least one episode of rejection in the first year after transplantation (Stehlik, Edwards et al. 2012). Clinical features of acute cellular rejection are unreliable resulting in a variety of monitoring techniques which may include frequent blood tests, lung function tests, electrocardiograms echocardiograms and biopsies of the heart tissue.

The current gold standard for heart transplant rejection diagnosis is a series of endomyocardial biopsies (EMB) (Miller, Fildes et al. 2013). Typically, EMB is performed through the jugular or femoral veins and is invasive, painful and commonly associated with risks of procedural complications (From, Maleszewski et al. 2011). With rejection most likely to occur within the first year after transplant, EMB is performed and repeated frequently post-transplant exposing patients to long-term complications including, but not limited to, severe tricuspid valve regurgitation. Additional limitations include, evidence indicating discrepancies in biopsy readings by different pathologists sufficient to demonstrate adverse treatment implications (Winters and McManus 1996) and finally, the notion that biopsy cannot be used to identify patients at risk of rejection, limiting the ability to initiate therapy to interrupt the development of rejection. For these reasons, the gold standard has been considered flawed resulting in many attempts to develop non-invasive tools to detect heart transplant rejection.

Gene expression profiling (GEP) of circulating leukocytes has been recently introduced as a new non-invasive modality for cardiac allograft rejection monitoring. This is based on the assumption that recirculating peripheral blood mononuclear cells (PBMC) may reflect earlier host responses to the allograft than those at local sites. The test uses real-time polymerase chain reaction (PCR) technology to measure the expression of 20 genes (11 informative, 9 control and normalization). Using a multigenic algorithm, a score ranging from 0 to 40 is generated.

Some researchers found that this score may discriminate between quiescence and moderate/severe acute rejection. The lower scores are associated with a very low likelihood of moderate/severe graft rejection (Starling 2006). The score however, may be influenced by several factors including time post-transplant, peripheral alloimmune activity, corticosteroid dose, and cytomegalovirus infection (Yamani 2007, Starling 2006). According to Starling and colleagues (2006), the candidates for GEP testing are clinically stable cardiac transplant recipients, >15 years of age, > 6 months post-transplant, and at low risk for moderate/severe cellular rejection. It was also reported that the frequency of performing a GEP test to monitor the rejection should be individualized according to the patient's rejection history, immunosuppression regimen, time post transplant, and transplant centre protocol. The GEP test is not recommended for patients at high risk for acute rejection or graft failure, <15 years of age, pregnant women, patients who had a blood transfusion within 12 months before the transplant, received hematopoietic growth factors within the previous 30 days, high dose steroids within the past 21 days, or are on >20 mg/day of prednisone equivalent.

AlloMap® gene expression test, XDx, Inc, South San Francisco, CA, is the first commercially available molecular test developed for acute rejection monitoring. The test was introduced for clinical use in January 2005. It uses simple blood samples, and is performed at CLIA-certified XDx laboratory in South San Francisco.

Currently, potential non-invasive alternatives to biopsy range from imaging techniques to genetic expression profiling with limited established evidence (Miller, Fildes et al. 2013). The Heartsbreath test™ (HBT) was developed by Menssana Research, Inc. and is an intrinsically safe, painless and non-invasive test for heart transplant rejection. The HBT is currently indicated for use as an aid in the diagnosis of grade 3 heart transplant rejection in patients who have received heart transplants within the previous year (Menssana 2004). It is meant for use in addition to, and not as a substitute for, EMB. The HBT works specifically by measuring the amount of methylated alkanes in a patient's breath with the rationale based on two observations the first being that allograft rejection is accompanied by oxidative stress resulting from increased production of reactive oxygen species in the myocardium (Schimke, Schikora et al. 2000) and, the second, that reactive oxygen species degrade cellular membranes by lipid peroxidation of polyunsaturated fatty acids generating alkanes that are excreted in the breath as volatile organic compounds and may provide markers of the intensity of rejection (Kneepkens, Ferreira et al. 1992). The HBT subtracts the amount of methylated alkanes in a patient's breath from the amount of methylated alkanes in the room air (Phillips 1997). The value generated by the test is compared to the results of a biopsy performed during the previous month to measure the probability of the implanted heart being rejected. The tests greatest value may be in helping to separate less severe organ rejection (grade 0,1 and 2) from more severe organ rejections (grade 3). In general, the evaluation of non-invasive techniques for the identification of heart transplant rejection is difficult due to the imperfect nature of the current gold standard.

The FDA approved the HBT under the Humanitarian Device Exemption program in February of 2004 to be used in patients who have had heart transplants within the past year (FDA 2004). A Humanitarian Use Device (HUD) is a device that is intended to benefit patients by treating or diagnosing a disease or condition that affects or is manifested in fewer than 4,000 individuals in the United States per year (FDA 2010). A device manufacturers research and development costs could exceed its market returns for diseases or conditions affecting small patient populations. The HUD provision of the regulation provides an incentive for the development of devices for use in treatment or diagnosis of diseases affecting these populations. The labeling for an HUD must state that the device is a humanitarian use device and that, although the device is authorized by Federal Law, the effectiveness of the device for the specific indication has not been demonstrated.

## Medical Technology Assessment Committee (MTAC)

### *AlloMap in the Detection of Cardiac Allograft Rejection*

#### **06/04/2007: MTAC REVIEW**

**Evidence Conclusion:** The CARGO study was an observational study conducted to develop and evaluate a gene expression profiling test (AlloMap test) from peripheral blood mononuclear cells sample to discriminate between quiescence (grade 0 rejection) and moderate /severe (grade >3A) rejection in heart transplant patients, according to the International society for Heart Lung Transplantation (ISHLT) grading. The endomyocardial biopsy (EMB) was used as the gold standard for detecting acute cellular rejection. EMB however has its limitation. It may only detect rejection after cellular infiltration and/or graft damage has occurred, and cannot be repeated beyond a certain frequency. In addition, its histopathological interpretation and grading is often not clear-cut, and subject to sampling error and inter observer variability. Overall the results of the study showed that at a predefined threshold of 20 (score range 0-40), the test had an 84% sensitivity to detect a grade >3A rejection compared to the endomyocardial biopsy. After one year post-transplant the test had a very high negative predictive value (99.6%) i.e. very high ability to rule out moderate /severe rejection. It however had a very low positive predictive value (6.8%) and low specificity (approximately 40%). The study evaluated the ability of the test to discriminate between

quiescence and moderate/severe rejection of the transplant. There is no published evidence to date on the clinical outcomes associated with using the test for long-term monitoring of cardiac rejection, on the predictive capacity of the test for future clinical events, or its effect on improving the management of the patients, e.g. tailoring and individualizing immunosuppressive medications. The “Invasive Monitoring Attenuation through Gene Expression” (IMAGE) ongoing study might provide evidence on the long-term health outcomes associated with this gene expression testing.

**Articles:** The literature search yielded just over 20 articles, the majority of which were reviews and editorials. There was a relatively large observational study (CARGO) that evaluated the ability of gene expressing profiling of peripheral blood test to discriminate between quiescence and from moderate/severe rejection in cardiac allograft recipients, two small case series, and a few other observational studies published in abstract forms.

The CARGO study was selected for critical appraisal. Deng MC, Eisen HJ, Mehra MR, et al for the Cardiac allograft Rejection Gene Expression Observational (CARGO) study Investigators. Noninvasive discrimination of rejection in cardiac allograft recipients using gene expression profiling. *Am J Transplant.*2006;6:150-160. See

[Evidence Table.](#)

The use of AlloMap in the detection of cardiac allograft rejection does not meet the *Group Health Medical Technology Assessment Criteria.*

### **08/19/2003: MTAC REVIEW**

#### **Heartsbreath Test in the Detection of Cardiac Allograft Rejection**

**Evidence Conclusion:** The HARDBALL (heart allograft rejection: detection with breath alkanes in low levels) study was a three year multicenter case-control study supported by the National Heart Lung and Blood Institute (Philips, Boehmer et al. 2004). The original clinical study evaluated a new marker of heart transplant rejection, the breath methalayed alkane contour (BMAC) with the idea that rejection is accompanied by oxidative stress which degrades membrane polyunsaturated fatty acids, evolving alkanes and methylalkanes which are excreted in the brain as volatile organic compounds (VOCs). Prior to scheduled EMB, the HBT was employed on 539 heart transplant recipients to collect 1061 breath VOC samples. The breath VOCs were analyzed by gas chromatography and mass spectroscopy, and the BMAC was derived from the abundance of C4-C20 alkanes and monomethylalkanes. The gold standard of rejection was the concordant set of International Society for Heart and Lung Transplantation (ISHLT) grades in biopsies read by two cardiac pathologists. The authors of the HARDBALL study reported that the abundance of breath markers of oxidative stress were significantly greater in grade 0,1 or 2 rejection than in healthy normal persons. Whereas in grade 3 rejection, the abundance of breath markers of oxidative stress was reduced most likely due to accelerated catabolism of alkanes and methyl alkanes that comprise the BMAC. The authors also reported finding that in identifying grade 3 rejection, the negative predictive value of the breath test (97.2%) was similar to EMB (96.7%), and that the breath test could potentially reduce the total number of biopsies performed to assess for rejection in patients at low risk for grade 3 rejection. The sensitivity of the breath test was 78.6% vs. 42.4% with biopsy. However, the breath test had lower specificity (62.4%) and a lower positive predictive value (5.6%) in assessing grade 3 rejection than biopsy (specificity 97%, positive predictive value 45.2%). Additionally, the breath test was not evaluated in grade 4 rejection. Breath test results revealed nine breath samples whose levels represented markers of grade 3 rejection. The cross-validated model, indicated that the HBT had a sensitivity of 59.5% and specificity of 58.8% for detecting grade 3 heart transplant rejection, compared to biopsy. The negative predictive value of the breath test for grade 3 rejection was 97.3% such that in a patient with a negative breath test, EMB would contribute little additional clinical information. Limitations include a surprising lack of consistency between biopsy interpretation by the pathologists at the transplant program site and the independent pathologist working with the authors. The study results are made difficult to interpret given these disparities. Further studies should investigate the HBT in populations with concurrent patient illness which theoretically, could affect the markers of oxidative stress. It is also important to note that the primary investigator has substantial financial and professional ties with the developer of the device under investigation. The major potential benefit of the HBT would be that it may reduce the risk of a patient getting the wrong treatment because of an erroneous biopsy report. Despite the clear potential benefits that a non-invasive approach such as the HBT could offer, there is no evidence to demonstrate that the use of the HBT will result in better patient management and improvements in health outcomes. Ultimately, a clinically meaningful investigation of the HBT would require assessment in multicenter, outcome based trials with adequate power, blinding and randomization to control for baseline differences between groups and determine whether additional testing provides a significant advantage over the standard of care in any of the proposed uses of these laboratory tests.

**Articles:** A search of the PubMed database as well as the Clinical Trials database was completed for the period from database inception through June 2013 for studies on the diagnostic value of the Heartsbreath Test for patients with heart allograft rejection. The search strategy used the terms non-invasive, heart transplant, rejection, heartsbreath and test with variations. Articles were limited to those published in English language and with enrolled

human subjects. The search was supplemented by an examination of article bibliographies in addition to the PubMed related articles function. The HARDBALL study was selected for critical appraisal:

Phillips M, Boehmer JP, Cataneo RN, et al. Heart allograft rejection: detection with breath alkanes in low levels (the HARDBALL study). *The Journal of Heart and Lung Transplant* 2004;23(6):701-708. [See Evidence Table](#)

The use of Heartsbreath test in the detection of cardiac allograft rejection does not meet the *Group Health Medical Technology Assessment Criteria*.

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">NCD Manual, Part 1 – Electrocardiographic Services</a> <a href="#">Electrocardiographic Services (20.15)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

#### For Non-Medicare Members

##### I. External Loop Recorder

A. Cardiac ambulatory monitoring using either:

1. An external intermittent cardiac event monitor (i.e., external loop recorder), **or**
2. An external intermittent cardiac event monitor with real-time data transmission and analysis, **or**
3. External ECG monitoring by continuous rhythm recording and storage (e.g. – ZioPatch)

B. Use of the above devices is considered medically necessary when **ONE of the following** is met:

1. To evaluate syncope or episodic lightheadedness or to document an arrhythmia in persons with a non-diagnostic Holter monitor, or in persons whose symptoms occur infrequently (less frequently than daily) such that the arrhythmia is unlikely to be diagnosed by Holter monitoring **or**
2. Following a cryptogenic stroke **or**
3. To document ST segment depression for suspected ischemia; **or**
4. To document the benefit after initiating drug therapy for an arrhythmia; **or**
5. To document the recurrence of an arrhythmia after discontinuation of drug therapy; **or**
6. To document the results after an ablation procedure for arrhythmia

##### II. Implantable Loop Recorder

Group Health has elected to use the Loop Recorder, Implantable (A-0122) MCG\* for medical necessity determinations.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Cardiac rhythm abnormalities are common. Many are harmless, but some cause symptoms such as palpitation, chest pain, pre-syncope and syncope, and others may be a signal for potential stroke or cardiac arrest. Electrocardiographic (ECG) documentation of the cardiac rhythm during symptoms is necessary for making accurate diagnosis, therapeutic decisions, assessing the effectiveness of suppression, and monitoring adverse drug effects. However, symptoms of arrhythmia are often infrequent and episodic, and the underlying heart rhythm may not be detected during physical examination and routine ECG that permits a few seconds of recording. It is thus essential to have extended periods of ECG recording while the patients are pursuing their normal routine (Kowey 2003, Naccarelli 2007, and Saarel 2008).

Devices used:

- *Holter monitors* are portable devices that record heart rhythms continuously for up to 48 hours. These devices are used to record events that occur at least once a day.
- *Non-implantable cardiac event monitors* are portable devices that record heart rhythms intermittently for up to 30 days. These devices capture ECG data before, during and after the time of activation.
- *Standard loop recorders* have just a few minutes of memory. Newer, more sophisticated devices have extended memory features that can store up to several hours of ECG data. Recording can be patient-activated when symptoms occur or automatically triggered based on a computer algorithm designed to detect arrhythmias. These devices are used to record infrequent or irregular events.
- *External mobile cardiovascular telemetry* consists of a monitor that continuously records the electrocardiographic rhythm from external electrodes placed on the patient's body. Segments of the ECG data are automatically (i.e., without patient intervention) transmitted to a remote surveillance location by cellular or landline telephone signal. The transmitted events are triggered automatically by preprogrammed algorithms or by the patient during a symptomatic episode. There is continuous, real-time data analysis in the device and attended surveillance of the transmitted rhythm segments by a surveillance center technician. The surveillance center technician reviews the data and notifies the physician depending on the prescribed criteria. These devices are used to record suspected asymptomatic arrhythmias.

The most commonly used method for extended ECG recording is the Holter monitor which records an ECG continuously for 24 to 48 hours via leads placed on the chest to yield 2 or 3 channels of ECG data. The Holter monitor provides complete rhythm recording and excellent quality tracing. However, it has a diagnostic yield of only 5-28% due to its limited time of recording which is usually too short to capture infrequent arrhythmias. In addition, some clinically important arrhythmias such as atrial fibrillation may be asymptomatic and pass unnoticed by the Holter recording (Kowey 2003, Naccarelli 2007, Rothman 2007, Saarel 2008).

External patient-activated loop event monitoring (LOOP) devices were found by researchers to improve the diagnostic yield of arrhythmias up to 63%. These may be used for up to 30 days; however, they have limited storage, and require appropriate patient activation during the occurrence of symptoms. Patient activation may be a difficult task for the elderly or those whose arrhythmias cause functional impairment. It was reported that one in four patients does not activate the recorder during symptomatic episodes despite the education received on operating the device. Developments are continuously being made to improve the diagnostic yield of the rhythm monitors. Newer loop recorders continually record and erase so that data gathered from 1 to 4 minutes before, and those recorded 30-60 seconds after activation of the device can be retained. Other loop monitors are automatically activated and start the recording once an abnormal rhythm of any kind is detected, without patient activation. An implantable form of continuous-loop event recorder is also currently available. It is a small device in the size of pacemaker that is implanted subcutaneously to the right or left side of the sternum, and is triggered by placing an activator over it. The device has a programmable antegrade and retrograde memory, and may be left in place for up to 18 months and can be explanted once the diagnosis is made or battery life has ended. Data from the device however, cannot be transmitted wirelessly (Zimetbaum 1999, Kowey 2003, Naccarelli 2007 Rothman 2007).

Mobile Cardiac Outpatient Telemetry (MCOT, Cardionet®, CardioNet device or recorder) was introduced in 1999 for continuous real-time ambulatory electrographic monitoring and analysis. The device consists of a three-electrode, and a two-channel sensor that transmits wirelessly to a small PDA sized portable monitor which can be clipped to the waist or worn on a strap around the neck. Rhythm strips are recorded continuously and analyzed by an automated arrhythmia analysis algorithm. When an arrhythmia is detected (according to the physicians'predesignated thresholds) the monitor can transmit the ECG data to the monitoring center utilizing a cellular modem or telephone data line. Patients are monitored for 24 hours/day for up to 30 days, by central station technicians with immediate referral to the prescribing physician for evaluation of rate and rhythm changes and their symptoms. The patient can also initiate the recording and transmission of ECG data if symptoms are felt. MCOT thus potentially improves diagnosis of arrhythmias by allowing continuous monitoring of cardiac rhythm for extended periods of time, detecting asymptomatic arrhythmias, and allowing the patients to submit their symptoms and level of activity from a menu to the device (FDA web page, Rothman 2007, Naccarelli 2007).

The CardioNet ECG monitor was approved by the Food and Drug Administration in 2002 for cardiac monitoring for non-life-threatening arrhythmia detection, its evaluation, and monitoring of antiarrhythmic therapy.

## Medical Technology Assessment Committee (MTAC)

Date Sent: February 28, 2017

## **Mobile Cardiac Outpatient Telemetry (MCOT)**

### **06/04/2008: MTAC REVIEW**

**Evidence Conclusion:** The literature search revealed only one randomized controlled study (Rothman 2007), and several observational studies. Rothman and colleagues' study was a multicenter, randomized, controlled study that compared the diagnostic yield of the mobile cardiac outpatient telemetry (MCOT) system (CardioNet, USA) with the patient-activated external loop devices (LOOP). Patients with symptoms of syncope, pre-syncope or severe palpitations, and a nondiagnostic 24-hour Holter, were randomized to receive one of the two monitoring devices for up to 30 days. The patients and investigators were not blinded to the monitor received, but the electrophysiologist who reviewed the monitor strips and verified the diagnosis was blinded to the patient allocation. There was a higher noncompliance rate in the MCOT group, and 14% of all participants did not complete the study. The study compared the MCOT (CardioNet) system with the patient-activated external loop device and not to the auto-triggered or the implanted loop systems which are known to have better diagnostic yield. Overall, the results of the study show that diagnosis (confirmation or exclusion) of arrhythmias was made in 88% of the patients randomized to the MCOT group, vs. 75% of the patients in the LOOP group ( $P < 0.001$ ). A significant difference was also observed for patients with syncope or presyncope, where a diagnosis was made in 89% of patients in the MCOT group vs. 69% in the LOOP group ( $p = 0.008$ ). Conclusion: There is fair evidence from one RCT with limitations, that CardioNet system may have a higher diagnostic yield compared to the patient-activated external loop device for up to one month. There is no published evidence to date to determine that the device is superior to the auto-triggered loop system that was found to have better diagnostic yield, or to the implanted loop system. There is insufficient evidence to determine the efficacy and safety of the CardioNet system for detecting less frequent syncopal episodes. There is insufficient evidence on the efficacy of CardioNet system in assessing the safety and efficacy of antiarrhythmic agents, or outpatient monitoring for medication titration and dose adjustments.

**Articles:** The search yielded around 50 articles. Many were reviews, or articles that dealt with the analysis of data or feasibility of using the device. Only one randomized controlled study (Rothman 2007) that compared the diagnostic yield of MCOT to the external patient-activated loop event monitoring up to 30 days, was identified. There were a few other relatively small observational prospective and retrospective studies that evaluated the safety and diagnostic yield of the CardioNet system. Rothman and colleagues' RCT was selected for critical appraisal. Rothman SA, Laughlin JC, Seltzer J, et al. The diagnosis of cardiac arrhythmias: A prospective multi-center randomized study comparing mobile cardiac outpatient telemetry versus standard loop event monitoring. *J Cardiovasc Electrophysiol* 2007;18:241-247. See [Evidence Table](#).

The use of Mobile Cardiac Outpatient Telemetry (MCOT) in the detection of arrhythmias does not meet the *Group Health Medical Technology Assessment Criteria*.

### **08/03/2009: MTAC REVIEW**

#### **Mobile Cardiac Outpatient Telemetry (MCOT)**

**Evidence Conclusion:** There is no new published evidence that would alter the conclusion of the previous MTAC review. The only published RCT (Rothman 2007) that compared mobile cardiac outpatient telemetry to LOOP event monitoring was reviewed earlier in 2008. The study was randomized, controlled and multicenter. However, it was not blinded, had a 14% drop-out rate, non-compliance was more common in the MCOT group, and analysis was not based on intention to treat. Moreover, the mobile cardiac outpatient telemetry (MCOT) system (CardioNet, USA) was compared with the patient-activated external looping event recorders. The study did not compare MCOT with the implanted loop recorders, and was not designed to compare it with the auto-trigger loop recorders which were used in only 16% of the patients in the LOOP group. Both the implanted and auto-trigger loop recorders are reported to have higher diagnostic yield than the patient activated loop recorders. Overall the results of the study indicate that MCOT was superior to loop recordings with a diagnosis made in 88% MCOT patients vs. 75% LOOP patients ( $p = 0.008$ ). A significant difference in the diagnostic yield was also observed for patients with syncope or presyncope (89% vs. 69% respectively,  $p = 0.008$ ). More recently only retrospective case series (Saarel 2008, and Tayal 2008) on the use of MCOT for the detection of suspected arrhythmias were published. Saarel and colleagues (2008) reported on the use of MCOT among 54 children and adolescents with suspected arrhythmia. Thirty three subjects transmitted ECGs during symptoms yielding a diagnostic rate of 61%. The remaining 21 (39%) failed to transmit ECG while experiencing symptoms. Comparing the diagnostic yield of MCOT with historical data from transtelephonic electrocardiographic event monitors (TTMs) showed no significant differences between the two systems. Tayal and colleagues (2008) performed a retrospective analysis of 56 patients with cryptogenic stroke (undetermined cause). This showed that MCOT detected 27 asymptomatic atrial fibrillation in thirteen patients (23%). 23 (85%) of these episodes were less than 30 seconds in duration, and the remaining 4 (15%) were 4-24 hours in duration. None of the published studies to date indicate that the MCOT (CardioNet system) is superior to the auto-trigger LOOP device currently used, or that it leads to an improvement in net health outcome. Conclusion: There is fair evidence from one RCT with limitations, that CardioNet system may have a higher diagnostic yield compared to the patient-activated external loop device for up to one month.

There is insufficient evidence however to determine that the device is superior to the auto-triggered or the implanted loop systems that were found to have better diagnostic yield than the patient-activated external loop monitors. There is insufficient evidence to determine that CardioNet system improves the management of patients e.g. monitoring for medication titration and dose adjustments. There is insufficient evidence to determine that CardioNet system improves patients' health outcomes.

**Articles:** The search did not reveal any controlled trial on MCOT published after the RCT reviewed earlier in MTAC. Only two relatively small retrospective case series were identified; one reported on the use of MCOT among adult patients with stroke, and the other evaluated its use among children and adolescents with suspected arrhythmias. None were selected for critical appraisal.

The use of Mobile Cardiac Outpatient Telemetry (MCOT) in the detection of arrhythmias does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Zio®Patch**

### **12/16/2013: MTAC REVIEW**

**Evidence Conclusion:** There is a lack of published literature on the use of Zio®Patch for detecting atrial fibrillation and other arrhythmias in asymptomatic or symptomatic patients. A pilot study conducted by Rosenberg and colleagues (2013) compared the Zio®Patch with the traditional 24 hours Holter monitor in 74 patients with paroxysmal atrial fibrillation who were referred to Holter monitoring for evaluation. The Zio®Patch was well tolerated and had a mean monitoring period of 10.8 +2.8 days (range 4-14 days). During the simultaneous 24 hour recording time when the patients wore both devices, there was a strong correlation between the Zio®Patch and the Holter monitor ( $r=0.96$ ) for identifying AV events and estimation AF burden. 18 additional cardiac events were recorded with the Zio®Patch due to longer duration of use. Other clinically relevant cardiac events recorded by the Zio®Patch after the 24 hours of monitoring, including symptomatic ventricular pauses, led to change in medications or referrals for pacemaker placement. Overall clinical management was changed in 28.4% of the patients as a result of the Zio®Patch findings. The authors concluded that the Zio®Patch was well tolerated and allowed longer monitoring that resulted in meaningful changes in clinical management. They indicated that more studies are needed to examine the long-term impact of the device in AF management. The other published study (Turakhia et al, 2013) was only a retrospective analysis of data obtained from the device manufacturer. No comparison was made with Holter monitor or any other ambulatory cardiac rhythm monitor. There are no published studies, to date, that compared the Zio®Patch to any of the other longer-term outpatient ambulatory cardiac rhythm monitors. Conclusion: There is weak evidence from one small single-center pilot study that Zio®Patch was well tolerated and allowed longer monitoring than Holter monitoring. This resulted in the detection of more AF episodes and cardiac events in symptomatic patients and making changes in the clinical management among more than one fourth of the study participants. There is insufficient published evidence on the use of Zio®Patch for detecting atrial fibrillation and other arrhythmias in asymptomatic patients with AF. There is insufficient evidence to determine the equivalence or superiority of Zio®Patch to any of the other longer-term outpatient ambulatory cardiac rhythm monitors.

**Articles:** The literature search revealed only two published studies on the use of Zio®Patch as a noninvasive monitoring device for arrhythmias in general in one study, and for atrial fibrillation in the other. A retrospective study among 285 patients seen in emergency departments was identified from a review article, but it was not published in a peer review journal; it was only presented in a conference. The two published studies were critically appraised. Rosenberg MA, Samuel M, Thosani A, et al. Use of a noninvasive continuous monitoring device in the management of atrial fibrillation: a pilot study. *Pacing Clin Electrophysiol*. 2013;36:328-333. [See Evidence Table](#), Turakhia MP, Hoang DD, Zimetbaum P, et al. Diagnostic utility of a novel leadless arrhythmia monitoring device. *Am J Cardiol*. 2013;112:520-524. [See Evidence Table](#).

The use of Zio®Patch the detection of arrhythmias does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Implantable Loop Recorder**

### **BACKGROUND**

Syncope has a complex differential diagnosis. Syncope that remains unexplained after standard evaluation does not appear to be associated with excess mortality (Savage et al., 1985) or serious adverse cardiovascular events (Kapoor, 1990). However, syncope recurrences are associated with fractures, automobile accidents and other complications (Kapoor, 1987).

Standard techniques for diagnosing syncope include history and physical examination, laboratory testing, exercise stress testing, Holter monitoring, tilt table testing and external loop recording. External loop recorders ("King of Hearts" model) store ECG data up to 4 minutes prior to and 1 minute after activation by a patient. They are worn on the wrist or around the waist, generally for up to 1 month.

The implantable loop recorder (ILR) is a new diagnostic tool for unexplained infrequent syncope. The ILR is a 61x19x8mm, recording device produced by Medtronic Reveal. It stores an ECG signal in a circular buffer capable of retaining 21 minutes of uncompressed signal or 42 minutes of compressed signal (can be divided into 1-3 parts). The ILR requires the patient or family member to use a hand-held pager-sized activator to “freeze” the memory buffer during or immediately following an episode of syncope. The device is implanted into the left infraclavicular region. Using local anesthesia, a 2 cm incision is made, a pocket the size and shape of the device is made and the ILR is placed in the pocket. The ILR can monitor patients for up to 14 months. The device is removed after a diagnosis of syncope is made or at the end of battery life.

Medicare approved coverage for this implantable device effective 10/1/1999. Group Health added it to the medical criteria subject area at that time.

MTAC reviewed this device at the February 2000 meeting and found the technology appears to be promising and safe for patients whose syncope is undiagnosed but there is not enough evidence to draw conclusions regarding reproducibility, safety and accuracy. The Health Plan Medical Director Group at their February 2000 meeting reviewed the MTAC findings and determined that there was good reason to recommend coverage for patients who had infrequent, undiagnosed episodes of syncope.

**02/10/1999: MTAC REVIEW**

**Evidence Conclusion:** The one study evaluating the potential of the ILR to diagnose unexplained syncope obtained a diagnostic yield of 59% during a mean of 10.5 months of recording. Possible selection bias, conflict of interest on the part of the investigators and a lack of comparison with external loop recorders limit the ability of this study to determine efficacy of the ILR. Two studies evaluating the external loop recorders found point estimates for diagnostic findings of 25% and 36% after approximately one month of recording.

**Articles:** Krahn D, Klein G, Yee R, Takle-Newhouse T, Norris C. Use of an extended monitoring strategy in patients with problematic syncope. *Circulation* 1999; 99: 406-410. See [Evidence Link](#).

The use of implantable loop recorder does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Anti-Malignin Antibody Test for Cancer Detection

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies (and/or) provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

A tumor marker is a biological substance or irregularity that indicates the presence of a tumor. These markers are used in clinical practice for diagnosis, anatomical localization, and monitoring a variety of malignancies. The more specific the marker is for the tumor histotype, the more useful it is as a marker; and the earlier the marker is detected, the earlier a possible diagnosis can be made.

Serum measurement of the majority of markers did not prove to be very reliable for screening purposes or for the early detection of cancer. These tests measure the tumor-associated antigens that appear on the surface of the cell membrane following the malignant transformation. Serum tests become more reliable as the tumor load increases and more antigens are released in to the bloodstream. The tumor-associated antigens are recognized by the immune system of the host that in turn produces specific antibodies. Theoretically, antibodies are more readily detected than antigen early in the disease (*Abrams 1994, Botti 1997*).

Malignin, a 10 kDa polypeptide, has been found by some researchers to be elevated in most patients with a wide range of malignancies regardless of site or cell type. Two researchers in Boston (Drs. S. Bogoch and E. Bogoch) reported that they discovered anti-malignin antibodies (AMAs) in the serum of patients with cancer. The antibodies were described as IgM produced by the patient against the oncoprotein malignin. Bogoch reported that antibody concentration is reduced or eliminated in terminal cancer or in the presence of a large tumor mass present for 3 or more years (*Bogoch 1982*). The human antimalignin antibody serum (AMAS) test was developed to measure the antibody concentrations against malignin. It is claimed that the test may potentially be useful in the early detection of cancer as well as managing and monitoring the progress of the cancer.

The AMAS test is based on the specific immunoabsorption of the antibody from serum to Target® reagent. The Target® reagent consists of malignin bound covalently to bromoacetylcellulose (*Abrams 1994, Botti, 1997*). After washing with cold saline, the serum sample is added to the reagent, the AMA eluted with acetic acid, and the results are quantified. The test should be performed within 24 hours of serum collection to reduce the false-positive results that increase with the use of frozen stored serum.

The AMAS test does not replace the conventional screening and diagnostic procedures but, as reported, it may be performed with other routine procedures and in relation to risk factors, history, clinical signs and symptoms, and other factors.

#### Medical Technology Assessment Committee (MTAC)

##### **Anti-Malignin Antibody Test**

**10/03/2005: MTAC Review**

**Evidence Conclusion:** The two studies reviewed (Bogoch 1982, and Thornwaite 2000) compared the serum antimalignin antibody levels in patients with diagnosed cancer to those of healthy controls. Thornwaite studied it for patients with breast cancer, and Bogoch for patients with carcinomas in different organs. Both studies had their limitations. The test was performed on patients already diagnosed with or without cancer, there is no indication

that the antibody cutoff-level used was validated, the authors did not discuss how they selected the study participants, and the patients with terminal cancers were excluded from the analysis.

**Articles:** The search yielded 16 articles. Three empirical studies were identified: Bogoch 1982, studied the relation of antimalignin antibody and malignin to survival, Bogoch 1991, published in an abstract form, and Thornthwaite (2000) compared AMAS testing for breast cancer with histopathology and other cancer markers. Another article identified by the search (Abrams 1994), compiled the results of the test performed in 42 practices in 11 states that performed AMAS test for the detection and monitoring of cancer.

*The following articles were critically appraised:* Thornthwaite JT. Anti-malignin antibody in serum and other tumor marker determinations in breast cancer. Cancer Letters. 2000;148:39–48. See [Evidence Table](#).

The use of Anti-Malignin Antibody does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Artificial Spinal Discs for Single-Level Lumbar or Cervical Disc Disease

- Bryan™
- Charité™
- Prestige™ Artificial Discs
- ProDisc-C™
- ProDisc-L™
- Two-level cervical artificial disc replacement for the treatment of cervical degenerative disc disease

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. ### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Lumbar Artificial Disc Replacement (LADR) (150.10)</a> .
Local Coverage Determinations (LCD)	<a href="#">Non-Covered Services (L35008)</a> . And for facility-based services billed using a UB form, see <a href="#">Non-Covered Services (L34886)</a> .
Local Coverage Article	None

#### For Non-Medicare Members

- I. Artificial cervical discs may be considered medically necessary for the following:
  - A. For treatment in adults with symptomatic cervical degenerative disc disease when **ALL** of the following are met:
    1. FDA-approved prosthetic intervertebral discs is used;
    2. Performed at one level or two contiguous levels from C3-C7;
    3. Objective evidence in the clinical record documents cervical radiculopathy and/or myelopathy; and
    4. Patients have failed at least six weeks of conservative management (which may include rest, application of heat/ice, physical therapy, exercise, pain and/or anti-inflammatory medications).
  - B. A subsequent, second-level, anterior total cervical disc replacement using an artificial intervertebral disc following complete decompression may be considered medically necessary in skeletally mature patients with symptomatic cervical disc degeneration when **ALL** of the following are met:
    1. The planned subsequent procedure is at a different cervical level than the initial cervical artificial disc replacement; and
    2. Clinical documentation that the initial cervical artificial disc replacement is fully healed; and
    3. Criteria A, 1-4 are met
- II. Prosthetic intervertebral discs are considered investigational for **ALL** of the following:
  - In patients with isolated axial neck pain without cervical radiculopathy or myelopathy;
  - When requested adjacent to a prior fusion; or
  - At a level of prior surgery
  - When more than two levels are requested
- III. Lumbar Disc
 

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Degeneration of the intervertebral disc, also known as degenerative disc disease (DDD) is the leading cause of pain and disability among adults in the United States as well as other parts of the world. Disc degeneration can occur at any level of the spine but is most common in the lower neck (cervical disc disease) and in the low back (lumbar disc degeneration). DDD may cause pain in the affected area, and may also radiate along the nerves emerging from the spinal canal at that level.

Most DDDs can be treated nonoperatively to relieve the pain. Conservative treatments include physical therapy, nonsteroidal anti-inflammatory medications, and analgesics. Acupuncture, spinal manipulations, axial traction, and muscle relaxants are other alternative therapies that may be used to alleviate the pain and discomfort. A number of patients may not benefit from the non-invasive therapy and resort to surgical treatment. Spinal interbody fusion, a procedure that involves the fusion of two or more vertebrae to eliminate the pain caused by their abnormal motion, has been the surgical standard of care for lumbar DDD for decades. Anterior cervical discectomy combined with fusion (ACDF) is also a well established treatment for cervical degenerative disc disorders. Interbody fusion reduces the pain caused by the treated segment, however the rigid fusion also leads to a reduction in normal spine motion, and an increase in the biomechanical stress at spinal levels adjacent to the fusion, which in turn accelerates degenerative changes of the discs at these levels (Lee 2004, Mobbs et al, 2007, Sasso 2008, Yang 2008, Heidecke 2008).

Recently arthroplasty performed with artificial discs have emerged as a surgical alternative to interbody fusion. The technology is rapidly developing and offers the promise to restore the normal spinal movement without the kinematic and biochemical issues of fusion. Potential benefits of disc arthroplasty include maintenance of a range of motion, avoidance of adjacent segment degeneration, restoring disc height, correcting spinal misalignment, greater maintenance of maneuverability, and earlier return to previous level of function. On the other hand, potential disadvantages of the artificial disc may include implant migration and material wear (Yang 2008, Burkus 2010, Cepoiu-Martin 2011).

The Charité, the first artificial intervertebral disc used, was developed Germany in the 1950s, but was not commercially available until 1987 after undergoing major design modifications. The third generation Charité (DePuy Spine) consists of two chromium alloy endplates and a sliding ultra-high molecular weight polyethylene core. The ProDisc-L (Synthes Spine, West Chester, PA) is another disc implant, also developed in Europe, for disc replacement at one level from L3-S1. It has a ball and socket design and is composed of three components; two metal endplates and a plastic inlay. More recently researchers developed artificial disc devices to replace cervical intervertebral discs. These include ProDisc-C (Synthes Spine, West Chester, PA), Bryan Cervical Disc (Medtronic Sofamor Danek, Memphis, TN), and Prestige Cervical Disc (Medtronic Sofamor Danek). ProDisc-C has a similar design to the ProDisc-L, Bryan disc prosthesis has two metal endplates and a polyethylene core, and PRESTIGE has two main pieces of stainless steel that articulate against one another with a ball and trough.

The Prestige ST, ProDisc-C and Bryan artificial disc systems have received US Food and Drug Administration (FDA) premarket application approval as Class III devices in July 2007, December 2007, and May 2009 respectively. FDA clearing of the artificial disc systems required post-approval studies to evaluate the long-term safety and effectiveness of the devices. The post-approval studies are expected to demonstrate 3, 5, 7, and 10-year data for cervical discs.

### Lumbar

The Charité® (DePuy) and ProDisc®-L (Synthes Spine) have received approval from the US Food and Drug Administration. The approval was contingent on completion of post-marketing studies to evaluate the longer term safety and effectiveness of the devices. The post-approval studies are expected to demonstrate the 5-year data for lumbar discs. The Charité® and ProDisc®-L devices are indicated for:

1. Spinal arthroplasty in skeletally mature patients, with pain from degenerative disc disease (DDD).
2. One level of the spine (L3-S1 for the ProDisc-L, L4-S1 for the Charité).
3. Patient may have no more than a grade 1 spondylolisthesis.
4. Patients must have failed to find pain relief after at least 6 months of non-surgical therapies.

Contraindications to total lumbar disc replacement include active infection, allergy to any of the device materials, osteoporosis, marked cervical instability, severe spondylosis, clinically compromised vertebral bodies at the level to be treated, and DDD at more than one level.

Several other contraindications are listed for each of the disc systems. Multilevel total disc replacement and disc replacement with prior spinal fusion are considered off-label uses.

### **Cervical**

The cervical artificial discs are FDA approved for the following:

1. Reconstruction of cervical disc from C3-C7 following single-level discectomy for intractable.
2. Symptomatic cervical disc disease confirmed by imaging.
3. Patient is skeletally mature.
4. Cervical disc disease should have failed at least six weeks of non-operative treatment prior to implantation.

Contraindications to total cervical disc replacement include systemic infection, infection at the operating site, allergy to any of the device materials, osteoporosis, marked cervical instability, severe spondylosis, clinically compromised vertebral bodies at the level to be treated, and symptomatic cervical disc disease (SCDD) at more than one level.

Several other contraindications are listed for each of the disc systems. Multilevel total disc replacement and disc replacement with prior spinal fusion are considered off-label uses.

## **Medical Technology Assessment Committee (MTAC)**

### ***Artificial Disc in the Treatment of Back Pain***

#### **02/07/2005: MTAC REVIEW**

**Evidence Conclusion:** The trial reviewed on Charité artificial spinal disc was randomized, controlled, and multicenter, but had some limitations. Authors concluded that the clinical outcomes and incidence of major neurological complications at 2 years of follow-up were equivalent to those of BAK fusion. The trial however, was not designed as an equivalence study. Equivalence trials are planned and analyzed differently from superiority studies, and generally require larger sample sizes. Lack of significant superiority is not necessarily the same as equivalence, and the absence of statistical significance may be due to insufficient power to detect differences between the study groups. The comparison group in this trial was the BAK fusion technique, which was the preferred fusion procedure at the time, but might not be the current up-to-date procedure. Moreover, the 24-months follow-up period might not be sufficient to determine the long-term safety and effectiveness of the implant as well as its impact on other discs and on the bony structures on the back of the spine.

**Articles:** The search yielded 56 articles. The majority were review articles, or reports that dealt with the design, technical aspects and/or evolution of the technology. The search revealed four articles published by the same group of authors reporting on the Charité artificial disc evaluated in a multicenter RCT in the US. The article that reported the results of the trial in all centers was selected for critical appraisal.

The search also revealed a report on the early 6 months results for the first 53 patients randomized in an ongoing multicenter RCT of ProDisc in the United States. The system is not currently FDA approved.

Geisler FH, Blumenthal SL, Guyer RD, et al. Neurological complications of lumbar artificial disc replacement and comparison of clinical results with those related to lumbar arthrodesis in the literature. : Results of a multicenter, prospective, randomized investigational device exemption study of Charité intervertebral disc. *L Neurosurg (Spine)* 2004;1:143-154. See [Evidence Table](#).

The use of artificial disc in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

### ***Artificial Disc in the Treatment of Back Pain***

#### **10/04/2006: MTAC REVIEW**

**Evidence Conclusion:** There is insufficient evidence that artificial discs approved by the FDA or pending approval are effective, particularly in the long-term. There is only one completed RCT and this is on the Charité device.

There are no completed published RCTs on the Prestige or ProDisc devices. The Charité RCT may not have used appropriate equivalence trial methods, including failure to compare the new device to an intervention with proven effectiveness. The safety of the artificial discs after a minimum of 2 years appears similar to that of surgical fusion. Authors of the Charité had financial links to the manufacturer, which could introduce bias.

**Articles:** An April, 2005 Blue Cross BlueShield TEC report was identified. In their literature search, they found one completed RCT, the same study included in the first MTAC review. There was also a systematic review (Freeman

& Davenport, 2006) that searched the literature through April 2006 and also identified the same single completed RCT. *Literature on individual devices identified through Medline search:*

Charité device: Several additional publications on the RCT previously reviewed by MTAC (Geisler et al., 2004) were identified: Blumenthal et al. (2005) reported updated data on primary outcomes (more patients had reached 24 month follow-up). McAfee et al. (2005) reported on radiographic outcomes e.g. restoration of disc height. Regan et al. (2006) examined outcomes in the treatment group according to centers' surgical volume. McAfee et al. (2006) reported on the re-operation rate of patients in the RCT as well as other patients, for a total sample size of 688. The updated study on the primary outcomes (Blumenthal et al., 2005) and the study on re-operation rates (McAfee et al., 2006) were critically appraised. The other publications were not evaluated further because they do not add substantially to our ability to evaluate the long-term safety and efficacy of the Charité device.

ProDisc device: The RCT identified in the previous MTAC search comparing ProDisc to surgical fusion is still ongoing. The study is taking place at 19 centers and has an enrollment goal of 500 patients. At the time of the first MTAC review, an article reporting initial findings for 53 patients at one center was identified. A 2005 article was identified that reported additional preliminary findings from the same center, this time for 78 patients. This study was not critically appraised because results from all centers are not yet available.

Prestige device (not included in 2005 MTAC review): There was a 2004 publication reporting on preliminary findings from a randomized controlled trial on Prestige II conducted at four sites in Europe. This study was critically appraised. The article appears to report on all randomized patients, although not all patients had completed the final follow-up. No subsequent publications on outcomes of this RCT were identified. In addition, an older case series with 17 patients using the Prestige I device was identified, but not evaluated further due to the small size and the availability of higher-grade evidence.

Blumenthal S et al. A prospective, randomized, multicenter food and drug administration investigational device exemptions study of lumbar total disc replacement with the Charité artificial disc versus lumbar fusion. *Spine* 2005; 30: 1568-1575. See [Evidence Table](#).

McAfee PC et al. Revisability of the Charité artificial disc replacement. *Spine* 2006; 31: 1217-1226. See [Evidence Table](#).

Porchet F, Metcalf NH. Clinical outcomes with the Prestige II cervical disc: preliminary results from a prospective randomized clinical trial. *Neurosurgery Focus* 2004; 17: 36-43. See [Evidence Table](#).

The use of artificial disc in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Artificial Disc in the Treatment of Back Pain 10/01/2007: MTAC REVIEW**

**Evidence Conclusion:** The Prestige cervical disc system was first reviewed by MTAC before final FDA approval. At that time, there was one relatively small published RCT reporting preliminary findings (Porchet & Metcalf, 2004). At the time of data analysis, the investigators did not find a significant difference in pain and disability outcomes at 12 months for patients who underwent either artificial disc replacement or anterior cervical fusion. Limitations of this RCT included insufficient follow-up (only about two-thirds of participants had completed the 12-month follow-up and about 15% had completed the 24-month follow-up), unclear equivalence study methods, and funding from the device manufacturer. A larger multicenter RCT among patients with symptomatic single-level cervical degenerative disc disease (DDD) was identified for the evidence update (Mummaneni et al., 2007). Mummaneni and colleagues randomized 541 patients to receive either the Prestige cervical disc system or anterior cervical discectomy and fusion. Using a composite success measure developed by the investigators that considered efficacy and safety, the Prestige artificial disc system was found to be superior to ACDF in a completer analysis. In an intention to treat analysis with a "worst case scenario" analysis, Prestige was found to be non-inferior to ACDF. Advantages of the Mummaneni study were that it was randomized and there was a high follow-up rate. Disadvantages are that the study was non-blinded, and the authors have financial links with the manufacturer. In conclusion, there is fair evidence from one reasonably valid multicenter RCT that use of the Prestige artificial disc in conjunction with discectomy is at least non-inferior to ACDF in "clinical success" defined as a composite outcome incorporating efficacy and safety. The evidence would be strengthened by longer-term follow-up data and studies conducted by impartial researchers. The Porchet & Metcalf, 2004 study does not add substantially to the body of evidence, especially since only preliminary findings were reported in the published literature.

**Articles:** At the time of the previous MTAC review of artificial discs (October 2006), there was one published randomized controlled trial on the Prestige disc with 55 patients from 4 sites in Europe. The article reported preliminary findings of the RCT (Porchet & Metcalf, 2004). No follow-up publication was identified that reported final results of this RCT. The updated literature search identified a new, larger RCT. This study randomized 541 patients at 32 sites in the United States to discectomy with artificial disc replacement or ACDF (Mummaneni et al., 2007). This was the key study submitted to the FDA for device approval. The Mummaneni et al. RCT was critically appraised: Mummaneni PV, Burkus JK, Haid RW et al. Clinical and radiographic analysis of cervical disc arthroplasty compared with allograft fusion: a randomized controlled trial. *J Neurosurg Spine* 2007; 6: 198-207. See [Evidence Table](#).

The use of Prestige artificial disc in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Artificial Disc in the Treatment of Back Pain**

### **02/01/2010: MTAC REVIEW**

**Evidence Conclusion:** The published randomized controlled trials on lumbar and cervical artificial disc replacement, reviewed for this report, were all US FDA investigational device exemption (IDE) studies designed to show that artificial disc replacement is at least as good as fusion for lumbar DDD, or ACDF for cervical disc disease (non-inferiority design). Lumbar total disc replacement with artificial intervertebral discs (Charité, and ProDisc-L). The trials on artificial total lumbar disc replacement compared the procedure with interbody fusion among patients 18 to 60 years of age, who had a single level DDD at L4-5 or L5-S1 (Charité) or L3-S1 (ProDisc-L) confirmed radiographically, and failed conservative treatment of at least six months. The trials were randomized, controlled and multicenter, but were not blinded and sponsored by the manufacturer which are sources of bias. All trials except the CHARITE IDE trial had a maximum study duration of two years which does not allow determining the long-term efficacy, durability, or safety of total disc replacement or its impact on adjacent risk degeneration. CHARITE IDE trial (Guyer et al 2009) was the only published RCT with long-term follow-up. However, the five-year outcomes were reported for only 35% of the randomized participants in the original two-year trial (6 of the initial 14 investigational sites refused to participate in the five-year continuation study, and a number of patients were lost to follow-up). This reduces the statistical power of the study which was based on the initial population size. Moreover, the investigational procedure was compared to interbody fusion using the BAK cage technique, which currently is not the best-accepted fusion technique. These, together with non-blinding and other limitations of the original trial make it hard to interpret or generalize the results of the long-term follow-up. The trial on ProDisc-L (Zigler 2007) was also randomized, controlled, and multicenter. However, it had only 2 year follow-up duration which does not allow determining the long-term effectiveness, harms, or durability of the device. Moreover 11.5% of fusion patients and 9% of ProDisc-L patients were not included in the analysis, which was not based on intention to treat. There is also a concern that the investigators used a revised version of the ODI score that had not been validated.

In conclusion, there is insufficient evidence to determine the long-term efficacy, durability, or safety of artificial disc replacement for patients with lumbar degenerative disc disease, or to determine whether it is associated with the risk of adjacent risk degeneration. Cervical total disc replacement with artificial intervertebral discs (ProDisc-C, Bryan, and PRESTIGE). The trials on artificial total cervical disc replacement compared the procedure in conjunction with discectomy to anterior cervical decompression and fusion (ACDF) among patients between 18 and 60 years of age (>21 years in Bryan disc trial) with radiculopathy or myelopathy from a single-level cervical disc disease From C3 to C7, that failed conservative treatment of at least 6 weeks. The trials were randomized, controlled and multicenter, but were not blinded, the postoperative care was not standardized and left to the discretion of the surgeon, and the majority of the investigators had financial ties to the manufacturer, all of which are sources of bias. Moreover the 2-year follow-up duration insufficient to examine the long-term efficacy, safety, and durability of the artificial disc replacement, or to determine whether it is associated with the risk of adjacent risk degeneration. In conclusion, the short-term results of the trials provide fair evidence that the use of the ProDisc-C, Bryan, or PRESTIGE artificial cervical disc systems in conjunction with discectomy is at least non-inferior to ACDF in "clinical success" defined as a composite outcome incorporating efficacy and safety, among patients with symptomatic single-level cervical disc disease. There is insufficient evidence however, to make any conclusion on whether total intervertebral cervical disc would need revision, would deteriorate with time, or would increase the risk of adjacent segment degenerative disc disease.

**Articles:** *Lumbar artificial disc replacement* The updated literature search identified two randomized controlled trials that compared total lumbar disc replacement with Charité (Guyer 2009) or ProDisc-L (Zigler 2007) systems versus lumbar fusion. Guyer et al reported on 5-year follow up of patients enrolled in the Charité IDE trial that was the key study submitted to the FDA for device approval. Zigler et al's trial was also the key trial for FDA approval for ProDisc-L. Both RCTs was critically appraised. Guyer RD, McAfee PC, Banco RJ, et al. Prospective, randomized multicenter Food and drug Administration investigational device exemption study of lumbar total disc replacement with the Charité artificial disc and versus lumbar fusion: Five-year follow-up. *Spine J.* 2009;9:374-386. See [Evidence Table](#). Zigler J, Delamarter R, Spivak JM, et al. Results of the prospective, randomized, multicenter Food and Drug Administration investigational device exemption study of the ProDisc-L total disc replacement versus circumferential fusion for the treatment of 1-level degenerative disc disease. *Spine.* 2007;22:1155-1162. See [Evidence Table](#). *Cervical artificial disc replacement:* The literature search revealed two RCTs on ProDisc-C total disc replacement as well as two trials on Bryan cervical disc arthroplasty (conducted by the same principle investigators, and published in 5 articles). Two studies, one for each system (Murrey 2009 for ProDisc-C, and Heller 2009 for Bryan cervical disc arthroplasty), were selected for critical appraisal based on the methodological quality of the trial, population size and duration of follow-up. Murrey D, Janssen M, Delamarter R, et al. Results of a prospective, randomized, controlled, multicenter Food and Drug Administration investigational device exemption study of the ProDisc-C total disc replacement versus anterior discectomy and fusion for the treatment of 1-level

symptomatic cervical disc disease. Spine. 2009;9:275-286. See [Evidence Table](#). Heller JG, Sasso RC, Papadopoulos SM, et al. Comparison of Bryan cervical disc arthroplasty with anterior cervical decompression and fusion. Clinical and radiographic results of a randomized, controlled, clinical trial. Spine. 2009;34:107-107. See [Evidence Table](#).

The use of artificial spinal discs in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Artificial Disc in the Treatment of Back Pain**

#### **02/13/2012: MTAC REVIEW**

**Evidence Conclusion:** *CERVICAL* The three large published trials on cervical arthroplasty were industry sponsored studies submitted to the U.S. Food and Drug Administration for premarket approval of the devices: Prestige, ProDisc-C, and Bryan cervical disc. All three trials were designed as noninferiority trials i.e. attempting to show that cervical artificial disc replacement is at least as good as ACDF for cervical disc disease. They had similar inclusion and exclusion criteria, similar follow-up schedules, and similar outcome measures and success criteria defined by the FDA. The three trials are still ongoing as the FDA required that the investigators conduct post-approval studies to evaluate the longer term safety and effectiveness of the devices. The post-approval studies are expected to provide 3, 5, 7, and 10-year data for cervical discs. Each of the three studies compared total replacement with an artificial disc (Prestige, ProDisc-C, or Bryan) in conjunction with discectomy to a single-level anterior cervical decompression and fusion (ACDF) among patients between 18 and 60 years of age (>21 years in Bryan disc trial) with a single level cervical radiculopathy or myelopathy between C-3 and C-7 that had failed conservative treatment of at least 6 weeks. The trials were relatively large, randomized, controlled, and multicenter, but were not blinded, the postoperative care was not standardized and left to the discretion of the surgeon, and the majority of the investigators had financial ties to the manufacturers who supported the trials, all of which are sources of bias. The 24 months interim analyses of the three trials were previously reviewed by MTAC. The conclusion of the last 2010 MTAC assessment of the technology was as follows, "The short-term results of the trials provide fair evidence that the use of the ProDisc-C, Bryan, or Prestige artificial cervical disc systems in conjunction with discectomy is at least non-inferior to ACDF in "clinical success" defined as a composite outcome incorporating efficacy and safety, among patients with symptomatic single-level cervical disc disease. There is insufficient evidence however, to make any conclusion on whether total intervertebral cervical disc would need revision, would deteriorate with time, or would increase the risk of adjacent segment degenerative disc disease." After the last MTAC review of 2010, mid-term follow-up data were published for all three trials: 48 months postoperative data for ProDisc and Bryan artificial discs and 60 months postoperative data for Prestige cervical disc. These mid-term follow-up data were only available for just over two thirds of the population in the Bryan disc trials, and around 50% for each of the 60 months follow-up data for the Prestige disc trials and the 48 months follow-up for ProDisc-C trial. The published results of all three studies show that the one level cervical disc arthroplasty appears to be at least as effective as cervical fusion in up to 2 years of follow-up. The results the extended, mid-term analyses suggest that the outcomes the artificial disc arthroplasty continues to be noninferior to those of fusion. However, the follow-up rates are poor, and the results on sustained effect and durability should be interpreted with caution. The 48 and even 60 months follow-up duration is still insufficient to determine the long-term efficacy, durability, and safety of the system, and the potential risk on adjacent risk degeneration. The trials are still ongoing and long-term results for up to 10 years follow-up are expected. In conclusion, the additional information does not change the conclusions of the previous reports; data on long-term safety and efficacy is still lacking, and there is no evidence to date to determine if one of these three FDA approved artificial discs is superior to the others. A recent update of the Blue Cross and Blue Shield Association Technology Evaluation Center (TEC) (November 2011) concluded that artificial intervertebral disc arthroplasty for the treatment of patients with cervical degenerative disc disease does not meet their criteria. The TEC update however did not include Sasso et al's 2011 article that reports on the 48 months outcomes of all participating centers in the Bryan cervical disc trial. At the time of the TEC review only one center had published the 48 month follow-up results (BCBS 2011). *LUMBAR* As indicated in the last 2010 MTAC review, the published randomized controlled trials on lumbar artificial disc replacement were U.S. Food and Drug Administration (FDA) investigational device exemption (IDE) studies that were designed to show that artificial disc replacement is at least as good as fusion for lumbar DDD. The studies (reviewed in earlier reports) compared the procedure with interbody fusion among patients 18 to 60 years of age, who had a single level DDD at L4-5 or L5-S1 (Charité) or L3-S1 (ProDisc-L) confirmed radiographically, and failed conservative treatment of at least six months. The trials were randomized, controlled and multicenter, but were not blinded and sponsored by the manufacturer which are sources of bias. All trials except the Charite IDE trial had a maximum study duration of two years, which does not allow determining the long-term efficacy, durability, or safety of total disc replacement or its impact on adjacent risk degeneration. Charite IDE trial (Guyer et al 2009) was the only published RCT with long-term follow-up. However, the five-year outcomes were reported for only 35% of the randomized participants in the original two-year trial (6 of the initial 14 investigational sites refused to participate in the five-year continuation study, and a number of patients were lost to

follow-up). This reduces the statistical power of the study which was based on the initial population size. Moreover, the investigational procedure was compared to interbody fusion using the BAK cage technique, which currently is not the best-accepted fusion technique. These, together with nonblinding and other limitations of the original trial make it hard to interpret or generalize the results of the long-term follow-up. The trial on ProDisc-L (Zigler 2007) was also randomized, controlled, and multicenter. However, it had only 2 year follow-up duration which does not allow determining the long-term effectiveness, harms, or durability of the device. Moreover 11.5% of fusion patients and 9% of ProDisc-L patients were not included in the analysis, which was not based on intention to treat. There is also a concern that the investigators used a revised version of the ODI score that had not been validated. Yajun, et al's meta-analysis, 2010 (Evidence table 1) pooled the results of five studies involving 837 patients. The meta-analysis had valid methodology and analysis, and according to its reviewers, four of the five trials had good methodological quality. They indicated however, that the studies had limited population sizes and did not indicate that the assessors of the outcomes were blinded. The pooled results of the analysis showed that at 2 years of follow-up the patient functioning ability as measured by the Oswestry Disability Index (ODI) in the total disc replacement (TDR) group was better than the fusion group but, according to the authors a mean difference of 4 Oswestry points is not clinically relevant. There was also a statistically significant but clinically irrelevant difference in the pain score in favor of the TDR. After performing a sensitivity analysis excluding one large study that compared TDR with BAK cages, the difference in ODI, pain, and patient satisfaction were no longer significant. The authors concluded that TDR is not superior to fusion in treating lumbar degenerative disc disease. In conclusion, there is still insufficient published evidence to date, to determine the long-term efficacy, durability, or safety of artificial disc replacement for patients with lumbar degenerative disc disease, or to determine whether it is associated with the risk of adjacent risk degeneration.

**Articles:** *CERVICAL DISC* The literature search revealed four articles reporting on long-term outcomes of three pivotal clinical trials on Prestige ST, ProDisc-C, and Bryan artificial discs (one in a single center, and the other on the entire population studied). The search also identified a RCT on KineflexIC artificial disc with 2 year follow-up, and a recent meta-analysis (Cheerag, et al. 2011) that pooled the 2-year follow-up results of the three first trials. No trials comparing the three FDA approved artificial disc systems to one another were identified. All three initial studies on Bryan, ProDisc, and Prestige cervical discs initial trials with 2-year outcomes that were submitted to the FDA for premarket approval were previously reviewed by MTAC. The reports on long-term follow-up outcomes of the studies were reviewed and their results added to the last MTAC report to update the findings and conclusions. The meta-analysis was not critically appraised as it does not add more evidence to 24 months interim results of the individual trials. Pooling these results still provide 2-year results when long-term safety, durability, and efficacy are needed. The recent RCT on KineflexIC was also not selected for appraisal as it only provides 24 months data. The following initial trials and more recent publications were critically appraised: Burkus JK, Haid RW, Traynelis VC, et al. Long-term clinical and radiographic outcomes of cervical disc replacement with The Prestige disc: results from a prospective randomized controlled trial. *J Neurosurg Spine* 2010; 13:308-318. See [Evidence Table](#). Delamarter, RB, Murrey D, Janssen ME, et al. Results at 24 months from the prospective, randomized, multicenter Investigational Device Exemption trial of ProDisc-C versus anterior cervical discectomy and fusion with 4-year follow-up and continued access patients *SAS Journal*. 2010; 4:122–128. See [Evidence Table](#). Heller JG, Sasso RC, Papadopoulos SM, et al. Comparison of Bryan cervical disc arthroplasty with anterior cervical decompression and fusion. *Clinical and radiographic results of a randomized, controlled, clinical trial. Spine*. 2009; 34:101-107. See [Evidence Table](#). Mummanemi PV, Burkus JK, Haid RW et al. Clinical and radiographic analysis of cervical disc arthroplasty compared with allograft fusion: a randomized controlled trial. *J Neurosurg Spine* 2007; 6: 198-207. See [Evidence Table](#). Murrey D, Janssen M, Delamarter R, et al. Results of a prospective , randomized, controlled, multicenter Food and Drug Administration investigational device exemption study of the ProDisc-C total disc replacement versus anterior discectomy and fusion for the treatment of 1-level symptomatic cervical disc disease. *Spine J*. 2009;9:275-286. See [Evidence Table](#). Sasso RC, Anderson PA, Riew D, et al. Results of cervical arthroplasty compared with anterior discectomy and fusion: Four-year clinical outcomes in a prospective randomized, controlled, trial. *J Bone Joint Surg A*. 2011;93:1684-1692. See [Evidence Table](#). *LUMBAR* The literature search for studies published after the MTAC 2010 re-review of the technology, did not identify more recent reports on extended follow-up of the key trials on the Charité IDE or ProDisc-L used for the treatment of a single level generative disc disease (DDD). There was a recently published RCT (Delamarter et al 2011) conducted by the same investigators of Pro-disc-L total replacement, but for the treatment of two-level lumbar DDD which is not the focus of the current review. The search also revealed one meta-analysis of studies on artificial lumbar disc replacement for single level DDD, a systematic review, and one case series on with a 2-7 years follow-up of 57 patients who received an artificial Charite III total disc arthroplasty. The meta-analysis was selected for critical appraisal: Yajun W, Yue Z, Xiuxin H. A meta-analysis of artificial total disc replacement versus fusion for lumbar degenerative disc disease. *Eur Spine J*. 2010;19:1250-1261. See [Evidence Table](#).

The use of cervical artificial disc in the treatment of back pain meeting the *Group Health Medical Technology Assessment Criteria* is inconclusive.

The use of artificial lumbar spinal discs in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Two-level cervical artificial disc replacement for the treatment of cervical degenerative disc disease**

### **BACKGROUND**

Degenerative disc disease (DDD) is defined as any changes that occur at any level of the spine. It's the leading cause of pain and disability among adults in the United States as well as other parts of the world. Disc degeneration is most common in the lower neck (cervical disc disease) and in the low back (lumbar disc degeneration). DDD may cause pain in the affected area, and may also radiate along the nerves emerging from the spinal canal at that level.

Most DDDs can be treated nonoperatively to relieve the pain. Conservative treatments include physical therapy, nonsteroidal anti-inflammatory medications, and analgesics. Acupuncture, spinal manipulations, axial traction, and muscle relaxants are other alternative therapies that may be used to alleviate the pain and discomfort. A number of patients may not benefit from the non-invasive therapy and resort to surgical treatment. Spinal interbody fusion, a procedure that involves the fusion of two or more vertebrae to eliminate the pain caused by their abnormal motion, has been the surgical standard of care for lumbar DDD for decades. Anterior cervical discectomy combined with fusion (ACDF) is also a well-established treatment for cervical degenerative disc disorders. Interbody fusion reduces the pain caused by the treated segment. However, the rigid fusion also leads to a reduction in normal spine motion, and an increase in the biomechanical stress at spinal levels adjacent to the fusion, which in turn accelerates degenerative changes of the discs at these levels [1-4].

Recently arthroplasty performed with artificial discs have emerged as a surgical alternative to interbody fusion. The technology is rapidly developing and offers the promise to restore the normal spinal movement without the kinematic and biochemical issues of fusion. Potential benefits of disc arthroplasty include maintenance of a range of motion, avoidance of adjacent segment degeneration, restoring disc height, correcting spinal misalignment, greater maintenance of maneuverability, and earlier return to previous level of function. In addition, many trials [5, 6] have shown that cervical disc arthroplasty (CDA) is as safe and effective as ACDF for the treatment of CDD at a single level. On the other hand, potential disadvantages of the artificial disc may include implant migration and material wear [3, 7, 8].

The Charité, the first artificial intervertebral disc used, was developed Germany in the 1950s, but was not commercially available until 1987 after undergoing major design modifications. The third generation Charité™ (DePuy Spine) consists of two chromium alloy endplates and a sliding ultra-high molecular weight polyethylene core. The ProDisc-L (Synthes Spine, West Chester, PA) is another disc implant, also developed in Europe, for disc replacement at one level from L3-S1. It has a ball and socket design and is composed of three components; two metal endplates and a plastic inlay. More recently researchers developed artificial disc devices to replace cervical intervertebral discs. These include ProDisc-C (Synthes Spine, West Chester, PA), Bryan Cervical Disc (Medtronic Sofamor Danek, Memphis, TN), Prestige Cervical Disc (Medtronic Sofamor Danek), Mobi-C Cervical Disc (LDR Spine USA), and Kineflex|C Spinal System (SpinalMotion Inc.). ProDisc-C have a similar design to the ProDisc-L, Bryan disc prosthesis has two metal endplates and a polyethylene core, and Prestige has two main pieces of stainless steel that articulate against one another with a ball and trough.

The Prestige ST, ProDisc-C and Bryan artificial disc systems have received the US Food and Drug Administration (FDA) premarket application approval as Class III devices in July 2007, December 2007, and May 2009 respectively. The Mobi-C has received the US Food and Drug Administration (FDA) premarket application approval on August 2013.

Contraindications to total cervical disc replacement include systemic infection, infection at the operating site, allergy to any of the device materials, osteoporosis, marked cervical instability, severe spondylosis, clinically compromised vertebral bodies at the level to be treated, and symptomatic cervical disc disease (SCDD) at more than one level.

### **09/21/2016: MTAC REVIEW**

#### **Two-level cervical artificial disc replacement for the treatment of cervical degenerative disc disease**

**Evidence Conclusion:** Anterior cervical discectomy and fusion (ACDF) versus cervical disc arthroplasty (CDA) for two contiguous levels cervical disc degenerative disease: a meta-analysis of randomized controlled trials (Zou et al., 2016) (evidence table 1) This meta-analysis of RCT aimed to determine the safety and efficacy of cervical discarthroplasty (CDA) at two contiguous levels cervical disc degeneration. The search was performed between January 2000 and July 2015. Evaluation of study quality was performed using the

Cochrane Collaboration's tool for assessing risk of bias. Mean follow-up of included studies ranged from 20-48 months. CDA group patients showed fewer blood loss, lower post-operative complications, lower reoperation rate and better range of motion at all angles and levels. No significant difference was identified in mean surgical time, neck disability index and neck and arm pain VAS scores. Limitations remain in the variety of artificial intervertebral disc types. Furthermore, there is limited number of articles on artificial cervical disc for 2 levels. Overall, CDA is more effective; the study has valid methodology with some limitations.

**Cervical total disc replacement with the Mobi-C cervical artificial disc compared with anterior discectomy and fusion for treatment of 2-level symptomatic degenerative disc disease: a prospective, randomized, controlled multicenter clinical trial** (Davis et al., 2013) (evidence Table 2) This multicenter RCT, FDA investigational device exemption pivotal trial aimed to compare the Mobi-C cervical artificial disc to anterior discectomy and fusion (ACDF) for treatment of cervical DDD at 2 contiguous levels of the cervical spine. This study shows that the overall study success rates met the non-inferiority margin and provided statistical superiority of the total disc replacement (TDR) treatment over ACDF. Results should be interpreted with caution since several authors had received clinical or research support for this study from LDR, the sponsor. In addition, many other authors had financial ties with LDR.

**Two-level total disc replacement with Mobi-C cervical artificial disc versus anterior discectomy and fusion: a prospective, randomized, controlled multicenter clinical trial with 4-year follow-up results** (Davis et al., 2015) (evidence Table 3) This is a 4-year follow-up result of the study performed by the same author in 2013. The follow up in the 2013 study presented earlier is 24 months. The current study follow-up is 48 months. At 48 months, total disc replacement (TDR) had greater improvement than ACDF in: neck disability index scores, 12-Item Short Form Health Survey Physical Component Summary scores, patient satisfaction, and overall success. In addition, TDR patients had lower subsequent surgery rates and showed a lower rate of adjacent-segment degeneration; TDR also maintained segmental range of motion. The study shows that TDR continue to be safe, effective and superior to ACDF at 48 months for the treatment of degenerative disc disease at 2 contiguous cervical levels.

A systematic review and meta-analysis of RCTs [9] indicated that CDA is more effective and safer than ACDF for the treatment of symptomatic cervical disc disease in mid- to long-term follow-up. However, only one study including 2-level was included in the review. A prospective, randomized study [10] compared the safety and effectiveness of the Bryan Cervical Disc in patients with myelopathy caused by two-level cervical disc disease in Han Nationality. The authors found that the Bryan Cervical Disc replacement was shown to be reliable and safe for the treatment of patients with two-level cervical disc disease.

**Conclusion:**

- Two-level cervical artificial disc replacement shows positive outcomes on the short-term
- There is low evidence to support the effectiveness and safety of two-level cervical artificial disc replacement over anterior cervical discectomy and fusion (ACDF) on the short-term for the treatment of cervical degenerative disc disease
- Studies with longer term follow-up are needed to confirm these findings

**Articles:** The literature revealed a number of articles; the following articles were selected for critical appraisal: Anterior cervical discectomy and fusion (ACDF) versus cervical disc arthroplasty (CDA) for two contiguous levels cervical disc degenerative disease: a meta-analysis of randomized controlled trials (Zou et al., 2016) [See Evidence Table 1](#). Cervical total disc replacement with the Mobi-C cervical artificial disc compared with anterior discectomy and fusion for treatment of 2-level symptomatic degenerative disc disease: a prospective, randomized, controlled multicenter clinical trial (Davis et al., 2013) [See Evidence Table 2](#). Two-level total disc replacement with Mobi-C cervical artificial disc versus anterior discectomy and fusion: a prospective, randomized, controlled multicenter clinical trial with 4-year follow-up results (Davis et al., 2015) [See Evidence Table 3](#).

The use of Two-level cervical artificial disc replacement for the treatment of cervical degenerative disc disease does meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Artificial Hearts

- AbioCor
- SynCardia

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Artificial Hearts and Related Devices (20.9)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

#### For Non-Medicare Members

For [Ventricular Assisted Devices](#), see specific criteria

**Total artificial hearts with FDA PMA, 510(k), or HDE clearance** may be considered medically necessary as a bridge to heart transplantation in patients meeting **ALL of the following criteria**:

1. Has biventricular heart failure
2. Not responding to medical or surgical treatment
3. Is at imminent risk of death
4. Currently listed as heart transplantation candidate
5. Body size appropriate for the device
6. Is able to tolerate the necessary anticoagulation.

**Total artificial hearts** are considered unproven in all other circumstances, including but not limited to the following:

1. Use as destination therapy
2. Use of a total artificial heart that does not have FDA PMA, 510(k), or HDE clearance

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

#### Artificial Hearts

Congestive heart failure is a major health problem affecting more than five million patients in the United States. There is a wide variety of options for medical management of heart failure, but many patients eventually deteriorate and fail to respond to any of the medical therapies, and require mechanical circulatory support for survival. In order to provide long-term systemic flow for patients with end-stage heart failure, the National Heart Institute established the artificial heart program in the mid 1960s with the intent to develop a totally implantable mechanical heart.

The AbioCor (Abiomed Inc, Danvers, MA, USA) is the world's first fully implantable total artificial heart. This was first implanted in 2001 at the Jewish Hospital in Louisville, KY. AbioCor is a pneumatically-driven biventricular cardiac support device designed to last at least 18 months. It is made of titanium and Angioflex, a proprietary polyurethane plastic and can produce a flow of up to 8 L/min, sufficient for moderate activity. It is divided into the implantable components and the external drive system. The implanted components consist of the thoracic unit, controller, Transcutaneous Energy Transmission system, and a battery that provides about 30 minutes of power

that is designed to allow patients to conduct activities such as taking a shower without an external power source. The external drive system consists of the AbioCor console and support electronics worn or carried by the patient in a waist belt (providing power for 2-4 hours) and an RF communication system for a computer (Samuels 2003, Meyer 2011).

In September 2006, the FDA granted restricted approval of the AbioCor device through the Humanitarian Use Device (HUD) provision. A HUD is a device that the FDA determines is intended to benefit fewer than 4,000 U.S. patients per year. The FDA approval included an agreement by the manufacturer to conduct a post-marketing study, evaluating the AbioCor device in an additional 25 patients. According to the FDA, the AbioCor artificial heart is indicated for use in patients who have both ventricles failing, have end-stage heart disease, are not transplant candidates, are less than 75 years old, are not treatable by single left ventricular heart assist devices for destination therapy, and are not able to be withdrawn from heart support measures. It should not be used for patients who are eligible for a heart transplant, have only left sided heart failure, cannot be successfully treated for blood clotting disorders, or in those where the device will not fit (FDA webpage accessed November 2011).

SynCardia temporary CardioWest™ Total Artificial Heart (TAH), originally developed 30 years ago as the Jarvik TAH and later renamed the CardioWest TAH, continues to be used clinically in over 50 centers within the US and Europe. This is an implantable artificial heart intended to keep hospitalized patients alive while they are waiting for a heart transplant. It is a pulsating bi-ventricular device that is implanted into the chest to replace the patient's left and right ventricles and all four valves of the native heart. The device is sewn to the patient's remaining atria. Hospitalized patients are connected by tubes from the heart through their chest wall to a large power-generating console, which operates and monitors the device. SynCardia was approved by the FDA in 2004 for use only in the hospital as a "bridge to transplant" for patients waiting for a heart transplant who have both sides of their heart failing (biventricular heart failure), do not respond to other treatments, are at imminent risk of death, and are waiting for a donor heart. The temporary CardioWest™ TAH is should not be used in patients who are not eligible for a heart transplant, do not fit the device, cannot be adequately anticoagulated, or have left sided heart failure only (Meyer 2011, FDA Web page accessed November 2011).

SynCardia temporary CardioWest™ Total Artificial Heart (TAH) has not been previously reviewed by MTAC; AbioCor was reviewed by MTAC in 2007 and did not meet its evaluation criteria. The technology is being reviewed due to the coverage of SynCardia temporary CardioWest™ Total Artificial Heart by other health plans as a bridge to heart transplant.

## Medical Technology Assessment Committee (MTAC)

### AbioCor

#### 04/02/2007: MTAC REVIEW

**Evidence Conclusion:** There are no published empirical studies on the safety and efficacy of the AbioCor permanent total artificial heart. Unpublished data consists of a feasibility study with 14 patients submitted to the FDA by the device manufacturer. The 12 patients who survived the operation experienced multiple serious adverse effects; only 1 was discharged from the hospital.

**Articles:** The Medline search yielded 32 articles. These consisted of reviews/commentaries, several empirical studies on technical aspects of the device or device implantation, case reports and 2 case series reporting on 7 patients. The study submitted to the FDA, which included 14 patients, has not been published.

The use of the AbioCor implantable replacement heart in the treatment of irreversible heart failure does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 12/19/2011: MTAC REVIEW

### AbioCor

**Evidence Conclusion:** *AbioCor TAH* There is no new published evidence after the initial small feasibility study conducted by the AbioCor manufacturer among 14 patients with end-stage heart failure who were not transplant candidates. *SynCardia temporary CardioWest™ Total Artificial Heart* The published evidence on CardioWest TAH consists of a retrospective study, and a few case series of patients receiving the device as a bridge to transplantation. Due to the eligibility criteria for the implantation, it would be unethical to conduct a randomized trial. The only valid control would be no intervention as the eligible patients for the implant are those who failed medical therapy, and are not candidates for left ventricular assist device (LVAD). The results of Copeland and colleagues' case series (Evidence table 1) show that 68% of the critically ill patients who received the CardioWest implant survived to heart transplantation and hospital discharge. Adverse events included bleeding in 20% of cases and device malfunction in 5% of cases. Other complications that occurred at a lower rate included mediastinal infection, fit complications, and stroke. The cause of death was multi-organ failure in 50% of the cases, and sepsis or valve entrapment among the rest. A similar experience was observed in a French study among 42 patients. In this series 12 (28.5%) patients died while receiving device support, and 30 patients

(71.5%) underwent transplantation. Actuarial survival rates for the transplanted patients were 90% (n = 25), 81% (n = 14), and 76% (n = 10) at 1, 5, and 10 years, respectively. Causes of death during device support included multi-organ failure (50%), sepsis, acute respiratory distress syndrome, and alveolar hemorrhage. There were no device malfunctions that led to patient death. Adverse events included stroke in 3 patients (7%) and infections in 35 patients (85%) during support.

**Articles:** The literature search for AbioCor total heart transplant did not reveal any study conducted after the initial small feasibility study (Dawling 2003) conducted by the AbioCor manufacturer among 14 patients with end-stage heart failure who were not transplant candidates. The search for SynCardia CardioWest temporary TAH identified a few case series for patients who received the device as a bridge to transplantation, and a retrospective study comparing the device to left ventricular assist devices. The larger case series was selected for critical appraisal. Copeland JG, Smith RG, Arabia FA, et al. Total artificial heart bridge to transplantation: A 9-year experience with 62 patients. *J Heart Lung Transplant* 2004;23:823-831. See [Evidence Table](#).

The use of the AbioCor implantable replacement heart in the treatment of irreversible heart failure does not meet the *Group Health Medical Technology Assessment Criteria*.

The use of the SynCardia implantable replacement heart in the treatment of irreversible heart failure does meet the *Group Health Medical Technology Assessment Criteria*.

Local Coverage Article	None

#### For Non-Medicare Members

For artificial pancreas coverage the member must meet both [continuous subcutaneous insulin infusion \(CSII\) pumps](#) and the [continuous glucose monitor criteria](#), and must meet **ONE of the following**:

1. Type 1 diabetes for at least one year and 4 or more insulin injections per day; **OR**
2. Type II diabetes with documentation of undetectable endogenous insulin production (undetectable C-peptide level). This is measured by taking a fasting C-peptide level (at a time when the blood glucose is over 200mg/dl). This requires that a blood glucose level be done at the same time as the fasting C-peptide level.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Diabetes mellitus is a metabolic disorder resulting from a defect in insulin secretion, insulin action or both. More specifically, in type 1 diabetes, the pancreas is unable to produce insulin which results in increased blood glucose levels, and ultimately, leads to complications which may affect the eyes, kidneys, nerves, heart and blood vessels. As a result, an essential part of diabetes management is to maintain blood glucose levels to as near normal as possible over all hours of the day. Implementation of this approach requires the individual to be capable of and committed to a day-to-day medical program. It requires ongoing compliance with multiple daily glucose measurements accompanied by appropriate adjustments in insulin dose and insulin injection. Additionally, successful intensive diabetic management requires response to a variety of external factors including changes in diet, exercise, and presence of infection.

Typically, patients self-monitor their blood glucose via fingerprick in an effort to optimize glycemic control, however, this technique is tedious and uncomfortable for the patient. In addition, this technique only provides information about a single point in time making it difficult to recognize trends. In any case, intensive glucose monitoring and insulin therapy can be challenging as they require obtaining, retaining, processing and applying vast amounts of information in the course of everyday life (Watkins, Connell et al. 2000; Boland, Monsod et al. 2001; Brauker 2009).

Evolving technologies such as continuous subcutaneous insulin infusion (CSII), and continuous glucose monitoring (CGM) have allowed patients to safely maintain glycemic goals and prevent other related complications. While there is evidence to support the efficacy of CSII (Misso, Egberts et al. 2010), the reliability and robustness of CGMs leaves much to be desired. Even with the aid of these devices, maintaining blood glucose concentrations within a suggested optimal range is a constant struggle.

Most recent technologic advancements have integrated these components into an Artificial Pancreas Device System (APDS). In addition to CSII and CGM, the APDS incorporates a control algorithm designed to facilitate communication between the different components thus automating the process of maintaining blood glucose concentrations at or near a specified target or range and, ultimately, improving glucose control, preventing complications, and decreasing disease burden. With a wide range of current products available on the market, there is potential for a large variety of different types and designs of ADPSs.

In an effort to help advance the development of the diabetes technologies, the U.S. Food and Drug Administration (FDA), in 2011, established three new product classifications for APDSs including threshold suspend, single hormonal control, and bihormonal control, all of which are regulated as class III device systems (general controls and premarket approval). In September of 2013, Medtronic's MiniMed® 530G was the first system approved under this new product classification. ADPSs have not previously been reviewed by the Medical Technology Assessment Committee (MTAC) and are currently being reviewed due to provider request.

The development of an "artificial pancreas" has been the "holy grail" for management of Type 1 diabetes for several decades. To understand why this is such a difficult task it helps to understand what the normal non-diabetic person's body actually does in response to changes in blood glucose. Within the pancreas we all have 1-2 million groups of cells called the Islets of Langerhans which function together to help maintain the blood glucose levels within a quite narrow range (of around 70-160mg/dl). The islets make two main hormones (insulin from the beta-cells and glucagon from the alpha cells) which work together in concert. These islet cells monitor the blood glucose flowing through them constantly. Whenever the blood goes up (after a meal, for example) the islets increase the amount of insulin that they are secreting from the beta-cells and decrease the amount of glucagon that they are secreting from the alpha cells. Whenever the blood glucose drops below normal the beta-cells turn off completely (so that no insulin is secreted) and the alpha cells crank out lots of glucagon. Glucagon (as well as other hormones like epinephrine, growth hormone and cortisol) stimulate the liver to release glucose into the blood stream (the liver stores about 300 grams of glucose in the form of a kind of starch called glycogen). The insulin and glucagon are released directly into the portal circulation of blood flowing from the pancreas to the liver. In other words, a non-diabetic person is functioning with millions of blood glucose measurements being done every day with the results connected to a continuously variable secretion of both insulin and glucagon released directly into the blood flowing to the liver. Even though the commercially made components of an "artificial pancreas" may seem very sophisticated they are a very crude and imprecise way of trying to do what the real non-diabetic person's pancreas can do.

First consider the delivery of insulin. Rather than having both insulin and glucagon being released directly into the blood flowing to the liver we have a continuous subcutaneous infusion of insulin alone. The insulin is absorbed out of the subcutaneous fat into the peripheral systemic circulation and only then gets to the liver. This can give a fairly accurate and stable basal delivery of insulin but when larger amounts of insulin are delivered immediately before meals (bolus insulin delivery) the rate of rise and fall of insulin in the bloodstream is a lot slower than in a healthy non-diabetic person's body.

Second, consider the measurement of blood glucose. Typically diabetic patients test the capillary glucose level in their fingertips 2-8 times per day. This can give useful information but does not show the constant rising and falling of blood glucose excursions throughout the day. If needle sensors are placed in the subcutaneous tissue this can give a reading of interstitial fluid glucose (similar to plasma glucose) every 10-20 minutes throughout the day and so can show the trends as the blood glucose rises and falls. Several companies now make these continuous glucose monitoring systems (CGMS). There are two practical issues with CGMS, however: a) the interstitial fluid glucose lags behind the actual plasma glucose by 15-20 minutes and so can give a falsely low or high value if it is measured at times when the blood glucose is rising rapidly (after a meal) or is falling rapidly (after exercise or after injecting a bolus of insulin), and b) the glucose oxidase enzyme system for measuring blood glucose can drift over time and so the readings from a CGMS will be inaccurate unless they are calibrated several times a day by doing a capillary blood glucose test at a time when the blood glucose is expected to be stable (not rising or falling rapidly).

The concept of an "artificial pancreas" is that a person could wear both an insulin pump and a CGMS device and that the insulin pump uses the information from the CGMS to automatically make adjustments to the rate of insulin infusion. The person would not need to worry about testing their blood glucose or of thinking about what they eat and when they exercise but could go about their day-to-day life safe in the knowledge that their blood glucose would stay within normal limits. It is because of the practical limitations of the technology (outlined above) that we are still a long way away from that idealized situation.

## Medical Technology Assessment Committee (MTAC)

### Artificial Pancreas

#### 02/14/2014: MTAC REVIEW

**Evidence Conclusion:** In this review, the results of four RCTs were included. One of these studies compared sensor-augmented insulin pumps to multiple daily insulin injections while two of them compared threshold suspension systems with standard insulin pumps. The last study compared two closed-loop algorithms to patient self-control with CSII. **Effectiveness:** Comparison of the effectiveness of sensor augmented pump therapy versus multiple daily injections (MDI) was examined in a one year multicenter, randomized and controlled phase of the sensor-augmented pump therapy for hemoglobin A<sub>1c</sub> reduction (STAR-3) study. Compared with 241 subjects on MDI, those on pump therapy (n=244) experienced greater reductions in A<sub>1c</sub> levels by three months, with the trend continuing throughout the remainder of the study. By the end of the study, the baseline A<sub>1c</sub> level (8.3% in the two study groups) had decreased to 8.1% in the MDI group compared with 7.5% in the pump therapy group ( $P<0.001$ ). Participants were offered an optional six-month continuation phase which allowed subjects in the pump therapy group to continue therapy and allowed subjects in the MDI group to cross over to pump therapy. The continuation phase resulted in a sustained lower mean A<sub>1c</sub> value for patients in the pump therapy group and decreased the mean A<sub>1c</sub> values to 7.6% ( $P<0.001$ ) among MDI subjects who crossed over to pump therapy for the continuation phase. (Bergenstal, Tamborlane et al. 2010; Bergenstal, Tamborlane et al. 2011). See [Evidence Table](#). In the three-month automation to simulate pancreatic insulin response trial (ASPIRE), 247 patients with type 1 diabetes and nocturnal hypoglycemia were randomized to sensor augmented insulin pump therapy with the threshold suspend feature (Paradigm group) or to the standard sensor-augmented insulin pump therapy (control group). The primary efficacy outcome was the area under the curve (AUC) for nocturnal hypoglycemic events. At the end of three months, the mean AUC for nocturnal hypoglycemic events was found to be significant through supportive analysis at 37.5% lower in the Paradigm group than in the control group ( $P<0.001$ ) (Bergenstal, Klonoff et al. 2013). See [Evidence Table](#). In another trial, 95 adults and children with type 1 diabetes were randomized to use of a sensor-augmented insulin pump with threshold suspension or a standard insulin pump. After six months, the combined incidence of moderate and severe hypoglycemic events was significantly lower in patients using the pump with the threshold suspension compared with the standard insulin pump (9.5 vs. 34.2 per 100 patient-months) (Ly, Nicholas et al. 2013). See [Evidence Table](#). Most recently, Luijf and colleagues compared two validated closed-loop algorithms versus patient self-control with CSII in terms of glycemic control. The investigators concluded that both the algorithm developed by the University of Cambridge (CAM) and the algorithm developed by the University of Pavia, Padova, University of Virginia and University of California Santa Barbara (international artificial pancreas [iAP]) provide safe glycemic control. This study, however, occurred in a highly controlled environment for short periods of time. While the algorithms may have the benefit of less time in hypoglycemia, this came at the expense of higher mean glucose values when compared to self-management (open loop) and thus, more time spent in hyperglycemia (Luijf, DeVries et al. 2013). See [Evidence Table](#).

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

**Safety and Adverse Events:** Safety and adverse events were included as endpoints in two of the four selected studies. In the STAR 3 study, data on adverse events were collected at each follow up clinic visit. Severe hypoglycemia was defined as an episode requiring assistance and was confirmed by documentation of a blood glucose value of less than 50 mg per deciliter (Bergenstal, Tamborlane et al. 2010). In the ASPIRE study, the primary safety endpoint was the change in glycated hemoglobin level. The change in the glycated hemoglobin level from randomization to study end was not significant in both groups, and the difference in hemoglobin level between groups was only 0.05 percentage points. Beyond that, no episodes of diabetic ketoacidosis occurred in either group and no severe hypoglycemic events occurred in the Paradigm group. During the study phase there were seven adverse events thought to be related to the study device which included skin irritation and device malfunction resulting in severe hyperglycemia (Bergenstal, Klonoff et al. 2013). Generally speaking, the studies had the advantage of randomization and control, however, the lack of blinding makes the evidence vulnerable to bias. In addition, the Ly et al. study relied on patient recall for their results and some of the experimental subjects may have had more contact with physicians opening up the results to recall and observation bias. Sample size ranged anywhere from 48 to 495 participants and most of the studies, with the exception of the STAR 3 Trail, did not report on the racial and ethnic composition of the study samples, and for those that did, participants were predominantly white. Furthermore, inclusion criteria were extremely selective with few studies including children younger than 12 years. In the same way, the data lack generalizability because management was limited to expert settings and among highly motivated patients. Further limitations include heterogeneity in definitions of hypoglycemia and short duration of follow-up ranging anywhere from 24 hours to 18 months. With many complications of diabetes developing over many years it would be ideal to see results allowing for multiple periods of sensor wear and to evaluate changes in subject needs over time. With that said, at the current point in time, APDSs are a rapidly evolving technology that should only be considered in select patients.

**Conclusion:** The results of the published studies suggest that APDS may be effective in reducing hypoglycemia in highly selected, motivated and compliant groups of individuals. There is some evidence to support the safety of APDS in highly compliant adult patients.

**Articles:** The search revealed over 500 articles many of which were commentary, discussion, or systematic review articles. Articles were screened for randomized, comparison studies of outcomes between patients using APDS and a control group of patients using currently available technology. The following articles were selected for critical appraisal: Bergenstal RM, Tamborlane WV, Ahmann A, et al. Effectiveness of sensor-augmented insulin-pump therapy for type 1 diabetes. *New England Journal of Medicine*. 2010;**363**(4):311-320. See [Evidence Table](#). Bergenstal RM, Klonoff DC, Garg SK, et al. Threshold-based insulin-pump interruption for reduction of hypoglycemia. *New England Journal of Medicine*. 2013;**369**(3):224-232. See [Evidence Table](#). Ly TT, Nicholas JA, Retterath A, et al. Effect of sensor-augmented insulin pump therapy and automated insulin suspensions vs standard insulin pump therapy on hypoglycemia in patients with type 1 diabetes a randomized clinical trial. *JAMA*. 2013;**310**:1240-1247. See [Evidence Table](#). Luijf YM, DeVries JH, Zwinderman K, et al. Day and night closed-loop control in adults with type 1 diabetes. *Diabetes Care*. 2013;**36**: 3882-3887. See [Evidence Table](#).

The use of Artificial Pancreas does meet the *Group Health Medical Technology Assessment Criteria*.

Local Coverage Article	None

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this procedure is as safe as standard procedures and/or provides better long-term outcomes than current standard procedure.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Interbody fusion in the lumbar spine is performed to treat painful symptoms caused by instability of the vertebrae, such as spondylolisthesis, spinal stenosis, or degenerative disc disease. Traditional methods of spinal fusion include bone grafts or metal implants; however, insertion of these implants is not without risk. The technique requires excision of the problematic disc often coupled with decompression procedures, followed by instrumentation and bone grafting to provide stabilization and to promote a solid fusion. These procedures have the potential to destabilize the spine, cause significant morbidity and reduce the clinical effectiveness. Numerous open and minimally invasive techniques have been developed all with their advantages and disadvantages. The transaxial anterior lumbar interbody fusion was developed to capitalize on the presacral access route to the L5-S1 intervertebral space preventing the need for the surgeon to cut through paraspinous muscles and remove laminae and facet joints, potentially lessening postoperative patient pain and the likelihood of complications.

The Axial Lumbar Interbody Fusion System (AxiaLIF®) (TranS1®, Inc., Wilmington, NC) is a minimally invasive approach to the L5-S1 disc space. It consists of techniques and surgical instruments for creating a presacral access route to perform percutaneous fusion of the L5-S1 or L4-S1 vertebral bodies. The procedure utilizes fluoroscopic guidance for a blunt guide introducer that is passed through a 15-20 mm incision lateral to the coccyx and advanced along the midline of the anterior surface of the sacrum. It was designed to mitigate soft tissue trauma during lumbar fusion surgery. This approach minimizes the need to cut through soft tissue lessening patient pain and the likelihood of complications. In addition, the procedure allows patients to be discharged from the hospital the day after surgery allowing quicker return to work.

The AxiaLIF system was cleared by the U.S. Food and Drug Administration (FDA) 510(k) process. According to the FDA 510(k) letter to the manufacturer, the system is indicated for patients requiring fusion to treat pseudoarthrosis, unsuccessful previous fusion, spinal stenosis, spondylolisthesis (grade 1 or 2), or degenerative disc disease defined as back pain of discogenic origin with degeneration of the disc confirmed by history and radiographic studies. The AxiaLIF is not intended to treat severe scoliosis, sever spondylolisthesis (grade 3 or 4), tumor or trauma. Its usage is limited to anterior supplemental fixation of the lumbar spine at L5-S1 in conjunction with legally marked facet and pedicle screw system.

The AxiaLIF has not previously been reviewed by the Medical Technology and Assessment Committee (MTAC) and is currently being reviewed for decision-making guidance.

## Medical Technology Assessment Committee (MTAC)

### AxiaLIF

#### 12/16/2013: MTAC REVIEW

**Evidence Conclusion:** *Efficacy* The literature search revealed five case series that report on outcomes associated with AxiaLIF. The largest, published in 2011, was a retrospective analysis of 156 patients from 4 clinical sites in the US. Ultimately, the mean pain and ODI scores improved by approximately 63% and 54% respectively ( $P < 0.001$ ) and the overall radiographic fusion rate at 2 years was 94%. The study did not report any adverse events. The patient population was reported to be homogenous, however, the variable nature and progression of the disease compromises the reliability of this claim. Limitations of this study include the retrospective analysis, industry funding as well as selection bias. Outcome measures were not all objective and relied on patient reporting. Only half of the patients were accounted for in the preoperative and postoperative ODI outcome (Tobler, Gerszten et al. 2011). Several smaller case series were also identified and are summarized in a table 1. Ultimately, all of the studies report similar results and conclusions but are subject to the bias of any retrospective series. Further limitations include a lack of control subjects, potential for selection bias as only one of the studies enrolled consecutive patients and unclear study objectives. All studies, with the exception of the publication by Patil and colleagues, received industry funding from TranS1 (Patil, Lindley et al. 2010; Gerszten, Tobler et al. 2012; Marchi, Oliveira et al. 2012). *Safety* Two publications addressed the safety of AxiaLIF with conflicting results. The first study was a 5-year surveillance study of 9,152 patients (Gundanna, Miller et al. 2011) and the second, a retrospective review of 68 patient records (Lindley, McCullough et al. 2011). Gundanna and colleagues reported minimal complications (1.3%) in their study while Lindley et al. reported high complication rates (23.5%). The observed adverse events across both the studies included pseudoarthrosis, superficial infection, sacral fracture, pelvic hematoma, failure of wound closure, and rectal perforation. Although both studies were designed to be systematic in their investigation, neither study had a control group for comparison and the results are dependent on either spontaneous reporting or the accuracy of medical records. In addition, both of the studies are subject to a variety of bias due to patient selection and industry funding.

**Conclusion:** There is insufficient evidence to determine the efficacy of AxiaLIF compared to standard fusion procedures. There is insufficient evidence to establish whether the AxiaLIF is as safe as standard fusion procedures.

**Articles:** Currently, there are no randomized control trials that compare the AxiaLIF with other approaches to lumbosacral interbody fusion. The literature related to the safety and efficacy is primarily comprised of case series. The following studies were selected for review: Tobler WD, Gerszten PC, Bradley WD, Raley TJ, Nasca RJ and Block JE. Minimally invasive axial presacral L5-S1 interbody fusion. *Spine* 2011;**36**(20):E1296-E1301.

[See Evidence Table](#). Gerszten PC, Tobler W, et al. Axial presacral lumbar interbody fusion and percutaneous posterior fixation for stabilization of lumbosacral isthmic spondylolisthesis. *Journal of Spinal Disorders & Techniques* 2012;**25**(2):E36-E40. [See Evidence Table](#). Marchi L, Oliveira L, et al. Results and complications after 2-level axial lumbar interbody fusion with a minimum 2-year follow up. *Journal of Neurosurgery: Spine* 2012;**17**(3):197-192. [See Evidence Table](#). #### For Non-Medicare Members

Group Health has elected to use the Bone Anchored Hearing System (GHC-0564) MCG\* for medical necessity determinations.

**\*The MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting this service, please send the following documentation to support medical necessity:**

- Most recent audiogram/hearing test
- Most recent clinical notes from requesting provider &/or specialist (otolaryngology, ENT)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

#### Vibrant Soundbridge System

The Vibrant Soundbridge System is an implantable alternative to standard hearing aids. It is intended for use in adults with moderate to severe sensorineural hearing loss, who desire an alternative to an acoustic hearing aid. Common limitations of conventional hearing aids are acoustic feedback, sound and voice distortion, and need for frequent servicing and maintenance (FDA documents, Sterkers et al., 2003; Luetje, 2002).

The Soundbridge system consists of a middle-ear implant known as the Vibrating Ossicular Prosthesis (VORP) and an external portion, the amplification system called the Audio Processor. The Audio Processor is about 1.2 inches in diameter and designed to be worn behind or above the ear. It contains a microphone that converts environmental sound to electrical signals. These signals are delivered to the VORP, causing the Floating Mass Transducer (FMT), one of its components, to vibrate. The vibration manually stimulates the auditory ossicles and is perceived by the patient as sound (manufacturer's documents).

Potential adverse effects of the Vibrant Soundbridge include the usual risks of major ear surgery and a possible decrease in residual hearing (FDA documents).

The Vibrant Soundbridge has been available commercially since February 1998 in Europe and received FDA approval in the US in August 2000. The FDA recommends that patients have experience with appropriately fitting conventional hearing aids before using the Vibrant Soundbridge.

**Bone Anchored Hearing Aid (BAHA) (Entific Medical Systems)**

The BAHA is an alternative device for hearing-impaired patients who are unable to wear traditional hearing aids. According to the manufacturer, the BAHA can be beneficial to individuals with chronic inflammation or infection of the ear canal, an incomplete ear canal e.g. congenital ear malformation and single-sided hearing loss. The BAHA is based on bone conduction technology, sound transmission without involvement of the skin and soft tissue and thus can be used by individuals with an impaired or diseased external or middle ear (Tjellstrom & Hakansson, 1995).

The BAHA device consists of an implant and an external sound processor attached to a subcutaneous abutment. The implant, a titanium fixture, is implanted behind the ear where it “osseointegrates” or bonds with the living bone. After healing from surgery, a percutaneous abutment is attached to the fixture. The sound processor “snaps” into the abutment. The sound processor, which transmits sound directly via the bone to the inner ear can be connected and disconnected at will (FDA and manufacturer’s documents)

The BAHA was developed in Sweden in the 1980s. It was approved by the FDA in August 1996 and was introduced in the US market in January 1997. There are several different models, all of which were considered by the FDA to be Class II devices, substantially equivalent to air conduction hearing aids with digital sound processing.

**Medical Technology Assessment Committee (MTAC)**

**Vibrant Soundbridge**

**06/06/2005: MTAC REVIEW**

**Evidence Conclusion:** There are studies with pre- and post-implantation data, but no controlled studies on the efficacy of either the Vibrant Soundbridge or the BAHA. Data from case series suggest that patients who meet eligibility requirements may experience improvement and hearing from the Vibrant Soundbridge and BAHA. Lack of blinding and lack of a control group limit the validity of case series. The publications are further limited by small sample sizes and/or missing data.

**Articles:** *Vibrant Soundbridge:* Only case series were identified. Most were conducted in Europe where there is longer experience with the device compared to the U.S. Two studies were selected for review: The largest case series, a French study (n=125), and the strongest US study (n=54). The US study was the one used by the FDA to grant approval. *BAHA:* Only case series were identified, all with sample sizes <100. The two best-case series were reviewed. They were selected based on sample size and length of follow-up. There were two publications on one of the studies, so a total of three articles were reviewed. *The studies that were critically appraised are:* Sterkers O, Boucarra D, Labassi S. A middle ear implant, the Symphonix Vibrant Soundbridge: Retrospective study of the first 125 patients implanted in France. *Otol Neurotol* 2003; 24: 427-436. See [Evidence Table](#) Luetje CM, Brackman D, Balkany TJ et al. Phase III clinical trial results with the Vibrant Soundbridge implantable middle ear hearing device: A prospective controlled multicenter study. See [Evidence Table](#) Mylanus EA, van der Pouw KC, Snik AFM et al. Intraindividual comparison of the bone-anchored hearing aid and air-conduction hearing aids. *Arch Otolaryngol Head Neck Surg* 1998; 124: 271-276. See [Evidence Table](#) Hol MKS, Snik AFM, Mylanus EAM et al. Long-term results of bone-anchored hearing aid recipients who had previously used air-conduction hearing aids. *Arch Otolaryngol Head Neck Surg* 2005; 131: 321-325. See [Evidence Table](#) Lustig LR, Arts A, Brackmann DE. Hearing rehabilitation using the BAHA bone-anchored hearing aid: Results in 40 patients. *Otol Neurotol* 2001; 22: 328-334. See [Evidence Table](#)

The use of Vibrant Soundbridge or the BAHA in the treatment of hearing loss does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Bariatric Surgery

- Adjustable gastric banding, Laparoscopic or Open (Lap Band)
- EndoGastric Solutions Stomaphy X™ Endoluminal Fastener
- Gastric Bypass for GERD
- Gastric Electrical Stimulator
- IntraGastric Balloons
- Laparoscopic Sleeve Gastrectomy
- Roux-en-Y Gastric Bypass (RYGB)
- Vertical Banded Gastroplasty (VBG)
- Vertical Sleeve Gastrectomy (VSG)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

## Background

The NIH has defined overweight as a BMI between 25 kg/m<sup>2</sup> and 29.9 kg/m<sup>2</sup>, and obesity as a BMI of > 30 kg/m<sup>2</sup>. According to national survey data, an estimated one-third of adults in the United States are overweight. Overweight and obesity are associated with an increased risk of mortality. Individuals with a BMI > 30 have a 50-100% increased risk of premature death compared to individuals with a BMI between 20 and 25. In addition, overweight and obesity are associated with an increased risk of coronary heart disease, type 2 diabetes, hypertension, certain cancers and musculoskeletal disorders such as knee osteoarthritis (Surgeon General report: USPSTF).

Lifestyle changes, including diet, exercise, and behavior modification, are generally considered first-line therapy for overweight and obesity. Pharmacotherapy can be used as an adjunctive therapy when lifestyle changes alone are ineffective. Medical management of obesity has been found to be less effective with individuals who are morbidly obese (BMI > 35) than for those with lower BMI, particularly in terms of sustained weight loss. The NIH has stated that bariatric surgery is an option for patients with a BMI > 40 or a BMI > 35 with comorbid conditions, who have failed medical treatment (Fisher and Schauer, 2002; NIH, 1998).

There are two main strategies for surgically inducing weight loss, gastric restriction and intestinal malabsorption. Restrictive procedures mechanically reduce the size of the stomach. This limits the amount of food a patient can consume at a single meal and causes early satiety. Substantial dietary compliance is required, because individuals are still able to consume high-calorie liquids or soft foods. Malabsorption procedures involve bypassing a portion of the intestines which decreases the proportion of nutrients that are absorbed from food. Some types of surgeries use elements of both strategies (Fisher and Schauer, 2002; Southern California-RAND EBPC 2004).

Two currently accepted bariatric surgery methods are Vertical Banded Gastroplasty (VBG) and Roux-en-Y gastric bypass (RYGB). VBG is a restrictive procedure that uses staples to create a narrow gastric inlet or pouch and a non-adjustable band is placed around the new inlet to prevent enlargement. RYGB includes both restrictive and malabsorptive elements. The stomach is reduced to a small gastric pouch, and this pouch is connected to a segment of the jejunum, bypassing the duodenum and proximal small intestine. RYGB can be performed as open surgery or laparoscopically.

Adjustable gastric banding is a restrictive technique, using the Lap-Band System® (Inamed). A small gastric pouch is formed by laparoscopically placing a silicone ring (the Lap-Band) around the upper part of the stomach just below the gastro-esophageal junction. The band is connected via tubing to an access port that is secured beneath the skin of the abdomen. The band has a reservoir that is accessed percutaneously and filled with saline. The size of the band can be adjusted by adding or removing saline. The Lap-Band is removable, either laparoscopically or via an open procedure. In the clinical study presented by the manufacturer to the FDA, 60% of

the band removal procedures were laparoscopic. The Lap-Band has been used in Europe and Australia since early 1990s and was approved by FDA in June, 2001 (manufacturer's Web site).

## Medical Technology Assessment Committee (MTAC)

### Vertical Banded Gastroplasty (VBG) and Roux-en-Y gastric bypass (RYGB)

#### 2/10/1999: MTAC REVIEW

**Evidence Conclusion:** The published scientific evidence consists of several large case series and one randomized controlled trial from multiple institutions published over a 10 year period of time. Vertical Banded Gastroplasty (VBG) Data from 4 case series and 1 RCT totaling 403 patients undergoing VBG with 75-100% follow up at 3 years demonstrates between 15 and 31% weight loss. Reoperation or revisional surgery was required in 3% of patients in one series and 36% in another series. Mortality was 1-3% overall. Roux-en-Y (REY)-Data from 2 case series and 1 RCT totaling 532 patients in the REY groups with 60-86% follow up at 3 years demonstrates that Roux-en-Y gastric restrictive surgery results in between 33 and 35% weight loss. Reoperation or revisional surgery was required in 6% of patients in one series and not reported in the other series. Mortality was 1% overall.

**Articles:** MacLean, LD et al. *Surgery*, 1993;113:380-388. See [Evidence Table](#). Sugerman, HJ, et al. 1989: *Am J Surg.*;157 93-100. See [Evidence Table](#).

Sjostrom CD, Peltonen M, Wedel H, Sjostrom L. Differentiated long-term effects of intentional weight loss on diabetes and hypertension. *Hypertension* 2000; 36: 20-25. See [Evidence Table](#).

The use of gastric restrictive surgery (VBG or REY) meets the *Group Health Medical Technology Assessment Criteria*.

#### 12/8/2006: MTAC REVIEW

### Vertical Banded Gastroplasty (VBG) and Roux-en-Y gastric bypass (RYGB)

**Evidence Conclusion:** There is some evidence that Lap-Band surgery is more effective than optimal non-surgical management for patients with BMI between 30-35 kg/m<sup>2</sup> with co-morbidities. This evidence is not conclusive due to the size of the single RCT, and its limitations. Evidence from non-randomized studies suggests that gastric bypass surgery is more effective for weight loss than the Lap-Band technique for patients who meet standard eligibility criteria for bariatric surgery (BMI > 40 kg/m<sup>2</sup> or > 35 kg/m<sup>2</sup> with co-morbidities) and for the sub-set of patients with BMI > 50 kg/m<sup>2</sup>. Gastric surgery was not associated with more complications than the Lap-Band procedure, and studies generally found a higher reoperation rate after Lap-Band surgery. There may be residual confounding in the non-randomized studies. There are no randomized controlled trials comparing the safety and effectiveness of Lap-Band surgery to either gastric bypass or optimal non-surgical management for adults with BMI > 35 kg/m<sup>2</sup>. There is evidence from one randomized controlled trial that Lap-Band surgery is more effective for weight loss than a non-surgical intervention (i.e. supervised dieting, pharmacotherapy) for patients with BMI between 30-35 kg/m<sup>2</sup> with co-morbidities (O'Brien et al., 2005). However, in the two years of follow-up 4 of the 39 patients who received the Lap-Band experienced prolapse of the posterior gastric wall. In addition, limitations of the study were that it was not blinded, follow-up was only two years, and the nonsurgical intervention was not well described beyond 6 months. The best evidence comparing the Lap-Band and Roux-en-Y gastric bypass comes from two non-randomized comparative studies (Weber et al., 2004; Cottam et al. 2006). Both matched patients who did and did not receive the Lap-Band according to age, sex and BMI. The Weber study included patients with BMI > 40 kg/m<sup>2</sup> or BMI > 35 kg/m<sup>2</sup> who had co-morbidities and the Cottam study did not specify eligibility criteria but mean BMI was 47 kg/m<sup>2</sup>. Both studies found significantly more weight loss at 2-3 years and fewer co-morbidities in the group that underwent gastric bypass. In the Weber et al. study, the rate of reoperation was somewhat higher in the gastric bypass group than the Lap-Band group during the first 30 days (n=7 vs. n=1), but after 30 days the rate was higher in the Lap-Band group (n=26) than the gastric bypass group (n=4). The Cottam et al. study found a slightly higher rate of major reoperation in the gastric bypass group compared to the Lap-Band group (8% vs. 5%), but this difference was not statistically significant. A third non-randomized study compared the Lap-Band and laparoscopic Roux-en-Y gastric bypass in super morbidly obese patients (BMI > 50 kg/m<sup>2</sup>). Similar to the studies of patients with lower mean BMI, there was greater reduction in BMI and a higher proportion of excess weight loss in patients who received gastric bypass compared to the Lap-Band. There appeared to be a greater reduction in co-morbidities and fewer complications in the gastric bypass group, but numbers were too small to accurately compare the groups in these areas. Reoperations were necessary in 15% of the Lap-Band group and 6.5% of the gastric bypass group. In all of the non-randomized studies, there may be confounding variables, differences between groups that affect the outcome (such as differences in commitment to losing weight). A large case series conducted in Italy (n=1893) provides additional information on the safety of the Lap-Band technique. Reported post-operative mortality was 1 out of 200 procedures (0.5%) and was restricted to patients with preoperative cardiovascular complications. The most common post-operative complications were

gastric pouch dilation (5%) and tube port complications (4%). The ideal study would be a randomized controlled trial comparing long-term outcomes of gastric surgery with the Lap-Band and commonly accepted bariatric surgery procedures or optimal non-surgical management. One randomized controlled trial was identified and critically appraised. It compared the Lap-Band to non-surgical treatment. Five non-randomized comparative studies were identified comparing the Lap-Band to gastric bypass. One study conducted in Sweden was excluded because it compared two case series of patients treated at different institutions. A second study was excluded because only preliminary findings were reported: there was 60% follow-up at 1 year and 15% at 2 years. The other three studies were critically appraised. A large case series from Italy (n=1863) was also reviewed to evaluate the long-term safety of Lap-Band surgery.

**Articles:** *Evidence tables were created for the following studies:* O'Brien PE, Dixon JB, Laurie C et al. Treatment of mild to moderate obesity with laparoscopic adjustable gastric banding or an intensive medical program. *Ann Intern Med* 2005; 144: 625-633. See [Evidence Table](#). Weber M, Miller MK, Bucher T. Laparoscopic gastric bypass is superior to laparoscopic gastric banding for treatment of morbid obesity. *Ann Surg* 2004; 240: 975-983. See [Evidence Table](#). Cottam DR, Atkinson J, Anderson A et al. A case-controlled matched-pair cohort study of laparoscopic Roux-en-Y gastric bypass and Lap-Band patients in a single US center with three year follow-up. *Obesity Surg* 2006; 16: 534-540. See [Evidence Table](#). Browne WB, Julliard K, Castro AE et al. Laparoscopic gastric bypass is superior to adjustable gastric band in super morbidly obese patients. *Arch Surg* 2006; 141: 683-689. See [Evidence Table](#). Angrisani L, Furbette F, Doldi SB et al. Lap-Band adjustable gastric banding system: The Italian experience with 1863 patients operated on over 6 years. *Surg Endosc* 2003; 17: 409-412. See [Evidence Table](#).

The use of adjustable gastric banding and lap-band in the treatment of obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 12/15/2014: MTAC REVIEW

##### **Vertical Banded Gastroplasty (VBG) and Roux-en-Y gastric bypass (RYGB)**

**Evidence Conclusion:** There is a lack of good quality RCTs with long-term follow-up that compared laparoscopic gastric banding versus Roux-en-Y gastric bypass or laparoscopic sleeve gastrectomy. The few published RCTs were small, with short follow-up duration, and methodological limitations. Colquitt and colleagues' 2014 systematic review and meta-analysis on surgery for morbid obesity was the last published update of previous Cochrane reviews and updates on that topic conducted by the same group of authors over the last decade. This last August 2014 update (Evidence table 1) included RCTs on bariatric surgery published through December 2013. The meta-analysis included 15 trials (N=1,180 participants) that compared different bariatric surgery procedures used for weight loss (seven additional trials compared surgery to non-surgical weight loss therapies). The meta-analysis had valid methodology and analysis, but the majority of the studies included had uncertain or high risk of bias. The overall results for the comparisons made among the three most commonly performed procedures were as follows: Laparoscopic gastric bypass (LRYGB) vs. laparoscopic adjustable gastric banding (LAGB)  
The review found moderate quality evidence from 3 RCTs with uncertain risk of bias that LRYGB achieved significantly greater weight loss and BMI reductions up to 5 years after surgery vs. LAGB. Two trials reported longer duration of hospitalization with LRYGB, and one study showed that it was associated with larger number of late major complications vs. LAGB. On the other hand, one study showed that a large proportion of those undergoing LAGB required reoperation for band removal (the authors warned against generalizability of results of this study due to high drop-out rates). The evidence on QoL and co-morbidities was of very low quality. LAGB vs laparoscopic sleeve gastrectomy (LSG) One relatively small study (Himpens et al, 2006) with methodological limitations (reviewed earlier by MTAC) showed that reductions in weight and BMI were statistically significantly higher with LSG vs LAGB. The study also showed that symptoms of GERD were resolved in a higher proportion among patients in the LSG group vs. LAGB (no tests of significance were provided). Open or LRYGB vs. LSG  
The RCTs included showed no statistically significant differences between the two procedures in the reductions in weight or BMI. Serious adverse events were reported in one trial and were higher in the LRYGB group. There were no statistically significant differences between the 2 procedures in their effect on comorbidities and complications except for one study that showed significantly more improvement in diabetes mellitus with LRYGB. The authors of the review concluded that the outcomes were similar between RYGB and LSG and that both procedures had better outcomes than LAGB. There was no good evidence from RCTs to determine whether any procedure was more effective than another in controlling comorbidities. The studies had relatively short-term follow-up durations, which was insufficient to study the long-term effects of the surgical procedures.

Wang et al, 2013 (Evidence table 2) conducted a meta-analysis of 11 randomized and non-randomized controlled studies (N=1,004 participants) that compared LAGB with LSG. The pooled results suggest that LSG is associated with greater excess weight loss (EWL% mean difference -12.55 [95% CI, -15.66, -9.43] at 6 months and -4.97 [95% CI, -7.58, -2.36] at 12 months). LSG was also associated with better improvement in type 2 DM than LAGB (pooled OR of 0.34; 95% CI 0.16-0.73). The meta-analysis combined the results of a small number of randomized and

non-randomized studies with small sample sizes and short-term follow-up durations. The authors concluded that larger RCTs with long-term follow-up are needed to compare the efficacy of LSG, LAGB, and LRYGB. Dogan and colleagues (2014) compared the safety and effectiveness of LAGB, LRYGB, and LSG in a matched retrospective cohort study involving 735 patients who underwent the procedures in two centers in the Netherlands between 2007 and 2010. The results showed that LRYGB was associated with a significantly higher excess weight loss compared to LSG in the first year after which there was no significant difference in weight loss between the two procedures. After 3 years of follow-up LAGB had a higher complication rate compared to the other two procedures. Revision surgery was needed in 21% of LAGB, and 9% of LSG underwent conversion to RYGB. The authors concluded that LRYGB is a safe and effective treatment in morbidly obese patients with good long-term outcomes. LSG was comparable to LRYGB regarding weight loss and complication rate; and that LAGB was inferior to both LRYGB and LSG. Arterburn, et al (2014) compared the short and long-term outcomes of LRYGB and LAGB in a retrospective cohort study of 7,457 adult patients who underwent laparoscopic bariatric surgery from January 2005 through December 2009 in 10 health care systems (including Group Health) in the US. 1,507 underwent LAGB and 5,950 underwent RYGB. The primary outcomes were change in BMI, composite of 30-day rate of major adverse outcomes, subsequent hospitalization, and subsequent intervention. The results indicate that RYGB led to a significantly greater loss in BMI than LAGB (14.8 loss with RYGB vs. 8.0 LAGB,  $p < 0.001$ ). RYGB was associated with a higher rate of short-term complication, and long-term subsequent hospitalization. LAGB on the other hand was associated with a higher risk of long-term subsequent interventions procedures. The study was large and included a diverse group of patients, but was retrospective and not randomized. Data were obtained from records which did not include all required information, and the subsequent interventions and hospitalizations may have been due to causes unrelated to the bariatric procedures. Trastulli et al (2013) conducted a systematic review to evaluate the safety and effectiveness of LSG in terms of weight loss, comorbidity remission, and efficacy for the management of patients with type 2 diabetes mellitus. The review included 15 RCTs, 6 of which compared LSG with LGB and 2 vs. LAGB. Three of these studies were judged by the authors to have good quality and the rest were of fair quality. The authors could not perform a meta-analysis due to the heterogeneity of the studies, but performed some cumulative analyses when suitable. The results of these analyses indicate that the complication rate was 12.1% (range 10-32%) with LSG vs. a mean of 20.9% (range 10-26.4%) with LGB. Only two trials compared LSG with LAGB, one reported 0% hospital morbidity for both procedures, and the other (Himpens 2006) a total of 7 (17.5%) complications with LAGB (all were late) vs. 2 (5%) complications with SLG (all were postoperative). The percentage of excess weight loss (%EWL) ranged from 49% to 81% in the LSG group, 62.1% to 94.4% in the LGB group, and 28.7%-48% in the LAGB group) in a follow-up duration ranging from 3 months to 3 years. Type 2 DM remission ranged from 26.5% to 75% with LSG and 42%-93% with LGB. Buchwald and colleagues (2009) performed a systematic review and meta-analysis of 621 experimental and observational studies (N=136,134 participants) on bariatric surgery that were published in English between 1990-2006, and that reported on the resolution of type 2 diabetes. Nineteen studies with 43 treatment arms and 11,175 patients reported on both weight loss and diabetes resolution separately for diabetic patients (N=4,070). The analysis indicated that overall, 78.1% of diabetic patients had complete resolution, and diabetes was improved or resolved in 86.6% of patients. Weight loss and diabetes resolution were greatest for patients undergoing biliopancreatic diversion/duodenal switch, followed by gastric bypass, and least for banding procedures. Insulin levels declined significantly postoperatively, as did hemoglobin A1C and fasting glucose values. Conclusion: The limited published evidence comparing LAGB to LRYGB or LSG suggest that LAGB is not the most effective surgical procedure for the morbidly obese patients. The literature indicates that LAGB may have shorter operative time, shorter length of hospital stay, and lower rate of early complications; but it is also associated with higher rates of late complications and risk of surgical interventions compared to other bariatric surgery procedures. There is no good published quality evidence to date, to determine the comparative effectiveness of LAGB to LSG or LRYGB on the resolution of co-morbidities and improvement of health-related quality of life.

**Articles:** The literature search for studies published after the 2006 MTAC review, revealed over 500 publications, many of which were unrelated to the current review. Very few small randomized controlled trials compared the effects of one surgical bariatric procedure versus another. The search identified a recently updated Cochrane review (Colquitt et al, 2014) on surgery for weight loss in adults; a meta-analysis that compared LAGB with LSG (Wang et al, 2013), a multicenter retrospective matched cohort study (Dogan et al, 2014) that compared gastric bypass, LAGB and LSG in morbidly obese patients; three systematic reviews with no meta-analyses of RCTs on bariatric surgeries; a comparative effectiveness study of laparoscopic adjustable gastric banding vs. laparoscopic gastric bypass; as well as several cohort studies with no control or comparison groups that reported on short and long-term outcomes of gastric banding and LSG procedures. The two most recent meta-analyses were selected for critical appraisal.

The use of LAGB in the treatment of obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

## **EndoGastric Solutions Stomaphy X™ Endoluminal Fastener**

### BACKGROUND

Obesity Surgery The EndoGastric Solutions StomaphyX™ endoluminal fastener and delivery system is a sterile, single-use device for use in transoral tissue approximation and ligation in the GI tract. The system consists of an ergonomic, flexible fastener delivery device and sterile polypropylene fastener implants. The device is introduced into the body through the mouth under endoscopic visualization. Once inside the stomach, the stomach wall is suctioned into the tissue port on the StomaphyX™ creating a large plication. Non-resorbable polypropylene fasteners are then deployed across the fold to hold the tissue in place. Typically 10 to 20 folds are required depending on the patient's anatomy. The pleats created in the stomach will reduce its size, which would potentially lead to early satiety and weight loss. According to the manufacturer, the StomaphyX™ procedure is incisionless, adjustable, and revisable. It is usually performed as an outpatient procedure, and is intended for individuals who want an alternative to invasive weight loss surgery, or those who have had previous gastric bypass surgery and are regaining weight. The EndoGastric Solutions StomaphyX™ endoluminal fastener and delivery system was cleared for marketing by the FDA in February 2007 for use in endoluminal trans-oral tissue approximation and ligation in the GI tract. The InScope™ Tissue Apposition System is a sterile, single patient used disposable suture system for approximating and securing soft tissue within the gastrointestinal tract. It is intended to perform suturing in conjunction with endoscopes having a working channel of 2.8 mm or larger. The system can be used to treat variety of defects endoscopically including ulcers and perforations (FDA Web site). The InScope™ Tissue Apposition System was cleared by the FDA for marketing in January 2007 to be used for the placement of sutures and approximation of soft tissue. GERD According to the Montreal Consensus, gastroesophageal reflux disease (GERD) is defined as a condition which develops when the reflux of stomach contents cause troublesome symptoms and/or complications. GERD is a mechanical disorder that is caused by a defective lower esophageal sphincter, a gastric emptying disorder, or failed esophageal peristalsis. Typical symptoms of GERD include heartburn and regurgitation; however, overtime reflux can cause ulceration, Barrett's esophageous, airway disease, and esophageal cancer. It is estimated that 40% of individuals in the United States suffer from GERD on a monthly basis. Current treatment options for GERD include long-term use of acid suppression medications or surgical intervention. While treatment with acid suppressing medications such as proton pump inhibitors and histamine 2-receptor blockers are effective, they do not treat the underlying mechanical disorder. Additionally, not all patients respond to these therapies (Zagol 2011, Stefanidid 2010). Surgery is another treatment option for patients with GERD. According to the Society of American Gastrointestinal and Endoscopic Surgeons (SAGES), surgical therapy should be considered in patients with a diagnosis of reflux who (Stefanidid 2010): Have failed medical management (due to inadequate symptom control, severe regurgitation not controlled with acid suppression, or medication side-effects). Opt for surgery despite medical management (due to quality-of-life considerations, lifelong need for medication intake, expense of the medication, etc.). Have complications of GERD (e.g., Barrett's esophagus, peptic stricture). Have extra-esophageal manifestations (asthma, hoarseness, cough, chest pains, aspiration). There are a variety of surgical procedures used for the treatment of GERD. Currently, there is no consensus on the best procedure for all patients. The choice of procedure is often based on anatomic considerations and expertise; however, the laparoscopic Nissen fundoplication has emerged as one of the most widely used techniques. With fundoplication, the gastric fundus is wrapped around the lower end of the esophagus to reduce gastric reflux. The fundal wrap can be either total (360°) or partial (less than 360°). Studies suggest that approximately 90% of patients who undergo Nissen fundoplication achieve symptom relief. Side effects of this procedure include dysphagia, hyperflatulence, inability to belch, bloating, and postsurgery bowel symptoms (AGA 2008, Stefanidid 2010). Transoral incisionless fundoplication using the EsophyX device (EndoGastric Solutions, Inc., Redmond, WA) has been proposed as a less invasive alternative to traditional surgical procedures. This procedure attempts to decrease the reflux of stomach acid into the esophagus through the reconstruction of an anti-reflux barrier. The EsophyX device is inserted transorally, under direct endoscopic visualization, into the stomach and is positioned at the junction of the stomach and the esophagus. Once positioned, the device uses suction and transmural fasteners to facilitate the recreation of the esophageal gastric valve. The result is an omega shaped valve 3-5 cm in length and 200-300° in circumference. This procedure may also reduce hiatal hernias that are less than 2 cm in size through the use of a built in vacuum invaginators. As this procedure is incisionless and can often be performed on an outpatient basis it is an attractive alternative to conventional surgical procedures (Jafri 2009, Louis 2010). The EsophyX system had been cleared by the FDA for use in

transoral tissue approximation, full-thickness plication and ligation in the gastrointestinal tract for the treatment of GERD in patients with symptomatic chronic GERD who require and respond to pharmacological therapy. This device may also be used to narrow the gastroesophageal junction and reduce hiatal hernia  $\leq 2$  cm in size in patients with symptomatic chronic GERD. The EsoPhyX system has not been previously reviewed by the Medical Technology Assessment Committee and is being review based on request from bariatric surgery and a member appeal.

#### **04/09/2008: MTAC REVIEW**

##### **EndoGastric Solutions Stomaphy X™ Endoluminal Fastener**

**Evidence Conclusion:** There is insufficient published evidence to determine the efficacy and safety of the EndoGastric Solutions StomaphyX™ endoluminar fastener for weight loss. There is insufficient published evidence to determine the efficacy and safety of the InScope™ Tissue Apposition System for endoscopic gastric sutures.

**Articles:** The literature search did not reveal any published studies, on the EndoGastric Solutions StomaphyX™ endoluminar fastener and delivery system, or on the InScope™ Tissue Apposition System. Information about the systems was obtained from the FDA and the manufacturer's Web sites.

The use of endoluminar fasteners in the treatment of obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **8/15/2011: MTAC REVIEW**

##### **EndoGastric Solutions Stomaphy X™ Endoluminal Fastener**

**Evidence Conclusion:** Two case-series were selected for review that evaluated the safety and effectiveness of transoral incisionless fundoplication (TIF) for the treatment of GERD. The first study followed 110 subjects for a median of 7 months and the second study followed 86 subjects for 12 months. The primary outcome in both of these studies was GERD Health-Related Quality of Life (GERD-HRQL). Both studies found significant reductions in GERD-HRQL compared to baseline. However, results from these studies should be interpreted with caution as both studies were case-series (lowest-quality evidence). Serious adverse events included two perforations and a post-TIF intraluminal bleeding that required a blood transfusion. Other adverse events included: left shoulder pain, abdominal pain, sore throat, nausea, and epigastirc pain (Barnes 2011; Cadière 2008). Conclusion: There is insufficient evidence to determine the safety and efficacy of transoral incisionless fundoplication for the treatment of GERD. Assessment objective: To determine the safety and efficacy of transoral incisionless fundoplication using the ExophyX system for the treatment of GERD.

**Articles:** No randomized controlled trials were identified that addressed the safety or efficacy of transoral incisionless fundoplication using the ExophyX system for the treatment of GERD. Studies were not selected for review if they included less than 25 subjects. The largest studies with the longest duration of follow-up were selected for review. The following studies were critically appraised: Barnes WE, Hoddinott KM, Mundy S, Williams M. Transoral incisionless fundoplication offers high patient satisfaction and relief of therapy-resistnat typical and atypical symptoms of GERD in community practice. *Surg Innov* 2011; 18:119-129. See [Evidence Table](#) Cadière GB, Buset M, Muls V, et al. Antireflux transoral incisionless fundoplication using EsoPhyX: 12-month results of a prospective multicenter study. *World J Surg* 2008; 32:1676-1688. See [Evidence Table](#)

The use of endoluminar fasteners in the treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Vertical Sleeve Gastrectomy (VSG)**

#### **BACKGROUND**

Obesity is a rapidly growing health problem in the United States and worldwide. According to data from the National Health and Nutrition Examination Survey (NHANES), over two thirds of the adults in the US are overweight or obese. Overweight is defined as Body Mass Index [BMI] between 25 and 29 kg/m<sup>2</sup>, and obesity is defined as BMI of 30.0 kg/m<sup>2</sup> or higher. Obesity can be further subdivided into class 1: (BMI 30 to less than 35), class 2: (BMI 35 to less than 40), class 3: severe or morbid obesity (BMI of 40 or higher), and class IV: super obese or super morbid (BMI >50 kg/m<sup>2</sup>). Obesity leads to substantial morbidity, lower social functioning and quality of life, as well as premature mortality. It is associated with development and /or aggravation of many chronic conditions including cardiovascular diseases, hypertension, type 2 diabetes mellitus, sleep apnea, some forms of cancer, depression, and osteoarthritis (Duval 2006, Ogden 2006, Sturm 2007, Flegal 2012). Diet, behavioral modification, and exercise are the primary recommended treatments for obesity, but were found to have limited success among the morbidly obese. Drug therapy may be indicated for some, but has its side effects, and the majority regain the lost weight over time. Bariatric surgery is considered as an alternative therapy for morbidly obese individuals. Studies showed that bariatric surgery was more effective than behavioral and medical

therapy, had long-term control of obesity, and improved comorbidities as type 2 diabetes. There are several surgical techniques for weight loss, but the Roux-en-Y gastric bypass (RYGB) and the adjustable gastric banding (AGB) are the two most commonly performed procedures across the world. However, surgery is a major intervention and may be associated with risk of complications and perioperative mortality. The morbidly obese individuals usually have a higher incidence of co-existing medical problems, and are more likely to develop short and long-term complications after bariatric surgery (Karamanakos 2008, Almogy 2004, Fuks 2009). Sleeve gastrectomy (SG), also known as vertical sleeve gastrectomy (VSG), vertical gastrectomy (VG), greater curvature gastrectomy, parietal gastrectomy or vertical gastropasty, was initially described in the late 1980s, as a first step procedure performed before RYGB or biliopancreatic diversion-duodenal switch in the super obese patients with severe comorbidities. It was intended to achieve a significant weight loss prior to performing a more restrictive and malabsorption operation among those at high surgical or anesthesiologic risk. After a period of initial weight loss, the surgical risk would be reduced and the second definitive surgery could be performed. More recently, SG have been increasingly used as stand-alone operation for the morbidly obese patients due to its technical simplicity and short-term outcomes in weight loss (Lee 2007, Rubin 2008, Akkary 2008, Mellissas 2008, Keuper 2008, Kehagias 2011). Sleeve gastrectomy is a purely restrictive operation with no malabsorptive effects. It involves removing the fundus and greater curvature portion of the stomach leaving a narrow tubular stomach that is approximately the size and shape of a banana. It preserves the integrity of the pylorus and does not include intestinal bypass as part of the technique. The technique is simple, but some components of the surgery can result in serious complications if not performed correctly (Peterli 2009, Gill 2010, Brethauer 2011). There are several mechanisms contributing to the weight loss with SG; removing 80-90% of the stomach and leaving behind only a sleeve restricts the amount of the food that can be ingested and gives the sensation of fullness with minimal oral intake. Hormonal change represented by the decrease in the ghrelin level due to resection of the fundus may be another factor for the weight loss, as well as the accelerated gastric emptying, and the behavioral modification of the patients. The exact underlying mechanism is still unknown, and the long-term effects of the surgery are still under investigation (Rubin 2008, Akkary 2008, Moy 2008, Karamanakos 2008, Brethauer 2011). Sleeve gastrectomy has many potential advantages. Preservation of gastric function including the pylorus eliminates dumping, and being purely restrictive, SG does not result in malabsorption. Moreover, it can be performed laparoscopically (laparoscopic sleeve gastrectomy or LSG) even in the super-obese patients. SG does not require implantation of any artificial device or adjustments as the laparoscopic adjustable gastric band. It can also be performed in patients with disorders which preclude intestinal bypass e.g. anemia or Crohn's disease. However, the procedure is irreversible and has potential complications associated with the relatively long staple line such as bleeding and leakage. Leakage is the most concerning complication after SG and may result from the placement of the final staple line across the gastroesophageal junction or distal esophagus resulting in a staple line disruption. It may also result from mid-sleeve stenosis due to stenosis in the lumen or twisting or kinking of the sleeve at the incisura. Other reported complications associated with the sleeve gastrectomy include pulmonary embolism, subphrenic abscess, liver failure, stricture, wound infection, and need for reoperation. On the long-term, sleeve gastrectomy may potentially lead to gastroesophageal reflux disease due to an increase in the gastric pressure associated with the procedure (Moy 2008, Fuks 2009, Brethauer 2011). The First Report from the American College of Surgeons Bariatric Surgery Center Network indicates that obesity is a life-long disease, and thus short-term safety and efficacy of bariatric surgery should not be the deciding factor for selection of the procedure, and long-term follow-up beyond 1 year is needed; more importantly 5 years or longer. The report also notes that specifically longer term assessment of the sleeve gastrectomy is critical as the gastric pouch enlargement over time may limit its ultimate effectiveness (Hutter 2011).

#### **04/06/2009: MTAC REVIEW**

#### **Vertical Sleeve Gastrectomy (VSG)**

**Evidence Conclusion:** The evidence consists of two RCTs (Himpens et al 2006, and Karamanakos et al (2008), and several case series. Himpens and colleagues compared laparoscopic sleeve gastrectomy to gastric banding in 80 patients with a median BMI 38 kg/m<sup>2</sup> and Karamanakos and colleagues compared it with laparoscopic Roux-en-Y gastric bypass in 32 patients with mean BMI of 46 kg/m<sup>2</sup>. The longest follow-up duration reported was 3 years in Himpens's study. The two trials were randomized and controlled but had their limitations. The authors did not discuss specific inclusion criteria e.g. the BMI threshold and other characteristics. In addition there was no standardized technique for performing sleeve gastrectomy, no standardized size or design for the gastric sleeve, and no optimal dilator size to create the lesser curvature conduit. All these variables could affect weight loss and make it difficult to compare sleeve gastrectomy with other established bariatric procedure. Himpens and colleagues found that the weight loss after 1 and 3 years was more significant with sleeve gastrectomy vs. gastric banding. However, the late weight loss after the two procedures was insufficient; it ranged from 1 to 48 kg with sleeve (median 29.5 kg), and 0 to 40 kg with gastric banding (median 17 kg). The number of reported adverse events associated with sleeve gastrectomy was small. However, some events were severe and required re-operations as intraperitoneal bleed, ischemia of the sleeve, anastomosis leak, and insufficient weight loss. Other reported

complications of SG included pulmonary embolism, GERD, gastric erosion, gastric pain, vomiting, and others. Karamanakos and colleagues' trial showed no significant difference in the weight loss at 12 months between the two procedures. However, the study was too small, and had insufficient power to detect significant differences between the two study groups. In conclusion, there is insufficient published scientific literature to date to determine the long term efficacy, safety, and durability of the weight loss associated with sleeve gastrectomy procedure as a stand-alone treatment option for obese patients. There is also insufficient evidence to determine the optimum BMI threshold where SG would be recommended or encouraged.

**Articles:** The search yielded over 130 articles. Many were reviews and opinion pieces. There were three randomized controlled trials; one compared SG with adjustable gastric banding, another compared it with Roux-en-Y gastric bypass, and the third compared two different techniques for sleeve gastrectomy. There were also a number of case series with different population sizes and follow-up durations. Only four were relatively large with sample sizes over 100, one was conducted in the US and three were conducted overseas. The US series (Lee et al 2007) had the largest sample size, longest follow-up duration, and non-randomized comparison groups. The two RCTs that compared SG with alternative bariatric surgeries were selected for critical appraisal as well as the Lee et al's case series. The citations for the critically appraised studies are:

The use of Vertical Sleeve Gastrectomy for the treatment of obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

## 2/11/2013: MTAC REVIEW

### Vertical Sleeve Gastrectomy (VSG)

**Evidence Conclusion:** There is some evidence from very few small RCTs, and non-randomized prospective studies that laparoscopic sleeve gastrectomy performed as a stand-alone surgery, leads to short to mid-term significant weight loss, and improvement in comorbidities in obese patients. However, there is insufficient evidence to determine whether the weight loss and resolution of comorbidities will be sustained long-term. There is insufficient evidence to determine the long-term comparative effectiveness and safety of sleeve gastrectomy and Rou-en-Y gastric bypass or adjustable gastric banding for the treatment of obesity and obesity-related comorbidities. There is insufficient evidence to determine the long-term net health outcomes of laparoscopic sleeve gastrectomy. The studies that reported on long-term outcomes were small case series with no comparison or control group. Himpens and colleagues (2010) reported on the results of 6 years follow-up of 53 patients who underwent laparoscopic SG (different population from that in the RCT published by the same group of investigators in 2006). The results showed that after the sixth postoperative year weight gain was observed in 31 cases (75.6%). The mean BMI in this group of patients was  $39.9 \pm 5.9$  at baseline,  $26.6 \pm 4.3$  at 3 years, and  $31.1 \pm 6.2$  at 6 years. New gastroesophageal reflux symptoms were also reported after 6 years; 18% of the patients in the stand-alone SG group reported occasional vomiting, and 23% reported frequent episodes of GERD. In another follow-up of a case series, D'Hondt and colleagues (2012) also reported a trend towards decrease in weight loss by time (median % excess weight loss [EWL] was 78.5% at 12 months, 72% at 24 months, and 54.4% at 72 months). When % EWL above 50% was considered, the total success rate of SG was 92.9% at 1 year, 89.5%, 87%, 85.7%, 64.3% and 54.5% after 2, 3, 4, 5, and 6 years respectively. There is also insufficient evidence to establish criteria for patient selection or an optimum BMI threshold where SG is recommended or encouraged.

**Articles:** The search for studies published after the 2009 MTAC review revealed one RCT comparing laparoscopic sleeve gastrectomy versus laparoscopic Roux-en-Y gastric bypass in patients with BMI <50 kg/m<sup>2</sup>, another very small RCT that compared the effects of the two procedures on the glucose metabolism, two non-randomized prospective comparative studies, and one case control study that compared the outcomes of SG to one or more other bariatric surgery. The literature search also revealed one network meta-analysis and two systematic reviews without meta-analyses that evaluated the different procedures for bariatric surgery, as well as a number of prospective and retrospective case series with or without comparison groups.

The two RCTs and two prospective comparative studies were selected for critical appraisal. The network meta-analysis was not selected for further critical appraisal as it compared changes of BMI levels with different bariatric surgeries vs. standard care, and included only two earlier studies on SG. The following studies were critically appraised: Peterli R, Wölnerhanssen B, Peters T, et al. Improvement in glucose metabolism after bariatric surgery: comparison of laparoscopic Roux-en-Y gastric bypass and laparoscopic sleeve gastrectomy: a prospective randomized trial. *Ann Surg*. 2009;50:234-241. See [Evidence Table](#) Kehagias I, Karamankos SN,

Argentou M, et al. Randomized clinical trial of laparoscopic Roux-en-Y gastric bypass versus laparoscopic sleeve gastrectomy for the management of patients with BMI<50 kg/m2. *Obes Surg*. 2011;21:1650-1656. See [Evidence Table](#) Leyba JL, Aulestia N, Llopis SN. Laparoscopic Roux-en-Y gastric bypass versus laparoscopic sleeve gastrectomy for the treatment of morbid obesity. Laparoscopic sleeve gastrectomy versus laparoscopic adjustable gastric banding for the treatment severe obesity in high risk patients. *JLS* 2011;15:486-491. See [Evidence Table](#)

The use of Vertical Sleeve Gastrectomy for the treatment of obesity does meet the *Group Health Medical Technology Assessment Criteria*.

### **Laparoscopic Sleeve Gastrectomy as Initial Procedure in a Planned Two-Stage Operation for Patients with Severe Morbid Obesity**

#### **BACKGROUND**

Individuals with BMI >60 are considered to be “super obese.” Super obesity is associated with an increased risk of multiple health problems including arthritis, breathing problems, cancer, depression, diabetes, heart disease, hypertension, venous disorders and death. In addition, surgical treatment for obesity, such as a Roux-en-Y gastric bypass, is believed to be more dangerous in super obese than less obese patients, particularly for individuals who carry their weight in the belly area. Laparoscopic sleeve gastrectomy (LSG) is a bariatric procedure that involves the laparoscopic removal of 70-80% of the left side of the stomach. This results in a stomach that is approximately the size and shape of a banana. LSG is technically simpler than other bariatric procedures including gastric bypass surgery, since it does not require re-routing of the intestines. In addition, the procedure does not require implantation of any artificial device as with other obesity treatments such as the Lap-Band. LSG is most commonly used as the first stage in a two-stage procedure. Patients may be able to lose 80 or more pounds after an LSG, reducing their BMI to the point that a Roux-en-Y gastric bypass or biliopancreatic diversion with duodenal switch can be done more safely. The second operation is generally performed 8-12 months after the LSG. LSG is sometimes performed as a stand-alone procedure, but this application is not yet recognized by the American Society for Bariatric Surgery (ASDS). LSG has not been reviewed previously by MTAC.

#### **04/02/2007: MTAC REVIEW**

### **Laparoscopic Sleeve Gastrectomy as Initial Procedure in a Planned Two-Stage Operation for Patients with Severe Morbid Obesity**

**Evidence Conclusion:** There is insufficient evidence on the safety and efficacy of laparoscopic sleeve gastrectomy for obesity. Only case series were available; there are no randomized controlled trials or cohort studies. The case series were generally small, and the largest series (Cottam et al., 2006) was compromised by a low follow-up rate. Follow-up data 12 months after the stage-one LSG were available for fewer than half of the treated patients. Mean weight loss in 46% of patients with follow-up data was 45± 17%.

**Articles:** The search yielded 6 case series; all but one included fewer than 50 patients. The only published case series with a sample size of >100 patients was critically appraised for MTAC: Cottam D, Qureshi FG, Mattar G et al. Laparoscopic sleeve gastrectomy as an initial weight-loss procedure for high-risk patients with morbid obesity. *Surg Endosc* 2006; 20: 859-863.

The use of laparoscopic sleeve gastrectomy in the treatment of severe morbid obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Gastric Electrical Stimulator for Obesity**

#### **BACKGROUND**

Gastric electric stimulation is a new technique that has been proposed as a treatment for obesity. It involves the application of a small electrical current to the stomach through leads that are implanted in the muscular layer of the gastric wall. Although the exact mechanism of action is not fully understood, it is thought that electrical stimulation of the stomach wall can induce early satiety and reduce appetite. It may also have an effect on hormones related to satiety and/or appetite (Mizrahi 2012, Stamin 2012, Verdam 2012). Currently, no gastric electric stimulation devices are FDA approved for the treatment of obesity. This technology was previously reviewed by the Medical Technology Assessment Committee (MTAC) in 2001 for the treatment of chronic, intractable (drug refractory) nausea and vomiting secondary to gastroparesis of diabetic or idiopathic etiology. It did not meet MTAC criteria for this indication. It has not been previously reviewed for the treatment of obesity. It is being reviewed based on a request from Group Health Bariatric Surgery.

#### **2/11/2013: MTAC REVIEW**

### **Gastric Electrical Stimulator for Obesity**

**Evidence Conclusion:** A recent RCT that included 190 obese subjects evaluated the effects of gastric electric stimulation on weight loss. All patients underwent implantation with the gastric electric stimulator. Patients were instructed to consume a diet with a 500 k/cal per day deficit, and were required to attend monthly support group meetings. Patients in the treatment group had their devices activated. The devices for patients in the control group were kept inactive. After 12 months, there was no significant difference in the percent of excess weight lost between the treatment and the control group. The mean percent of excess weight loss was 11.7 in the treatment group and 11.8 in the control group (P=0.71). Adverse events included: endoscopy-detected gastric lumen lead penetration during the 2-lead implantation procedure (N=26), low battery between month 10 and month 12 (N=22), lead dislodgement (N=2), and pocket infection (N=1). There were no deaths or major complications. Medtronic/Transeurionix sponsored the study (Shikora 2009). An earlier study conducted by the same author also found no significant difference in the percent of excess weight loss between treatment (device on) and control (device off) subjects at 6 months; however, due to methodological limitations results from this study should be interpreted with caution (Shikora 2004). Conclusion: Evidence from a RCT suggests that there is no significant difference in the percent of excess weight lost between patients who received treatment with gastric electric stimulation plus a lifestyle intervention and patients who were treatment with lifestyle intervention alone.

**Articles:** The literature search revealed several small, case-series and two randomized controlled trials (RCTs) that evaluated the safety and efficacy of gastric electric stimulation for the treatment of obesity. The RCTs were selected for review. The following studies were selected for review: Shikora SA, Bergenstal R, Bessler M, et al. Implantable gastric stimulation for the treatment of clinically severe obesity: results of the SHAPE trial. *Surg Obes Relat Dis* 2009;5:31-7. See [Evidence Table](#) Shikora SA. "What are the yanks doing?" the U.S. experience with implantable gastric stimulation (IGS) for the treatment of obesity - update on the ongoing clinical trials. *Obes Surg* 2004;14 Suppl 1:S40-8. See [Evidence Table](#)

The use of Gastric Electric Stimulation for the Treatment of Obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Gastric Bypass for GERD**

### BACKGROUND

Obesity is a rapidly growing health problem in the United States and worldwide. According to the National Health and Nutrition Examination Survey (NHANES), more than one third of the adults and almost 17% of the youths in the US are obese defined as Body Mass Index [BMI] 30.0 kg/m<sup>2</sup> or higher. It is estimated that at least 5% of the total population are morbidly obese (i.e. with BMI >40 kg/m<sup>2</sup>). Obesity is associated with the development and /or aggravation of many chronic conditions including cardiovascular diseases, hypertension, type 2 diabetes mellitus, sleep apnea, some forms of cancer, depression, and osteoarthritis. Obesity may also be a predisposing factor for gastroesophageal reflux disease (GERD); obese patients are nearly three times as likely to experience GERD symptoms as those with normal BMI. However, researchers have found that the prevalence of GERD, even in the setting of severe obesity is <50%, which suggests that severe obesity itself is not sufficient to cause GERD. The mechanism by which obesity may increase gastroesophageal reflux is not fully understood, but several pathophysiologic mechanisms have been proposed to explain the association between the two conditions. Obese individuals may experience extrinsic gastric compression by surrounding adipose tissue leading to the increase in intragastric pressure and subsequent relaxation of the lower esophageal sphincter (LES), as well as anatomical disruption of the gastroesophageal junction. The latter may result in the formation of hiatal hernia which was found to be more prevalent in obese individuals than in those with normal weight (Ortega 2004, Nelson 2005, Duval 2006, Ogden 2012, Sturm 2007, Tai 2009, Prachand 2010, Flegal 2012).

The initial treatment of GERD symptoms involves lifestyle and dietary modification, which are often combined with acid inhibiting therapy. These generally alleviate GERD symptoms, but are usually unsuccessful in morbidly obese patients. If conservative measures fail, surgery is often considered as an alternative approach. Laparoscopic Nissen fundoplication has been the standard operation for these cases with medically refractory GERD. However, its use is controversial among obese patients due to conflicting results concerning its long-term effectiveness and sustainability. Fundoplication affects only the LES and lower gastroesophageal junction without addressing weight. Bariatric operations, which are intended primarily to induce weight loss in the morbidly obese, are considered as a potential alternative approach for treating GERD in obese patients. The success of these surgeries depends on the technique used. Restrictive techniques such as laparoscopic adjustable gastric banding and sleeve gastrectomy result in weight reduction by reducing the stomach volume leading to early satiety. However, some patients reported persistence or worsening acid reflux symptoms after these surgeries. Malabsorptive techniques such as jejunio-ileal bypass and biliopancreatic diversion result in weight reduction by functional shortening of the digestive tract and /or by diverting gastric juices. The Roux-en-Y gastric bypass (RYGB), a more technically complex operation, has both restrictive and malabsorptive properties and is described by some as a reliable procedure for treating severe GERD in obese individuals. It does not directly affect the cardio-esophageal competence, but may prevent GERD through weight loss and physically altering the anatomy of the

gastrointestinal tract and preventing acid reflux into the esophagus (Nelson 2005, El-Serag 2008, Ikramuddin 2008, De Groot 2009, Prachand 2010, Reavis 201).

## 2/11/2013: MTAC REVIEW

### Gastric Bypass for GERD

**Evidence Conclusion:** There is insufficient published evidence from randomized controlled trials to determine the comparative effectiveness and safety of Roux-en-Y gastric bypass (RYGB) surgery and Nissen fundoplication for the treatment of GERD in obese patients. The methodological quality of the published studies is low due to non-randomization of the patients, small population sizes, differences in definitions of obesity and evaluation of GERD symptoms, lack of objective outcome assessment, as well as other inherent limitations of observational studies. In a non-randomized trial, Braghetto and colleagues (2012) evaluated postoperative results after fundoplication, RYGB, or a combination of the two procedures for the treatment of 139 obese patients with GERD and Barrett's esophagus. The authors did not explain why and how they selected the patients for each operation, and patients were not equally distributed among the different procedures. They noted however, that those with BMI >35 kg/m<sup>2</sup> were selected for RYGB. Compared to the other two groups, patients in the RYGB had significantly higher BMI and weight. Patients underwent careful clinical assessment of symptoms and endoscopic/histological studies at baseline, and at 3-5 years after surgery. Manometric studies and 24-intra-esophageal pH studies were performed in all patients at baseline and among 116 (83%) after surgery. Overall the results of the study showed that the reflux symptoms and erosive esophagitis improved after all three surgeries compared to baseline. The improvement observed was significantly higher in the two approaches that included gastric bypass versus fundoplication alone. The gastric bypass surgery alone did not modify the lower esophageal sphincter (LES) pressure, but led to the highest reduction in body weight and BMI. In an earlier very small (N=12) study with data obtained from a prospectively maintained database, Patterson and colleagues (2003) also showed that laparoscopic Roux-en-Y gastric bypass and laparoscopic Nissen Fundoplication were both effective in treating heartburn symptoms and acid reflux in obese patients. The LES resting pressure increased significantly after the fundoplication but not after the RYGB surgeries. Results from a number of other case series show that RYGB resulted in weight loss, improvement of GERD symptoms, regression of esophagitis, and reduction of number of antireflux medications used in obese patients with GERD. The studies did not evaluate the effect of lifestyle and dietary habits of the patients after the surgery, and do not provide sufficient evidence to determine the long-term benefits of gastric bypass in these obese patients with GERD.

**Articles:** The literature search did not reveal any randomized controlled trial that compared gastric bypass surgery to other standard medical or surgical treatment for severe GERD in obese patients. There was one non-randomized prospective study that compared outcomes of three different laparoscopic procedures for the treatment of obese patients with GERD and Barrette's esophagus, a very small study that compared bypass surgery to fundoplication, and another small study that compared vertical banded gastroplasty vs. Roux-en-Y gastric bypass in patients with GERD and morbid obesity. Other published studies on bypass surgery for GERD were all case series with population sizes ranging from less than ten to just over 200 patients. The study that included fundoplication as a comparative surgery as well as 4 relatively large and/or more recent case series were selected for critical appraisal. Braghetto I, Korn O, Csendes A, et al. Laparoscopic treatment of obese patients with gastroesophageal reflux disease and Barrett's esophagus: a prospective study. *Obes Surg* 2012;22:764-772. The use of gastric bypass surgery for treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

## 06/20/2016: MTAC REVIEW

### Roux-en-Y Gastric Bypass (RYGB) Surgery for Obese Patients with Severe Gastroesophageal Reflux Disease (GERD)

**Evidence Conclusion:** The literature search did not identify any published randomized controlled trials to date, that compared gastric bypass surgery to Nissen fundoplication or other standard medical or endoscopic procedures used for the treatment of severe GERD in morbidly obese patients. The studies published after the last MTAC reviews were all case series, and retrospective analyses of registered data in a database with no control or comparison groups. Due to their inherent biases, particularly selection bias; and lack of control groups, case

series represent a level IV of evidence in the hierarchy of evidence. Case series cannot prove a cause and effect relationship, but may only generate hypotheses for future research. Overall, the results the published case series suggest that gastric bypass leads to significant weight loss in obese patients, and is associated with improvement in GERD symptoms, and/or reduction of number of antireflux medications used by obese patients with severe GERD. These series generally relied on subjective outcomes, did not evaluate the effect of confounding factors, lifestyle and dietary habits of the patients after the surgery, and do not provide sufficient evidence to determine the long-term durability of the observed outcomes. Madalosso and colleagues, 2016 (Evidence table 1), recently published 3-years results of a prospective case series to assess the impact of Roux-en-Y gastric bypass (RYGB) on gastroesophageal reflux disease (GERD) in morbidly obese patients. The study did not compare gastric bypass to Nissen fundoplication, sham procedure, or any other surgical or medical therapy. In addition, the 39 months follow-up data were available for only 53 of the 94 (56%) patients recruited. The authors compared the postoperative outcomes to the baseline values, and had the advantage of including objective measures. The overall results of the analysis suggest that RYGB surgery was associated with a significant weight loss, reduction in GERD symptoms, and decrease in esophageal acid exposure. These results have to be interpreted with caution due to the nature of the study, potential selection bias, confounding, lack of a control group, and high dropout rate. Dupree, et al (2014) retrospectively analyzed data from the Bariatric Outcomes Longitudinal Database (BOLD)\*, focusing on patients with pre-existing GERD. 33,876 patients underwent LRYGB, and 4,832 underwent LSG from 2007-2010. The results of the analysis showed that LRYGB was associated with complete resolution of GERD symptoms in 62.8% of the patients (symptoms were stable in 17.6% and worse in 2.2 %). For those who underwent LSG, 84.1% continued to have GERD symptoms, and 9.0% reported worsening of symptoms. Pallati and colleagues (2014) also used the same database (BOLD) to compare the efficacy of various bariatric procedures on the improvement of GERD symptoms, 36,938 patients out of 116,136 registered in the database from 2007–2009, had evidence of GERD before undergoing a bariatric surgery. After excluding patients undergoing concomitant hernia repair or fundoplication, 22,870 patients with 6 months follow-up were included in the analysis. 14,078 of these patients underwent RYGB, 8,207 LAGB, and 585 underwent LSG procedures. The analysis showed that GERD symptom score were significantly improved with the three surgeries, with the highest improvement reported with RYGB (56.5%) followed by AGB (46%) and SG (41%). Worsening of symptoms occurred in 2% of patients undergoing RYGB (4.6% with SG, and 1.2% with LAGB). The remainder of patients had no change in their GERD status. The study did not show any objective measure of GERD improvement. The results of Dupree et al and Pallati et al's analyses of data obtained from the Bariatric Outcomes Longitudinal Database should be interpreted cautiously. These were retrospective analyses influenced by the quality of the database and the extent of variables/patient characteristics it includes, such as alcohol consumption, cigarette smoking and other factors that have a potential impact on GERD. In addition, according to the authors the documented data on GERD was only based on the use of acid suppression medication with no objective data to confirm the gastroesophageal reflux e.g. 24-hour pH monitoring. Varban and colleagues (2015), retrospectively analyzed data from the Michigan Bariatric Surgery Collaborative (MBSC) registry to assess the use of acid-reducing medication (ARM) at one year after bariatric surgery in morbidly obese patients. Approximately 50% of the patients were reported to have GERD at baseline. 51% of those who underwent RYGB had GERD, and 40.6% of them were using an ARM at baseline, compared to 29.2% at 1-year after surgery. It was also reported that 19.2% of the patients not using ARM at baseline started using one after RYGB.

#### *Conclusion:*

- Due to the nature of the published studies, lack of comparison groups and objective outcome assessment, it is hard to determine whether the observed improvement of GERD symptoms were due to a direct effect of gastric bypass and reduction of abdominal pressure, or due to a placebo effect, masking of GERD by the change in diet after surgery, or undervaluation of the disease due to satisfaction with weight loss.
- There is insufficient published evidence to determine the comparative effectiveness and safety of gastric bypass surgery to Nissen fundoplication or other standard medical or endoscopic procedures used for the treatment of severe GERD in morbidly obese patients.
- There is insufficient published evidence to determine the long-term safety and efficacy of gastric bypass surgery in reducing GERD symptoms morbidly obese patients.
- There is insufficient published evidence to determine the effect gastric bypass surgery on the progression or regression of Barrett's esophagus in morbidly obese patients with GERD

**Articles:** The literature search did not reveal any randomized controlled trial that compared gastric bypass surgery to other standard medical or surgical treatment for severe GERD in obese patients with or without Barrett's esophagus. The empirical studies on gastric bypass surgery for patients with GERD were all observational studies that assessed the impact of RYGB on GERD in morbidly obese patients that underwent the surgery either as an initial operation or after a failed fundoplication surgery. The search also identified an analysis using a prospective database (Bariatric Outcomes Longitudinal Database) for patients who underwent bariatric surgery by a participant in the American Society of Metabolic and Bariatric surgery center of Excellence program; a recent meta-analysis that compared RYGB versus laparoscopic sleeve gastrectomy to treat morbid obesity-related comorbidities

including GERD; and a number case series on the role of RYGB for failed antireflux surgery. The use of bypass surgery for a failed fundoplication as well as the comparison of different bariatric surgeries were outside the scope of the current review. The largest observational study with the longer follow-up duration was selected for critical appraisal. Madalosso CA, Gurski RR, Callegari-Jacques SM, et al. The Impact of Gastric Bypass Gastroesophageal Reflux Disease in Morbidly Obese Patients. *Ann Surg.* 2016 Jan; 263(1):110-116. See [Evidence Table 1](#).

The use of Roux-en-Y Gastric Bypass (RYGB) Surgery for Obese Patients with Severe Gastroesophageal Reflux Disease (GERD) does not meet the *Group Health Medical Technology Assessment Criteria*.

### ***Intragastric balloons for the treatment of obesity or morbid obesity***

#### **BACKGROUND**

Obesity is a chronic disease that is strongly associated with numerous conditions including cardiovascular disease (heart failure, stroke, hypertension), diabetes mellitus, sleep apnea, cancers, osteoarthritis and disability [1]. The prevalence of obesity has been increasing and it is projected that, by the year of 2030, 20% of the world's adult population will be obese [1]. Obesity can be categorized based on body mass index (BMI). A body mass index (BMI) between 25 kg/m<sup>2</sup> and 29 kg/m<sup>2</sup> is considered overweight while obesity is defined as BMI greater than 30 kg/m<sup>2</sup> [1]. Moderate and morbid obesity are defined as BMI between 30 to 39.9 kg/m<sup>2</sup> and BMI >40 kg/m<sup>2</sup> respectively [2]. The cause of obesity is multifactorial [3]. First, the chronic imbalance between energy intake and energy expense leads to obesity. Second, interactions between genetic, behaviors, social and environmental factors play a crucial role in the pathogenesis of obesity[3].

Management of obesity includes conservative therapy such as diet modification, physical exercise, psychosocial interventions, pharmacotherapy such as orlistat and bariatric surgery[4]. A study investigating the effect of diet on weight loss [5] showed that hypocaloric diet and exercise alone led to a non-sustainable weight reduction (5%). Similarly, pharmacotherapy results in additional benefits. Bariatric surgery seems to be an alternative method for long term management [6] but can be associated with adverse events. Despite the benefits of these approaches, some patients might not be able to lose weight or sustain weight loss.

For patients who have failed weight reduction with diet and exercise alone, intragastric balloon (IGB) may be an alternative. Performed for the first time in 1980s [7], IGB is a minimally invasive procedure that diminishes the capacity of the stomach resulting in premature satiation and prolonged satiety and subsequently induces weight loss; Other mechanism resides in the regulation of hormone-mediated signal transduction [4, 8]. IGB insertion is a restrictive procedure in which a spherical, saline-filled balloon is endoscopically positioned in the stomach under mild sedation and left inflated for six months [9]. One or two balloons can be inserted and different fill volumes (400-700ml) and fill media have been described. These include air, fluid, combination of air and fluid. Some balloons can be swallowed and do not need to be endoscopically inserted.

Early designs were removed from the market due to severe complication such as migration resulting in intestinal obstruction but the introduction of the dual-balloon from ReShape Medical (San Clemente, CA) is believed to reduce the risks of obstruction and perforation. The ReShape Integrated Dual Balloon System (Reshape Dual Balloon) and ORBERA Intragastric Balloon System were approved by the Food and Drug Administration (FDA) in 2015.

#### **03/21/2016: MTAC REVIEW**

#### ***Intragastric balloons for the treatment of obesity or morbid obesity***

**Evidence Conclusion:** Zheng et al., 2015 [4]: Short-term effects of intragastric balloon in association with conservative therapy on weight loss: a meta-analysis (Evidence table 1) This meta-analysis aimed to confirm the safety and efficacy of intragastric balloon (IGB). The outcomes measured were weight loss, BMI, percent excess weight loss and safety. 11 RCTs were included after searching MEDLINE, EMBASE, CENTRAL plus other sources through December 2014. The quality of included studies was assessed and weighted mean differences were determined from the analysis. Modest efficacy for intragastric balloon as a conjunction therapy to conservative therapy was achieved in six months group (SMG). The incidences of the adverse events were higher in the intervention group (IGB plus conservative therapy). The authors concluded that short-term efficacy for 6 months treatment of intragastric balloon in association with conservative therapy is clinically significant. However, the findings should be interpreted with cautious due to several limitations. Ponce et al., 2015 [10] The REDUCE pivotal trial: a prospective, randomized controlled pivotal trial of a dual intragastric balloon for the treatment of obesity (Evidence table 2): This is a RCT, multicenter, sham controlled which aimed to investigate the safety and effectiveness of a dual balloon system plus diet and exercise in the treatment of obesity compared to diet and exercise alone. The study measured the percent excess weight loss (%EWL), the proportion of DUO patients

achieving at Least a 25% EWL as primary outcomes. 326 patients were randomized to dual gastric balloon plus diet and exercise (Duo) or Sham endoscopy plus diet and exercise (Diet) and followed up for 48 weeks. The %EWL was greater in Duo arm compared to Diet arm. The response rate among DUO was 48.8 in the intention to Treat (p<0.0001). Improvements in comorbid conditions were observed. The authors concluded that the reshape duo balloon had an excellent safety profile and was significantly more effective than diet and exercise. However, the results should be interpreted with cautious due to many limitations. Other small sample size RCTs [11-14] with short follow-up duration and meta-analysis [15], suggested that IGB may be safe and effective on the short term. Conclusion: The results indicate that intragastric balloon in combination with diet and exercise may have a short term effect in reducing weight in obese patients. The findings also indicate that intragastric balloon may be temporarily more effective than diet and exercise. However, the follow-up duration was insufficient to determine the safety and durability of the outcomes. There is insufficient data to determine whether intragastric balloon is safer and more effective than standard weight loss surgeries or pharmacotherapy. Intragastric balloon was reviewed by Interregional New Technology Committee (INTC) which concluded that “based on low-quality evidence of benefit as compared to conventional weight-loss management and lack of long-term evidence regarding safety and efficacy, it could not be concluded whether or not the benefit of intragastric balloon outweigh the harms at this time”.

**Articles:** The search identified a meta-analysis [4] and RCTs comparing IGB to diet and exercise and or sham balloon. However, the search did not identify RCTs making direct comparison between IGB and standard weight loss surgeries or pharmacotherapy. The following studies were selected for critical appraisal: Zheng, Y., M. Wang, et al. (2015). "Short-term effects of intragastric balloon in association with conservative therapy on weight loss: a meta-analysis." Journal of translational medicine 13(1): 1-9. [See Evidence Table 1](#). Ponce, J., G. Woodman, et al. (2015). "The REDUCE pivotal trial: a prospective, randomized controlled pivotal trial of a dual intragastric balloon for the treatment of obesity." Surgery for Obesity and Related Diseases 11(4): 874-881. [See Evidence Table 2](#).

## Clinical Review Criteria

### Eating Disorders – Anorexia Nervosa

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### Inpatient Care

Group Health has elected to use the MCG\* 20<sup>th</sup> Edition - Anorexia Nervosa: Inpatient Care (B-001-IP) for medical necessity determinations.

##### Partial Hospitalization

Group Health has elected to use the MCG\* 20<sup>th</sup> Edition - Anorexia Nervosa: Partial Hospitalization (B-GHC-001-PHP) for medical necessity determinations.

##### Intensive Outpatient

Group Health has elected to use the MCG\* 20<sup>th</sup> Edition - Anorexia Nervosa: Intensive Outpatient (B-GHC-001-IOP) for medical necessity determinations.

##### Acute Outpatient

Group Health has elected to use the MCG\* 20<sup>th</sup> Edition - Anorexia Nervosa: Acute Outpatient (B-001-AOP) for medical necessity determinations.

##### Residential Care

Group Health has elected to use the MCG\* 20<sup>th</sup> Edition - Anorexia Nervosa: Residential Care (B-GHC-001-RES) for medical necessity determinations.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed by our Behavioral Health department, you may request a copy of the criteria that is being used to make the coverage determination. Call the Behavioral Health unit for more information regarding the case under review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

In January 2006, Group Health adopted and integrated into its clinical review criteria, the MCG (formerly Milliman) Care Guidelines for determining appropriate levels of care based on symptoms and functional impairment. These criteria are independently developed and based on a review of the scientific literature, expert input, and clinical practice. In addition, the MCG Care Guidelines are updated yearly. Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning."

Inpatient anorexia nervosa services are provided or authorized with the overall goals of assessing and stabilizing the member's acute symptoms, in order that treatment can be continued effectively in a less restrictive and disruptive level of care. Under specific circumstances (e.g. initiation of ECT), the inpatient level of care may be required for safe administration of certain treatments.

Inpatient anorexia nervosa treatment is utilized when it is the most appropriate and effective level of care that can safely be provided for the member's immediate condition. Service authorization is based on the member's contract and the MCG Care Guidelines for inpatient mental health treatment. When treating children or adolescents, the parents or guardians must be included in both the evaluation and treatment planning processes, except for children age 13 or older who refuse to have a parental figure involved.

#### Definitions

##### Binge Eating

According to DSM 5:

An episode of binge eating is characterized by both of the following

1. Eating, in a discrete period of time (e.g. usually less than a 2-hour period), an amount of food that is definitely larger than what most people would eat in a similar period of time under similar circumstances.
2. A sense of lack of control over eating during the episode (e.g. a feeling that one cannot stop eating or control what or how much one is eating).

The binge-eating episodes are associated with 3 (or more) of the following:

1. Eating much more rapidly than normal
2. Eating until feeling uncomfortably full
3. Eating large amounts of food when not feeling physically hungry
4. Eating alone because of feeling embarrassed by how much one is eating.
5. Feeling disgusted with oneself, depressed, or very guilty afterward.

There is marked distress regarding binge eating.

The bingeing occurs, on average, at least once a week for 3 months, and is not associated with recurrent use of inappropriate compensatory behavior, and does not occur exclusively during the course of bulimia nervosa or anorexia nervosa.

##### Overeating

According to DSM 5 - In Overeating, there is a consumption of excess food, with no engagement in inappropriate compensatory behavior and no excessive concern with body shape and weight characteristics that are seen in bulimia nervosa.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

In January 2006, Group Health adopted and integrated into its clinical review criteria, the MCG (formerly Milliman) Care Guidelines for determining appropriate levels of care based on symptoms and functional impairment. #### Criteria

##### **Inpatient Behavioral Health Level of Care**

Group Health has elected to use the MCG\* Eating Disorder: Inpatient Behavioral Health Level of Care (B-GHC-904-IP) for medical necessity determinations.

##### **Partial Hospitalization**

Group Health has elected to use the MCG\* Eating Disorder: Partial Hospitalization (B-GHC-904-PHP) for medical necessity determinations.

##### **Intensive Outpatient**

Group Health has elected to use the MCG\* Eating Disorder: Intensive Outpatient (B-GHC-904-IOP) for medical necessity determinations.

##### **Acute Outpatient**

Group Health has elected to use the MCG\* Eating Disorder: Acute Outpatient (B-GHC-904-AOP) for medical necessity determinations.

##### **Residential Care**

Group Health has elected to use the MCG\* Eating Disorder: Residential Care (B-GHC-904-RES) for medical necessity determinations.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed by our Behavioral Health department, you may request a copy of the criteria that is being used to make the coverage determination. Call the Behavioral Health unit for more information regarding the case under review.

#### **Definitions**

##### **Binge Eating**

According to DSM 5:

An episode of binge eating is characterized by both of the following:

1. Eating, in a discrete period of time (e.g. usually less than a 2-hour period), an amount of food that is definitely larger than what most people would eat in a similar period of time under similar circumstances.
2. A sense of lack of control over eating during the episode (e.g. a feeling that one cannot stop eating or control what or how much one is eating).

The binge-eating episodes are associated with 3 (or more) of the following:

1. Eating much more rapidly than normal
2. Eating until feeling uncomfortably full
3. Eating large amounts of food when not feeling physically hungry
4. Eating alone because of feeling embarrassed by how much one is eating.
5. Feeling disgusted with oneself, depressed, or very guilty afterward.

There is marked distress regarding binge eating.

The bingeing occurs, on average, at least once a week for 3 months, and is not associated with recurrent use of inappropriate compensatory behavior, and does not occur exclusively during the course of bulimia nervosa or anorexia nervosa.

##### **Overeating**

According to DSM 5 - In Overeating, there is a consumption of excess food, with no engagement in inappropriate compensatory behavior and no excessive concern with body shape and weight characteristics that are seen in bulimia nervosa.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

In January 2006, Group Health adopted and integrated into its clinical review criteria, the MCG (formerly Milliman) Care Guidelines for determining appropriate levels of care based on symptoms and functional impairment. These criteria are independently developed and based on a review of the scientific literature, expert input, and clinical practice. In addition, the MCG Care Guidelines are updated yearly. Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning." Inpatient anorexia nervosa services are provided or authorized with the overall goals of assessing and stabilizing the member's acute symptoms, in order that treatment can be continued effectively in a less restrictive and disruptive level of care. Under specific circumstances (e.g. initiation of ECT), the inpatient level of care may be required for safe administration of certain treatments.

Inpatient anorexia nervosa treatment is utilized when it is the most appropriate and effective level of care that can safely be provided for the member's immediate condition. Service authorization is based on the member's contract and the MCG Care Guidelines for inpatient mental health treatment. When treating children or adolescents, the parents or guardians must be included in both the evaluation and treatment planning processes, except for children age 13 or older who refuse to have a parental figure involved.

CMS Coverage Manuals	<a href="#">Chapter 15 of the coverage manual, 80.2 - Psychological Tests and Neuropsychological Tests.</a>
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

Group Health has elected to use the MCG\* Neuropsychological Testing (B-805-T) for medical necessity determinations.

##### Exclusions

Neuropsychological testing will not be authorized for any of the exclusions found in the member's contract, including learning disabilities.

##### Computerized Neuropsychological Assessment Devices (CNAD)

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

##### **If requesting this service, please send the following documentation to support medical necessity:**

- Last 6 months of PCP or specialty notes that describe the members cognitive deficits

**\*The MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

In January 2007, Group Health adopted and integrated into its clinical review criteria, the MCG Care Guidelines for determining appropriate levels of care based on symptoms and functional impairment. Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning." The MCG Care Guidelines do not include any criteria regarding neuropsychological testing thus the need to develop these criteria. These criteria are based upon literature from the American Psychological Association as well as the Clinical Neuropsychological Society regarding standards for psychological testing.

#### Explanation to Differentiate Psychological and Neuropsychological Testing

Psychological tests assess a range of mental abilities and attributes, including achievement, personality, cognitive, and behavioral functioning. They are used to address a variety of questions about people's functioning, diagnostic classification, co-morbidity, and choice of treatment approach. For example, personality tests and inventories evaluate the thoughts, emotions, attitudes, and behavioral traits that contribute to an individual's interpersonal functioning. The results of these tests determine an individual's personality strengths and weaknesses, and may

identify certain disturbances in personality, or psychopathology. Basic assessment of memory and intellectual functioning is also part of psychological testing.

Psychological Testing is indicated in the following circumstances:

- Differential diagnosis of behavioral or psychiatric conditions when the member's history and symptomatology are not readily attributable to a particular psychiatric diagnosis and the questions to be answered by testing could not be resolved by a psychiatric/diagnostic interview, observation in therapy, or an assessment for level of care at a mental health or substance abuse facility; or
- Develop treatment recommendations after the member has been tried on various medications and/or psychotherapy, has not progressed in treatment, and continues to be symptomatic.
- A patient has had a recent mild traumatic brain injury (i.e. concussion) and a screening of his/her cognitive status is desired early on after the injury to answer more immediate questions about cognitive and emotional functioning as well as ability to return to accustomed life's activities at that time.
- There has been a recent change in patient's memory (i.e. within past six months) or changes in memory have been present for extended period of time and it is not significant or complex. Psychological testing can clarify /determine extent of memory and cognitive change and impact on functioning.
- Majority of Pre surgical evaluations (spinal cord stimulator, complex spine surgery, bariatric surgery)

### **Neuropsychological Testing**

Neuropsychological testing is a sub classification of psychological testing and is a well-established method for evaluating patients who demonstrate complex cognitive or behavioral abnormalities. Areas of brain functioning that are typically assessed are basic motor and sensory-perceptual functions; attention, concentration, speed and efficiency of information processing; learning and memory functions; language and verbal intellectual functions; spatial, perceptual and nonverbal intellectual functions; reasoning and complex problem solving functions; and executive regulatory and monitoring functions. A Neuropsychological evaluation is both a neuro-diagnostic procedure, as well as the most in-depth and comprehensive way of identifying in individual's cognitive strengths and limitations.

Neuropsychological testing is indicated when:

- There is the presence of a significant cognitive deficit, mental status abnormality, behavioral change, or memory loss that requires quantification, monitoring of change, diagnostic clarification, differentiation of cause (e.g., organic cognitive vs. psychiatric disease) and determination of the patient's ability to function.
- There is the presence of a known neurological disease or condition (i.e. dementia, CVA, traumatic brain injury, multiple sclerosis, Parkinson's, etc.) and testing is needed to determine the impact of the disease or condition on brain functioning and the patient's ability to function in his or her personal situation. Patients with mild traumatic brain injury (TBI) should not be referred prior to 3 months post injury as the majority of mild TBI patients recover essentially back to baseline over the initial 3 months post injury period.
- There is a medically complex, not well understood case with memory and cognitive deficits as significant presenting concerns and/or barriers to effective functioning.
- Further assessment of a patient with persisting cognitive symptoms or complaints is needed where a range of previous workups including but not limited to a Neurology consult, brain imaging, Mini-mental State Examination (MMSE), a previous Clinical Psychological evaluation and so forth have been negative or non-contributory.
- As part of pre and post procedure evaluation for deep brain stimulation procedure for Parkinson's Disease

### **Summary**

When to refer for psychological testing as compared to neuropsychological testing:

- If the primary concern is differential diagnosis (is it bipolar, is it psychosis, is there a personality disorder present), refer for psychological testing.
- Majority of pre surgical evaluation, refer for psychological testing.
- There is the presence of cognitive and/or memory concerns and it has not been present for extended period of time (i.e. greater than six months), and there is not the presence of other complicated medical conditions, refer for psychological testing.
- If cognitive, memory and behavioral concerns have been present for extended period of time, there are significant medical complications, and/or previous assessments (psychological evaluation, neurology

consult) have been unable to clarify diagnosis or functioning status of patient, refer for neuropsychological testing.

- Pre surgical evaluation for deep brain stimulation for Parkinson's Disease is referred for neuropsychological testing

#### Background

In January 2007, Group Health Cooperative's Behavioral Health Service adopted and integrated into its clinical review criteria, the MCG for determining appropriate levels of care based on symptoms and functional impairment. These criteria are independently developed and based on a review of the scientific literature, expert input, and clinical practice. In addition the MCG Criteria are updated annually.

Mental health partial hospital services are provided or authorized with the overall goals of assessing and improving the member's symptoms and function. Also Group Health Cooperative's Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning."

Partial hospitalization designates a structured, intensive, multidisciplinary treatment program that provides psychiatric, medical, and nursing care which meets the standards for licensure as a partial hospital program. The program is usually offered in an inpatient setting, but the patient goes home in the evening and on weekends. The program delivers a highly structured environment and 20 or more hours of treatment per week. Patients are expected to participate 5 to 7 days per week. Patient must be medically stable and live near treatment setting.

Service authorization decisions are also based on the member's contractually covered services and MCG Guidelines Behavioral Health criteria.

## Clinical Review Criteria

### Mental Health – Residential Care

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Must use the Medicare Benefit Policy Manual [Chapter 2](#) and [Chapter 4](#).

##### For Non-Medicare Members

These criteria apply to members whose contract includes coverage for residential care.

##### Medical Necessity Criteria for Coverage of Admission:

Inpatient Mental Health Residential Admission for a mental health clinical disorder is medically necessary when MCG\* Guidelines, current edition, Admission Guidelines for Residential Acute Behavioral Health Level of Care are met.

Residential Acute Behavioral Health Level of Care, Adult ORG: B-901-RES (BHG)

Residential Acute Behavioral Health Level of Care, Child or Adolescent ORG: B-902-RES (BHG)

##### Medical Necessity Criteria for Coverage of Continued Stay:

Continued Inpatient Mental Health Residential Stay for a mental health clinical disorder is medically necessary when MCG\* Guidelines, current edition, Continued Care Guidelines for Residential Acute Behavioral Health Level of Care are met.

Residential Acute Behavioral Health Level of Care, Adult ORG: B-901-RES (BHG)

Residential Acute Behavioral Health Level of Care, Child or Adolescent ORG: B-902-RES (BHG)

##### Exclusions:

Residential psychiatric services will not be authorized for any exclusion criteria referenced in a member's contract.

**\*The MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed by our Behavioral Health department, you may request a copy of the criteria that is being used to make the coverage determination. Call the Behavioral Health Unit for more information regarding the case under review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Residential care is intended for patients who need around-the-clock behavioral care but do not need the high level of physical security and frequency of psychiatric and nursing intervention that are available on an inpatient unit. Patients admitted to residential care are unlikely to need physical restraint or extensive nursing care. Psychiatrists typically round less often and nurses are generally on site for fewer hours each day than on an inpatient unit. However, the treatment team is generally composed of a similar mix of professionals as on an inpatient unit. Although it is sometimes assumed that residential care implies a longer length of stay than inpatient care, randomized controlled trials (RCTs) have shown that residential care is an efficacious short-term alternative to inpatient care for voluntary patients with urgent behavioral health conditions.

In January 2007, Group Health adopted and integrated into its clinical review criteria, the MCG Care Guidelines for determining appropriate levels of care based on symptoms and functional impairment. These criteria are independently developed and based on a review of the scientific literature, expert input, and clinical practice. In addition the MCG criteria are updated yearly. Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning."

Mental health, acute residential treatment is utilized when it is the most appropriate and effective level of care that can safely be provided for the member's immediate condition. Service authorization is based on the member's contract and the MCG Care Guidelines for mental health acute residential treatment, and with the overall goals of assessing and stabilizing the member's acute symptoms, in order that treatment can be continued effectively and safely in a less restrictive and disruptive level of care. When treating children or adolescents, the parents or guardians must be included in both the evaluation and treatment planning processes, except for children age 13 or older who refuse to have a parental figure involved.

#### For Non-Medicare Members

Group Health has elected to use the MCG\* 20<sup>th</sup> Edition - Psychological Testing (B-807-T) for medical necessity determinations.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed by our Behavioral Health department, you may request a copy of the criteria that is being used to make the coverage determination. Call the Behavioral Health unit for more information regarding the case under review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

In January 2007, Group Health adopted and integrated into its clinical review criteria, the MCG Care Guidelines for determining appropriate levels of care based on symptoms and functional impairment. Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning." The MCG Care Guidelines do not include any criteria regarding psychological testing thus the need to develop these criteria. These criteria are based upon literature from the American Psychological Association regarding standards for psychological testing.

#### Explanation to Differentiate Psychological and Neuropsychological Testing

##### Psychological Testing

Psychological tests assess a range of mental abilities and attributes, including achievement, personality, cognitive, and behavioral functioning. They are used to address a variety of questions about people's functioning, diagnostic classification, co-morbidity, and choice of treatment approach. For example, personality tests and inventories evaluate the thoughts, emotions, attitudes, and behavioral traits that contribute to an individual's interpersonal functioning. The results of these tests determine an individual's personality strengths and weaknesses, and may identify certain disturbances in personality, or psychopathology. Basic assessment of memory and intellectual functioning is also part of psychological testing.

Psychological Testing is indicated in the following circumstances:

- Differential diagnosis of behavioral or psychiatric conditions when the member's history and symptomatology are not readily attributable to a particular psychiatric diagnosis and the questions to be answered by testing could not be resolved by a psychiatric/diagnostic interview, observation in therapy, or an assessment for level of care at a mental health or substance abuse facility; or

- Develop treatment recommendations after the member has been tried on various medications and/or psychotherapy, has not progressed in treatment, and continues to be symptomatic.
- A patient has had a recent mild traumatic brain injury (i.e. concussion) and a screening of his/her cognitive status is desired early on after the injury to answer more immediate questions about cognitive and emotional functioning as well as ability to return to accustomed life's activities at that time.
- There has been a recent change in patient's memory (i.e. within past six months) or changes in memory have been present for extended period of time and it is not significant or complex. Psychological testing can clarify /determine extent of memory and cognitive change and impact on functioning.
- Majority of Pre surgical evaluations (spinal cord stimulator, complex spine surgery, bariatric surgery)

**Neuropsychological Testing**

Neuropsychological testing is a sub classification of psychological testing and is a well-established method for evaluating patients who demonstrate complex cognitive or behavioral abnormalities. Areas of brain functioning that are typically assessed are basic motor and sensory-perceptual functions; attention, concentration, speed and efficiency of information processing; learning and memory functions; language and verbal intellectual functions; spatial, perceptual and nonverbal intellectual functions; reasoning and complex problem solving functions; and executive regulatory and monitoring functions. A Neuropsychological evaluation is both a neuro-diagnostic procedure, as well as the most in-depth and comprehensive way of identifying in individual's cognitive strengths and limitations.

Neuropsychological testing is indicated when:

- There is the presence of a significant cognitive deficit, mental status abnormality, behavioral change, or memory loss that requires quantification, monitoring of change, diagnostic clarification, differentiation of cause (e.g., organic cognitive vs. psychiatric disease) and determination of the patient's ability to function.
- There is the presence of a known neurological disease or condition (i.e. dementia, CVA, traumatic brain injury, multiple sclerosis, Parkinson's, etc.) and testing is needed to determine the impact of the disease or condition on brain functioning and the patient's ability to function in his or her personal situation. Patients with mild traumatic brain injury (TBI) should not be referred prior to 3 months post injury as the majority of mild TBI patients recover essentially back to baseline over the initial 3 months post injury period.
- There is a medically complex, not well understood case with memory and cognitive deficits as significant presenting concerns and/or barriers to effective functioning.
- Further assessment of a patient with persisting cognitive symptoms or complaints is needed where a range of previous workups including but not limited to a Neurology consult, brain imaging, Mini-mental State Examination (MMSE), a previous Clinical Psychological evaluation and so forth have been negative or non-contributory.
- As part of pre and post procedure evaluation for deep brain stimulation procedure for Parkinson's Disease

**Summary**

When to refer for psychological testing as compared to neuropsychological testing:

- If the primary concern is differential diagnosis (is it bipolar, is it psychosis, is there a personality disorder present), refer for psychological testing.
- Majority of pre surgical evaluation, refer for psychological testing.
- There is the presence of cognitive and/or memory concerns and it has not been present for extended period of time (i.e. greater than six months), and there is not the presence of other complicated medical conditions, refer for psychological testing.
- If cognitive, memory and behavioral concerns have been present for extended period of time, there are significant medical complications, and/or previous assessments (psychological evaluation, neurology consult) have been unable to clarify diagnosis or functioning status of patient, refer for neuropsychological testing.
- Pre surgical evaluation for deep brain stimulation for Parkinson's Disease is referred for neuropsychological testing

## Clinical Review Criteria

### Biofeedback for Anxiety Disorders

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

National Coverage Determination (NCD)

[Biofeedback Therapy \(30.1\).](#)

[Biofeedback Therapy for the Treatment of Urinary Incontinence \(30.1.1\)](#)

##### For Non-Medicare Members

Biofeedback for fecal incontinence is considered medically necessary.

The following indications for biofeedback are not medically necessary. There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

- Abdominal pain, recurrent
- Anxiety disorders
- Arthritis
- Asthma
- Autism
- Back pain
- Bell's palsy
- Bruxism and sleep bruxism
- Cardiovascular disorders
- Chronic fatigue
- Chronic pain
- Chronic obstructive pulmonary disease (COPD)
- Depression
- Epilepsy
- Facial palsy
- Fibromyalgia
- Hand hemiplegia
- Headaches (e.g. migraine, tension, cluster headaches) Hypertension
- Insomnia
- Knee pain
- Low back pain
- Low vision
- Lupus [systemic lupus erythematosus (SLE)]
- Motor function after stroke, injury, or lower limb surgery
- Movement disorders
- Myalgia or muscle pain
- Neck pain
- Orthostatic hypotension in patients with a spinal cord injury
- Post-traumatic stress disorder (PTSD)
- Raynaud's disease
- Side effects of cancer chemotherapy
- Temporomandibular joint disorders
- Tinnitus

- Urinary disorders
- Post-prostatectomy urinary dysfunction
- Urinary incontinence in adults
- Urinary retention
- Vesicoureteral reflux
- Voiding dysfunction
- Vestibulodynia, vulvodynia, vulvar vestibulitis

### ***Biofeedback for the Treatment of Urinary Incontinence***

[See Treatment of Urinary Incontinence](#)

### ***Neurofeedback for ADHD (EEG Biofeedback)***

See the [neurofeedback criteria document](#)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## **Background**

Biofeedback is a technique designed to help individuals self-regulate certain physiological processes that are not normally considered to be under voluntary control or responses that are ordinarily easily regulated, but for which regulation has broken down due to trauma or disease. This is achieved through conveying audio and visual information about physiological processes such as blood pressure, heart rate, skin temperature, galvanic skin response (sweating), or muscle tension in real-time to raise awareness of physiological activities and train patients to control them. The goal of biofeedback is that eventually the patient will learn to control physiologic response without the aid of monitors (Kaiser 2011, Roditi 2011).

Different types of biofeedback include (Kaiser 2011, Magnusson 2008, Kapitza 2010):

- Electroencephalography (EEG) biofeedback, which monitors the activity of brain waves linked to different mental states.
- Electrocardiography (EKG) biofeedback, which tracks the patient's heart rate.
- Electromyography (EMG) biofeedback, which uses sensors to measure tension in specific muscles.
- Galvanic skin response biofeedback, which uses sensors to signal anxiety based on the activity of a person's sweat glands and the amount of perspiration on the skin.
- Skin temperature biofeedback, which involves attaching sensors to the fingers or feet to indicate stress when the temperature is low.
- Respiratory biofeedback, which uses sensors to measure breathing.
- Postural biofeedback, which uses sensors to measure body motion.

Biofeedback has been used to treat a variety of medical conditions such as urinary incontinence, ADHD, headaches, anxiety, and back pain.

## **Medical Technology Assessment Committee (MTAC)**

### ***Biofeedback for Anxiety Disorders***

**02/13/2012: MTAC REVIEW**

**Evidence Conclusion:** There is insufficient evidence to determine the safety and efficacy of biofeedback for the treatment of generalized anxiety disorders.

**Articles:** The literature search revealed several studies evaluating biofeedback for the treatment of generalized anxiety disorder. All of the studies had small sample sizes and the majority were published more than 20 years

ago. The newest study was a randomized controlled trial that evaluated the efficacy of a biofeedback enhanced virtual reality system. This study was not selected for review as the treatment group contained only 4 subjects (Gorini 2010). Conclusion: There is insufficient evidence to determine the safety and efficacy of biofeedback for the treatment of generalized anxiety disorders.

The use of biofeedback for anxiety disorders does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Biofeedback for Chronic Back Pain**

#### **02/13/2012: MTAC REVIEW**

**Evidence Conclusion:** The Kaiser review included four randomized controlled trials that ranged in size from 42 to 128 patients. Findings from these trials suggest that pain and disability improved with biofeedback, cognitive behavioral therapy (CBT), biofeedback plus CBT, placebo biofeedback, and rehabilitation; however, no significant differences were found between biofeedback and the other treatments. The body of evidence was limited by heterogeneity in the patient population, biofeedback protocols, and comparator treatments. Additionally, the studies were small with short follow-up periods. Biofeedback vs. CBT alone vs. waitlisted controls (Newton-John 1995) • N=44 • Type of biofeedback: Electromyography biofeedback (EMG). • Both the biofeedback and the CBT groups showed improvement in pain intensity, pain belief, and depression; however, there no significant differences between the two groups. There was no improvement in the waitlisted control group. Biofeedback plus CBT vs. CBT alone vs. waitlisted controls (Glombiewski 2010) • N=128 • Type of biofeedback: EMG • Both the combined group and the CBT alone group showed improvement in pain intensity compared to waitlisted control; however, there no significant differences between the two groups. Active biofeedback vs. placebo biofeedback (Kapitza 2010) • N=42 • Type of biofeedback: Respiratory biofeedback. • There was no significant difference in pain reduction between the two groups. Biofeedback plus rehabilitation vs. rehabilitation alone (Magnusson 2008) • N=47 • Type of biofeedback: Postural biofeedback. • Although the combined group showed improvements in pain, range of motion, and quality of life, the study did not report if they were statistically significantly different from the rehabilitation alone group. Conclusion: There is insufficient evidence to determine the safety and efficacy of biofeedback for the treatment of chronic back pain.

**Articles:** The 2007 American College of Physicians and the American Pain Society (ACP/APS) guideline evaluated the evidence on biofeedback for chronic back pain. The studies evaluating this treatment were of poor quality and therefore they were unable to evaluate the net benefits of biofeedback. The conclusions of the ACP/APS guideline were supported by a 2009 BMJ clinical © Group Health Cooperative. All Rights Reserved. evidence review (Chou 2009). In 2011, the Kaiser Permanente Medical Technology Assessment Team (MTAT) also reviewed biofeedback for the treatment of chronic back pain. No additional studies were identified after the Kaiser review. The following technology assessments were selected for review: Kaiser Permanente TPMG New Medical Technologies. Biofeedback for chronic neck and low back pain. May 2011.

The use of biofeedback for back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Biofeedback for Migraine and Tension Type Headaches**

#### **02/13/2012: MTAC Review**

**Evidence Conclusion:** A recent meta-analysis that included 94 RCTs and quasi-experimental studies evaluate the efficacy of different types of biofeedback for the treatment of migraine and tension-type headaches. Results from this analysis suggest that biofeedback was more effective than no treatment for headache reduction in patients with migraine headache (small effect size); however, there was no significant difference between biofeedback and placebo or relaxation. For patients with tension-type headache, biofeedback was significantly more effective than no treatment, placebo, and relaxation for headache reduction (small to medium effect size). There was no significant difference between biofeedback treatment modalities for the reduction of migraine headache pain (Nestouric 2008). A meta-analysis is only as good as the studies that it includes. The studies included in the meta-analysis had several limitations. • The majority of the studies included in the meta-analysis were small. The mean number of subjects per study was 40 for migraine studies and 45 for tension-type headache studies. • The type and number of sessions of biofeedback varied. • Several studies failed to describe basic treatment and patient characteristics. • Several studies used unstructured diagnostic systems. Conclusion: Migraine • Results from a recent meta-analysis suggest that biofeedback may be more effective than no treatment, but not placebo or relaxation for headache reduction. Tension-type headaches • Results from a recent meta-analysis suggest that biofeedback may be more effective than no treatment, placebo, and relaxation for headache reduction. • Another recent BMJ Clinical Evidence review found insufficient evidence to determine whether EMG biofeedback is effective for treating chronic tension-type headaches (Krishnan 2009).

**Articles:** Several meta-analyses and randomized controlled trials (RCTs) were identified that evaluated the efficacy of biofeedback for the treatment of migraine and tension-type headaches. The most recent meta-analysis was selected for review. A RCT published after the meta-analysis was also identified that evaluated the efficacy of

a pain program that included education and training in pain theory plus EMG and temperature biofeedback compared to the pain program alone. This study was not selected for review due to methodological limitations (i.e., small sample size, high loss to follow-up, power not addressed, and baseline characteristics were not presented) (Mullally 2009). The following study was selected for review: Nestoriuc Y, Martin A, Rief W, Andrasik F. Biofeedback treatment for headache disorders: a comprehensive efficacy review. *Appl Psychophysiol Biofeedback*. 2008;33:125-140. See [Evidence Table](#).

The use of biofeedback for Migraine and Tension-type Headaches does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Bioimpedance Spectroscopy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

##### Local Coverage Determination (LCD)

[Non-Covered Services \(L35008\)](#) And for facility-based services billed using a UB form, see [Non-Covered Services \(L34886\)](#)

##### For Non-Medicare Members

Group Health has elected to use the Bioimpedance Spectroscopy (A-0667) MCG\* for medical necessity determinations. This service is not covered per MCG guidelines.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Lymphedema is a chronic progressive disorder of the lymphatic system characterized by interstitial accumulation of protein rich fluid. This occurs when lymphatic transport is reduced causing lymphatic stasis and subsequent protein accumulation within tissues. Accumulation of protein and fluid in the tissues triggers an inflammatory response and swelling that eventually leads to fibrosis. Primary lymphedema is rare and results from congenital anatomic abnormalities of the lymphatic system such as lymphatic hypoplasia or dysfunction of lymphatic valves. Secondary lymphedema on the other hand, is more common and may result from disease, trauma, surgery, or radiation therapy. In the United States, the most common cause of secondary lymphedema is malignancy and its related treatment, particularly in breast cancer patients treated with axillary surgery and/or radiation therapy (Warren 2007).

The proportion of women who develop breast cancer-related lymphedema (BCRL) is estimated to range from 3-15% for women who had sentinel node biopsy and up to 49% among those who underwent axillary lymph node dissection. This big variation in reported incidence of lymphedema is due to lack of a standardized assessment and differences in diagnostic criteria. Lymphedema may cause limb swelling, heaviness, pain, pitting of the skin, tightness, inflammation, reduced mobility, and impaired limb function (Taylor 2006, Smoot 2011).

Accurate assessment of lymphedema may facilitate earlier diagnosis and monitoring of treatment response. Physical assessment of BCRL is performed by comparing the affected versus the unaffected arm, or by comparing postoperative with preoperative measurements. Physical measurements used include limb circumferential assessment with a tape measure, and limb volume measurement using water displacement or optoelectric perometry (also known as infrared volumetry). Circumferential measurement is the most common clinical assessment measure used. Limb circumference is used to

calculate volume by assuming either cylindrical or truncated cone geometry. It thus indirectly measures the limb volume, and may be confounded by changes in muscle and fat mass. In addition, it may be hard to use for the hand due to its irregular shape. Water volumetry or displacement, in which the limb is lowered in a water tank, has been considered by many as the reference method for determining limb volume. It is a reliable method and provides a way of including volumetric measurements of the hand or foot in the total limb volume measurements. However, water displacement cannot distinguish changes due to fat or muscle from extracellular fluid accumulation. The Perometer is an opto-electrical device that has a square frame in which the extended extremity is placed. The frame emits infrared light and slides up and down scanning the patient's extremity and recording cross sectional information every 3 mm. Limb volume is then calculated based on the assumption that the cross-section is an ellipse or circle. Many investigators consider perometry the modern gold standard for the assessment of limb volume. It is however, bulky in size, not available in most clinics, and cannot be used for bed-ridden patients. In more challenging cases radiologic imaging studies as lymphoscintigraphy, magnetic resonance imaging, or computerized tomography may be necessary to diagnose lymphedema (Sander 2002, Warren 2007, Jain 2010, Czerniec 2010, Smoot 2011).

While circumference and volume measures are reliable measures for changes in limb volume, they are not specific to lymphedema. Bioimpedance analysis (BIA) or bioimpedance spectroscopy (BIS) has been proposed as an alternate method to differentiate the extracellular fluid compartment from the total limb volume. It attempts at measuring lymph volume directly and detecting early increase in the extracellular fluid at a subclinical stage of lymphedema before it manifests as a change limb volume.

BIS is a noninvasive procedure that uses skin electrodes to pass a low level alternating current through the limb and measures the opposition or impedance to the flow of this current. Current flows along the path of least resistance through the body and thus follows tissues with the highest water content. Tissues as fat and bone act as insulators, while electrolyte body fluids conduct electrical current and as the fluid increases, impedance to current flow decreases, i.e. changes in impedance are inversely proportional to the volume of the extracellular fluid in the extremity. The level of impedance is not only a function of the type of tissue, but also the frequency of the current. At low frequencies, cell membranes are non-conductive and current passes only through the extracellular fluid, while at high frequencies, the current passes through cell membranes in addition to the extra- and intracellular fluids. BIS thus gives a measure of electrical impedance and not volume (Warren 2007, Jain 2010, Czerniec 2010).

## Medical Technology Assessment Committee (MTAC)

### **Bioimpedance Lymph Analysis**

#### **06/20/2011: MTAC REVIEW**

**Evidence Conclusion:** The 2010 report prepared for the AHRQ assessed the diagnosis and treatment of secondary lymphedema in general, not specifically for cancer breast-related lymphedema. However, the reviewers indicated that most of the diagnostic studies involved patients with breast cancer. They noted that based on the evidence from the studied reviewed, there does not appear to be a gold standard for grading or measuring the severity of lymphedema. However, based on the extent of use and consistent evidence for reliability and validity, the reviewers of the AHRQ report recommend that measures of limb volume or circumference be considered the gold standard for diagnosing secondary lymphedema. They indicated that there was very little evidence to allow making conclusions about the reliability of bioimpedance lymph analysis (BIA) which was listed among other tests. BIA was found to have good validity when compared with tape measured circumference or perometry, but lower correlation coefficients than those for the circumference- displacement comparisons. The AHRQ report also indicated that the diagnostic testing studies do not provide sufficient evidence to determine whether any of the test methods would influence the choice of lymphedema treatment or patient outcome. Two more recent studies published after the AHRQ report and critically appraised for this MTAC review do not provide any additional evidence on the accuracy, validity or reliability of BIA, or on its impact on patient management or outcome.

**Articles:** The search revealed a recent comprehensive review on the diagnosis and treatment of secondary lymphedema prepared for the Agency for Healthcare Research and Quality (AHRQ) Technology Assessment (TA) Program in May 2010. The literature search for this AHRQ report was made through January 2010. Two more recent studies that compared the accuracy and/or reliability of BIS to other physical measures used for the assessment of breast cancer-related lymphedema were critically appraised. [Czerniec SA](#), [Ward LC](#), [Refshauge KM](#), et al Assessment of breast cancer-related arm lymphedema--comparison of physical measurement methods and self-report. [Cancer Invest.](#)

2010;28:54-62. See [Evidence Table](#). Smoot BJ, Wong JF, Dodd MJ. Comparison of diagnostic accuracy of clinical measures of breast cancer-related lymphedema: Area under the curve. *Arch Phys Med Rehabil*. 2011;92:603-610. See [Evidence Table](#)

The use of bioimpedance lymph analysis does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Blepharoplasty

- Blepharoptosis
- Brow Lift

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	<a href="#">Blepharoplasty, Eyelid Surgery, and Brow Lift (L36286)</a> For cosmetic purposes See <a href="#">Non-Covered Services (L35008)</a> . And for facility-based services billed using a UB form, see <a href="#">Non-Covered Services (L34886)</a> .
Local Coverage Article	None

#### For Non-Medicare Members

Blepharoplasty or brow ptosis repair will be considered medically necessary when **ONE of the** following are met:

- I. **Blepharoplasty** is considered medically necessary and **NOT cosmetic when one of the following** is met:
  - A. Blepharoplasty for the following diagnoses may be considered medically necessary for an affected upper or lower lid without meeting visual loss criteria:
    1. Trichiasis
    2. Ectropion
    3. Entropion
  - B. In the absence of one of the conditions listed above unilateral or bilateral upper lid blepharoplasty or levator resection may be considered medically necessary for reconstructive purposes when the operative eye **meets ALL of the following** criteria:
    1. Visual field less than 20° above central fixation – (untaped eye) OR limited to 10 to 15 degrees (untapped eye) laterally
    2. MRD1 (marginal reflex distance from pupil center to upper eyelid) of 2 mm or less is required for the treatment of ptosis. Submission of MRD1 is not required for dermatochalasis
    3. Frontal or lateral photograph demonstrates visual field limitation consistent with the visual field examination, AND
    4. Does not have unstable myasthenia gravis or a thyroid condition
    5. **ALL of following** information must be submitted:
      - Visual fields, including physician interpretation
      - MRD1 (marginal reflex distance) measurement
      - Documentation of clinically decreased vision
      - Lateral and full face photographs
- II. **Brow ptosis repair** may be considered medically necessary for reconstructive purposes when the operative eye meets all of the following criteria:
  - A. Photographs demonstrate the eyebrow is below the super orbital rim
  - B. Visual field less than 20° above central fixation
  - C. MRD1 of 2 mm or less
  - D. Frontal or lateral photograph demonstrates visual field limitation consistent with the visual field examination, AND
  - E. Does not have unstable myasthenia gravis or a thyroid condition

- F. **ALL of following** information must be submitted:
- Visual fields, including physician interpretation
  - MRD1 (marginal reflex distance) measurement
  - Documentation of clinically decreased vision
  - Lateral and full face photographs
- III. **Blepharoplasty in anophthalmia** is considered medically necessary when
- A. The upper eyelid position interferes with the fit of eye prosthesis in the socket.
- IV. Blepharoplasty of the lower lids for excessive skin that does not correct a functional issue is considered **cosmetic** under the member benefit.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

This service is covered when it is medically indicated and determined not to be for cosmetic. The Medicare coverage language includes the identification of how to determine medical necessity. This is the language that has been adopted by Group Health.

In order to determine coverage, the clinical history submitted by the requesting physician should include the reason for the surgery and the identification of the procedure to be done.

Electric Bone Growth Stimulators (Non-invasive and Implantable)

Group Health has elected to use the Bone Growth Stimulators, Electrical and Electromagnetic (A-0565) MCG\* for medical necessity determinations.

Ultrasonic Bone Growth Stimulators

Group Health has elected to use the Bone Growth Stimulators, Ultrasonic (A-0414) MCG\* for medical necessity determinations.

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting these services, please send the following documentation to support medical necessity:**

- Last 6 months of clinical notes from requesting provider &/or specialist (Orthopedics/podiatry )
- Copies of last 12 months of x-rays of involved area

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Electrical stimulation has been used as treatment for nonunion of fractures since the early 1950's with a reported success rate of 80-85%. New devices have made the use of this method of treatment more attractive. Bone Stimulators are covered in Group Health plans that include coverage for durable medical equipment. The criteria for coverage had previously been part of the Durable Medical Equipment Formulary. The average contracted cost of the device is \$3,000. Because of the renewed attention on this mode of treatment by Group Health orthopedists, the referral management staff requested that clearer criteria be developed for reviewing coverage requests (1/97).

Fracture healing is a highly complex biological process. The healing process is delayed in approximately 10% of the 6 million fractures that occur annually in the United States. A portion of these delayed unions do not heal by 9 months after fracture and are categorized as non-unions (Hadjiargyrou, 1998). There are two types of bone growth stimulators: electric and ultrasonic.

Electrical stimulation has been found to offer a reasonable means of treatment for nonunion that have failed to respond to previous bone grafting over an extended period of time. The effective use of electrical stimulation devices requires an understanding of the various principles and concepts employed by the four types of stimulators currently available. While the exact mechanism of electrically-induced osteogenesis is uncertain, current theories indicate that several factors probably are involved and more than one mechanism may be responsible.

Ultrasound, a form of mechanical energy that is transmitted through and into biological tissues, has a variety of diagnostic and therapeutic clinical applications. Research on the use of ultrasound to accelerate the healing of fractures has been done largely using animal models. For example, a study with rabbits found that bones exposed to ultrasound healed in about half the time as untreated bones. Data from animal models suggest that ultrasound may accelerate healing by increasing the blood flow at the fracture site (Rubin, 2001).

Exogen (Smith and Nephew) manufactures a low-intensity ultrasound device for treating fractures, Sonic Accelerated Fracture Healing System (SAFHS). According to the manufacture, the SAFHS system is a portable, battery-operated device that produces ultrasonic waves of 30 milliwatts per cm<sup>2</sup> (comparable to ultrasound intensity levels used on sonograms for fetal monitoring). Patients apply the ultrasound waves directly to the fracture site.

The FDA approved the use of low-intensity ultrasound for fresh fractures in 1994 based on two randomized controlled trials and Exogen's registry data. In 2000, the FDA extended the use of ultrasound to treating established non-unions.

## Medical Technology Assessment Committee (MTAC)

### Ultrasonic Bone Stimulator

#### 10/10/2001: MTAC REVIEW

**Evidence Conclusion:** *Fresh fractures:* Two of the RCTs (Heckman, Kristiansen) were conducted by some of the same investigators. Both found a significantly shorter time to healing for fractures in patients treated with an ultrasonic bone stimulator healed than those treated with a placebo device. Both studies had similar methodological flaws, the most serious of which was that neither study had a primary intention to treat analysis and about 30% of fractures were not included in the analysis. Both studies include a brief description of a secondary intention-to-treat analysis which found statistically significant differences between the ultrasonic bone stimulation and placebo groups; no point estimates, tables or figures were included to support these analyses. Both studies were funded by Exogen and included co-authored by an Exogen employee which could bias the study design and analysis. A third RCT was conducted by investigators without financial ties to Exogen. That study did not find a significant difference in time to radiographic healing between patients receiving ultrasonic bone stimulation versus placebo. This was a small study which may not have had sufficient statistical power to detect a difference if one existed. The threats to validity in the RCTs limit the ability to draw conclusions about the effect of ultrasonic bone stimulation on health outcomes among patients with fresh fractures. *Non-union fractures:* There were no published articles to evaluate the efficacy of ultrasound treatment to heal non-union fractures.

**Articles:** The search yielded 35 articles. Articles that were opinion pieces, editorials, reviews or on technical aspects of the treatment of fractures with ultrasound were not reviewed. There were 3 RCTs on the use of ultrasound with fresh fractures. Evidence tables were created for these 3 RCTs. There were no published articles on non-union fractures. There was one published abstract by Gebauer, but insufficient information was given in the abstract to evaluate it as evidence. *Citations for the RCTs reviewed:* Emami A, Petren-Mallmin M, Larsson S. No effect of low-intensity ultrasound on healing time of intramedullary fixed tibial fractures. J Orthop Trauma 1999; 13: 252-7. See [Evidence Table](#). Kristiansen TK, Ryabi JP, McCabe J, Frey JJ, Roe LR. Accelerated healing of distal radial fractures with the use of specific, low-intensity ultrasound. J Bone Joint Surg 1997; 79-A: 961-73. See [Evidence Table](#). Heckman JD, Ryabi JP, McCabe J, Frey JJ, Kilcoyne RF. Acceleration of tibial fracture-healing by non-invasive low-intensity pulsed ultrasound. J Bone Joint Surg 1994; 76-A: 26-34. See [Evidence Table](#)

The use of Ultrasonic Bone Stimulator for treatment of fresh and non-union fractures has been approved by the FDA and therefore meets *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

###### 1) Breast Cancer

Brachytherapy as an adjunct to whole breast radiation is covered when recommended by the treating practitioner. Patients eligible for brachytherapy as a sole treatment alternative to whole breast radiation therapy must meet **ALL of the following** criteria:

- a) Age  $\geq$  50
- b) Diagnosis of unifocal invasive ductal cancer
- c) Tumor size  $\leq$  3cm
- d) Negative surgical margins at 2mm
- e) Negative nodal status
- f) Does not have **ONE of the following**: lobular disease, DCIS, EIC, anatomic limitations, or angiolymphatic space invasion.

###### 2) High-Dose Rate Brachytherapy for Prostate Cancer

- a) High-dose rate (temporary seed implantation) prostate brachytherapy may be considered medically necessary under the following conditions:
  - When combined with external beam radiation as a "boost" or
  - When used for early stage prostate disease as monotherapy.

#### **Standard brachytherapy is covered without medical necessity review for:**

Coronary Artery Brachytherapy, Intravascular Coronary Brachytherapy  
 Endobronchial Brachytherapy - Lung Cancer  
 High-Dose or Low-Dose Brachytherapy for Cervical and Endometrial Cancer  
 Prostate Cancer

Procedure	Criteria
AccuBoost peripheral breast brachytherapy	There is insufficient evidence in the published medical

Radioactive Seeds for Treatment of Recurrent High-Grade Glioblastoma

literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Brachytherapy, also called internal radiation therapy, allows a physician to use a higher total dose of radiation to treat a smaller area and in a shorter time than is possible with external radiation treatment. Brachytherapy involves placing a radioactive material directly inside or next to the tumor. It has been proven to be very effective and safe, providing a good alternative to surgical removal of the prostate, breast, and cervix, while reducing the risk of certain long-term side effects.

There are two types of brachytherapy – temporary and permanent. In temporary brachytherapy, the radioactive material is placed inside or near a tumor for a specific amount of time and then withdrawn. Temporary brachytherapy can be administered at a low-dose rate (LDR) or high-dose rate (HDR).

Permanent brachytherapy, also called seed implantation, involves placing radioactive seeds or pellets (about the size of a grain of rice) in or near the tumor and leaving them there permanently. After several weeks or months, the radioactivity level of the implants eventually diminishes to nothing. The inactive seeds then remain in the body, with no lasting effect on the patient.

## Medical Technology Assessment Committee (MTAC)

### ***Breast Cancer Brachytherapy***

#### BACKGROUND

In the last two decades, the treatment of early-stage breast cancer has shifted from radical mastectomy to breast conserving therapy (BCT). This involves lumpectomy followed by whole breast external beam radiotherapy (WBRT). Several large randomized controlled trials with long-term follow-up showed that BCT has equivalent survival rates to the modified radical mastectomy among patients with early stage breast cancer. In addition, BCT has better cosmesis and less psychological and emotional trauma for women compared to mastectomy.

Researchers believe that whole breast irradiation after lumpectomy reduces local breast recurrence by eliminating residual cancer at the surgical site, as well as occult areas of in-situ or infiltrating cancer in remote areas in the breast. The use of BCT is underutilized in the United States mainly due to the long course of conventional whole-breast radiation therapy, which is typically delivered daily 5 days per week for 5 to 7 weeks. This may be a problem for working women, elderly patients, or those living at a considerable distance from a treatment center. WBRT may also delay or be delayed by the initiation of systemic adjuvant chemotherapy. Investigators also found that treating the entire volume of the breast may deliver small radiation doses to the adjacent tissues leading to acute and chronic toxicity to the skin, heart, lung, and contralateral breast (Fisher 1995, 2002, Baglan 2001, Veronesi 2002, Chen 2007, Cuttino 2007). Recently, accelerated partial breast radiation therapy (APBI) has been proposed as an alternative approach to WBRT. APBI involves the treatment of the lumpectomy bed plus a 1-2 cm margin of breast tissue. This is based on the assumption that the microscopic tumor rarely extends 2 cm beyond the initial resection cavity when the margins are negative on final pathologic examination. Reducing the target allows the delivery of APBI and completing the treatment in less than one week. Several methods for delivering APBI were proposed and/or used. These approaches include multicatheter interstitial brachytherapy, balloon catheter brachytherapy, 3-D CRT (conformal radiation therapy) and intraoperative radiation therapy. These techniques are widely different in terms of radiation delivery, degree of invasiveness, length of treatment, and acceptance by radiation oncologists (Chen 2007, Chao 2007). Breast brachytherapy involves the placement of radioactive sources inside the breast to deliver a relatively high dose of radiation to the tissue immediately surrounding the lumpectomy site, and very little dose to the surrounding normal structure. The interstitial

multicatheter system, the most common method used, involves the placement of a number of catheters into the breast to guide the radioactive materials to the intended area. Pellets of iridium-192 are then inserted into the catheters over the course of the treatment. The catheters are briefly connected to a dose-rate brachytherapy machine for internal radiation treatment, which takes about ten minutes each. After the course of treatment is completed the catheters are removed. The procedure requires significant technical expertise, and can be difficult and challenging (Chen 2007, Bovi 2007, Haley 2008, Kacso 2008). Balloon-based brachytherapy Several balloon-based brachytherapy devices were developed as an alternative to the interstitial multicatheter system to be more user-friendly to the clinician and more accessible and better tolerated by the patient. The MammoSite brachytherapy (MSB) system (Hologic, Marlborough, MA) was the first developed balloon-based brachytherapy device. It consists of a small balloon connected to an inflation channel and a catheter for the passage of a high dose rate brachytherapy dose (Iridium-192 [192Ir]). The device is implanted in the lumpectomy cavity during or following breast surgery. The balloon is inflated with sterile saline containing a small amount of radiographic contrast to a size that completely fills the cavity and ensures conformance of the tissue to the balloon. A computed tomography scan is obtained to assess the balloon conformance to the lumpectomy cavity and determine its symmetry, diameter, distance from skin, planning target volume, and the dose distribution. After treatment is completed in several days, the balloon is deflated and the catheter is removed. The treatment with the MammoSite device generally delivers 34 Gy in 10 fractions (3.4 Gy /fraction twice daily with a minimum of 6 hours between the fractions on the same day). Investigators recommend the system for patients with ductal carcinoma in situ, invasive ductal carcinoma, and primary tumors with a diameter less than 3cm. It may not be suitable for patients with small breast or for tumors located in the upper inner quadrant because of the requirement for skin-to-cavity distances (Bensaleh 2009, Njeh 2010). Xofigo (Xofigo, Inc., Fremont, CA) electronic brachytherapy is a modified form of balloon-based brachytherapy. Similar to MammoSite, Xofigo consists of a balloon catheter that is percutaneously inserted into the lumpectomy cavity. The system uses 50 kiloVolt (kV) X-ray source (an electronic radiation source) rather than radioisotope, such as iridium-192 high dose rate (HDR) source. The x-ray source consists of a miniature x-ray tube that is inserted in the balloon catheter and delivers the radiation therapy to the patient. The system may be operated at variable currents and voltages to change the dose rate and penetration properties. The Xofigo does not require a high-dose rate afterloader unit, or treatment in a shielded vault. Another potential advantage is the lower energy dose deposited in adjacent normal tissues, compared to other forms of balloon brachytherapy. It is unknown if these advantages would be outweighed by a potential harm of fat necrosis as a result of a significant dose inhomogeneity (Strauss 2009, Dickler 2009). SenoRx Contura device (SenoRx, Inc, Aliso Viejo, CA) differs from MammoSite in that it has multiple lumens for passage of 192Ir HDR source. In addition to the central lumen, the Contura balloon has 4 surrounding channels to accommodate the HDR source. The surrounding channels have 5 mm offset around the central channel. The approach provides additional flexibility, and has the potential of improving normal tissue sparing. The device includes a port which can be connected to suction to remove seroma fluid or air in an effort to improve conformity (Strauss 2009, Njeh 2010). Image guided radiation therapy: AccuBoost peripheral breast brachytherapy The AccuBoost® peripheral breast brachytherapy system (Advanced Radiation Therapy of Billerica, MA) was developed to provide a means of delivering partial breast irradiation treatment regimen noninvasively under mammographic image guidance. The AccuBoost system consists of three main components: (1) A conventional mammography unit to immobilize the breast and localize the lumpectomy site. (2) Computed Radiography (CR) system to provide radiographic images of the lumpectomy cavity (and/or implanted fiducial markers) for cavity/ margin localization at the beginning of each fraction. The CR system can also record the exit dose distribution and provide information on the therapeutic dose. (3) AccuBoost Applicators: high dose rate (HDR) Ir192 brachytherapy source remote afterloading system to deliver brachytherapy in a peripheral noninvasive manner. The applicators are made from tungsten in the form of half-cylinders. The patient's breast is compressed to a thickness of 3-8 cm between two mammography paddles and imaged with a radiopaque coordinate grid. The radiation oncologist determines the isocenter coordinates and appropriate applicator size and shape based on the image. The collimating HDR 192Ir brachytherapy applicators are then applied on either side of the breast along a common axis and the brachytherapy dose delivered. The process is repeated along an orthogonal axis to distribute the entrance dose (Rivard 2009, Yang 2009, AccuBoost website). MammoSite, multi-lumen MammoSite, Xofigo Electronic brachytherapy, and SenoRx Contura device are all FDA approved to deliver intracavity radiation to the surgical margins following lumpectomy for breast cancer. AccuBoost® system for delivering guided radiation therapy is also FDA approved.

## **06/12/2002: MTAC REVIEW**

### **Breast Cancer Brachytherapy**

**Evidence Conclusion:** The studies reviewed aimed at determining the equivalence between brachytherapy and external beam radiation, yet none of them was designed or analyzed in a fashion to study equivalence, which is a major threat to their validity. The authors set no equivalence boundary but took the lack of statistically significant difference between the two treatments as a proof of equivalence, which could lead to an erroneous judgment.

Moreover, the studies were prospective, with a historical control group. The patients were not randomly assigned to the treatment group, and it is not discussed if they were consecutive, which may be a source of selection bias. The cohorts of women treated with brachytherapy were prospectively followed for a variable period of time (median 36 months in Vicini's study, and 74 months in King's study). The follow-up period was as short as a few months among some patients, and the dropout rate in the brachytherapy group was 82% after 5 years in Vicini's study. The reason for this high dropout rate was not discussed. In the two studies, data on the control group were obtained from retrospective chart reviews. Patients in the brachytherapy group received the treatment at either a low- or high-dose rate, but were analyzed as one group. There were some differences in the baseline characteristics that were not adjusted for in the analysis of the results. The overall control and cosmetic outcomes of the brachytherapy as a sole treatment after lumpectomy were similar to that achieved by the external beam radiation therapy. However, these results cannot be generalized mainly due to the design of the study as well as the selection, observation and other biases in the studies. Randomized controlled studies with large sample size, power, and longer follow-up periods are needed to determine the long-term benefits and harms of brachytherapy used as a sole treatment after breast conservative therapy.

**Articles:** The search yielded 81 articles. Many were review articles, opinion pieces, or addressed brachytherapy as a boost, not a sole treatment after lumpectomy. The literature did not include any randomized controlled trials, or meta-analyses. There was a number of small case series with no control group, and two prospective studies that compared brachytherapy with external beam irradiation. These two studies were selected for critical appraisal. Vicini FA, Baglan KL, Kestin KL, et al. Accelerated treatment of breast cancer. *J Clin Oncol* 2001;19:1993-2001. See [Evidence Table](#). King TA, Bolton JS, Kuske RR, et al. Long-term results of wide field brachytherapy as the sole method of radiation therapy after segmental mastectomy for T<sub>is, 1, 2</sub> breast cancer. *Am J Surg* 2000;180:299-304. See [Evidence Table](#).

The use of brachytherapy in the treatment of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## 02/07/2005: MTAC REVIEW

### Breast Cancer Brachytherapy

**Evidence Conclusion:** Brachytherapy as an adjunct or boost to whole breast radiation therapy:

The two randomized controlled trials reviewed (Polgar 2002, and Poortmans 2004) evaluated brachytherapy for early stage breast cancer with no or limited spread to the axillary lymph nodes. Both trials compared boost to no boost therapy after breast conserving surgery and whole breast external radiation therapy. Different techniques for the boost therapy were used (brachytherapy and electrons in Polgar's trial, and electrons, photon beams, and interstitial brachytherapy in Poortman's trial). The trials were not blinded, and the patients were randomized to boost or no boost treatment, but were not randomized to the different boost techniques used. The latter was selected according to the physicians' preference. Poortman et al's trial was still ongoing, and in this publication the authors did not present a comparison between boost and no boost treatments, but compared the outcomes of the different boost techniques used. Polgar et al reported a significant improvement with the boost vs. no boost treatment. The analysis provided however does not indicate that there was a statistically significant improvement as reported by the authors. The boost treatment was also found to be associated with an increased incidence of moderate to severe complications. Brachytherapy as a sole treatment alternative to whole breast radiation therapy. Vicini 2003, and Polgar 2004 were prospective cohort studies with a comparison group. Patients however, were not randomly assigned to the treatment groups but matched to historical controls from the records or databases. The criteria used to assess the effect of the treatment included the degree of local control, disease free, relapse-free, and cancer free survival, as well as cosmetic outcome, and side effects. These two studies aimed at determining the similarity between brachytherapy and external beam radiation, yet none of them was designed or analyzed in a fashion to study equivalence, which is a major threat to their validity. The authors set no equivalence boundary but took the lack of statistically significant difference between the two treatments as a proof of equivalence, which could lead to an erroneous judgment. In conclusion, interstitial brachytherapy may be a promising treatment but the studies reviewed do not provided sufficient evidence to conclude that it may be used as an alternative to whole breast radiation therapy after breast conserving surgery. Randomized controlled studies with large sample size, power, and longer follow-up periods are underway to determine the long-term benefits and harms of brachytherapy used as a sole treatment after breast conservative therapy.

**Articles:** The search revealed more than 200 articles. Many were reviews, editorials, or dealt with the technical aspects of the technology. There were several case series, retrospective studies, and small trials. Others compared mastectomy with external beam radiation therapy, and in one trial brachytherapy was compared to WBRT without breast lumpectomy. Studies were selected for review according to the following criteria: 1. Evaluating brachytherapy as an adjunct to whole breast radiation therapy or as a sole treatment after breast-conserving surgery, 2. Prospective design, and 3. Including a comparison or control group. Two large RCTs on the use of brachytherapy as a boost to WBRT were identified and critically appraised. Several studies on the use of brachytherapy as an alternative to WBRT were published after MTAC reviewed the technology in 2002. All

evaluated brachytherapy for early stage breast cancer with no or limited spread to axillary lymph nodes. Harms et al (2002), Keisch et al (2003), Perera et al (2003), Richard et al (2004), and Shah et al (2004) studies were case series with no control or comparison groups. These studies mainly evaluated the safety of the treatment rather than efficacy. Only two of the identified studies (Vicini 2003 and Polgar 2004) included a comparison group and were selected for critical appraisal. *Evidence tables were created for the following studies: For the use of brachytherapy as an adjunct to whole breast radiation therapy: Polgar C, Fodor J, Orosz Z, et al. Electron and high dose-rate brachytherapy boost in the conservative treatment of stage I-II breast cancer. First results of the Randomized Budapest Boost Trial. *Strahlenther Onkol* 2002;178:1205-1211. See [Evidence Table](#) Poortmans P, Bartelink H, Horiot JC, et al. The influence of the boost technique on local control in breast conserving treatment in the EORTC “boost versus no boost randomized trial. *Radiother Oncol* 2004;72:25-33. See [Evidence Table](#) For the use of brachytherapy as a sole treatment alternative to whole breast radiation therapy: Vicini F, Kestin L, Chen P, et al. Limited field radiation therapy in the management of early-stage breast cancer. *J Natl Cancer Inst* 2003;95:1205-1211. See [Evidence Table](#) Polgar C, Major T, Fodor J, et al. High dose-rate brachytherapy alone versus whole breast radiotherapy with or without tumor bed boost after breast conserving surgery: seven-year results of a comparative study. *Int J Radiat Oncol* 2004;60:1173-1181 See [Evidence Table](#)*

The use of brachytherapy as an adjunct or boost to whole breast radiation therapy in the treatment of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

The use of brachytherapy as a sole treatment alternative to whole breast radiation therapy in the treatment of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## **08/15/2011: MTAC REVIEW**

### **Breast Cancer Brachytherapy**

**Evidence Conclusion:** There is insufficient evidence to date to determine whether accelerated partial breast irradiation delivered by balloon-based brachytherapy or AccuBoost is safe and provides non-inferior or superior local tumor control and survival compared to conventional whole breast irradiation in patients with early stage breast cancer treated with breast conservative therapy. Polgar and colleagues' (2008) RCT, reviewed earlier, and Antonucci et al's study (evidence table 1) had several methodological flaws which limit generalization of their results. Large RCTs with long-term follow-up are needed to determine the equivalence or superiority of accelerated partial breast irradiation therapy to whole breast external beam radiation therapy. A phase 3 trial comparing APBI to whole breast irradiation in over 4,000 women with stage 0, I, or II breast cancer is underway. The trial is jointly conducted by the National Surgical Adjuvant breast and Bowel Project (NSABP) and the Radiation Therapy Oncology Group (RTOG). Patients in the APBI will be treated using one of three modalities: interstitial brachytherapy, MammoSite brachytherapy, or 3-D conformal EBRT. Outcome measures include overall survival, recurrence free survival, distant disease-free survival, toxicity, cosmesis, and convenience of the care. The primary aim of the trial is determining whether APBI would provide equivalent local breast control as WBRT in early stage breast cancer. Other ongoing trials include the Canadian RAPID trial which is recruiting over 2000 patients to be randomized to either whole breast irradiation or 3-D CRT, and an international phase III large trial supported by the European Brachytherapy Breast Cancer GEC-ESTRO Working Group. This trial will randomize 1170 women between WBRT and APBI using high-dose rate or pulsed-dose rate brachytherapy. The results of these, and a number of other ongoing trials, will provide data on the efficacy and toxicity of partial breast irradiation in the treatment of early stage breast cancer as compared to WBRT. They may also provide data on appropriate candidates for APBI and on the advantages and disadvantages of each method.

**Articles:** Objectives: To determine whether accelerated partial breast irradiation leads to non-inferior or superior local tumor control and survival compared to conventional whole breast irradiation, when used as an adjuvant therapy after lumpectomy in patients with early stage breast cancer. To determine whether the use of balloon-based brachytherapy systems is safe and effective for delivering adjuvant radiation therapy after lumpectomy in patients with early stage breast cancer. To determine whether the image guided radiation therapy using AccuBoost peripheral breast brachytherapy system is safe and effective for delivering adjuvant radiation therapy after lumpectomy in patients with early stage breast cancer.

Screening of articles/selection: The search revealed around 150 articles on accelerated partial breast irradiation (APBI). The majority of the published empirical studies were phase I/II trials with no comparison group, different sizes, and follow-up durations. There were no new randomized trials, published after the last review, on APBI therapy delivered by MammoSite, Axxent, Contura, or AccuBoost systems. The search identified a recently published interim analysis on the acute toxicity in a trial that compared conventional whole breast radiation with APBI plus IMRT, a nonrandomized study that examined the dosimetric advantage of Contura catheter vs. MammoSite, and a small case series of patients treated with Contura catheter. The literature search also revealed a report on four-year outcomes of a prospective

study, with no control group, on the efficacy and toxicity of 3-D-CRT to deliver APBI, and a feasibility study with 11 patients treated with intraoperative radiation using the Axxent electronic brachytherapy system. No published clinical studies on AccuBoost system were identified. A recent analysis comparing APBI with WBRT was critically appraised. See [Evidence Table](#). Antonucci JV, Wallace M, Goldstein NS, et al. Differences in patterns of failure in patients treated with accelerated partial breast irradiation versus whole-breast irradiation: a matched-pair analysis with 10-year follow-up. *Int J Radiat Oncol Biol Phys*. 2009;74:447-452. See [Evidence Table](#).

The use of brachytherapy as an adjunct or boost to whole breast radiation therapy in the treatment of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Coronary Artery Brachytherapy Intravascular Coronary Brachytherapy**

#### **BACKGROUND**

Percutaneous transluminal coronary angioplasty (PTCA) is a widely used therapy for obstructive coronary artery disease. It is limited however by the high rate of restenosis which occurs in 30-60% of patients after a successful PTCA. The main mechanisms of restenosis include elastic recoil of the vessel, rapid platelet deposition, vascular remodeling and neointimal hyperplasia. Endovascular stents have been shown to reduce stenosis by preventing the elastic recoil and pathological remodeling. However, stents do not prevent the restenosis caused by neointimal hyperplasia, but rather initiate an inflammatory reaction that induces more proliferation than other coronary devices. An effective treatment of restenosis within the stent will be the suppression of this neointimal hyperplasia. Radiation therapy which is known for its antiproliferative effect has been proposed as a treatment for in-stent restenosis. Over the past six years, studies on the use of various techniques to apply intracoronary radiation which is known as intracoronary brachytherapy have been showing encouraging results. Brachytherapy uses a relatively large localized dose of beta or gamma radiation. It does not provide an immediate outcome. If effective, it reduces the rate of restenosis in the vessel in the target area. This effect can be measured by angiograms performed six months after the procedure. Brachytherapy requires a multidisciplinary team to deliver it including an interventionalist cardiologist, a radiation oncologist, physicist and safety officer.

#### **06/13/2001: MTAC REVIEW**

### **Coronary Artery Brachytherapy Intravascular Coronary Brachytherapy**

**Evidence Conclusion:** GAMMA-One (Leon et al), beta-WRIST (Waksman et al), SCRIPPS (Teirstein et al), and the START (In press) trials are four of the well-designed RCTs evaluating the use of brachytherapy in the management of in-stent restenosis. There are several other ongoing studies. These trials showed that patients with in-stent restenosis treated with brachytherapy needed less revascularization than those treated with PTCA or PTCA and stents without radiation. In two of the studies, intracoronary brachytherapy tended to increase the risk of late thrombus formation, but this was statistically insignificant. Although these trials reported that major cardiac events (MACE) were lower among patients who received brachytherapy, none of them had adequate power, or follow-up to detect the difference in myocardial infarction and death rates alone. Brachytherapy may also cause acute damage in the coronary arteries including aneurysm, pseudoaneurysm, arterial dissection, or rupture of the artery. None of these acute complications was reported in any of these trials. In addition, radiation may lead to a long-term damage on the surrounding tissue, and have adverse effects on the clinical personnel. These long-term complications are unknown. The longest data available is the three-year follow-up in the SCRIPP trial (Teirstein et al). The nature of radiation needs a long-term follow-up.

**Articles:** The search yielded 79 articles. Many were just reviews and literature. There were eleven articles on randomized controlled studies, more than one publication for each of the major trials, GAMMA-one, beta-WRIST and SCRIPPS. The START trial was still in press. These major randomized controlled studies were evaluated in detail. *Evidence tables were created for the following studies:* Leon MB, Teirstein PS, Moses JW, et al. Localized Intracoronary Gamma-Radiation Therapy to Inhibit the Recurrence of Restenosis After Stenting. *N Engl J Med* 2001; 344: 250-256 See [Evidence Table](#) Teirstein PS, Massulo V, Jani S, Popma JJ, et al. Three-Year Clinical and Angiographic Follow-up After Intracoronary Radiation. *Circulation* 2000; 101: 360-365. See [Evidence Table](#) Waksman R, White L, Chan RC, et al. Intracoronary Gamma -Radiation Therapy After Angioplasty Inhibits Recurrence In Patients With In-Stent Restenosis. *Circulation* 2000; 101: 2165-2171 See [Evidence Table](#) The use of Coronary Artery Brachytherapy for the treatment of restenosis of stent passes all *Group Health Medical Technology Assessment Criteria*.

### **Endobronchial Brachytherapy - Lung Cancer**

#### **BACKGROUND**

Among all types of malignancy, lung cancer is one of the most difficult to manage, and is associated with the highest mortality rate. Its incidence is continuously increasing, with no improvement in mortality. 80-85% of the cases is non-small cell lung cancer (NSCLC). Squamous cell carcinoma and adenocarcinoma account for the majority of the NSCLC. Regardless of the histological type, surgery offers the best potential for cure. However,

approximately 75% of the patients present with locally advanced non-resectable disease at the time of diagnosis. The treatment options for these patients are chemotherapy and / or external irradiation therapy, which have low survival rates, and high rates of local recurrence. Endobronchial brachytherapy (EBT or EBB) is an additional treatment increasingly used for centrally localized lung cancer. It can be used alone, or with the external radiation therapy (XRT) to boost the total dose of irradiation used. In earlier studies, it was used as a palliative treatment in case of endobronchial recurrence after XRT. In later studies it is used in combination with high-dose of XRT as a potential curative primary treatment in selected cases. With brachytherapy, radioactive sources usually iridium-192 are placed at the tumor site in the involved branch of the tracheobronchial tree. These will deliver a radiation dose that rapidly and progressively declines with the increasing distance from the source. Any adverse effects on normal tissue should be confined to the immediate vicinity of the bronchus, sparing the lung parenchyma and the esophagus. The procedure is done on outpatient basis. Bronchoscopy is performed under topical anesthesia to determine the field of treatment. A guidewire is then placed in the instrumentation channel of the endoscope, and the bronchoscope is removed. An after-loading catheter is passed on the guidewire, the guidewire is removed, and an applicator for placement of the radiation source is inserted in the catheter. Depending on the number of airway branches involved, 1 to 4 catheters may be placed. The position of the catheter is verified by fluoroscopy. The applicator is then connected to the iridium-192 afterloading unit and the irradiation source advanced to the intended position under computer control. The application time ranges from 2 to 15 minutes depending on the dose, and length of the irradiated area. After removing the radioactive source, the catheters are removed, and the patient is observed for 30 minutes. High-dose brachytherapy may be delivered in fractionated doses by repeating the procedure at weekly or biweekly intervals, or twice a day until the entire dose is delivered. The dose varies individually and depends on the patient's clinical condition, history, and concurrent use of XRT. Endobronchial brachytherapy may be associated with acute complications. It could lead to fibrotic airway obstruction and may be linked to fatal hemoptysis depending on the dose, dose per fraction and the concurrent use of XRT.

#### **08/08/2001: MTAC REVIEW**

##### **Endobronchial Brachytherapy - Lung Cancer**

**Evidence Conclusion:** The RCTs reviewed were conducted to evaluate the effect of endobronchial brachytherapy either used alone, or in addition to external radiation therapy. Langendijk's study found a statistically significant benefit of adding EBT to XRT in treating atelectasis in patients with endobronchial obstruction in the main bronchus. Huber's study did not show any statistical difference between the two treatments. On the other hand, Stout's study found that external irradiation therapy, had a statistically significant better outcome than EBT (used alone) on the patients' survival and palliation of some symptoms. EBT was not found to be associated with a higher rate of fatal hemoptysis in all three trials. The studies had some limitations including likelihood of observation bias, incomplete data (all three RCTs), premature termination and lack of power (Langendijk). In conclusion, the efficacy and safety of endobronchial brachytherapy cannot be fully determined from the available evidence.

**Articles:** The search yielded 54 articles. Selection was based on study type. There were 3 articles on randomized control trials comparing the effect of external irradiation therapy (XRT) vs. endobronchial brachytherapy (EBT) / XRT + EBT, on patients with non-small cell lung cancer. Reviews, editorials and comments were reviewed, but no evidence tables were created. *The three RCTs selected for critical appraisal were:*

Huber RM, Fischer R, Hautmann H, et al. Does Additional Brachytherapy Improve the Effect of External Irradiation? A Prospective, Randomized Study in Central Lung Tumors. *Int.J.Radiation Oncology Biol. Phys.* 1997; 38 (3): 533-540. See [Evidence Table](#) Langendijk H, Jong JD, Tjwa M, et al. External Irradiation Plus Endobronchial Brachytherapy in Inoperable Non-small Cell Lung Cancer: a Prospective Study. *Radiotherapy and Oncology* 2001; 58: 257-268 See [Evidence Table](#) Stout R, Barber P, Burt P, et al. Clinical and Quality of Life Outcomes in the First United Kingdom Randomized Trial of Endobronchial Brachytherapy Treatment of Inoperable non-small Cell Lung Cancer. *Radiotherapy and Oncology* 2000; 56: 323-327 See [Evidence Table](#)

The use of endobronchial brachytherapy in the treatment of lung cancer does not meet the *Group Health Medical Technology Assessment Criteria 2* for effectiveness.

##### **High-Dose Rate Brachytherapy for Prostate Cancer**

###### **BACKGROUND**

Prostate cancer is one of the most common cancers, and the second leading cause of cancer death in men in the United States. The standard management options for localized disease included surgery, radiotherapy, and watchful waiting. However, the optimal treatment is not well defined. Both surgery and radiation therapy are reported to have equivalent outcomes, and each approach has its advantages and disadvantages. Researchers reported that for intermediate and high risk disease, external beam radiation therapy (EBRT) is the standard treatment, and that there is a dose response for biochemical relapse-free survival. However, dose escalation to >70 Gy is associated with an increase in genitourinary and gastrointestinal side effects. Several techniques have been developed to deliver high doses of radiation to the prostate while sparing surrounding normal tissue. Among

these are the three dimensional conformal radiotherapy (3DCRT), intensity modulated radiation therapy (IMRT), photon therapy, and brachytherapy (Vordermark 2006, Hoskin 2007, Rades 2007). Prostate brachytherapy was introduced in the late 1980s after the development of transrectal ultrasonography and sophisticated treatment planning software. It can be performed as monotherapy or in conjunction with hormone therapy or EBRT. Monotherapy is usually reserved for low-risk cancer, and the combined therapies are used for high-risk disease (Nelson 2007). Interstitial brachytherapy can be delivered using permanent low-dose-rate (LDR) seed implants or temporary high-dose-rate (HDR) implants. The latter entails the temporary placement of higher energy radioactive sources in and near the tumor. An automated machine called an afterloader sequentially moves a high-intensity radioactive source to and from a set of catheters in and around the prostate to deliver a pre-determined radiation dose to the patient's tumor. Following treatment, the radioactive source is withdrawn. Both LDR and HDR have the advantage of conforming high doses of radiation according to the precisely localized target, rapid dose fall-off, and no target movement during treatment. The dose distribution of the LDR mainly depends on the position of the implanted seed, while the HDR uses a steeping source, usually iridium-192, and is thus able to vary both the position and /or dwell time of the source. This has the potential of better target volume coverage and a greater sparing of neighboring organs at risk (Chin 2006). Unlike LDR brachytherapy, HDR brachytherapy usually requires hospitalization of the patient. HDR brachytherapy is also associated with a number of acute and chronic side effects, including urinary urgency and frequency, dysuria, nocturia, urinary retention, urethral stricture, rectal irritation, and impotence.

#### **06/06/2006: MTAC REVIEW**

##### **High-Dose Rate Brachytherapy for Prostate Cancer**

**Evidence Conclusion:** There is insufficient evidence to draw conclusions about the effectiveness and safety of HDR brachytherapy monotherapy compared to an accepted treatment for prostate cancer.

There is some evidence that HDR brachytherapy plus EBRT results in better biochemical control than EBRT alone. Data are from 2 comparative studies, one randomized and one non-randomized; both studies have threats to validity. There is insufficient evidence to determine whether HDR brachytherapy added to EBRT improves disease-specific or overall survival. In the randomized controlled trial, there was no significant increase in overall survival with HDR brachytherapy plus EBRT; data were not reported for disease-specific mortality. In the non-randomized study, there was not a significant difference in disease-specific mortality. Overall survival was significantly higher in the combined treatment group when 5-year outcomes were modeled using Kaplan-Meier analysis—actual patient data on survival were not reported .

There is insufficient evidence on adverse effects associated with HDR brachytherapy plus EBRT. In the RCT, rates of adverse effects did not differ significantly between groups—however, these comparisons were likely underpowered. In the cohort study, adverse effects were only reported for the HDR brachytherapy plus EBRT group; 29% of patients developed impotence.

**Articles:** Note: Studies were identified using N California report but selection of articles for critical appraisal was re-done for the MTAC report. *HDR brachytherapy monotherapy:* There were no randomized controlled trials or non-randomized controlled trials that compared the safety and effectiveness of HDR brachytherapy monotherapy to a different treatment such as observation, surgery or EBRT. All of the studies were case series. Two publications from a single institution compared series of patients who received either HDR brachytherapy or LDR brachytherapy (Vargas et al., 2005 ; Grills et al., 2004 ). No studies were selected for critical appraisal since none compared HRD brachytherapy to another treatment for prostate cancer. *Combination therapy (HRD brachytherapy plus EBRT):* There was one randomized controlled trial comparing HRD brachytherapy plus EBRT to EBRT alone. There were also two nonrandomized comparison studies and nine case series. One of the non-randomized comparative studies (Jo et al., 2005 ) was a survey that only reported on quality of life, not clinical outcomes and thus this study was excluded from further review. The RCT (Sathya et al., 2005) and the other non-randomized comparison study (Kestin et al., 2000) were critically appraised. *The studies reviewed were:* Sathya JR, Davis IR, Julian JA et al. Randomized trial comparing iridium implant plus external-beam radiation therapy with external-beam radiation therapy alone in node-negative locally advanced cancer of the prostate. J Clin Oncol 2005; 23: 1192-1199. See [Evidence Table](#) Kestin LL, Martinez AA, Stromberg JS et al. Matched-pair analysis of conformal high-dose-rate brachytherapy boost versus external-beam radiation therapy alone for locally advanced prostate cancer. J Clin Oncol 2000; 18: 2869-2880. See [Evidence Table](#)

The use of High-dose rate brachytherapy in the treatment of prostate cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **10/01/2007: MTAC REVIEW**

##### **High-Dose Rate Brachytherapy for Prostate Cancer**

**Evidence Conclusion:** High-dose rate (HDR) brachytherapy for prostate cancer was previously reviewed by MTAC on 6/5/06. The report conclusion indicated that there was insufficient evidence to determine the

effectiveness and safety of HDR brachytherapy monotherapy compared to an accepted treatment for prostate cancer. For the current review, the literature search revealed one more recent RCT conducted in the UK (Hoskin 2007), that compared external-beam radiation therapy (EBRT) given as a monotherapy vs. its combination with high-dose rate brachytherapy boost for the treatment of prostate cancer. The primary outcome was biochemical relapse free survival. The secondary outcomes were the overall and relapse-free survival, acute and late toxicity, and quality of life. The study had its advantages and limitations. It was randomized, controlled, had sufficient statistical power, high completeness rate, and analysis was based on intention to treat. However, the authors did not discuss blinding of the investigators to the patient allocation, the 55 Gy dose of external beam radiotherapy is considered suboptimal, and the technique of delivering the EBRT changed along the study. Moreover, the follow-up duration was relatively short and the primary outcome was biochemical relapse free survival which is a surrogate outcome for overall survival. It is considered acceptable by some investigators, due to the long natural history of the disease. Overall, the results of the trial indicate that the biochemical relapse-free survival was significantly higher among patients in the HDR brachytherapy in combination with external beam radiotherapy group versus those treated with external beam radiotherapy alone. The HDR brachytherapy was also associated with an improved quality of life, without any increase in toxicity. Soumarova and colleagues (2007) compared the acute genitourinary and gastrointestinal toxicity in 97 patients treated with external beam radiotherapy (3D conformal radiotherapy [CRT]) or 3D CRT combined with interstitial conformal HDR brachytherapy for the treatment of histologically verified localized carcinoma of the prostate. The study was prospective but non-randomized: 57 patients received 3D CRT and 40 patients were irradiated with 3D CRT+ HDR brachytherapy. The patients were followed by a radiation oncologist and urologist at 1-3 months intervals, and the acute genitourinary and gastrointestinal toxicities were evaluated using the RTOG criteria. The overall results of the study showed a lower incidence of acute gastrointestinal toxicity in HDR brachytherapy combination therapy group versus those in the 3D CRT monotherapy group. In conclusion the studies published to date do not provide sufficient evidence to determine the efficacy and safety of HDR brachytherapy in the treatment of histologically proven carcinoma of the prostate.

**Articles:** *HDR brachytherapy monotherapy:* The literature search did not reveal any randomized controlled trials or non-randomized controlled trials that compared the safety and effectiveness of HDR brachytherapy monotherapy to no, or a different mode of treatment as surgery or EBRT. All published studies on monotherapeutic brachytherapy for organ confined or locally advanced prostate cancer, were case series with variable sizes and duration of follow-up. None included a comparison or control group and thus were not critically appraised. *HDR brachytherapy in combination with external beam radiotherapy (EBRT):* There was one recent randomized controlled trial (Hoskin 2007) that compared HDR brachytherapy plus EBRT to EBRT alone, and a non-randomized controlled trial (Soumarova 2007) that compared the acute toxicity of EBRT with and without HDR brachytherapy, as well as several case series. The two studies were reviewed, Hoskin and colleagues RCT was presented in an evidence table.

Hoskin PJ, Motohashi K, Bownes P, et al. High dose rate brachytherapy in combination with external beam radiotherapy in the radical treatment of prostate cancer: initial results of a randomized phase three trial. *Radiother Oncol* 2007; May 24. See [Evidence Table](#)

The use of High-dose rate brachytherapy in the treatment of prostate cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## 10/18/2010: MTAC REVIEW

### High-Dose Rate Brachytherapy for Prostate Cancer

**Evidence Conclusion:** HDR brachytherapy as a monotherapy A recent retrospective cohort study combined data from two centers to evaluate the safety and efficacy of HDR brachytherapy compared to LDR brachytherapy for the treatment of prostate cancer. The primary outcome measures were biochemical control and rate of acute and chronic toxicities. There was no significant difference in biochemical control rates between the HDR brachytherapy and the LDR brachytherapy groups (88% vs. 89%, P=0.62). However, compared to patients treated with LDR brachytherapy, patients treated with HDR brachytherapy experienced significantly lower rates of acute and chronic dysuria, acute urinary frequency and urgency, and acute rectal pain. Results from this study should be interpreted with caution as there was no adjustment for confounding factors, treatment techniques evolved over the study period, the two centers had different treatment procedures, and approximately 29% of patients received neoadjuvant androgen deprivation (Martinez 2009). HDR brachytherapy combined with external beam radiation therapy. A retrospective cohort study that compared the efficacy of HDR brachytherapy in combination with 3D- conformal external beam radiation (3DCRT) with 3DCRT alone for the treatment of prostate cancer found no significant difference in biochemical control, overall survival, or cause-specific mortality between the treatment groups. As side effects were only reported for the combined group, it can not be determined if patients in the combined group experienced more side effects compared to patients in the 3DCRT alone group

(Zwahlen 2010). Conclusion: There is insufficient evidence to determine whether HDR brachytherapy given alone or in combination with EBRT is safe and effective for the treatment of prostate cancer.

**Articles:** The literature search did not reveal any randomized controlled trials that addressed the safety and efficacy of HDR brachytherapy. A retrospective cohort study that evaluated the safety and efficacy of HDR brachytherapy given as a monotherapy compared to LDR brachytherapy was selected for review. There were several studies that evaluated the safety and efficacy of HDR brachytherapy combined with EBRT; however, the majority of these were case series. A recent study by Zwahlen and colleagues was selected for review as it was the only study with a control group. The following studies were critically appraised:

Martinez AA, Demanes J, Vargas C, et al. High-dose-rate prostate brachytherapy: An excellent accelerated hypofractionated treatment for favorable prostate cancer. *Am J Clin Oncol* 2009 November 30. See [Evidence Table](#)  
Zwahlen DR, Andrianopoulos N, Matheson B, et al. High-dose-rate brachytherapy in combination with conformal external beam radiotherapy in the treatment of prostate cancer. *Brachytherapy* 2010; 9:27-35. See [Evidence Table](#)

The use of High-dose rate brachytherapy in the treatment of prostate cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

### **High-Dose vs. Low-Dose Brachytherapy for Cervical and Endometrial Cancer**

#### **BACKGROUND**

The standard treatment for cervical cancer is external beam radiation therapy (EBRT) combined with intracavity brachytherapy. There is no accepted standard treatment for early endometrial cancer. However, brachytherapy is often used, alone or in combination with EBRT. Intravaginal brachytherapy is believed to be useful for endometrial cancer in part because the vaginal apex is a common site of endometrial cancer recurrence. Brachytherapy refers to internal or local irradiation. In intracavity brachytherapy, radioactive sources are placed in body cavities that are close to the tumor. The relative balance between the two types of radiation treatment (brachytherapy and EBRT) depends on the stage and volume of disease. Generally, as the tumor volume increases, EBRT is favored to achieve a larger volume of homogenous dose (Stitt, 1999). Low-dose rate (LDR) brachytherapy has been available longer and is still used more frequently than high-dose rate (HDR) brachytherapy. There are several potential advantages of HDR brachytherapy, including the ability to treat large clinical patient volume, the lack of need for general anesthesia or bed rest, the ability to individualize treatment, complete radiation protection for staff and the application of multiple fractions on an outpatient basis. Disadvantages of HDR brachytherapy are the higher costs of staffing, equipment and the changing of iridium source every three months. In addition, optimal fractionation schemes for HDR brachytherapy are yet to be well defined and long-term complications are unclear (Stitt, 1999). In a LDR brachytherapy session, instruments need to be in place for 2-3 days. Cervical cancer treatment involves two procedures, approximately one week apart. Radium was used originally, but now cesium-137 is used. In contrast, with HDR brachytherapy, a treatment session takes minutes. Multiple sessions are generally required; five is a common number for treating cervical cancer. For the treatment of endometrial cancer (brachytherapy alone or in combination with EBRT after a hysterectomy), two sessions of about 1 hour each are required. High-dose rate is generally accepted as being between 50-500 cGy/minute (Tewari & DiSaia, 2002; Hogberg et al., 1999).

#### **06/11/2003: MTAC REVIEW**

### **High-Dose vs. Low-Dose Brachytherapy for Cervical and Endometrial Cancer**

**Evidence Conclusion:** Cervical cancer: With few exceptions, the studies reviewed did not find statistically significant differences in survival between patients receiving HDR and LDR brachytherapy for the treatment of cervical cancer. There were also no significant differences in adverse effects between the HDR and LDR groups. Although the studies suggest that the safety and effectiveness of the two treatments are similar, the studies were not designed as equivalence studies. The lack of a statistically significant finding could be due to a design flaw such as insufficient statistical power or bias. Neither of the RCTs discussed statistical power and both may have been underpowered to detect differences in survival and/or adverse effects between groups. This is particularly true because the results were reported separately by stage of disease which resulted in a smaller sample size for each comparison. The studies also had several threats to validity. Neither of the RCTs had adequate randomization (one allocated patients by birth month and the other alternated patient assignment to treatment group) which could introduce selection bias. In all three studies, there may have been baseline differences between groups that were not controlled for in the statistical analyses. The studies also differed in the extent of external beam radiation treatment the patients received. Endometrial cancer: There are no studies that specifically compare the safety and effectiveness of HDR and LDR brachytherapy for the treatment of endometrial cancer.

**Articles:** *Cervical cancer:* The search yielded 135 articles. Many of the studies were reviews, opinion pieces or dealt with technical aspects of the procedure. There were four studies that compared the outcomes of patients

who received high-dose or low-dose brachytherapy. Two of the studies were randomized and two were non-randomized. The two randomized studies and the prospective non-randomized study were critically appraised: Hareyama M, Sakata K, Oouchi A et al. High-dose versus low-dose-rate intracavity therapy for carcinoma of the uterine cervix. *Cancer* 2002; 94: 117-124. See [Evidence Table](#)  
Teshima T, Inoue T, Ikeda H. High-dose rate and low-dose rate intracavity therapy for carcinoma of the uterine cervix. *Cancer* 1993; 72: 2409-2414. See [Evidence Table](#)  
*Endometrial cancer*: The search yielded 36 articles. No randomized controlled trials were identified. There were no empirical studies comparing low-dose rate and high-dose rate brachytherapy. No articles were critically appraised.

The use of high-dose brachytherapy in the treatment of cervical and endometrial cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Prostate Cancer Brachytherapy**

#### **BACKGROUND**

At the December 14, 1994 Committee on Medically Emerging Technologies the efficacy of Transperineal Ultrasound Guided Iodine<sup>125</sup> or Palladium<sup>103</sup> Brachytherapy for Prostate Cancer was originally discussed. Dr. Blasko presented information on the 800 patients for which the procedure was performed. Only 252 of those patients had a minimum follow-up of two years. The conclusion of the committee was that there was inadequate follow-up data supporting the efficacy of Transperineal Ultrasound Guided Iodine<sup>125</sup> or Palladium<sup>103</sup> Brachytherapy for Prostate Cancer. The question of Transperineal Ultrasound Guided Iodine<sup>125</sup> or Palladium<sup>103</sup> Brachytherapy for Prostate Cancer was restated and evaluated at the January 16, 1997 Clinical Policy Committee Meeting. Committee members agreed that there was inadequate evidence to compare the benefits of the three active treatment options but that there was adequate evidence (large case series) to compare the complications of the three options. Among the three active treatment options, it was agreed that brachytherapy appeared to have the lowest rate of complications. Based on this information the Committee recommended to the Clinical Planning and Improvement Council and the Delivery System Operating Team that brachytherapy be added to the list of covered treatment options for localized prostate cancer. This recommendation was accompanied by the stipulation that educational material outlining the treatment options be developed for patient education in order that they can make an informed decision about their treatment course. Not all patients with Prostate Cancer are eligible candidates for Transperineal Ultrasound Guided Iodine<sup>125</sup> or Palladium<sup>103</sup> Brachytherapy for Prostate Cancer. Documentation of the screening criteria used to identification of the eligible candidates is the purpose of this document. In late 2001 the criteria were reviewed by Dr. Nico DeWette and updated based on the current practice and experience with Prostate Seed Implant and Combined Therapy

### **Radioactive Seeds for Treatment of Recurrent High-Grade Glioblastoma**

#### **BACKGROUND**

Gliomas are the most common primary tumors of the adult brain. Primary brain tumors are those that arise from brain tissue itself, rather than metastasizing to the brain from another location. One of the most commonly diagnosed types of glioma is glioblastoma multiforme (GBM) which is defined as a Grade 4 (high-grade) astrocytoma. High-grade tumors are by definition, rapidly growing and typically develop at a distinct focus in the brain and become more diffuse in their spread as they progress. Several therapies for high-grade glioblastomas are currently employed. No treatment has been shown to cure these tumors, most likely because tumor cells infiltrate into surrounding tissue and this tumor cell type has been shown to be moderately resistant to chemo and radiation therapy. Treatment for glioblastoma multiforme typically involves surgery to reduce the size of the tumor and external beam radiation therapy. External beam radiotherapy can be delivered using a standard x-ray machine or focused on a small area of three dimensionally localized tissue using stereotactic radiosurgery. Systemic chemotherapy is usually a third line treatment and. One proposed treatment for glioblastoma is the use of stereotactically implanted radioactive seeds (brachytherapy) at the site of the tumor. The potential advantage of brachytherapy is that it allows high dose radiation to be applied directly to the tumor site and may avoid radionecrosis caused by high doses of externally applied radiation and toxic effects of chemotherapy. Glioblastoma is typically associated with a fatal outcome. Brachytherapy for malignant brain tumors has been practiced since the early 1980s. Brachytherapy applied as a boost to external beam radiation therapy has become part of the initial treatment of patients with malignant gliomas. Previous reports on the use of brachytherapy for patients with malignant gliomas have suggested improved survival for some patients. The largest experience to date has been with temporary high-activity brachytherapy implants. However, temporary implants have certain disadvantages compared with permanently implanted seeds, including higher costs and the need for more rigorous radiation safety precautions during the period of implantation.

#### **13/13/2000: MTAC REVIEW**

### **Radioactive Seeds for Treatment of Recurrent High-Grade Glioblastoma**

**Evidence Conclusion:** Evidence identification was conducted by searching MEDLINE from 1990-1999 using the terms: glioblastoma, brachytherapy and neoplasm recurrence. The published scientific evidence consists of 4 case series with no comparison group or comparison only to historical controls. Case series do not provide reliable information regarding efficacy as they are subject to bias because they lack control groups that allow elimination of confounding and selection bias. Publication bias can also influence whether negative results are reported in the literature. The studies reviewed in November 2000 have a number of limitations including a small sample size, potential selection bias, lack of a proper control group, and in one of the studies, the fact that different methods variables were used to compare groups of patients. Given these limitations, there is insufficient evidence to draw conclusions about the efficacy and safety of brachytherapy for patients with glioblastoma. It was noted that glioblastoma has the worst prognosis and shortest survival times of any type of primary brain tumor. All treatments serve only to extend survival, usually by a matter of 2-3 months usually at the cost of significant treatment related morbidity. Recent improvement in imaging techniques and more complete surgical resection makes it impossible to use historical control patients as valid comparisons with respect to clinical outcomes.

**Articles:** The search yielded 20 articles. 18 articles were not directly relevant or were review articles, letters, or case reports. Two (2) empirically relevant case series were identified (evidence tables attached). *The articles selected for critical appraisal include:* Patel et al. Permanent Iodine-125 interstitial implants for the treatment of recurrent glioblastoma multiforme. *Neurosurgery* 2000; 46:1123-1130. See [Evidence Table](#)  
J Clin Oncol 1998;16:2202-12 entitled Iodine 131-labeled antineoascin monoclonal antibody 81C6 treatment of patients with recurrent malignant Gliomas: Phase I trial results. See [Evidence Table](#)  
Shrieve, DC et al, *Neurosurgery*, 1995, 36:275-284 See [Evidence Table](#)

##### For Non-Medicare Members

Breast implant removal is covered when all of the following criteria are met:

1. Breast implants were part of a reconstructive procedure meeting [criteria for breast reconstructive surgery](#).
2. One of the following clinical symptoms are present:
  - a. Infection related to implant
  - b. Implant extrusion
  - c. Ruptured implant
  - d. Baker Classification\* Class II to IV contracture
  - e. Interference with diagnosis and/or treatment of breast cancer

Additionally, breast implant removal is covered if the implants were placed for a diagnosis of breast cancer or other malignancy involving the breast. [See Breast Reconstruction or Breast Prostheses following Mastectomy/Lumpectomy](#).

**\*Baker Classification:**

- Class I augmented breast feels as soft as a normal breast
- Class II augmented breast is less soft and implant can be palpated, but is not visible
- Class III augmented breast is firm, palpable and the implant (or distortion) is visible
- Class IV augmented breast is hard, painful, cold, tender, and distorted

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Breast implant removal is medically necessary under limited circumstances.

#### Medical Technology Assessment Committee (MTAC)

##### **Silicone Breast Implant Removal**

##### **09/11/1999: MTAC REVIEW**

**Evidence Conclusion:** The committee reviewed the available data on the safety of silicone breast implants and concluded: There is no evidence linking silicone breast implants to cancer in women, The elective removal of existing implants is not recommended. There is concern and there may be a relationship between silicone breast implants and the development of connective tissue disease, although there is no epidemiological evidence Silicone breast implants can impede early detection of breast cancer in cases of cosmetic breast augmentation, but do not in cases of breast reconstruction following extractive surgery.

**Articles:** Committee reviewed the available data on the safety of silicone breast implants and concluded: There is no evidence linking silicone breast implants to cancer in women, The elective removal of existing implants is not recommended. There is concern and there may be a relationship between silicone breast implants and the development of connective tissue disease, although there is no epidemiological evidence. Silicone breast implants can impede early detection of breast cancer in cases of cosmetic breast augmentation, but do not in cases of breast reconstruction following extractive surgery. Capsular contracture does occur in many patients and patients should be advised, before implantation, that it is a possible side effect that is normal and not harmful to their health.

The use of silicone breast implant removal for prevention of breast cancer does not meet the Group Health *Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Breast Pump

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

To qualify for a hospital grade breast pump the member must meet **ONE of the following**:

- Direct breastfeeding is not possible because of a separation due to the prolonged or repeat hospitalization of either the infant or the mother.
- The infant has a medical condition or congenital anomaly that prevents effective breastfeeding.
- The mother has a medical condition or anatomical anomaly that prevents effective breastfeeding.

Hospital grade breast pump is not considered medically necessary after 12 months of age.

GHC will not cover rental of a heavy duty electrical/hospital grade breast pump when requested solely for convenience because it is considered not medically necessary. Purchase of a basic electric consumer pump (E0603) does not require medical necessity review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Breast-fed infants have a lower risk of diarrhea and otitis media than bottle-fed infants during the first year of life. For premature infants, breast milk helps prevent infections, speeds recovery from respiratory distress syndrome, increases weight gain, protects against retinopathy, and facilitates cognitive and visual development.

By contrast, the manual and electric breast pumps that are available commercially are not designed for reuse, and are most commonly sold to mothers with normal infants who are working, traveling, or for other reasons not always home to breast-feed the baby. Standard electric breast pumps or manual breast pumps may be necessary to initiate breast feeding in the postpartum period, within the first eight weeks following delivery. Manual breast pumps are sufficient for continuation of breastfeeding following the postpartum period. Current recommendations from the American Academy of Pediatrics are to continue breastfeeding of infants through one year of age.

Women may be able to breastfeed adopted infants through induced lactation. The process involves nipple stimulation with use of an electric breast pump beginning about two months before the adoptive mother expects to begin breast-feeding. In addition, hormonal therapy, such as supplemental estrogen or progesterone, may be prescribed to mimic the effects of pregnancy. Typically, hormone therapy for induced lactation is discontinued shortly before breast-feeding begins. At that point, the infant's suckling is thought to stimulate and maintain milk production.

Authorized under provisions of the Patient Protection and Affordable Care Act, the U.S. Department of Health and Human Services (DHHS) released health plan coverage guidelines, developed by a committee of the Institute of Medicine, that require health insurance plans to cover breast pumps and certain other women's preventive services. New health plans and non-grandfathered plans and issuers are required to provide coverage consistent with these guidelines in the first plan year (in the individual market, policy year) that begins on or after August 1, 2012.

The Centers for Disease Control and Prevention (CDC, 2010) recommended that infected women in the United States refrain from breast-feeding to avoid post-natal transmission of HIV-1 to their infants through breast milk. These recommendations also should be followed by women receiving anti-retroviral therapy. Passage of anti-retroviral drugs into breast milk has been evaluated for only a few anti-retroviral drugs; ZDV, 3TC, and nevirapine have been detected in the breast milk of women.

## Clinical Review Criteria

### Breast Reconstruction or Breast Prostheses Following Mastectomy/Lumpectomy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<b>Breast Reconstruction Following Mastectomy (140.2)</b>
Local Coverage Determinations (LCD)	<b>External Breast Prosthesis (L33317)</b>

##### For Non-Medicare Members

For breast reconstruction or breast prosthesis following a mastectomy or lumpectomy member must qualify both in A and B:

A. **ONE of the following** must be met:

1. Medically necessary lumpectomy or complete or partial mastectomy due to disease, injury or illness (such as breast cancer, chronic and severe fibrocystic disease, or infection unresponsive to medical therapy, chest wall surgery, or trauma) resulting in significant deformity;

**OR**

2. Prophylactic mastectomy to prevent the onset of breast cancer when a clinical determination has been made that there is a high risk for breast cancer;

B. And must be **ONE of the following procedures:**

1. **For the diseased/** injured/affected breast must meet one of the following:

- Tissue/muscle reconstruction procedures (flaps)
- Capsulotomy
- Capsulectomy
- Implantation of tissue expander
- Implantation of U.S. Food and Drug Administration (FDA) approved internal breast prosthesis
- Areolar and nipple reconstruction
- Areolar and nipple tattooing
- Breast implant removal and subsequent re-implantation

2. **For the non-diseased/non-injured/unaffected/contralateral** breast to produce symmetry in appearance must meet **ONE of the following:**

- Breast reduction by mammoplasty or maxtopexy
- Augmentation mammoplasty
- Augmentation with implantation of FDA internal breast prosthesis when unaffected breast is smaller than the smallest available internal prosthesis
- Areolar and nipple reconstruction
- Areolar and nipple tattooing
- One reconstructive procedure to produce a symmetrical appearance
- Breast implant removal and subsequent re-implantation performed to produce a symmetrical appearance when the original implant was in the unaffected breast prior to the disease in the affected breast.
- Capsulotomy
- Capsulectomy

The following products are covered for breast reconstruction when medical necessity criteria are met:

1. Alloderm
2. AlloMax
3. DermaMatrix
4. FlexHD
5. Neoform Dermis
6. Strattice tissue matrix
7. SurgiMend

**Autologous fat injections for post-mastectomy breast reconstruction (autologous fat grafting, autologous fat transfer, breast fat grafting, lipoinjection, lipofilling)**

- A. Autologous fat injection coverage is covered only for breast reconstruction (dimpling and contouring), if medical necessity criteria for breast reconstruction is met.
- B. Total breast reconstruction is not covered using the Brava system (autologous fat injection for complete reconstruction).

**The following are not covered:**

- A. All other bioengineered skin substitutes other than listed above - see Wound Care criteria
- B. Suction lipectomy or ultrasonically assisted suction lipectomy for correction of donor site asymmetry.
- C. Reconstructive surgical revisions are for restoration and not for cosmesis. Ongoing surgery for treatment of natural changes due to age or weight changes is considered cosmetic and not covered.

**Pulsed electromagnetic field (PEMF) for pain reduction after breast reconstruction surgery**

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies (and/or) provides better long-term outcomes than current standard services/therapies

**External breast prostheses and bras** - If the member has not undergone breast reconstruction, external breast prostheses and bras are covered after a medically necessary mastectomy or a lumpectomy, when surgery results in significant deformity.

- External prosthesis (one silicone every 2 years or one foam every 6 months) Post-mastectomy bras/forms, limited to 2 every 6 months. Replacements within this 6 month period are covered when medically necessary due to a change in the Member's condition.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

While breast reconstructive surgery can be considered a cosmetic procedure, under both state and federal law, carriers must provide coverage for this type of surgery in certain clinical circumstances.

The Women's Health and Cancer Rights Act (WHCRA) of 1988 (also known as Janet's Law) is a federal law that requires group health plans and carriers offering coverage in connection with group or individual plans to provide benefits for mastectomy-related services, including breast reconstruction surgery. WHCRA states that a group health plan or carrier (in a manner determined in consultation with the attending physician and the patient), must provide coverage for:

- All stages of reconstruction of the breast on which the mastectomy has been performed;
- Surgery and reconstruction of the other breast to produce a symmetrical appearance; and
- Prostheses and physical complications of mastectomy, including lymphedema.

U.S. Code – Title 29 Chapters - § 1185b, § 300gg-27, and § 300gg-52.

Washington state law also has provisions for the coverage of reconstructive surgery following a mastectomy. Both RCW 48.46.280 (HMOs) and RCW 48.330 (Health Care Service Contractors) require that carriers shall provide coverage for:

- Reconstructive breast surgery resulting from a mastectomy which resulted from disease, illness, or injury.

- All stages of one (1) reconstructive breast reduction on the non-diseased breast to make it equal in size with the diseased breast after definitive reconstructive surgery on the diseased breast has been performed.

In addition to the above statutes, guidance for interpretation of these state statutes is found in Carr v. Blue Cross of Washington and Alaska, 93 Wash. App. 941 (1999).

Group Health has developed the criteria above with these laws as a guide.

## Medical Technology Assessment Committee (MTAC)

### ***Autologous Fat Injections for Post-Mastectomy Breast Reconstruction***

#### BACKGROUND

Autologous fat transfer, also known as breast fat grafting (BFG), fat transplantation, lipofilling, or lipoinjection, is a process in which fat cells from one area of the body are transferred to another. Fat transfer was first performed by Neuber in 1893 for the correction of a depressed face scar, and two years later it was performed by Czerny for breast construction after excision of a large fibroadenoma. Since then, several surgeons have used free fat grafts for the reconstruction of breast defects. Autologous fat is considered an ideal injectable agent for soft tissue augmentation; it is easily available for most patients, easy to use, inexpensive, nontoxic, biocompatible, and potentially long lasting, and removable (Mu 2009, Fraser 2011, Bucky 2011). Breast fat grafting is a promising technique to correct contour deformities in breasts reconstructed with either prosthesis or autologous tissues. The value of the procedure is controversial due concerns about its safety and efficacy. The degree of reabsorption of the adipose tissue transplanted is unpredictable. The mechanism underlying the survival of dissected autologous fat after grafting is unknown, but is believed to be dependent on revascularization of fat granules. The lipogenic activity may vary by donor site (e.g. abdomen, thigh, and flank), patient age, weight, smoking habits, comorbidities, condition of recipient site (scarring, radiation, previous surgery) and other factors. One of the main concerns with autogenous fat grafting for the breast is the development of fat necrosis leading to liponecrotic cysts and microcalcifications that could be mistaken for cancerous calcifications. Compression of the breast tissue by the transferred fat may also make it difficult to identify subtle changes in architectural patterns seen with early breast cancer presentation. Another concern relates to the potential oncologic risks of breast fat grafting, as fat transfer into a previous breast-cancer area may potentially stimulate local recurrence. Other complications with autologous fat transfer include edema, hematoma, induration, infection, granuloma formation, oil cyst formation, fat liquefaction, sclerosis and resorption (Pulagam 2006, Mu 2009, Mizuno 2010, Fraser 2011, Bucky 2011, Rietjens 2011, Serra-Renom 2011). After gaining much popularity, the interest in autologous fat transfers waned in the 1950s and 1960s due to low rates of graft survival and the increased use of artificial material. The interest in autologous fat grafting for aesthetic and reconstructive purposes was renewed in the 1980s with the introduction of liposuction that provided a minimally invasive means of obtaining large amounts of adipose tissue in a semiliquid form. However, the procedure was again discontinued for some time due to concerns over post-operative calcifications and risk of obscuring developing malignant lesions. More recently, autologous fat transfer re-emerged after a number of surgeons introduced "lipomodelling" and used the technique alone or with in combination with other reconstructive procedures. Several harvesting and transplantation techniques have been developed and refined, yet no standard procedures have been adopted by all practitioners. There is no consensus on the ideal cannula, technique for harvesting, processing, or grafting the fat. Harvesting approaches include syringe aspiration and lipoaspiration. Once harvested, the fat is prepared for injection by one of several methods including: washing with physiological buffers, centrifugation for separating the cells from the debris, decantation, or concentrating it using cotton towels or other adsorbent media. For grafting, the fat is injected with a variety of delivery methods using sharp or blunt needles. It is reported that the fat "takes" if it is obtained using atraumatic methods, but it does not acquire the shape of the breast and remains flattened. It is difficult to remodel the grafted fat to acquire the desired cone shape. The procedure is not simple and should be performed by skilled and trained surgeons. It requires careful calculation of the amounts of fat injected at one time, number of injections needed, appropriate sites for injections, and proper administration of the transferred fat (Hyakusoku 2008, Mu 2009, Fraser 2011, Bucky 2011, Parrish 2010). In 1987, the American Society of Plastic and Reconstructive Surgeons (ASPRS) Ad-Hoc committee on New Procedures issued a position statement recommending that autologous fat transfer to the breast be prohibited due to its complications that may compromise breast cancer screening. In 2007, the ASPRS and the American Society for Aesthetic Plastic Surgery (ASAPS) again determined that fat grafting for

breast augmentation is not recommended due to the lack of clinical data on the efficacy and safety of the procedure, and also because it may interfere with the detection of breast cancer. In 2009, the ASPS Fat Graft Task Force took a more lenient position stating that, "Fat grafting may be considered for breast augmentation and correction of defects associated with medical conditions and previous breast surgeries." This Task Force based the recommendation on low quality evidence from case series, and/or expert opinion and the gave it a B grade. They emphasized that the patients should be made aware of the potential risks and complications of the procedure, and indicated that physicians should be cautious when considering high-risk patients (Gutowski 2009, Mizuno 2010).

#### **08/15/2001: MTAC REVIEW**

##### **Autologous Fat Injections for Post-Mastectomy Breast Reconstruction**

**Evidence Conclusion:** The published studies are limited to case series and case reports which do not provide sufficient evidence to determine the efficacy, safety, and durability of autologous fat transfer for breast reconstruction after a mastectomy. The studies used different techniques, donor site, volume of fat transplant, as well as various outcome measures and follow-up durations. The majority of the series included patients undergoing the procedure for breast augmentation, reconstructive surgery after mastectomy, as well as other indications. The largest published series of 880 patients over 10 years was reported by Delay, et al in 2009. The majority (83.4%) of the patient population underwent autologous fat grafting for breast reconstruction, the rest were for correction of congenital deformities, aesthetic breast surgeries, or to correct previous surgeries. The intervention was not compared to another procedure, and the study had several limitations including, but not limited to, lack of reporting inclusion/exclusion criteria, patient characteristics, and lack of clearly defined outcomes and reporting of duration or completeness of follow-up. The authors indicate that the procedure was successful to the patients and surgeons, but did not clearly define success other than comparison of photographs. They reported that the incidence of fat necrosis was 15% for the first 50 patients, and declined to 3% for the last 100 patients suggesting a surgical learning curve. The authors concluded, "None of the imaging results are likely to confuse the diagnosis of cancer for radiologists who are experienced in breast imaging. Oncologic follow-up (now at 10 years for our first patients) shows no increased risk of local recurrence or of development of a new cancer". Illouz and Sterodimas (2009), reported on a series of 820 consecutive patients who underwent autologous fat transplantation over 25 years. These included patients undergoing the procedure for breast reconstruction after a mastectomy, patients with congenital asymmetry, or women requesting breast augmentation. A total amount of fat transplanted in each breast ranged from 25-900 ml (mean 540 ml), and a mean of 3 sessions (range 1-5) were needed to achieve the desired results. The authors indicated that the majority of patients were satisfied with the results. They did not measure the longevity of the transplantation, did not discuss loss of follow-up, injected fat survival, or necrosis. They indicate that calcifications, cysts, and cancer were not apparent in the first year after the procedure, and thought that they may not be directly associated with the procedure. Long-term follow-up data that ranged from 2-25 years (mean 113.3 years) were only available for 28% of the patients. In conclusion, data from published studies do not provide sufficient evidence to determine the components of a successful, consistent, durable, and safe autologous fat transplantation for breast reconstruction. The Breast Reconstruction and Augmentation With Brava Enhanced Autologous Fat Micro Grafting (BRAVA) trial is an ongoing nonrandomized study on fat grafting of the breast post-mastectomy as well as other indications.

**Articles:** Assessment objective: To determine the safety and efficacy of autologous fat grafting for post-mastectomy breast reconstruction. Screening of articles: The literature search revealed around 100 articles on autologous fat grafting for post-mastectomy breast reconstruction and/or augmentation. No published meta-analyses or randomized controlled trials were identified; only case series and case reports. The majority of the published literature was on breast augmentation. The two largest published series of patients who underwent autologous fat transplantation to the breast, mainly for reconstruction after mastectomy, were selected for critical appraisal. Delay E, Garson S, Tousson G, et al. Fat injection to the breast: technique, results, and indications based on 880 procedures over 10 years. *Aesthet Surg J.* 2009;29:360-376.

See [Evidence Table](#) Illouz YG, Sterodimas A. Autologous fat transplantation to the breast: A personal technique with 25 years of experience *Aesth Plast Surg.* 2009;33:706-715. See [Evidence Table](#)

The use of autologous fat grafting does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **BRAVA® Breast Expansion System**

##### **10/21/2013: MTAC REVIEW**

**Evidence Conclusion:** The developer of the Brava device (Brava LLC, Miami, Fla.) conducted a multicenter, prospective, magnetic resonance imaging-documented study to determine the safety and efficacy of single-stage large-volume autologous fat transfer to the breast treated with the Brava external breast expander. The population included 81 women between the ages of 17 and 63 years who desired breast augmentation. It is not clear from the study if patients seeking reconstruction following mastectomy were included or excluded (Khouri, Eisenmann-

Klein et al. 2012). Currently, the evidence on the use of BRAVA® Breast Expansion System is limited and provided insufficient evidence to determine the safety and efficacy for use superficially in breast reconstruction surgery with autologous fat transfer. Conclusion: There is no evidence to permit conclusions concerning the safety and efficacy of the BRAVA Breast Expansion System used in breast reconstructive surgery with fat implants.

**Articles:** A search of PubMed and the National Institute of Health Clinical Trials records was completed for the period through September 2013 for studies on BRAVA® Breast Expansion System used for the treatment of patients following mastectomy for breast cancer. The search strategy used the terms *Brava, breast expansion, reconstructive surgery, fat implants, flap surgery* and *mastectomy* with variations. Articles were limited to those published in English language and enrolling human subjects. The search was supplemented by an examination of article bibliographies in addition to the PubMed *related* articles function. Screening of Articles: A literature search was conducted and revealed one publication (funded by the manufacturer) on the use of the Brava system plus autologous fat transfer in breast augmentation. There are no current publications on the use of the BRAVA Breast Expansion System in breast reconstruction. One ongoing clinical trial was discovered (Breast Reconstruction and Augmentation with the BRAVA Enhanced Autologous Fat Micro Grafting) with an estimated completion date of April 2014. No studies were selected for review.

The use of the BRAVA® Breast Expansion System does not meet the *Group Health Medical Technology Assessment Criteria*.

### ***Pulsed Electromagnetic Field (PEMF) for Pain Reduction After Breast Reconstruction Surgery***

#### **BACKGROUND**

Pulsed electromagnetic field (PEMF) therapy, also known as electromagnetic therapy uses an electromagnet to generate electric current, and nonthermal pulsed electromagnetic energy to deliver the current. PEMF utilize generators designed to create radiofrequency signals that are delivered through coils which do not come in direct contact with the skin. The electric current is generated in short bursts into the injured tissue without the production of heat or interfering with nerve or muscle function. Unlike electrical stimulation, FEMF therapy does not involve the use of current, leads, or electrodes. The FEMF devices are noninvasive and can be applied over or as part of the dressing in the wound healing area directly following a procedure for the postoperative management of a surgical wound (Kinney 2005, Gupta 2009, Strauch 2009). The mechanism of action of PEMF on tissue growth and repair is not completely known. In vitro and animal research showed that PEMF can increase blood flow, enhance circulation, induces collagen synthesis, granulocyte infiltration, and inhibit growth of some wound pathogens. The literature also suggests that this modality of therapy can modify the inflammatory process, reduce edema, and enhance tissue repair. The effects of PEMF are immediate and are not limited by pharmacokinetics because the induced currents are instantaneously present when the coil is transmitting into the affected area (Kinney 2005, Gordon 2007, Strauch 2009). Electromagnetic therapy is currently being used in physical medicine, orthopedic and sports injuries, and other musculoskeletal conditions. PEMF therapy use is proposed for other conditions as the reduction of pain and edema after facial surgery, breast surgery, and abdominoplasty. Several trials are currently underway or planned to study the use of PEMF in several other fields of medicine (Kinney 2005, Gupta 2009).

#### **06/18/2012: MTAC REVIEW**

### ***Pulsed Electromagnetic Field (PEMF) for Pain Reduction After Breast Reconstruction Surgery***

**Evidence Conclusion:** The two published trials on the use of pulsed electromagnetic field therapy (PEMF) to reduce pain and the use of pain medications after breast reconstruction surgery were small pilot studies with valid methodology. Both trials were randomized, blinded, used sham therapy as a control, and had sufficient power to detect statistically significant differences between PEMF and the sham therapy. Hedén and Pilla's trial randomized 42 women to receive bilateral active PEMF therapy, bilateral breast sham therapy, or one of the two therapies on each breast. The results of the study showed a significant difference between the active and sham therapies in the pain experienced and in the use of postoperative pain medication. Those who received PEMF on one breast and sham therapy on the other breast showed no significant differences between the two breasts or between them and the active treatment. This was attributed to the fact that the breast randomized to sham treatment received 40-60% of signal amplitude delivered to the active treatment breast due to the propagation of PEMF signal from the coil application. Based on this observation, Rohde and colleagues (2009) randomized their study participants to receive either bilateral active therapy or bilateral sham therapy. The trial included 24 patients and reported outcomes for only 48 hours. Similar to Hedén and Pilla's results, women who received PEMF therapy experienced less pain and used fewer narcotics in the 48 postoperative hours. Conclusion: The overall results of the published small pilot studies show that PEMF therapy may reduce pain and use of pain medication after breast reconstruction surgery. Both trials noted that no adverse events were reported, but neither studied the effect of PEMF on the reduction of postoperative edema, or on the speed and quality of wound repair

**Articles:** The literature search revealed two relatively small randomized controlled trails that evaluated the use of PEMF therapy after breast reconstruction therapy. Both trials were critically appraised.

Hedén P and Pilla AA. Effects of pulsed electromagnetic fields on postoperative pain: A double-blind randomized pilot study in breast augmentation patients. *Aesth Plast Surg.*2008;32:660-666. See [Evidence Table](#)

The use of Pulsed electromagnetic field (PEMF) therapy does not meet the *Group Health Medical Technology Assessment Criteria*.

**SERI® Surgical Scaffold for Breast Reconstruction**

**04/20/2015: MTAC REVIEW**

**Evidence Conclusion:** There is a lack of published evidence on the use of SERI® Surgical Scaffold for breast reconstruction after mastectomy. The largest published study to date, SURE-001 (Fine et al, 2014, Evidence table 1) was a prospective observational study with no comparison or control group. It included 139 patients undergoing two-stage, implant-based breast reconstruction using SERI® Surgical Scaffold in multiple centers in the US. The study is planned to follow the patients for 2 years, but the published article reports the interim data for 71 patients followed for 1 year after surgery. The patients underwent tissue expander placement during stage one of reconstruction, with SERI® sutured into place for soft-tissue support of the lower-breast mound. Once expansion was complete with drain placement, the second stage of surgery was performed, where the expander was replaced with a permanent breast implant. The primary outcome of the study was the investigator satisfaction at 6 months. Other outcomes included the investigator satisfaction at 12 months after stage 1 surgery; ease to use of SERI®; visibility and palpability of SERI® through the skin at first postoperative visit, and during follow-up; patient satisfaction, and adverse events associated with the implant. The interim results of the study showed that the mean investigator satisfaction scores were 9.2 at 6 months where a score of 10 indicates being very satisfied with results. The mean patient satisfaction with the treated breast was 4.3 at 6 months and 4.5 at 12 months with a score of 5 signifying very satisfied with results. Adverse events occurred in 18 of the 71 patients with 1 year follow-up after stage I surgery, and most occurred within the first 6 months. Tissue necrosis occurred in 8.5% of the patients, seroma in 7%, hematoma in 7%, cellulitis in 4.2%; implant loss in 4.2%, capsular contracture in 1.4% and breast infection occurred in 1.4%. These results have to be interpreted with caution as the study was only observational with no control or comparison group, and had a subjective primary outcome. The study was sponsored by Allergan, Inc. and all the investigators had financial ties to the manufacturer of SERI® Surgical Scaffold. Conclusion: There is insufficient evidence to determine the efficacy and safety of SERI surgical scaffold in women undergoing breast reconstructive surgery after mastectomy.

**Articles:** The literature search did not reveal any randomized controlled trials that compared the use of SERI® Surgical Scaffold versus currently used practices or alternative material used for tissue support. To date, the published empirical studies consist of one prospective case series with 139 women undergoing breast reconstruction after mastectomy (SURE-001 study, Fine et al, 2014), a very small retrospective case series, and case reports on the use of SERI® for other indications as abdominoplasty and brachioplasty.

The prospective case series was selected for critical appraisal. Fine NA, Lehfelddt M, Gross JE, et al. SERI Surgical Scaffold, Prospective Clinical Trial of a Silk-Derived Biological Scaffold in Two-Stage Breast Reconstruction: 1-Year Data. *Plast Reconstr Surg.* 2015; 135(2):339-351. See [Evidence Table 1](#)

The use of the SERI® Surgical Scaffold for Breast Reconstruction does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Bronchial Thermoplasty for Treatment of Severe Bronchial Asthma

- Alair Bronchial Thermoplasty System

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

Group Health has elected to use the MCG\* (A-0634) for medical necessity determinations. This service is not covered per MCG guidelines.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (pulmonary/allergy)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Asthma is an increasingly prevalent disease that affects over 20 million people in the United States. It is estimated that 15 -20% of asthma patients have a severe condition despite receiving the new effective therapies. Asthma is characterized by chronic inflammation of the airways, airway wall edema, bronchial hyper responsiveness, and remodeling of the airways that include increased airway smooth muscle mass. Each of these factors alone or in combination can result in recurrent episodes of wheezing, coughing, chest tightness, and breathlessness (Castro 2010, Cox 2011).

Although inflammation of the airways is a main feature of asthma, researchers believe that the contraction of the excess airway smooth muscles, in response to various asthma triggers, is the main cause of airway constriction and restricted airflow leading to breathing difficulty during asthma attacks. This led to a hypothesis that decreasing the mass and /or contractility of airway smooth muscle would reduce airway bronchoconstriction and ameliorate the symptoms of asthma. Based on this hypothesis, investigators suggested that the application of thermal energy to the airway wall, termed bronchial thermoplasty, can reduce the bronchoconstrictor response in asthma (Cox 2007, Pavord 2007, Wechsler 2008).

Bronchial Thermoplasty (BT) is a device-based approach for severe persistent asthma that involves the application of controlled heat from a radiofrequency (RF) source to the airway wall resulting in a prolonged reduction in airway smooth muscle mass. The Alair System (Asthmax Inc., Sunnyvale, CA) is the first device designed to use RF to selectively reduce the amount of excess airway smooth muscle in airways distal to the main stem bronchi down to 3 mm in diameter. The Alair system consists of the Alair RF catheter that has an expandable electrode array on the tip, and the Alair RF controller which supplies energy via the catheter to heat

the airway wall. The catheter is deployed under direct vision through a compatible flexible bronchoscope, which is navigated to the first target treatment site, typically the most distal airway in the targeted lobe. Once the bronchoscope is inserted in the airways, the catheter is passed through the bronchoscope and its electrode array expanded such that all its sides are in contact with the airway wall. The bronchoscopist steps on a footswitch attached to the RF controller for approximately 10 seconds. This delivers low-power, temperature-controlled RF thermal energy to the treated airway. A single activation of the catheter delivers RF energy over a distance of approximately 5 mm. The catheter is then repositioned so that other adjacent areas of the airways may be treated, following a mapped treatment plan, and avoiding overlap. All visible and reachable airways 3-10 mm in diameter that are distal to the main stem bronchi are treated with a series of contiguous activations. A systematic approach from distal to proximal, working methodologically from airway to airway across the lung being treated is recommended to ensure that all accessible airways are carefully identified and treated only once. BT is performed under conscious sedation in an outpatient setting, and the procedure takes 30-45 minutes to complete. The treatment is administered in three sessions approximately 3 weeks apart. A different region of the lung is treated during each session: one lower lobe in session 1; the second lower lobe in session 2; and both upper lobes in session 3. Depending on the patient size and anatomy, a range of approximately 60-100 energy cycles are performed (Duhamel 2010, Wechsler 2008, Castro 2010).

Patients are selected for BT by an asthma specialist and an experienced bronchoscopist, and should not be considered for the procedure if they have acute respiratory infection, known coagulopathy, active respiratory infection, or with asthma exacerbation or changing dose of systemic corticosteroids for asthma (up or down) 14 days before the procedure (Duhamel 2010).

This Alair Bronchial Thermoplasty system received marketing clearance from the U.S. Food and Drug Administration (FDA) in April 2010 for the control of severe persistent asthma in patients 18 years and older whose asthma is not well controlled with inhaled corticosteroids and long acting beta agonists. The FDA approved the system based on data from AIR2 trial, and is requiring a five-year post-approval study of the device to study its long-term safety and effectiveness. The FDA list of potential adverse events associated with the use of the device includes: upper respiratory tract infection, throat irritation, pharyngolaryngeal pain, rhinitis, nasopharyngitis, asthma (multiple symptoms), sinusitis, wheezing, dyspnea, airway bleeding, cough, laryngospasm, bronchospasm, bronchitis, excess mucus production, chest discomfort, increased airway reactivity, atelectasis, hemoptysis, bronchial stenosis, bronchiectasis, pneumothorax, and others.

## Medical Technology Assessment Committee (MTAC)

### **Bronchial Thermoplasty**

#### **04/18/2011: MTAC REVIEW**

**Evidence Conclusion:** The Asthma Intervention Research (AIR) trial examined the efficacy of BT in patients with moderate to severe asthma while AIR2 and Research in Severe Asthma (RISA) trials studied the efficacy of the procedure in patients with symptomatic severe asthma despite the use of high doses of inhaled corticosteroids (ICS) and long acting  $\beta_2$  adrenergic agonists (LABA). AIR and RISA trials compared BT in addition to usual care with standard medications versus usual care alone, and had no sham control. The AIR2 trial compared the BT to sham therapy, which was an advantage of the trial as it addressed the concern about the placebo effect of bronchial thermoplasty in the control of severe asthma. All three trials were supported by Asthmatx Inc., the manufacturer of Alair Bronchial Thermoplasty System, and the authors had financial ties to the industry and other pharmaceutical companies. The AIR trial conducted by Cox and colleagues ([Evidence Table 1](#)) enrolled 112 patients aged 18 to 65 years with moderate to severe asthma symptoms despite receiving combined therapy with ICS and LABA, and in whom the withdrawal of LABAs resulted in a worsening of asthma control. Eligible patients were randomly allocated to a treatment group that received BT in addition to the standard therapy, or to a control group that only received the standard treatment. Initially the patients were followed up for 12 months after which they were invited to participate in a 4-year safety study. The primary outcome for the first 12 months was the difference between the BT group and the controls in the change in rate of mild exacerbation between baseline and later time points. The trial results showed a significant difference between the BT group and the controls in the change of mild exacerbations rate from baseline to three months and 12 months. No such significant difference between the two treatment groups was observed for severe exacerbations. The 5-year follow-up of 80% of patients in the BT group showed no increase in rate of hospitalization or emergency department visits for respiratory symptoms in years 2 to 5 compared to year one. The AIR2 trial by Castro and colleagues ([Evidence Table 2](#)) enrolled 288 highly selected patients with severe symptomatic asthma despite treatment with high doses of ICS and LABA. They were randomized in a 2:1 ratio to receive BT or sham therapy in which the controls underwent three bronchoscopies and sham thermoplasty treatment that duplicated the BT procedure except for the delivery of radiofrequency energy. Patients were followed-up for 12 months and the primary outcome was improvement in Asthma Quality of Life Questionnaire (AQLQ) at 6, 9, and 12 months. Both the BT and sham therapy groups experienced a large improvement in the AQLQ that lasted for 12 months. The absolute difference

between the two groups was statistically significant, but was too small and might not be clinically relevant. Other secondary outcomes including the Asthma Control Questionnaire (ACQ) score, symptom scores, airflow, airway hyper responsiveness, and rescue medication use showed a trend towards more improvement with BT over sham treatment, but none was statistically significant. The authors did not study the effect of BT on step-down of maintenance asthma medications, which according to the national guidelines is the main goal in the long-term management. Both AIR and AIR2 trials show that BT therapy temporarily aggravated asthma symptoms and increased the risk of adverse events some of which required hospitalization.

**Articles:** The literature search revealed around 30 articles on bronchial thermoplasty. The majority were review articles, editorials, and correspondences. Three RCTs conducted by the same group of authors were identified (AIR, AIR2, and RISA trials). RISA trial was too small (N=32), AIR trial had a 5-year follow-up, and AIR2 trial had a sham comparison group. Both AIR and AIR2 trials were selected for critical appraisal. Castro M, Rubin AS, Lavolette M, et al for the AIR2 trial Study group Effectiveness and safety of bronchial thermoplasty in the treatment of severe asthma: a multicenter, randomized, double-blind, sham-controlled clinical trial. *Am J Respir Crit Care Med*, 2010;18:116-124. #### For Non-Medicare Members

Group Health has elected to use the MCG\* Scintimammography (A-0071) for medical necessity determinations. This service is not covered per MCG guidelines.

**\*MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting this service, please send the following documentation to support medical necessity:**

- Last 6 months of clinical notes from requesting provider and/or specialist (general surgery, oncology)
- Most recent imaging reports

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Mammography is the standard tool used for breast cancer imaging. Community screening programs have found that mammography has an overall sensitivity of 75% and a specificity of 92%. The sensitivity of mammography in randomized trials is in the range of 68-88% (Elmore 2005). However, mammography is less sensitive in women younger than 50 and in women with dense breasts (Brem 2008; Killela 2009). Breast-specific gamma imaging (BSGI) is intended for use when post-mammography evaluation is indicated. Other technologies currently used for post-mammography evaluation include ultrasound and magnetic resonance imaging (MRI). Each of these technologies has its advantages and limitations. Ultrasound is well tolerated, it does not use ionizing radiation or require intravenous contrast administration, and it is able to identify small non-palpable masses in dense breast tissue; however, it is time consuming to perform and increases the risk of false-positive results (Le-Petross 2011). MRI of the breast offers high sensitivity (93-100%), but it has a low specificity (65-79%), which leads to a high number of false-positive results (Zhou 2009). Additionally, MRI is not suitable for all patients; women with pacemakers, who are claustrophobic, and who cannot lie prone for the required length of the exam may not be suitable candidates for MRI (Ferrara 2010).

Imaging modalities can be roughly classified as either anatomical imaging or functional imaging. Anatomical imaging techniques, such as mammography and MRI, identify structural abnormalities in the body. Functional imaging techniques, such as BSGI, illustrate a physiological behavior. Functional imaging evaluates the metabolic activity of breast lesions through uptake of radioactive tracers. To conduct BSGI, patients are given an intravenous injection with a small dose of a tracing agent (Technetium Tc99m) that emits gamma rays. The tracer is absorbed

by the cells in the body. Cancer cells absorb more of the tracing agent due to their higher metabolic activity and increased blood supply. Thus, cancerous areas show up as “hot spots” on BSGI imaging. When used for screening, functional imaging techniques have an advantage over anatomical imaging techniques because they can usually reliably differentiate between an active tumor and scar tissue (Ferrara 2010). BSGI is not without limitations; it is limited by its inability to reliably image cancers smaller than 1 cm. The sensitivity of BSGI is also low (35%-65%). The advent of high-resolution breast-specific gamma cameras is thought to have increased the sensitivity of BSGI and its ability to detect cancers smaller than 1 cm (Brem 2008).

BSGI uses a specialized high-resolution, small field-of-view gamma camera. The cameras are compact and maneuverable and they can be placed close to the chest to image deep within the breast. Two camera manufacturers were identified. One camera is the Dilon 6800 made by Dilon Technologies of Newport News, VA. An earlier version of this camera, the Dilon 2000, was approved by the FDA in 1999, but the Dilon 6800 was not identified in the FDA database. The second technology is the LumaGem camera developed by Gamma Medica. A version of the LumaGem scintillation camera was cleared by the FDA in 2000. As with the Dilon camera, the breast-specific model described on the manufacturer’s Web site, the LumaGem 3200S, was not identified in the FDA database (Ferrara 2010).

## Medical Technology Assessment Committee (MTAC)

### **Breast Specific Gamma Imaging**

#### **02/05/2007: MTAC REVIEW**

**Evidence Conclusion:** No published studies were identified that compared the diagnostic accuracy of breast-specific gamma cameras and standard techniques for post-mammographic imaging such as MRI and ultrasound. In addition, there were no studies that evaluated change in clinical practice if the breast-specific gamma camera were used instead of, or in addition to, MRI or ultrasound. Two studies (Brem et al., 2005; Coover et al., 2004) were evaluated that examined the ability of a breast-specific gamma camera to identify cancers in high-risk women not identified by mammography or physical examination. Both studies were small and had industry funding, and only one included an independent blind comparison of the gamma camera findings to a reference standard for all patients (Brem et al., 2005). The reference standard in the Brem study was biopsy of positive findings and one-year follow-up for negative cases. In the Brem study, there were 14 false-positives (specificity=85%) and 2 true positives (sensitivity=100%) in 94 women. The confidence interval for sensitivity was very wide due to the small sample size (the 95% CI varied from 22% to 100%) so it is difficult to draw conclusions about accuracy from this study. The Coover study, which was weaker methodologically, identified 3 cancers with the breast-specific gamma camera in 37 women who had had negative mammograms. Although results from these studies are promising, additional appropriately designed studies with a larger number of women are needed to evaluate the accuracy of the breast-specific gamma cameras.

**Articles:** One published study with the Dilon 6800 camera was identified (Brem et al., 2005). This study included 94 patients and was critically appraised. An earlier study by the same lead author (Brem RF) evaluated a prototype of the Dilon gamma camera and was not evaluated further. There also appears to be unpublished data that were presented at a professional meeting in 2005 comparing the performance of the Dilon 6800 camera to breast MRI. One published study was identified that stated it used the LumaGem gamma camera to detect breast cancer in women with normal mammograms and clinical examinations (Coover et al., 2004). This study included 37 women and was critically appraised. A second, more recent study with 40 patients (Rhodes, 2005) may have used this or a similar technology, but the authors only stated that they used a prototype gamma camera. The Coover study was critically appraised. No studies were identified that used commercially available cameras to image patients in situations suggested by a manufacturer including patients dense breast tissue, multiple suspicious lesions or clusters of microcalcifications. *The studies reviewed were:* Brem RF et al. Occult breast cancer: Scintimammography with high-resolution breast-specific gamma camera in women at high risk for breast cancer. *Radiology* 2005; 237: 274-280. See [Evidence Table](#). Coover LR, Caravaglia G, Kuhn P. Scintimammography with dedicated breast camera detects and localizes occult carcinoma. *J Nucl Med* 2004; 45: 553-558. See [Evidence Table](#).

The use of breast-specific gamma imaging in the diagnosis of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **04/19/2010: MTAC REVIEW**

### **Breast Specific Gamma Imaging**

**Evidence Conclusion:** There is limited evidence regarding the accuracy of BSGI compared to MRI. The best available evidence was the Brem et al. study (2007), which compared the sensitivity and specificity of BSGI, using a high-resolution breast-specific gamma camera with MRI in patient with indeterminate breast findings. In this study, 23 patients with indeterminate breast findings underwent both a BSGI scan and a MRI. The results were

confirmed with pathological findings. The study found that compared to MRI, BSGI had a statistically significantly higher specificity (71% vs. 25%), and a lower sensitivity (89% vs. 100%). The authors indicated that this is not statistically significant; however, they used a qualitative rather than a quantitative approach to determine significance. Although an 11% difference in sensitivity may be of clinical relevance. This study compared BSGI to MRI using pathology as a gold standard; however, there were several limitations: the study had a small sample size, patient selection criteria were unclear, and it is not stated if reviewers were blinded to the results from the other imaging technique. There were no published studies that compared BSGI with MRI in high risk women or in younger women with dense breast tissue. Kaiser also reviewed this technology on March 23, 2009 and came to similar conclusions. Conclusion: There is insufficient evidence to date to determine whether BSGI improves diagnostic accuracy compared to MRI in patients with indeterminate breast findings.

**Articles:** The literature search revealed five relevant studies. Three were retrospective and two were prospective. All of the studies had methodological limitations. One of the prospective studies included a comparison group and was selected for review. Brem RF, Petrovitch I, Rapelyea JA et al. Gamma Imaging with 99mTc-Sestamibi and Magnetic Resonance Imaging in the Diagnosis of Breast Cancer-A Comparative Study. The Breast Journal 2007; 13: 456-469. See [Evidence Table](#).

The use of breast-specific gamma imaging in the diagnosis of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

### 12/19/2011: MTAC REVIEW

#### Breast Specific Gamma Imaging

**Evidence Conclusion:** Since the 2010 review, the literature search revealed only one small observational study that addressed the diagnostic accuracy of BSGI. This study was not selected for review due to methodological limitations (small sample size, patient selection criteria and baseline characteristic were not addressed, and confidence intervals were not provided) (Ozulker 2010). Conclusion: There is insufficient evidence to determine whether BSGI improves diagnostic accuracy when used as an adjunct to mammogram.

**Articles:** Since the 2010 review, the literature search revealed only one small observational study that addressed the diagnostic accuracy of BSGI. This study was not selected for review due to methodological limitations (small sample size, patient selection criteria and baseline characteristic were not addressed, and confidence intervals were not provided) (Ozulker 2010).

The use of breast-specific gamma imaging in the diagnosis of breast cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Canaloplasty

- Circumferential Viscodilatation and Tensioning of Schlemm's Canal for Primary Open-Angle Glaucoma

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Patients with a diagnosis of glaucoma are covered by Medicare.

##### For Non-Medicare Members

Canaloplasty is covered when all of the following criteria have been met:

- 1) Diagnosis of glaucoma with eye pressures inadequately controlled on maximum tolerated topical medications and laser treatment
- 2) Documented risk for greater problems with standard glaucoma surgery (trabeculectomy or valve implant) as defined by one of the following:
  - Myopic diopters greater than 5
  - Hyperopic diopters greater than 3
  - Moderate to severe dry eye
  - Blepharitis
  - Preservative allergy
  - Has allergy or side effects preventing the use of one or more of the standard glaucoma eye drops
  - Had problems with trabeculectomy or glaucoma valve implant surgery in the contralateral eye (such as bleb dysesthesia (chronic eye pain) or need for re-operation)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Glaucoma is a common eye disease caused by elevated intraocular pressure (IOP) that leads to optic nerve damage and visual field loss. Glaucoma is frequently referred to as the "silent thief of sight" because it is not usually associated with ocular or systemic symptoms but can cause irreversible blindness if left undiagnosed and untreated. It is estimated that over 2 million people in the United States have glaucoma, 80,000 of whom are legally blind as the result of the disease (Lee 2005).

Glaucoma has been classically categorized into primary or secondary angle-closure glaucoma (closure of the anterior chamber angle), and primary or secondary open-angle glaucoma (where the anterior chamber angle of the eye remains open). The condition is considered primary if the eye has no pre-existing disease and secondary in an eye with a pre-existing disease. Primary open-angle glaucoma is the most common type in the US. It occurs insidiously and is usually asymptomatic in its early stages. In the later stages, when the optic nerve is damaged, the patient experiences progressive worsening of vision, and eventually peripheral followed by central visual loss (Lee 2005, Rotchford 2005).

The treatment goal for patients with glaucoma is preventing functional vision loss by lowering the IOP to a level where progressive glaucomatous optic neuropathy is stopped, or at least slowed. Conventional treatment usually begins with the use of topical IOP-lowering agents. These include beta-blockers, alpha-adrenergic agonists, carbonic anhydrase inhibitors, cholinergic, and prostaglandin analogs. Laser trabeculoplasty has also been used to further lower the IOP to decrease or eliminate the need for antiglaucoma medications. Incisional filtering surgery is considered if the patient's IOP cannot be reduced with the maximal tolerated medical therapy, laser trabeculoplasty or a combination of both. Trabeculectomy is a filtration surgical procedure commonly used to lower the IOP. The procedure involves creating an opening in the anterior chamber angle to allow the aqueous humor

flow from the anterior chamber into a space beneath the conjunctiva under the surface of the eye. A successful trabeculectomy procedure is marked by an elevated conjunctival zone, the bleb, where the aqueous gathers in pockets prior to absorption into the surrounding blood vessels and lymphatics. Trabeculectomy with or without antimetabolites can successfully control IOP, but not without risks. It may be associated with numerous intraoperative or postoperative complications including hypotony, bleb leaks, bleb infections /endophthalmitis, hyphaema, loss of visual acuity, increased risk of cataract formation, scar tissue which causes obstruction of the channel created and in turn blocking the drainage of the aqueous humor, and several other complications (Lee 2005, Rotchford 2005, Lewis 2007).

Nonpenetrating glaucoma procedures were first introduced in the late 1950s and early 1960s, and revived in the 1980s and 1990s, as alternatives to standard filtration surgeries for controlling IOP in open-angle glaucoma without penetration of the intraocular space. These procedures include deep sclerectomy with and without an implant, and viscocanalostomy. The latter is performed by several techniques that basically involve the production of superficial and deep scleral flaps, excision of the deep scleral flap to create a scleral reservoir, and unroofing of Schlemm's canal. An ophthalmic viscoelastic device is then injected into the deep scleral lake and toward the cut ends of Schlemm's canal to open it and create a passage from the scleral reservoir to the canal. The superficial scleral flap is then sutured water tight trapping the viscoelastic until healing takes place (Filippopoulos 2008, Green 2007, Nouredin 2006).

Recent advances in technology, ocular ultrasound, and viscoelastics have led to the development of canaloplasty as a promising nonpenetrating surgical technique for lowering the IOP in patients with open-angle glaucoma. The procedure aims at increasing the flow of aqueous humor from the anterior chamber through the trabecular meshwork and Descemet's window into and around the Schlemm's canal and out through the collector channels, thus reducing the IOP by restoring the trabeculocanalicular outflow pathway. The procedure utilizes the full 360 degrees of the canal and outflow system without creating a fistula or need for a bleb. Unlike viscocanalostomy, canaloplasty aims at opening the entire length of the canal rather than opening only a section of it. Canaloplasty uses viscoelastic and specialized flexible microcatheter with an illuminated tip (iScience surgical Ophthalmic Microcannula) to forcibly open the Schlemm's canal (Lewis 2006, 2007, Godfrey 2009).

Similar to viscocanalostomy, canaloplasty is completed under a scleral flap. A one-half thickness parabolic shaped scleral flap is dissected. A deep flap is then dissected down to a depth very close to the ciliary body/choroid and carefully carried forward anteriorly until the Schlemm's canal is unroofed. The canal is identified and intubated with a cannula which has a lighted tip to identify its location as it passes through the canal. The cannula has a lumen to allow for the passage of viscoelastic for dilatation of the canal. Once it has passed the full length of Schlemm's, a 10-0 Prolene suture is tied to the cannula which is then withdrawn leaving the suture in its place. Tying off the suture provides tension that holds the canal open. The scleral flap is then tightly closed as well as the conjunctiva. The procedure is usually performed under special ultrasound imaging to help identify the canal and its instrumentation (Lewis 2006, 2007).

Canaloplasty has a steep learning curve. Identifying and entering the Schlemm's canal, inserting the catheter, placing the tension suture, and providing the right tension in the suture depend on the surgeon's skill and experience. The outcome of the surgery also depends on the selection of the patients; those who had previous trabeculectomies with scarring in the canal are not good candidates. According to the authors of a review article, the ideal candidates would be patients who cannot have a bleb because they wear contact lenses, have a dry eye, or for cosmetic reasons. The procedure is contraindicated in patients with angle recession, neovascular glaucoma, chronic angle closure, narrow-angle glaucoma, narrow inlets with plateau iris, and in patients with previous surgery which would prevent 360o catheterization of Schlemm's canal (Lewis 2006, Godfrey 2009).

In June 2008 The FDA cleared the iScience Interventional Canaloplasty Microcatheter for marketing for catheterization and vasodilatation of Schlemm's canal to reduce intraocular pressure in adult patients with open angle glaucoma.

## Medical Technology Assessment Committee (MTAC)

### Canaloplasty

#### 10/06/2008: MTAC REVIEW

**Evidence Conclusion:** There is insufficient published evidence to determine the safety and efficacy of canaloplasty in the management of open angle glaucoma among adults. There are no published controlled trials that compared the outcomes of canaloplasty to other established medical therapies, laser trabeculoplasty, or filtration surgeries as trabeculectomy. The only published studies were 2 relatively small case series, conducted in the same centers with the same group of investigators, and possibly with a population overlap. None had a control

or comparison group. Three of the principal authors had consulting agreement with iScience Interventional, the manufacturer of the microcatheter used. The interim analysis of one-year results of a multicenter case series (Lewis 2007) that included 94 patients from the 14 centers in US and Germany, showed that IOP dropped significantly after the procedure among all patients (from 24.7 + 4.8 mmHg at baseline to 15.3 + 3.9 mmHg at 12 months), and among the sutured subgroup (from 23.9 + 4.3 mmHg at baseline to 15.3 + 3.8 mmHg at 12 months). The medication use also dropped from a mean of 1.9 + 1 per patient to 0.6 + 0.9 per patient at 12 months. The most common adverse events observed were hyphaema and increased IOP which occurred at a rate of 3% each. The other published series that included 54 patients with open-angle glaucoma and cataract reported similar outcomes. None of the two studies compared the procedure to any other established surgical or nonsurgical intervention. Conclusion: There is insufficient evidence to determine that canaloplasty has the same or better effect than medical treatment in reducing intraocular pressure in adult patients with open angle glaucoma. There is insufficient evidence to determine that canaloplasty has the same or better effect than filtration surgical procedures as trabeculectomy in reducing intraocular pressure in adult patients with open angle glaucoma. There is insufficient evidence to determine that canaloplasty is safer for the patient than filtration surgical interventions as trabeculectomy.

**Articles:** The search yielded only two studies on canaloplasty: Lewis 2007, and Shingleton 2008. Both were prospective case series with no comparison or control groups. Lewis and colleagues reported the interim results of canaloplasty performed on 94 patients with open-angle glaucoma. Shingleton et al reported one-year results of canaloplasty combined with cataract surgery performed on 54 patients with open-angle glaucoma and cataract. The authors of the latter study were co-authors in the first study. Both studies involved the same 14 clinical sites and same group of ophthalmologists. It appears also that there could be an overlap of the patients participating in the two studies. Both reported on one year results. The published case series with the larger population size was selected for critical appraisal. Lewis R A, von Wolff K, Tetz M, et al. Canaloplasty: Circumferential viscodilation and tensioning of Schlemm's canal using a flexible microcatheter for the treatment of open-angle glaucoma in adults. Interim clinical study analysis. J Cataract Refract Surg 2007; 33:1217-1226. See [Evidence Table](#).

The use of canaloplasty in the treatment of primary open-angle glaucoma does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 10/05/2009: MTAC REVIEW

##### Canaloplasty

**Evidence Conclusion:** The available literature does not provide sufficient evidence to determine the safety and efficacy of canaloplasty in the management of open angle glaucoma among adults. There are no published controlled trials that compared the outcomes of canaloplasty to other established medical therapies, laser trabeculoplasty, or filtration surgeries as trabeculectomy. The only published studies were 2 relatively small case series, conducted in the same centers by the same study group, and possibly with a population overlap. Lewis and colleagues, reported on the one- and two-year interim results of canaloplasty with or without corneal phacoemulsification cataract surgery, and Shingleton et al (2008) reported on the results of a subgroup that underwent the two procedures. Neither of the two series had a control or comparison group. iScience Interventional, the manufacturer of the microcatheter used in the studies, supported the studies and had consulting agreement with three of the principal authors. In their first publication, Lewis and colleagues (2007) reported the one-year interim results of canaloplasty performed on 94 patients with open-angle glaucoma, and in their 2009 publication they reported on the results of the procedure among 127 patients. No explanation was provided why there were more patients in the 2-year follow-up. The interim analysis of one-year results showed that IOP dropped significantly after the procedure among all patients from 24.7 + 4.8 mmHg at baseline to 15.3 + 3.9 mmHg at 12 months. The medication use also dropped from a mean of 1.9 + 1 per patient at baseline to 0.6 + 0.9 at 12 months. Eyes that underwent a combined canaloplasty and posterior chamber intraocular lens (IOL) implantation had lower IOP and medication use than those undergoing canaloplasty alone. The two-year postoperative data were similar to those observed at the end of the first year follow-up with a minimal increase in the mean IOP and medication use. Overall 32% reduction in IOP and 74% reduction on medication use were achieved in 24 months. Surgical complications were reported in 15 patients (16%) in the first publication and in 10 patients in the second report, with hyphaema and increased IOP >30mmHg being the most common. Conclusion: There is insufficient evidence to determine that canaloplasty is better than or equivalent to medical treatment in reducing intraocular pressure in adult patients with open angle glaucoma. There is insufficient evidence to determine that canaloplasty is better than or equivalent to filtration surgical procedures as trabeculectomy in reducing intraocular pressure in adult patients with open angle glaucoma. There is insufficient evidence to determine that canaloplasty is safer than filtration surgical interventions as trabeculectomy.

**Articles:** The search yielded only one more recent report (Lewis et al 2009) on the 2 year results of the same case series on canaloplasty that was published earlier in 2007 and reviewed by MTAC in 2008. No randomized or nonrandomized controlled trials comparing canaloplasty to another treatment or intervention were identified.

The new report by Lewis and colleagues (2009) was critically appraised. Lewis R A, von Wolff K, Tetz M, et al. Canaloplasty: Circumferential viscodilation and tensioning of Schlemm's canal using a flexible microcatheter for the treatment of open-angle glaucoma in adults. Two-year interim clinical study results. J Cataract Refract Surg 2009;35:814-824 See [Evidence Table](#).

The use of canaloplasty in the treatment of primary open-angle glaucoma does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Capsule Endoscopy

- Given® AGILE Patency System
- M2A™ Capsule Endoscopy
- PillCam™ SB
- Wireless Capsule Enteroscopy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	In April 2011 Noridian retired <a href="#">Wireless Capsule Endoscopy (L23785)</a> . These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an article. Most LCDs are not retired because they are incorrect. Therefore, continue to use LCD 23785 for assessing medical necessity for GHC Medicare Members.

#### For Non-Medicare Members

Group Health has elected to use the Capsule Endoscopy (GHC-0134) MCG\* for medical necessity determinations.

**\*The MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 12 months of clinical notes from requesting provider &/or specialist (gastroenterology)
- Most recent lab work

#### Patency Capsule

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

#### Wireless Endoscopy

Approximately 5% of patients presenting with obscure gastrointestinal (GI) bleeding do not have a source identified after evaluation with upper endoscopy, colonoscopy and/or barium studies. Enteroscopy, evaluation of the small bowel, is indicated in many of these patients. Push enteroscopy, sonde enteroscopy and intraoperative enteroscopy are commonly used options. Push enteroscopy is relatively easy to perform, but is limited by its inability to examine beyond the mid to distal jejunum in most patients. Sonde-type enteroscopes are longer than push enteroscopes and in some cases can examine as far as the terminal ileum. Disadvantages include long

procedure times and a steep learning curve to master the technique. Intraoperative enteroscopy was first reported in 1976 and is considered the “gold standard” for evaluating the small bowel for the source of unexplained GI bleeding. However, this is an invasive procedure that requires a laparotomy (Adrain and Kversky, 1996).

The M2A (mouth-to-anus), a pill-sized disposable endoscope, is proposed as an alternative non-invasive tool for identifying obscure GI bleeding. The M2A capsule contains a video camera, lights, transmitter and batteries. It is swallowed by the patient and, as it moves through the digestive tract, it transmits video signals which are stored in a recorder attached to the patient’s belt. The M2A moves through the digestive tract with the aid of peristalsis and is then excreted normally by the patient. About five hours of continuous reading is possible. The video can be downloaded from the recorder to a computer workstation with special software (Reporting and Processing of Images and Data, RAPID).

The M2A capsule, manufactured by Given Imaging (Yoqneam, Israel), received FDA approval in August 2001.

M2A capsule endoscopy for unexplained chronic gastrointestinal blood loss or anemia was previously reviewed by MTAC in December, 2001. At that time there were no studies of health outcomes and no data on patients with unexplained chronic gastrointestinal blood loss.

#### Iron Deficiency Anemia:

Iron deficiency anemia (IDA) represents a major public health problem. Its estimated prevalence in the US is 2% of adult men and 9-12% of non-Hispanic white women. It is most commonly secondary to chronic occult bleeding from the gastrointestinal tract, and is one of the common reasons for referral to gastroenterology clinics (Apostolopoulos 2006, Killip 2007).

Obscure gastrointestinal bleeding (OGIB) is defined as bleeding of unknown origin that persists or recurs after a negative initial endoscopy. OGIB accounts for at 5-10% of all gastrointestinal (GI) bleeds, and may be overt or occult. Overt GI bleeding is clearly signified by rectal bleeding, bloody stools, or melena. Occult blood loss, on the other hand, is subtle and may only present as iron deficiency anemia or as a positive fecal occult blood test (Triester 2005, Concha 2007, Estevez 2006).

Diagnosing the cause of OGIB might be clinically challenging, especially when the origin of bleeding is a very small lesion in parts of the small bowel that is not apparent or accessible for direct viewing. Patients with OGIB may undergo multiple diagnostic procedures and invasive testing. Diagnostic work-up may include barium x-ray studies of the bowel, endoscopy, enteroscopy, computed tomography (CT), radionuclide scans, angiography, intraoperative endoscopy, and exploratory surgery.

Evaluation of the small bowel by conventional endoscopy has the advantage of allowing for intervention if the bleeding site is identified, but may be difficult due to the length, motility, tortuosity, looping, and free hanging course of the small bowel. Typically an endoscope will reach only the proximal small bowel. Enteroscopy is an extension of an upper endoscopy where a longer endoscope that reaches down to the ileum is used. There are different types of enteroscopes including the push type and the sonde-type. Push enteroscopy allows the evaluation of the jejunal mucosa up to 150 cm beyond the ligament of Trietz; however it is an invasive procedure that requires deep sedation or anesthesia, has a variable diagnostic yield (38-75%), and does not explore lesions in the ileum. Double balloon enteroscopy (DBE) is a modified push enteroscopy that is emerging as an alternative for operative enteroscopy. The balloons grip the intestinal wall allowing further insertion of the scope and the examination of larger areas of the small bowel reaching up to 300 cm in the oral direction. The entire small bowel could be potentially evaluated when a DBE is carried out with oral and anal approaches in conjunction (Lewis 2000, Mitchell 2004, Concha 2007).

Laparotomy with intraoperative enteroscopy is used after all other techniques fail to detect the source of bleeding, when there are adhesions that require lysis via a laparoscopic approach, or and when the risk of bleeding exceeds the risk of the procedure. It is considered the gold standard for a complete endoscopic evaluation of the small bowel. However, intraoperative endoscopy is invasive, risky, and may cause artifacts that could be falsely identified as the cause of bleeding. Moreover, it was reported that intraoperative endoscopy can examine only 50-80% of the small bowel, and detect the source of bleeding in up to 40% of undiagnosed cases (Mitchell 2004).

Other indirect methods for visual examination of the small bowel such as x-ray series and enteroclysis, radioisotope bleeding scans, angiography, computed scans, and MRIs have been found to have low sensitivities in detecting the source of bleeding, especially for vascular lesions which are the most frequent cause of OGIB (Estevez 2006, Leighton 2006).

Capsule endoscopy (M2A video capsule endoscope, Given Imaging Ltd, Yoqneam, Israel) was introduced in 2001 as a noninvasive direct endoscopic technique for visualization of the small bowel. It is a swallowable wireless capsule endoscope 26 mm in length and 11 mm in diameter. The device consists of an optical dome, 4 light emitting electrodes, a sensor, 2 batteries, and a micro transmitter. The capsule acquires and transmits digital images at the rate of 2/second to a sensory array attached to the patient's abdomen. It is able to capture video-images of the mucosal surface of the entire length of the small intestine directly for 7-8 hours. The capsule is propelled forward through the GI tract with the peristaltic movement, and is excreted normally by the patient after 8-72 hours. The images can be downloaded from the recorder to a computer workstation with special software (Hara 2005, Eliakim 2007).

The capsule endoscopy is noninvasive and easy to perform. However, it lacks the ability to obtain a tissue sample for biopsy, deliver therapy, or treat pathology when it is found. In addition, it was reported that some lesions could be missed due to rapid or delayed small bowel transit. It might also be difficult to identify the precise location of the pathology when it is discovered. Unlike endoscopy, the lesion cannot be washed and re-examined, and large amounts of intraluminal bile could be mistaken for blood. Interpretation of the small bowel images is highly subjective, and the potential inter-observer variation may compromise the reliability and accuracy of the technology. Moreover, some investigators have reported that the quality of the images taken by the capsule was not satisfactory, and that the duodenum was not effectively visualized. The 8 hour-battery life of the capsule is estimated to be enough time for 85% of the patients to image the entire small intestine. For the rest, the battery life expires before the capsule reaches the cecum. The major potential complication with capsule endoscopy is the risk of capsule retention due to stenosis, stricture, diverticulum, or fistula. The documented incidence of entrapment is 1%, however a retained capsule may potentially lead to intestinal obstruction, and its retrieval may necessitate surgical extraction (Concha 2007, Mazarola 2007, Enns 2007).

The PillCam TM, previously marketed as M2A TM, manufactured by Given Imaging (Yoqneam, Israel), received FDA approval in August 2001 for detecting problems in the small bowel in adults and children ten years of age or older. The most common application for capsule endoscopy is the evaluation of obscure gastrointestinal bleeding. The second most studied indication is the evaluation of suspected Crohn's disease. It is also being used to detect polyps, cancers, other causes of chronic inflammation, bleeding, and anemia. Capsule endoscopy is contraindicated in patients with intestinal blockage, strictures or fistulas, pregnant women, patients with swallowing disorders, or those with a cardiac pacemaker or other implanted electromagnetic devices.

### **Patency Capsule**

The capsule endoscopy is relatively noninvasive, easy to perform, well tolerated, and has a low incidence of complications. The most worrisome complication is capsule retention due to stenosis, stricture, diverticulum, or fistula. Overall, the documented incidence of capsule retention or entrapment is as low as 1%, but may be higher in some population at risk. Studies reported retention rates of 5-13% in patients with known Crohn's disease, and a rate of 21% in suspected bowel obstruction. A retained or impacted capsule may potentially lead to small bowel ileus, intestinal obstruction, or fragmentation of the capsule with potential toxic hazard. Risk factors for capsule retention include major abdominal surgery, known or suspected Crohn's disease, previous intestinal obstruction, prolonged NSAID use, ischemic bowel disease, radiation injury, and suspected bowel tumors. Retrieval of a retained capsule requires medical, endoscopic or surgical intervention (Sears 2004, Signorelli 2006, Concha 2007, Enns 2007, Caunedo-Alvarez 2008).

Due to the risk of capsule retention, wireless capsule endoscopy is contraindicated in patients with suspected small bowel strictures. In most centers, a radiographic evaluation of the small bowel patency is mandatory before performing a wireless capsule endoscopy in patients with a risk of small bowel strictures. Standard imaging techniques include small bowel (SB) follow-through, barium enema, enteroclysis, or CT enteroclysis. Limitations of these techniques include a tendency to underestimate or overestimate SB strictures. They can identify long or medium stenosis with great reduction in their lumen size, but may not detect a short intestinal stenosis or obstruction, leading to false negative results (Boivin 2005, Caunedo-Alvarez 2008, Karagiannis 2009).

Given Imaging, the manufacturer of the PillCam SB has developed a new system (The Given® Patency Capsule) to identify patients with strictures that may cause retention of the video capsule. The first generation was the M2A patency capsule, which due to the risk of obstruction, was modified to the AGILE Patency Capsule (PC). This consists of a dissolvable capsule and a scanner. The capsule is composed of a lactose body with 5% barium (to induce radiopacity) that surrounds a small radiofrequency identification tag (RFID). The body is coated with an impermeable cellophane membrane with two wax timer plugs located at each end of the capsule. The timer plugs

seal the capsule's body, and each has a small window or opening that allows penetration by gastrointestinal (GI) fluids.

The Agile patency capsule (PC) has the same dimensions and shape as the PillCam. Once the patient ingests the capsule, it is propelled through the GI tract by normal peristalsis. The Agile PC is designed to remain intact for 30 hours (40 hours in the first generation). It is assumed that it will be excreted intact if there is no bowel obstruction. In this case a PillCam capsule can be administered. If there is any kind of stricture hindering its passage for more than 30 hours, the patency capsule starts to disintegrate (except for the identification tag), allowing the insoluble outer membrane to collapse and be excreted deformed or in fragments. The persistence of the PC inside the GI tract can be verified by means of radiology or with a radiofrequency emitting external detector device locating the RFID (Signorelli 2006, Caunedo-Alvarez 2008).

It is reported that the Given patency capsule may provide direct evidence of functional patency of the gut lumen, even in those patients showing radiological evidence of small bowel stricture. This information may allow a distinction between rigid fibrotic strictures and flexible ones (Spada 2005, Karagiannis 2009).

The Given® AGILE Patency System received marketing clearance from the U.S. Food and Drug Administration (FDA) in 2006, as an accessory to the PillCam to verify adequate patency of the gastrointestinal tract in patients with known or suspected strictures prior to administration of the PillCam video capsule.

## Medical Technology Assessment Committee (MTAC)

### Capsule Endoscopy

#### 12/12/2001: MTAC REVIEW

**Evidence Conclusion:** There is insufficient published evidence on which to base a conclusion about the effect of M2A capsule endoscopy on health outcomes.

The search yielded 4 articles. One of these was a historical piece, One was a letter to the editor describing the use of the technology with 4 cases. The third was an empirical study conducted in dogs. The fourth was description of the technology including acceptability (e.g. ability to swallow, quality of images, mouth-to-evacuation time) in 10 normal human volunteers. There were no studies of health outcomes and no data on patients with unexplained chronic gastrointestinal blood loss. In addition to the studies found on Medline, there were several published abstracts in the Given Imaging reference list. None of the articles were suitable for critical appraisal.

The use of M2A™ (Given Imaging) capsule in the diagnosis of small bowel lesions/chronic bleed sites does not meet the *Group Health Medical Technology Assessment Criteria 2* for effectiveness.

#### 12/10/2003: MTAC REVIEW

### Capsule Endoscopy

**Evidence Conclusion:** The prospective comparative studies that were reviewed suggest that M2A capsule endoscopy has a significantly greater diagnostic yield than push enteroscopy among patients with unexplained gastrointestinal bleeding. The studies did not use the gold standard evaluation tool, an invasive surgical procedure, so diagnostic accuracy (e.g. sensitivity, specificity) cannot be calculated.

**Articles:** The search yielded 23 articles. The ideal study would be an independent, blind comparison of M2A and a gold standard diagnostic test. There were 5 comparative studies in patients with gastrointestinal bleeding. No articles specifically studied use of the M2A for anemia, but patients with anemia suggestive of overt bleeding were included in some of the GI bleeding studies. The methodology was similar in the 5 studies. All compared M2A evaluation with push enteroscopy and none of the studies included evaluation with intraoperative enteroscopy, the invasive "gold standard" procedure. The primary outcome in each study was diagnostic yield (the ability to diagnose the source of bleeding) of the two procedures. All 5 studies included blinded evaluation of test results. Results of the studies were similar; all found a higher rate of diagnostic yield with the M2A. Findings were statistically significant in 4 of the 5 studies and did not reach statistical significance in the smallest study. Sample sizes ranged from 20 to 60 patients. The two largest studies (n=52, n=60) were critically appraised: Mylonaki M, Fritscher-Ravens A, Swain P. Wireless capsule endoscopy: a comparison with push enteroscopy in patients with gastroscopy and colonoscopy negative gastrointestinal bleeding. *Gut* 2003; 1122-1125. See [Evidence Table](#) Saurin J-C, Delvaux M, Gaudin J-L. et al. Diagnostic value of endoscopic capsule in patients with obscure digestive bleeding: Blinded comparison with video push-enteroscopy. *Endoscopy* 2003; 35: 576-584. See [Evidence Table](#)

The use of M2A™ (Given Imaging) capsule in the diagnosis of small bowel lesions/chronic bleed sites does meet the *Group Health Medical Technology Assessment Criteria* for effectiveness.

## 12/03/2007: MTAC REVIEW

### Capsule Endoscopy

**Evidence Conclusion:** Diagnostic accuracy: Triester, Leighton and colleagues' meta-analyses (2005, 2006) as well as the other published meta-analyses compared CE with one or more alternative diagnostic modalities for evaluation the small bowel in patients with OGIB. Triester's meta-analysis included studies either published in full or in the abstract form. The studies compared the performance of CE mainly to push enteroscopy and barium radiography, none of which is considered as a gold standard, nor is able to identify all kinds of lesions in the entire small bowel. The performance of CE and other diagnostic modalities were thus measured as diagnostic yield, which mainly depends on subjective interpretation, rather than sensitivity and specificity. CE was found to be associated with significantly higher incremental yield and number needed to test around 3. A higher yield might indicate that CE is superior to the alternative method but does not assess sensitivity of the test, nor is it able to discriminate the false positive findings. Hartmann and colleagues' 2005, study (not included in the meta-analysis) compared capsule endoscopy to the gold standard of intraoperative enteroscopy. In that study 47 consecutive patients with OGIB and a negative initial work-up underwent both capsule and intraoperative endoscopy. The source of bleeding was located by intraoperative endoscopy in 72.3% of cases and by capsule endoscopy in 74.5%. Compared to the gold standard CE had a sensitivity of 97%, specificity of 85%, positive predictive value of 95% and negative predictive value equal to 86%. CE was not associated with any major adverse events, while one patient died of postoperative peritonitis after laparotomy. Apostolopoulos and colleagues 2006, compared the performance of CE to enteroclysis among 51 patients with unexplained iron deficiency anemia after negative endoscopic evaluation of the upper and lower gastrointestinal tract. This was a highly selected group of patients which may limit generalization of the results. Upper GI series and push enteroscopy were not included among the diagnostic procedures performed. The authors compared the yield of CE with enteroclysis which is not considered as a gold standard, and the results were presented as diagnostic yields not sensitivity and specificity. Its results show that CE had a diagnostic yield of 56.9% vs. 11.8% for the enteroclysis ( $p < .0001$ ). Impact of capsule endoscopy on patient management: The published studies, to date, on the influence of capsule endoscopy on patient management included highly selected groups of patients with wide variations in their baseline characteristics as age, indication of endoscopy, duration of bleeding, number and type of previous investigations undergone, as well as others variables. In addition, the investigators used different diagnostic criteria for the identification of the bleeding pathology, as reflected in the wide range of diagnostic yield. The latter was also influenced with the experience and number of researchers interpreting the CE images. Thus, the published studies with their potential biases and confounding factors, and with the lack of randomized controlled trials, do not provide sufficient evidence to determine that capsule endoscopy would lead to any incremental improvement in the management of patients. Impact of CE on patient outcome: There is insufficient evidence to determine the impact of CE on patient outcome. The published outcome studies were small case series with no control groups. The therapies and interventions received by the patients were not standardized and varied between studies. Patients were treated with medical, endoscopic or surgical interventions and complete resolution of bleeding was achieved in 40-85% of cases. This varied according to study, eligibility criteria, patient characteristics, bleeding condition, condition, and treatment received. Randomized controlled trials with long-term follow-up periods are needed to determine the effect of capsule endoscopy on patient management and outcomes. Assessment objective: To evaluate the diagnostic accuracy for the capsule endoscopy (CE) in identifying the lesion of, IDA or obscure gastrointestinal bleeding (OGIB)? To determine whether CE contributes substantially to improved diagnosis and/or replaces other diagnostic tests or procedures. To determine if diagnosing the source of IDA/OGIB with the CE would influence the management decisions? Would it result in providing more appropriate therapy? To determine whether using CE for locating the source of OGIB would improve the clinical and patient-oriented outcomes? Diagnostic accuracy: There were three meta-analyses (Triester 2005, Triester 2006, and Leighton 2006) that evaluated CE for OGIB and/or Crohn's disease. All three were conducted by the same investigators and the two meta-analyses on OGIB included the same studies. There was also another meta-analysis that compared CE to double-balloon enteroscopy, one study that compared CE with the gold standard intraoperative enteroscopy, and several other studies that compared the performance of CE with other diagnostic modalities. Almost all studies investigated the use of CE for patients with OGIB. Two very small studies investigated the use of CE for patients with iron deficiency anemia (IDA) after negative endoscopic evaluation of the upper and lower GI. Apostolopoulos et al 2006 performed CE on 51 out of 253 patients referred for the evaluation of iron deficiency anemia, and Bar-Meir et al 2004, assessed the diagnostic yield of a second CE for 20 patients with severe IDA).

Diagnostic/therapeutic impact:

**Articles:** The literature search identified several prospective studies on the influence of capsule endoscopy on management decisions and/or treatment outcomes. All were case series with no control or comparison groups. The largest more recent meta-analysis of studies that compared CE to other diagnostic modalities, the prospective study that compared it with intraoperative endoscopy, the study on its role in investigating unexplained iron deficiency anemia, a case series on its impact on patient management, as well as 4 outcome studies were

critically appraised. The four outcome studies were summarized in one table. *The following studies were critically appraised:* Triester SL, Leighton JA, Leontiadis GL, et al. A meta-analysis of the yield of capsule endoscopy compared to other diagnostic modalities in patients with obscure gastrointestinal bleeding. *Am J Gastroenterol*; 2005; 100:2407-2418. The use of M2A™ (Given Imaging) capsule in the diagnosis of unexplained iron deficiency anemia does not meet the *Group Health Medical Technology Assessment Criteria* for effectiveness.

**4/18/2011: MTAC REVIEW**

**Capsule Endoscopy**

**Evidence Conclusion:** There is limited published evidence on the usefulness and safety of Agile patency capsule in identifying patients who can safely undergo capsule endoscopy. There are no published randomized controlled trials, to date, that compared the accuracy of Agile capsule to any of the radiographic methods used to assess small bowel patency prior to capsule endoscopy. The case series by Herrerias and colleagues (2008) examined the ability of the Agile system in determining which patients with known strictures can safely undergo capsule endoscopy (CE). 106 eligible patients with evidence of intestinal stricture ingested the patency capsule and were followed up periodically with scanning devices until the capsule was excreted. The intestinal tract was considered sufficiently patent if the patency capsule was excreted intact without any changes in its original dimensions, or if the radiofrequency identification tag (RFID) was not detected by scanning the patients at 32-38 hours after ingestion. 59 patients (56%) excreted the patency capsules intact and underwent capsule endoscopy with the PillCam video capsule, with no cases of capsule retention. The majority of patients who excreted intact patency capsules still had to undergo fluoroscopy as the capsules were passed after the scheduled 38 hours (over 25% were excreted after 60 hours). A total of 17 patients had adverse events mainly abdominal pain; one patient had intestinal obstruction and underwent surgical resection of the proximal colon and terminal ileum. The authors indicate that no remnants of the capsule were found at surgery. The study may suggest that patients who pass the Agile Patency Capsule intact may be suitable candidates for capsule endoscopy, but does not provide sufficient evidence that it is safer and more accurate than other radiographic methods used.

**Articles:** The literature revealed a limited number of articles on the Given Patency System. The published empirical studies were all case series and mainly on the first generation of the patency capsule (M2A Patency Capsule). Only one case series on the newer generation, the Agile Patency System, was identified, and critically appraised. Herrerias J, Leighton JA, Costamagno G, et al. Agile patency system eliminates risk of capsule retention in patients with known intestinal strictures who undergo capsule endoscopy. [Gastrointest Endosc.](#) 2008;67:902-909. See [Evidence Table](#)

The use of patency capsule does not meet the *Group Health Medical Technology Assessment Criteria* for effectiveness.

## Clinical Review Criteria

### Capsule PH Monitoring System for Diagnosis of Gastro-Esophageal Reflux Disease (GERD)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">24-Hour Ambulatory Esophageal pH Monitoring (100.3)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

The disposable capsule pH monitor (Bravo pH Monitoring System) is considered an acceptable alternative to standard catheter-based ambulatory pH monitoring. Medical necessity review for standard catheter based ambulatory pH monitoring does not require medical necessity review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Gastro-esophageal reflux disease (GERD) is a common condition, with an estimated lifetime prevalence of 25-35% in the US. Patients with GERD often report a compromised quality of life due to symptoms, dietary restrictions, and functional limitations. Complications of GERD include esophagitis, strictures, ulcerations and Barrett's esophagus. GERD can be diagnosed clinically when patients present with classic symptoms, heartburn and regurgitation. It is more difficult to diagnose in the absence of typical symptoms. Some less typical symptoms such as chest pain and weight loss may indicate GERD or a more serious condition (Scott & Gelhot, 1999).

Diagnostic tests are often used when the diagnosis is unclear or when there is a concern about complications. Possible diagnostic methods are response of symptoms to omeprazole (a proton pump inhibitor), radiology, endoscopy and ambulatory pH monitoring. Radiographic studies may not be useful because only about one-third of patients with GERD have radiologic signs of esophagitis. Endoscopy is more useful for diagnosing Barrett's esophagus and other complications of GERD than for diagnosing GERD itself.

Ambulatory pH monitoring is currently considered the "gold standard" for diagnosing GERD. It involves placing a nasally passed catheter into the esophagus. The catheter is connected to a monitoring device worn on the patient's belt and levels of pH are recorded over 24-hours. Many patients find this test uncomfortable. Patients may restrict their daily activities which could result in false negative findings, or may not complete the test due to discomfort (Pandolfino & Kahrilas, 2005; Scott & Gelhot, 1999).

The Bravo pH monitoring system (Medtronic) is a non-invasive alternative to catheter-based ambulatory pH monitoring. This system involves attaching a radiotelemetry pH-sensing capsule (approximately the size of a gel cap) to the mucosal wall of the esophagus. The capsule is placed approximately 6 cm above the squamocolumnar junction using a customized delivery system that is removed after the capsule is in place. The capsule can be placed orally or trans-nasally, and the procedure is often done during endoscopy. .

The capsule measures the pH in the esophagus and transmits the information via radio signal to an external receiver. The pager-sized receiver can be worn on the patient's belt or waistband. The receiver has a range of 3-5 feet. At the end of the 24-hour or 48-hour testing period, the information from the receiver is uploaded to a

computer (Pandolfino, 2005; Medtronic website). Potential advantages of the Bravo system are increased comfort and patient compliance.

The Bravo system had been approved by the FDA and has not been previously reviewed by MTAC.

## Medical Technology Assessment Committee (MTAC)

### Capsule PH Monitoring System (Bravo System)

#### 08/01/2005: MTAC Review

**Evidence Conclusion:** Only one study was identified that compared the findings of pH monitoring using the Bravo system and the “gold standard”, catheter-based esophageal monitoring. This study (des Varannes et al., 2005) found that the Bravo system under-reported esophageal acid exposure compared to standard testing. The investigators used a correction factor obtained from their data to determine a cut-off value for abnormal acid exposure as measured by Bravo. After this correction, there was an 88% concordance in diagnostic yield between the two methods. As the authors noted in their conclusion, correction factors have not been standardized. Additional studies are needed to validate an appropriate cut-off value for diagnosing GERD with the Bravo system. The other study that was reviewed (Pandolfino et al, 2003) primarily evaluated the feasibility of using the Bravo system. The investigators were highly successful at placing the Bravo system and recording pH levels. The Pandolfino study included an analysis that compared patient satisfaction with the Bravo and conventional systems. Findings were that the Bravo patients reported more esophageal discomfort and the conventional patients reported more throat discomfort. Overall satisfaction was higher in the Bravo group. Both studies were limited by small sample sizes.

**Articles:** The search yielded 12 articles, four of which were empirical studies. The ideal study would be an independent, blind comparison of the accuracy of GERD diagnosis using the Bravo PH monitoring system with the “gold standard”, catheter-based esophageal PH monitoring. There was one study that compared these two diagnostic tests (des Varannes et al., 2005) and this was critically appraised. Another study that compared the findings of the Bravo pH monitoring system in healthy patients and patients with a clinical diagnosis of GERD (Pandolfino et al., 2003) was also critically appraised. There were also two case series (n=30 and n=60) that examined the feasibility of using the Bravo pH monitoring system and these were not evaluated further. des Varannes SB, Mion F, Ducrotte P et al. Simultaneous recordings of esophageal pH monitoring and a wireless system (Bravo). Gut 2005; Published on-line before journal publication. See [Evidence Table](#). Pandolfino JE, Richter JE, Ours T et al. Ambulatory esophageal pH monitoring using a wireless system. *Am J Gastroenterology* 2003; 98: 740-749. See [Evidence Table](#).

The use of capsule PH monitoring system (Bravo System) in the evaluation of gastroesophageal reflux disease (GERD) does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Thermal Capsulorrhaphy for Shoulder Instability

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Codes for this procedure appear to be covered.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Shoulder instability is a common orthopedic problem particularly in the young active population. It can occur from multiple minor traumatic events that result in stretching rather than detaching or tearing ligaments. Certain individuals may have a genetic predisposition that is complicated by repetitive overuse activities. Treatment is directed at reducing capsular volume. Most patients are suitable candidates for a trial of shoulder rehabilitation. Those who fail non-operative treatment may be candidates for surgical intervention.

A variety of surgical techniques are available to reliably prevent recurrent instability. There has been a recent trend towards arthroscopic stabilization and techniques for performing arthroscopic surgery have substantially developed in the past 20 years. Open surgical reconstruction used to be the traditional approach. Now it is reserved for patients with pathology inappropriate for arthroscopic techniques, and in cases where arthroscopic suturing is found to be inadequate intraoperatively.

Thermal capsulorrhaphy is a new treatment modality for shoulder instability, where the joint capsule is heated and reduced in length by laser or radiofrequency energy to regain shoulder stability. The use of heat can alter collagen within the glenohumeral capsule resulting in its contracture. It may be an alternative or an additional way to restore capsule tension and increase thickness of deficient tissues in shoulders with multidirectional and posterior instability.

Experimental studies showed that thermal energy might cause immediate deleterious effects such as loss of mechanical properties, collagen denaturation, and cell necrosis. Over-treatment can lead to severe immediate and permanent damage.

#### Medical Technology Assessment Committee (MTAC)

##### *Thermal Capsulorrhaphy*

**08/12/2002: MTAC REVIEW**

**Evidence Conclusion:** The literature reviewed does not provide enough evidence to support the use of thermal capsulorrhaphy for the treatment of shoulder instability.

**Articles:** The search yielded 21 articles. The majority were reviews, tutorials, and opinion pieces. There were only one cohort study with historical control, and one case series with 30 patients. Savoie FH, and Field LD. Thermal versus suture treatment of symptomatic capsular laxity. *Clin Sports Med* 2000;19:63-75. See [Evidence Table](#). Fitzgerald BT, Watson T, and Lapoint JM. The use of thermal capsulorrhaphy in the treatment of multidirectional instability. *L Shoulder Elbow Surg* 2002;11:108-113. See [Evidence Table](#).

The use of Thermal Capsulorrhaphy in the treatment of shoulder instability does not meet the *Group Health Medical Technology Assessment Criteria*.

**04/03/2006: MTAC REVIEW**

**Thermal Capsulorrhaphy**

**Evidence Conclusion:** The case series published after the last MTAC review of thermal capsulorrhaphy for shoulder instability in 2004 do not provide any new or additional evidence to support the use of procedure for the treatment of shoulder instability. The ongoing multicenter RCT comparing capsulorrhaphy with open inferior capsular shift for patients with shoulder instability might provide evidence on the efficacy of the intervention.

**Articles:** The search yielded 28 articles. The majority were reviews, tutorials, and experimental studies. All studies published after the last update was small prospective, or retrospective case series. The search also identified an ongoing RCT comparing electrothermal arthroscopic capsulorrhaphy versus open inferior capsular shift for patients with shoulder instability (Mohtadi NG et al, 2006).

The use of Thermal Capsulorrhaphy in the treatment of shoulder instability does not meet the *Group Health Medical Technology Assessment Criteria*.

- Last 6 months of cardiology notes

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Cardiovascular disease (CVD) is the most common cause of office visits, hospitalizations, and deaths in the United States. In recent years, there has been great progress in pharmacological therapies as well as technology-based diagnostic and therapeutic interventions for CVD. As a consequence, a greater number of patients survive acute events, but with a heavier burden of chronic conditions and clinical needs. In addition to medication and interventional cardiology, these patients also need structured support to restore their quality of life and to maintain or improve functional capacity.

Cardiac rehabilitation (CR) was initially developed in response to the profound deconditioning caused by the prolonged bed rest that was common in the management of patients following acute cardiac events in the first half of the 20th century. Since then it has developed into multidisciplinary programs to optimize the health of patients with an expanding range of cardiovascular disease (Gordon 2010). CR is a multifactorial, comprehensive intervention defined as the coordinated sum of interventions required to ensure the best physical, psychological, and social conditions so that patients with chronic or post-acute CVD event may, by their own efforts, preserve or resume optimal functioning in society, and through improved health behaviors, slow or reverse progression of disease (Taylor 2004). It is also viewed as the clinical application of preventive care by means of a professional multi-disciplinary integrated approach for comprehensive risk reduction and global long-term care of cardiac patients (Piepoli 2010).

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

The American Heart Association (AHA), the American College of Cardiology (ACC), and the American Association of Cardiovascular and Pulmonary Rehabilitation (AACVPR) consider cardiac rehabilitation / secondary prevention programs integral to the comprehensive care of patients with CVD. They recommend that all cardiac rehabilitation/secondary prevention programs should contain specific core components that aim at optimizing cardiovascular risk reduction, foster healthy behaviors and compliance with these behaviors, reduce disability, and promote an active lifestyle for patients with cardiovascular disease. The core components include baseline patient assessment, nutritional counseling, risk factor management (weight, blood pressure, lipids, diabetes mellitus and smoking), psychological interventions, physical activity counseling, and exercise training (Balady 2007). The goals of CR consist primarily of mobilizing the patient, optimizing drug therapy, implementing measures of secondary prevention, providing means for understanding the disease through education and advice, facilitating behavior modification, supporting the patient in overcoming the disease, treating psychological disturbances, and improving reintegration into professional life (Farin 2007). It is clearly understood and accepted that an isolated exercise program is not cardiac rehabilitation; however, physical activity and exercise training are considered the core components on which a comprehensive CR program is built (Piepoli 2010).

Most CR programs are held for groups in hospitals, gyms, or community centers. These may be inconvenient to patients (especially women and older patients) who may have problems with accessibility, dislike of groups, and/or work on domestic commitments. Home-based programs were thus introduced as an alternative to traditional CR in an attempt to increase participation rates. These programs have been defined as structured programs with clear objectives to the participants, including monitoring, follow-up, visits, letters, telephone calls from staff, or at least self-monitoring diaries (Dalal 2010).

## Medical Technology Assessment Committee (MTAC)

### Cardiac Rehabilitation

#### 12/20/2010: MTAC REVIEW

**Evidence Conclusion:** The majority of the studies on cardiac rehabilitation for heart failure or stable MI were small trials, with short follow-up duration, and mainly examined the safety and efficacy of exercise-based programs. The CR programs undergone in the trials differed in their duration (range 1-6 months), frequency (1-5 sessions per week), and session length (20-60 minute /session), and most exercise programs and rehabilitation interventions were tailored on the individual patient's needs. Several meta-analyses were thus conducted to pool the results of these trials to provide sufficient power to adequately address the effect of comprehensive CR programs on morbidity, mortality, HRQoL, and modifiable risk factors. Cardiac rehabilitation programs for patients with CHD: Several earlier meta-analyses examined the effects of exercise based cardiac rehabilitation on patients with MI and found a survival benefit of the programs. The latest of these meta-analyses was performed by Taylor and colleagues (2004) and included 48 trials with 8,840 participants. Most studies recruited patients at low risk of another event after an MI. The exercise program, as well as the duration of follow-up varied widely between studies. The results of the pooled analysis showed that, compared with usual care, CR reduced total mortality by 20% and cardiac mortality by 26%. There were also significant reductions in some modifiable risk factors including total cholesterol, triglycerides, systolic blood pressure, and smoking. There were no statistically significant reductions in the rate of recurrent MI or revascularization. The main analysis combined the results of exercise only trials with studies on comprehensive cardiac rehabilitation. A subgroup analysis performed by the authors showed a significant mortality benefit with comprehensive CR programs. A decrease in total and cardiac mortality with CR may be due at least in part, to the serial surveillance provided by the rehabilitation staff, which may lead to the detection of any deterioration in the clinical status before it progresses to a more morbid condition or event. Cardiac rehabilitation programs for patients with heart failure: Davies et al's Cochrane review in 2010, on the effect of exercise training in patients with systolic heart failure showed that exercise training reduces heart-failure related hospital admission and improves HRQoL in patients who were mainly men with a mean age ranging from 43-72 years, and with NYHA class II-III systolic HF. No effect on mortality was observed. All studies included in the analysis, except for one relatively small (N=200) trial, were exercise only interventions. The analysis included the HF-ACTION study which was a large trial (N=2,331) on the effect of exercise training on HF patients. CR programs aim at enhancing self-management and are not restricted to exercise but should also include education, risk factor management, pharmacological therapies, and psychological input. An earlier meta-analysis (van Tol 2006), evaluating the effect of exercise training on cardiac performance in 35 RCTs including 1,486 patients with stable mild to moderate CHF showed that exercise training leads to significant improvements in cardiac performance and quality of life. The meta-analysis did not study the effect on mortality or rate of hospitalization due to HF. Austin et al, 2008, reported on long term results of a trial that randomized 200 patients over 60 years of age with LV systolic dysfunction NYHA class II-III, to receive either standard care or undergo a comprehensive CR program for 24 weeks. Five-year follow up of 56% of the patients showed some long-term benefit on the functional performance and perceived exertion of the patients. In a more recent small study that included older HF patients, and HF patients with normal ejection fraction, Davidson and colleagues (2010) showed that a

multidisciplinary heart failure CR program significantly reduced hospital admission rates due to a cardiovascular or any other event. Home-based versus center based cardiac rehabilitation for patients with coronary heart disease: A large number of trials compared the outcome of home versus center-based CR on patients with CVD. The majority of trials were small in size with the exception of a more recent trial (Birmingham Rehabilitation Uptake Maximization [BRUM]), which included 525 participants after experiencing an acute MI or coronary revascularization. The results of this trial found no difference in risk factor control or self-reported physical activity between patients randomized to home versus center-based CR. The study was not designed as an equivalence trial, and a lack of significant difference between the two strategies does not necessarily indicate that they have similar effects. A recent Cochrane review (Dalal 2010) pooled the results of the 12 RCTs involving almost 1200 participants in total. The trials excluded high risk patients (those with arrhythmias or severe ischemia) and only 2 studies included HF patients. The patient characteristics as well as duration, frequency, and session lengths of CR programs varied widely between studies, and several of the home-based programs started with center-based CR then transitioned to CR at home. The results of the analyses showed no significant differences between the home versus center-based CR programs in risk factors control, HRQoL measures, and all cause mortality. The authors concluded that home-based and center-based CR programs appear to be equally effective in improving clinical and health related QOL outcomes in patients with low risk after MI or revascularization. The results may suggest that the outcomes between home-based and center-based CR are similar, however lack of significant differences does not necessarily imply that the two strategies are equally effective.

**Conclusion:** There is fair evidence that exercise-based cardiac rehabilitation programs reduces mortality, morbidity, and improves health related quality of life (HRQoL), and modifiable risk factors in low risk patients with coronary heart disease. There is fair evidence that exercise-based cardiac rehabilitation programs reduce hospital admission and improves HRQoL among low- to moderate- risk patients with stable heart failure. There is inconclusive evidence that home-based and center-based CR have similar benefits. The results of trials and meta-analyses comparing the two strategies suggest that they have similar outcomes. However, due to the study designs, a lack of significant statistical differences in the outcomes does not necessarily imply that the two strategies are equivalent.

**Articles:** The literature search revealed at least 15 meta-analyses on cardiac rehabilitation, and a large number of randomized controlled trials, and observational studies. The great majority of the meta-analyses and trials were performed on individual components of the cardiac rehabilitation (CR) program, mainly exercise-based programs, in stable patients post myocardial infarction or coronary revascularization, or in patients with heart failure. Overall, the randomized trials on the comprehensive CR were relatively small and with short duration of follow-up. One trial (Austin 2008), reported on 5 years outcome of patients with heart failure after undergoing a multidisciplinary 8-week CR program. The literature search also revealed 4 recent meta-analyses of RCTs that compared home-based cardiac rehabilitation versus center-based programs for patients with cardiovascular disease.

Studies (e.g. HF-ACTION) or meta-analyses (e.g. ExTraMATCH) that examined the safety and efficacy of exercise training or other single components of the program in patients with chronic heart failure or CAD were not included in the current review which evaluates the multidisciplinary cardiac rehabilitation program.

The following meta-analyses of trials on comprehensive CR for patients with heart failure or CHD, that compared and home-based vs. center-based CR as well as the RCT with 5-year follow-up were selected for critical appraisal. Davies EJ, Moxham T, Rees K, et al. Exercise training for systolic heart failure: Cochrane systemic review and meta-analysis. *Eur J Heart Fail* 2010;12:706-715. See [Evidence Table](#). #### Ultrafast CT (S8092) and CT Cardiography in the Screening and Diagnosis of Coronary Artery Disease(CAD) (CPT 75571)

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Coronary heart disease (CHD) remains the leading cause of death among men and women in the United States. It is valuable to detect coronary atherosclerosis early in its course, and try to alter its progression by modifying certain identifiable risk factors. The earliest detectable lesion of coronary atherosclerosis is a fatty streak, followed by crescent shaped lipid plaques, which may rupture and produce either progressive stenosis or sudden occlusion with myocardial infarction. It was previously thought that coronary artery calcification was the late result of end stage plaque degeneration. Now it is believed that calcium is present in all stages of plaque formation. Coronary artery calcification occurs in small amounts in the early lesions of atherosclerosis that appear in the second and third decades of life but is found more frequently in advanced lesions in older age (Janowitz 1993). Coronary artery calcium increases with increasing age in men, while women may experience accelerated calcification after menopause (Allison 2004).

The relation of arterial calcification to the probability of plaque rupture is unknown. Some investigators postulate that calcification may actively contribute to the susceptibility of plaque rupture and subsequent events. While

others believe that calcification may reflect stabilization and maturation of the plaque that would lead to fewer myocardial infarctions and CHD deaths (Lee 2002). Beckman 2001, reported that although radiographically detected coronary artery calcium can provide an estimate of total coronary plaque burden, calcium does not concentrate exclusively at sites with severe coronary artery stenosis due to arterial remodeling. Other researchers indicated that ultrafast scans cannot detect all calcium and that molecular calcium may go unnoticed. Thus calcium detected by ultrafast scans may represent only the tip of the iceberg (Rumberger 1996). Despite that, some investigators believe coronary artery calcium (CAC) detection may be able to globally define a patient's risk of CHD events.

Now that some believe that calcification can be used as a marker of the atherosclerotic process, and because calcific deposits are radio-opaque, numerous radiographic techniques have been used in the search for a noninvasive screening test for coronary artery disease. Fluoroscopy was used for decades to detect coronary artery calcium. However, its routine use for identifying patients with coronary artery disease is limited due to its low sensitivity to detect small amounts of coronary calcium that can be observed pathologically in complex atherosclerotic plaques. Conventional computed tomography (CT) have an advantage over fluoroscopy in its improved resolution, which is limited however when moving structures are imaged. This limitation has been overcome by the electron beam computed tomography (EBCT), and multidetector computed tomography (MDCT). Both technologies yield thin slice CT imaging using fast scan speeds that reduce motion artifact. 30-40 adjacent axial scans are usually obtained. The fast time scan allows the entire heart to be imaged over one or two breath holds. Images can be reconstructed to form three-dimensional or cross-sectional images. There are three methods for calcium quantification and scoring: The Agaston method, the volumetric method, and quantification of calcium mass. Agaston method is the most commonly used and is obtained by the summation of areas of the calcified lesions multiplied by a scaling cofactor; an Agaston score of zero indicates absence of coronary calcium, 1-99 is considered low, 10-400 is intermediate, and 400 high (Sanz 2006). Calcium scores can be calculated for a coronary artery segment, a coronary artery, or summed for the whole coronary system.

Ultrafast CT scanners became commercially available in 1983, before the first study of their use was published in 1989. In the 1990s, another form of CT, the helical or spiral computed tomography has been developed. In helical tomography, continuous scanning is performed in combination with a continuous table feed. Thus, the x-ray beam traces a spiral path through the patient. The entire heart can be imaged with 3 mm non-overlapping slices, within one breath hold (30 sec). The initial goal of using cardiac computed tomography was to identify patients at risk of coronary artery disease based on the amount of calcium present. However, in the past 5-10 years these ultrafast scans have been used to: 1) Assist in CHD risk assessment in asymptomatic individuals, and, 2) To assess the likelihood of the presence of CHD in patients who present with atypical symptoms that could be consistent with myocardial ischemia.

The EBCT scanners currently used are produced by GE Imatron, South San Francisco California. They were approved by the FDA as Class II devices.

The use of EBCT for CAC scoring was reviewed by MTAC in 2002 and 2004, and did not meet its evaluation criteria. It is being re-reviewed due to the recent publications of studies with clinically important outcomes.

## Medical Technology Assessment Committee (MTAC)

### *Ultrafast CT in the Screening and Diagnosis of CAD*

#### **02/11/2002: MTAC REVIEW**

**Evidence Conclusion:** There is insufficient published evidence to determine the value of Ultrafast CT as a screening test for coronary artery disease among asymptomatic patients. In the studies reviewed, ultrafast CT and angiography were done among patients because of suspected coronary artery disease. The prevalence of CAD in these studies was high and it may not be appropriate to extrapolate these results to scans done in the population at large, or those done for screening purposes. The studies reviewed show that ultrafast CT scanning had a high sensitivity and low specificity in detecting coronary artery disease among the participants. The sensitivity increased with age and was highest for symptomatic patients older than 50 years. The specificity on the other hand, increased with the number of calcified vessels and was highest among patients with 4-vessel calcification. The majority of studies did not address clinical end-points, as their primary outcome. Detrano, et al (1996) however, followed-up the patients for a mean of 30 months, to determine the relative prognostic value of coronary calcification for predicting CHD events among symptomatic patients. They found that cardiac events and deaths tended to be more frequent in the higher quartiles of calcium score. In conclusion, the results of these studies indicate that in a population where CAD is more prevalent, the absence of coronary calcification is more helpful in ruling out CAD than is the detection of calcium in confirming the presence of CAD. Ultrafast CT seems promising,

but as yet, there is no evidence that it may substitute angiography, but can be helpful in excluding or increasing the likelihood of significant CAD in certain situations.

**Articles:** The search yielded 39 articles, many of which were review articles, opinion pieces, or dealt with technical aspects of the scan. The search did not reveal any study that evaluated ultrafast scanning as a screening test for coronary heart disease. There were four studies that compared the Ultrafast CT scan with angiography and a few others that did not use a defined gold standard for comparison. There was only one study on the newer helical CT scan. The two studies with the stronger methodology, and larger sample sizes were selected for critical appraisal. Broderick's study that evaluated the performance of the helical CT scan was also reviewed. Budoff MJ, Georgiou D, Brody A, et al. Ultrafast computed tomography as a diagnostic modality in the detection of coronary artery disease. A multicenter study. *Circulation* 1996;93:898-904. See [Evidence Table](#). Detrano R, Hsiai T, Wang S, et al. Prognostic value of coronary calcification and angiographic stenoses in patients undergoing coronary angiography. *J Am Coll Cardiol* 1996;27:285-90. See [Evidence Table](#). Broderick LS, Shemesh J, Wilensky RL, et al. Measurement of coronary artery calcium with dual-slice helical CT compared with coronary angiography: Evaluation of CT scoring methods, observer variations, and reproducibility. *AJR* 1996;167:439-444. See [Evidence Table](#).

The use of ultrafast CT in the screening and diagnosis of CAD does not meet the *Group Health Medical Technology Assessment Criteria*.

## 12/08/2004: MTAC REVIEW

### Ultrafast CT in the Screening and Diagnosis of CAD

**Evidence Conclusion:** A screening test for preclinical coronary artery disease among asymptomatic individuals, and A diagnostic test for coronary artery disease among symptomatic patients. Use of EBCT for coronary artery disease screening among asymptomatic individuals: There is insufficient published evidence to determine the value of EBCT (Ultrafast CT) as a screening test for coronary artery disease among asymptomatic individuals. Ideally, a screening test should be highly sensitive in detecting previously undiagnosed disease, and should lead to changes in management that improves outcomes. The meta-analysis and observational studies reviewed evaluated EBCT coronary artery calcium as a risk predictor of future coronary events among asymptomatic individuals. These studies suggest that coronary artery calcium detected by EBCT may be an independent predictor for coronary events, and may add to the information provided by the Framingham risk score. However, the studies had some threats to validity that may limit generalization of the results. The majority is office-based and included self-referred individuals or others at high risk referred by their primary care physicians for further evaluation. Risk factors were self-reported and not measured in more than one study. Different techniques and scans were used, and there was no established cut-off level for calcium scores. The endpoints included revascularization in several trials, which could have been performed at a higher rate based on the results of the scan. The endpoint in one of the studies was all-cause mortality that might be due to other causes than coronary atherosclerotic diseases. None of these observational studies examined the influence of detecting coronary artery calcification on the management of the individuals, the health benefits, or effect on outcome. There is no evidence that more effective therapy or management could be provided by evaluating CAC score beyond that provided based on FRS. A recent RCT showed that the detection of coronary artery calcium among asymptomatic individuals was not associated with behavior modification or reduction of their cardiac risk scores. This RCT also had its limitations. Use of EBCT as a diagnostic test for coronary artery disease among symptomatic patients: The studies reviewed show that compared to coronary angiography as a gold standard; EBCT scanning had a high sensitivity and low specificity in detecting coronary artery disease among symptomatic patients. The sensitivity ranged from 81% to 99% among the studies reviewed in the meta-analysis, and the more recent study. The sensitivity was inversely related to the calcium score cutoff points. It was highest at a calcium score 0-10 which on the other hand had a specificity as low as 28%, i.e. high false positives which would be associated with further investigations that might be unnecessary. The studies were conducted among symptomatic patients with a high prevalence of coronary disease, and there is a potential of overestimation of the sensitivity, and positive predictive value, which might limit generalization of the results.

**Articles:** The search yielded 39 articles, many of which were review articles, opinion pieces, or dealt with technical aspects of the scan. The search did not reveal any study that evaluated ultrafast scanning as a screening test for coronary heart disease. #### **04/02/2007: MTAC REVIEW**

##### **Ultrafast CT in the Screening and Diagnosis of CAD**

**Evidence Conclusion:** This report focuses on the use of electron beam computed tomography for detecting calcium deposits in coronary arteries as 1. A screening test for preclinical coronary artery disease among asymptomatic individuals, and 2. A diagnostic test for coronary artery disease among symptomatic patients. Use of EBCT for coronary artery disease screening among asymptomatic individuals: Ideally a screening test for predicting outcomes should not only prove to independently contribute to risk stratification, but also to provide further prognostic information beyond and above the traditional risk factors i.e. in this case, the Framingham Risk Stratification. Constructing the Receiver Operator Characteristic (ROC) curves and measuring the Area Under the ROC curve (AUC) would determine if a new marker or test has an additive benefit. An ideal screening test would also lead to changes in the management that will improve health outcomes e.g. fewer events, extended life or better quality of life. Fletcher's meta-analysis (2004), reviewed for the previous update, offered some support that there is a linear relationship between CAC and CHD events, but the analysis did not address whether CAC adds any incremental value to Framingham Risk Score (FRS) for CHD risk prediction. Greenland and colleagues (2007) pooled the results of 6 observational studies published after Fletcher's meta-analysis. There was some heterogeneity between the studies in the assessment of risk factors, cut-off levels used for calcium scores, as well as in the endpoints. The latter included revascularization in several trials, which could have been performed at a higher rate based on the results of the scan. None of the studies included in the meta-analysis examined the influence of detecting coronary artery calcification on the management of the individuals, the health benefits, or effect on outcome. The pooled results of the studies in the meta-analysis showed that patients with any measurable calcium were at a significantly higher risk compared to those with a low-risk CAC (using a score of 0) over a 3-5 years period of observation. This analysis also showed that there was an incremental relationship between CAC and CHD risk. The authors however did not discuss if adding CAC scoring to the traditional factors would significantly increase the AUC. Arad and colleagues published two articles on the St Francis Health Study (Arad, Goodman 2005, and Arad, Spadaro 2005). The first was a prospective cohort study that investigated the accuracy of CAC scores in predicting atherosclerotic cardiovascular disease (ASCVD) events independent of standard risk factors. The second article reports on the results of an RCT embedded in the cohort study. This RCT investigated whether lipid-lowering therapy and antioxidants retard the progression of coronary calcification and prevent ASCVD events. The St Francis Health Study enrolled 4,903 mainly White, healthy men and women 50-70 years old. All participants underwent EBCT but only a subset (n=1,357) with CAC score >80th percentile for age and gender, also underwent risk factor assessment. Participants were followed up for an average of 4.3 years for a composite outcome of coronary death, nonfatal MI, surgical or percutaneous coronary revascularization, nonhemorrhagic stroke and peripheral vascular surgery. A multivariate regression analysis showed that CAC scoring predicted CAD events independent of standard risk factors, and that it was strongly predicted by age, male gender, and family history of premature coronary disease. The Receiver Operator Curve (ROC) showed that CAC score predicted CAD events more accurately than Framingham risk stratification (AUC= 0.79 vs. 0.68). It has to be noted however that this comparison was made only for participants with the highest percentiles of CAC, and that this study included all ASCVD outcomes while FRS predicts only the hard CHD outcomes. The majority of the observed events in this study were cardiovascular procedures rather than the traditional cardiac events. One other limitation of the study was low participation rate as only 2% of the eligible subjects were enrolled in the study. The RCT embedded in that study (Arad, Spadaro 2005) randomized 1,005 participants, with CAC score >80th percentile for age and gender, to receive a combination of atorvastatin, vitamin C, and vitamin E or a placebo. All participants in the two groups also received aspirin 80 mg daily. After 4.3 years of follow-up, active treatment group showed nonsignificant reduction in the primary or secondary outcomes. The results also showed no significant change in the progression of CAC. The lack of significant difference in ASCVD events might be due to the small sample size, short follow-up duration, and /or the administration of aspirin to the control as well as the active therapy group. Use of EBCT as a diagnostic test for coronary artery disease among symptomatic patients: There is no new published evidence on the use of coronary calcium scoring as a diagnostic test for CAD. The studies reviewed earlier for the last update showed that compared to coronary angiography as a gold standard; EBCT scanning had a high sensitivity and low specificity in detecting coronary artery disease among symptomatic patients. The sensitivity ranged from 81% to 99% among the studies and was inversely related to the calcium score cutoff points. It was highest at a calcium score 0-10 which on the other hand had a specificity as low as 28%, i.e. high false positives which would be associated with further investigations that might be unnecessary. The studies were conducted among symptomatic patients with a high prevalence of coronary disease, and there is a potential of overestimation of the sensitivity, and positive predictive value, which might limit generalization of the

results. *In conclusion:* There is some evidence that CAC may add a prognostic incremental value to Framingham risk score among selected asymptomatic individuals. Indirect evidence suggests that asymptomatic individuals at intermediate risk might potentially benefit from adding CAC to the risk assessment. The majority of the participants in the studies reviewed were Caucasians which may limit generalization of the results. The studies do not provide an optimal coronary calcium threshold. There is no single cutoff value that defines a high score. The coronary calcification differs according to age, sex, and race. There is no evidence to date that CAC scoring would result in an intervention that would improve CHD related health outcomes among individuals at an increased risk for CHD. The test results may lead to unnecessary invasive procedures, or overtreatment in some patients.

**Articles:** The search yielded around 50 articles. Many were review articles, opinion pieces, or dealt with technical aspects of the scan. Use of EBCT for coronary artery disease screening:

The search identified a recent meta-analysis of observational studies (Greenland 2007) and several prospective cohort studies that evaluated EBCT coronary artery calcium (CAC) score as a risk marker predicting the likelihood of future coronary events among asymptomatic patients. It also revealed two articles on the St. Francis Heart Study (Arad, Goodman 2005, and Arad, Spadaro 2005). The first reported on the prospective cohort study, and the second on the RCT embedded in the cohort. The meta-analysis and the two articles on the St. Francis Heart Study were selected for critical appraisal. Use of EBCT for coronary artery disease diagnosis:

The search did not reveal any newly published large valid study on the use of CAC scoring in the detection of coronary artery stenosis among symptomatic patients. *The following articles were critically appraised:* Greenland P, Raggi P, Harrington R, et al. ACC/AHA 2007 clinical expert consensus document on coronary artery calcium scoring by computed tomography in global cardiovascular risk assessment an in evaluation of patients with chest pain. J Am Coll Cardiol. 2007;49:378-402. See [Evidence Table](#). Arad Y, Goodman KJ, Roth M, et al. Coronary calcification, coronary disease risk factors, C-reactive protein, and atherosclerotic cardiovascular disease events. The St. Francis Heart Study. J Am Coll Cardiol. 2005;46:158-165. See [Evidence Table](#). Arad Y, Spadaro LA, Roth M, et al. Treatment of asymptomatic adults with elevated coronary calcium scores with atorvastatin, vitamin C, and vitamin E. The St. Francis Heart Study randomized clinical trial. J Am Coll Cardiol.2005;46:166-172. See [Evidence Table](#).

The use of EBCT in the treatment of coronary artery calcium scoring does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Implantable Pulmonary Artery Pressure Monitoring Device for Patients with Heart Failure

- **CardioMEMS**

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### **For Medicare and Non-Medicare Members**

*\* Please note this device is going under active investigation.*

*\* For Medicare members, as of September 1, 2016- CMS does not have any NCD or LCD coverage regarding CardioMEMS. For Medicare members see below for Non-Medicare member coverage.*

*\* For Non-Medicare members, as of September 1, 2016- this is considered a non-covered service as the benefit has not been established outside of the research setting.*

Please send all cases to Medical Director for review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Heart failure (HF) is a major public health problem in the United States and worldwide. According to the Centers for Disease Control and Prevention, about 6 million people in the US have clinically manifest HF, and the prevalence continues to rise. Hospitalization for patients with chronic HF is also on the rise despite the major advances in medical and device therapy. Statistics show that HF is the primary diagnosis in over one million hospitalizations annually. The most frequent cause of hospitalization in these patients is recurrent episodes of decompensation resulting from volume overload or changes in ventricular function. Studies show that over 90% of hospitalizations for worsening HF are due to signs and symptoms of congestion leading to the decompensated state. Patients hospitalized for HF are at high risk for all-cause rehospitalization with a 1-month readmission rate of 25%. The prognosis of patients hospitalized with HF is suboptimal especially for those with serial readmission (Hoppe 2009, Adamson 2011, Go 2013, and Yancy 2013).

Treatment strategies for patients with decompensated HF are limited and it is important to detect impending acute decompensated heart failure (ADHF) early and accurately. Historically, clinical symptoms and signs of dyspnea, orthopnea, weight gain, and leg edema, were used as indicators of congestion and volume overload, but these are not sensitive to the early changes in volume that increase the risks of decompensation. Investigators found that pressure increase is the cause of clinical congestion and that persistent increases are apparent several days or weeks before the onset of worsening signs and symptoms. It is thus suggested that the increase in intracardiac and pulmonary artery pressures are more accurate measures than volume status in determining whether the patient's condition is worsening. Some researchers also found that successful treatment of acutely decompensated HF patients is associated with a decrease in diastolic pressures to values equivalent or below those present at baseline, and that continuous monitoring pressure during treatment may allow the clinicians to tailor the treatment more accurately. Based on these observations, it is hypothesized that ambulatory implantable hemodynamic monitoring (IHM) may provide information that would help avoid discharging patients from the hospital before decreasing the pressure sufficiently and returning the patient to a chronic compensated state. Continuous hemodynamic monitoring after the hospital discharge is also believed to proactively detect signs of congestion and reduce the risk of hospitalization (Zile 2008, Hoppe 2009, Abraham 2011, Adamson 2011, Mooney 2015).

Recent research has thus focused on ambulatory hemodynamic monitoring in chronic HF as a surrogate marker to optimize the patients' medical therapy in the ambulatory setting before the onset of acute hemodynamic decompensation. The concept of remote device monitoring is referred to as telemonitoring. Several implantable systems have been developed to measure various cardiac pressures and tailor medical therapy accordingly "pressure guided therapy". Among these devices is the CardioMEMS HF System, the focus of the current review.

The CardioMEMS HF System (St Jude Medical, Inc, USA) is a permanently implantable pressure measurement system designed to directly measure systolic, diastolic and mean pulmonary artery pressure (PAP) to help guide heart failure management in an outpatient setting. It is a miniaturized wireless electromechanical sensor implanted in conjunction with a right heart catheterization procedure via transvenous access. Its design is based on the microelectromechanical principles of resonance whereby an external antenna wand emitting radiofrequency energy can cause varying degrees of oscillations in the sensor depending on the ambient pressure. The CardioMEMS HF system comprises: 1. A battery free, leadless sensor (15mm x 3mm) that consists of a coil and capacitor encased in silicone, with a nitinol wire loop at each end of the sensor, 2. A transverse delivery system designed to deploy the implantable sensor in the distal PA; and 3. The Champion Electronics System (CardioMEMS) which acquires and processes signals from the implantable sensor and wirelessly transfers PA pressure measurements to a secure database to be reviewed and evaluated by the treating physician (Loh 2013, Adamson 2011, Mooney 2015, FDA webpages).

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Atherosclerosis is a progressive disease that usually starts early in life. It begins with thickening of the vessel wall due to proliferation of smooth muscle cells, and progresses with the accumulation of lipids carbohydrates, calcium deposits, fibrous tissue, and blood products within the lesions resulting in hard calcified plaques (Libby 2000). Acute manifestations of atherosclerosis such as acute myocardial infarction, stroke, or sudden cardiac death are due to thrombosis following rupture of an unstable plaque. It is thus valuable to detect coronary atherosclerosis early in its course, and try to alter its progression by modifying certain identifiable risk factors. Several noninvasive imaging techniques to identify and quantify atherosclerosis have evolved in the last decades. These include echocardiography, stress echocardiography with perfusion, MRI, electron beam computed tomography, carotid artery imaging, and others.

B-mode ultrasound is a well-established method to evaluate atherosclerosis of peripheral arteries, and ultrasonographic assessment of easily accessible arteries has been advocated as surrogate markers for less accessible vessels. To consider a test as a surrogate marker, it should have the ability to predict the risk of a disease, and to improve with the improvement of the disease process (Feinstein 2002).

Atherosclerosis predominantly affects the intima of the vessel wall, however ultrasound imaging cannot discriminate between the intima and media, and is thus applied to the intima-media complex. Carotid artery intima-media thickness (IMT or CIMT) involves a high-resolution ultrasound imaging of the distance between the lumen-intima interface and the media-adventitia interface, reflecting the arterial wall characteristics. It can be measured at several areas along the vessel wall; at the posterior aspect of the common carotid artery, the anterior wall of the internal carotid artery or at the common carotid artery bifurcation. Researchers differ on the choice of wall or segment of the carotid artery to image. It is believed however that imaging from different segments will most likely increase the likelihood of providing more relevant information, based on the fact that atherosclerosis tend to develop in an asymmetric manner. IMT thickness measurements can be calculated as the average of arterial wall thickness, the maximal measured value, or the average of maximal values of different segments. The

inter-reader variability is fairly high, and there is no clear cut-off point above which atherosclerosis can be defined. The cut-off points to determine the presence of an atherosclerotic plaque were arbitrarily chosen. It was suggested that an average thickness of the combined intima and media ranging between 0.5 and 1.2 mm is considered to be normal, and that  $\geq 1.2$  mm is used to define the presence of a plaque. It was also reported that the abnormal range of IMT is age dependent, and an IMT  $>1.00$  mm is considered highly abnormal in younger patients, and is sometimes used as the cutoff in clinical trials (Feinstein 2002).

The estimated progression of atherosclerosis per year is 0.02 to 0.05 mm (Feinstein 2002). IMT may be a potential useful marker for coronary atherosclerosis, as well as an indicator for its progression or regression, on the condition that the carotid atherosclerosis reflects coronary atherosclerosis. Still the occurrence of an acute event does not only depend on the condition of the coronaries, and carotid IMT does not visualize coronary arteries, and does not provide detailed insight into plaque composition or stability.

## Medical Technology Assessment Committee (MTAC)

### *Carotid IMT in the Evaluation of Risk for CVD or to Monitor the Treatment Effect on CAD*

#### 04/04/2005: MTAC REVIEW

**Evidence Conclusion:** *Use of IMT as a screening tool, or risk predictor of CVD:* The literature search did not reveal any RCT that investigated carotid IMT as a screening tool for CHD. Ideally subjects would be randomized to receive or not receive a screening test, then followed up for a sufficient period of time, then compare the outcomes in the two groups. Carotid IMT was only evaluated in cohort studies as a risk predictor for future coronary heart disease. The ARIC study and Cardiovascular Health Study (CHS) were two large population based cohort studies that assessed the association of IMT with coronary artery disease. ARIC study included 12,841 men and women aged 45-64 years, and followed them up for 4-7 years. CHS followed 4,476 adults aged 65 years or older for 6 years. The primary outcome was the first coronary heart disease event in ARIC study, and incidence of myocardial infarction and stroke in CHS. The Rotterdam study was a cohort study of 8,000 patients aged 55 years or older, followed up for 4.2 years. A case-control study with 374 subjects was nested in that study to determine the contribution of carotid IMT in the prediction of future coronary and cerebrovascular diseases when added to the traditional risk factors. All three studies investigated the association of the carotid IMT to the incidence of coronary heart disease (and stroke in two studies) but the added value of the carotid IMT to the predictive value of the established risk factors was only quantified in the Rotterdam's study. Carotid IMT was measured only once at baseline. Different sites of the carotid artery were imaged and different methods of measurements were used, as well as different standards or cutoff values for the threshold thickness. The results of these studies suggest that the carotid IMT is associated with the incidence of coronary heart disease events, however the Rotterdam's study suggest that the information provided by IMT measurement does not seem to have clinically important additional predictive value over that calculated using the established risk factors. In conclusion, there is evidence for an association between carotid artery IMT and risk of coronary heart disease events, but there is no evidence that measuring carotid IMT, or treating patients based on this measurement would reduce their risk of CVD. There is also insufficient evidence to support the additive value of carotid IMT markers over the global risk assessment strategies using Framingham risk stratification. *Use of carotid ITM to monitor effect of treatment on CAD:* Several studies evaluated the effect of statins on the progression of atherosclerosis using imaging of carotid ITM thickness as an outcome measure. In these studies carotid IMT was used a surrogate marker for coronary atherosclerosis. The LIPID trial randomized 522 subjects to receive pravastatin 40 mg/day or placebo in addition to a low-fat diet. Total cholesterol, triglycerides, HDL, and LDL cholesterol were measured at randomization repeatedly during follow-up. Ultrasound scans of the common carotid artery were performed before randomization, and after 2 and 4 years using B-mode ultrasonography. The study showed a regression of the common carotid artery IMT following pravastatin therapy. Carotid IMT was only an intermediate marker, and the relation between the IMT and cardiovascular events was not studied. A change in carotid intima-media thickness does not necessarily indicate a change in cardiovascular risk.

**Articles:** The search revealed 214 articles. The majority were review articles, opinion pieces, or dealt with specific subgroups of patients. *As a screening tool/ risk predictor for coronary artery disease:* The search did not reveal any randomized controlled trial that evaluated the use of carotid IMT as a screening test for coronary artery disease. There were several prospective studies that investigated carotid IMT as a risk predictor for CHD including two large population based-studies conducted in the USA (ARIC study and CHS). The search also revealed few other studies conducted in Europe (e.g. Rotterdam study in the Netherlands, and KIHHD study in Finland). ARIC study and CHS were selected for critical appraisal, as well as Rotterdam study that evaluated the benefit of adding carotid IMT measurement to traditional risk factors used to predict risk of CHD. Chambless LE, Heiss G, Folsom AR, et al. Association of coronary heart disease incidence with carotid artery wall thickness and major risk factors: The Atherosclerosis Risk in Communities (ARIC) Study, 1987-1993. *Am J Epidemiol.* 1997;146:483-494. See [Evidence Table](#). O'Leary DH, Polak JF, Kronmal RA, et al, for the Cardiovascular Health Study Collaborative Research Group. Carotid-artery intima and media thickness as a risk factor for myocardial infarction and stroke in

older adults. *N Engl J Med*. 1999;340:14-22. See [Evidence Table](#). Iglesias del Sol A, Moons KGM, Hollander M, et al. Is Carotid Intima-media thickness useful in cardiovascular diseases risk assessment. The Rotterdam Study. *Stroke* 2001;32:1532-1538. See [Evidence Table](#) As a monitoring tool measure efficacy of a therapeutic intervention: The search revealed several earlier studies conducted in the 1990s to examine the effect of statins and lipid modifying therapy on the progression of atherosclerosis, using changes in the carotid IMT, measured by B-mode Ultrasonography, as their surrogate outcome. Among these studies were ACAPS, BCAPS, KAPS, LIPID, REGRESS, PLAC II as well as others. These studies did not have clinical outcomes, only the intermediate endpoint of carotid IMT. The LIPID trial with a large population size and long follow-up period of 4 years was selected for critical appraisal. MacMahon S, Sharpe N, Gamble G, et al. Effects of lowering average or below-average cholesterol levels on the progression of carotid atherosclerosis. Results of the LIPID atherosclerosis substudy. *Circulation*. 1998;97:1784-1790. See [Evidence Table](#). As a diagnostic tool for coronary artery disease: The search revealed at least six studies that investigated the potential use of carotid intima media thickness in the diagnosis of coronary artery disease. In these studies results of carotid ultrasonography were compared to those of coronary angiography, and/ or exercise tests, or SPECT among symptomatic patients with a suspected CAD. None of these studies was critically appraised as it not the purpose of this review to evaluate the technology as a diagnostic test.

The use of carotid IMT in the evaluation of risk for CVD or to monitor the treatment effect on CAD does not meet the *Group Health Medical Technology Assessment Criteria*.

- Any genetic counseling notes if applicable
- Results of prior genetic testing
- Last 6 months of specialist notes of that is being reviewed (i.e., neurological notes, medical oncology notes, cardiology notes)

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Trisomy 21, also known as Down syndrome, is the most common chromosome abnormality among live born infants. Prenatal diagnosis of trisomy 21 requires invasive sampling of fetal genetic material through amniocentesis or chorionic villus sampling carrying a risk of about 1% miscarriage. They are therefore reserved for pregnancies considered to be at high risk of fetal trisomy 21.

Maternal blood cell -free fetal DNA analysis is a noninvasive test that is used to screen for trisomy 21 (Down syndrome), trisomy 13 (Patau syndrome), and trisomy 18 (Edwards syndrome). The test provides direct

assessment of fetal chromosome status by analyzing circulating cell-free fetal DNA that is extracted from a maternal blood sample. According to the manufacturer, the test is indicated for use from 10 to 22 weeks of gestation for pregnant women at high-risk for fetal aneuploidy. The problem is distinguishing the maternal cell fragments from the fetal cell fragments causing both false negative and false positive results. There are several companies who market this test under their own brand names (MaterniT21™, Harmony™, or Verify™).

## Medical Technology Assessment Committee (MTAC)

### MaterniT21

#### 08/20/2012: MTAC REVIEW

**Evidence Conclusion:** Kaiser identified two observational studies that evaluated MaterniT21. The first study was a case-control study that evaluated 212 samples with by trisomy 21 matched with 1,483 euploid samples, 62 samples with trisomy 18 matched with 183 euploid samples, and 12 samples with trisomy 13 matched with 36 euploid samples. All of the samples were taken from women at high-risk for fetal aneuploidy. Before adjustment the test had a sensitivity of 98.6% and a false positive rate of 0.2% for detecting trisomy 21. After adjusting for guanine cytosine content and removing repetitive regions, the test had a sensitivity of 99.1% and a false positive rate of 0.1% for diagnosing trisomy 21. After adjustment for guanine cytosine content the test had a sensitivity of 100% and a false positive rate of 0.3% for diagnosing trisomy 18, and a sensitivity of 91.7% and a false positive rate of 0.9% for diagnosing trisomy 13 (Palomaki 2011, Palomaki 2012). The second study was a cohort study that included 480 samples from women at high-risk for fetal aneuploidy. Results from this study suggest that before adjusting for guanine cytosine content and removing repetitive regions this test has a sensitivity of 100% and a false positive rate of 0.2% (Ehrich 2011). Based on this evidence Kaiser concluded that despite a promising diagnostic performance, MaterniT21 suffers from an extremely sparse, vendor-involved body of evidence specific to a high-risk population, and lacks studies examining the prospective impact of MaterniT21 on patients' decisions of whether to pursue chorionic villus sampling or amniocentesis (Kaiser 2012). **Conclusion:** Kaiser concluded that there is insufficient evidence to determine whether the MaterniT21 prenatal test to detect Down syndrome is medically appropriate for any patient.

**Articles:** In March 2012, Kaiser review MaterniT21 for the detection of trisomy 21. No additional studies were identified since the Kaiser review. The following technology assessment was selected for review: Kaiser Permanente. Sequenom's MaterniT21 prenatal test to detect Down syndrome. March 2012.

[http://cl.kp.org/pkc/national/cpg/intc/materials/MaterniT21toDetectTrisomy21\(G121107\).pdf](http://cl.kp.org/pkc/national/cpg/intc/materials/MaterniT21toDetectTrisomy21(G121107).pdf).

The use of MaterniT21 does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Ceramic on Ceramic Hip Replacement Systems

- Ceramic TRANSCEND® Articulation Hip System

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

This service is covered and no medical necessity review required.

##### For Non-Medicare Members

This service is not recommended for coverage, as the evidence indicates that squeaking with movement is a common side effect, resulting in frequent requests for replacement and insufficient evidence of efficacy.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Total hip replacement (THR) is a widely performed procedure to relieve pain and restore joint function in patients with osteoarthritis or injury. In THR, the femoral head is replaced with a synthetic ball fixed through a stem to the femur. The ball fits into a synthetic acetabular cup fixed in the pelvis. Several artificial cup-femoral head material combinations are currently in use. Soft-on-hard combinations consist of a cup made of ultra-high molecular weight polyethylene and head made of stainless steel, cobalt-chromium (Co-Cr) alloy or alumina. There are also hard-on-hard combinations where both the cup and the head are made of Co-Cr (metal-on-metal, MOM) or alumina (ceramic-on-ceramic, COC).

The initial metal-on-metal designs of the 1960s had high premature failure rates compared with metal-on-polyethylene devices. However, the metal-on-polyethylene devices have been associated with polyethylene wear debris, leading to osteolysis and aseptic loosening. Second-generation metal-on-metal implants, believed to have lower wear rates, were introduced in the 1990s. Still, the newer MOM implants may generate metallic debris, and there is concern about the long-term effects of these metallic particles (Figueiredo-Pina et al., 2008; Keurentjes et al., 2008). Advantages of ceramic-on-ceramic implants are durability and biocompatibility. First generation COC implants, however, had relatively high fracture rates. The ceramic material has undergone modifications, and a third-generation ceramic, released in the mid-1990s, is believed to have better wear properties. This has reduced, though not eliminated, the risk of fracture. Potential remaining disadvantages of ceramic-on-ceramic systems include cup migration and osteolysis (Lusty et al., 2007; Takata et al. 2007; Zhou et al., 2006). One documented problem with ceramic-on-ceramic bearings is a squeaking sound during walking or other movement. The cause of squeaking remains unknown; possible sources include suboptimal anteversion and inclination of the cup, focally increased surface roughness, and lack of lubrication fluid between the articulating surfaces (Keurentjes et al., 2008). Squeaking problems have led to some revision surgeries to replace the hip systems (FDA website).

#### Medical Technology Assessment Committee (MTAC)

##### Ceramic TRANSCEND® Articulation Hip System

##### 10/08/2003: MTAC REVIEW

**Evidence Conclusion:** There was only one published empirical study on the Ceramic TRANSCEND® Articulation Hip System, a case series with 333 patients (Garino). This study provides insufficient evidence to make conclusions about the effect of the TRANSCEND® system on health outcomes. As a case series, it is subject to selection bias and there was no comparison or control group. The authors found an improvement in the mean Harris hip score and short form-12, but details of the data analysis were not provided. There were 4 ceramic-related complications requiring intraoperative revision and 4 patients received revision surgery; there were no

ceramic fractures. There is also insufficient evidence to make conclusions about the effectiveness of two similar ceramic hip systems made by Howmedica Osteonics, which D'Antonio compared to a cobalt-chrome-on-polyethylene hip system in an RCT. D'Antonio did not present statistical comparisons among groups, but scores on the outcome variables appear to be similar (e.g. patients in all three treatment groups had Harris hip scores in the "excellent" range at follow-up). The study may have been underpowered to detect clinically meaningful differences and there were other threats to validity. No ceramic fractures were reported during a mean of 35 months' follow-up; there was a 2-3% rate of intraoperative insert chips.

**Articles:** The search yielded 170 articles. Many of the articles were reviews, opinion pieces, non-clinical studies or evaluated other, similar technologies. Preliminary findings from the key clinical study (case series) resulting in FDA approval was published in 2000 and this study was critically appraised. No published randomized or non-randomized controlled trials on the TRANSCEND® system were identified. There was one RCT on a similar ceramic-on-ceramic system manufactured by Howmedica Osteonics. The case series and RCT were critically appraised: Garino JP. Modern ceramic-on-ceramic total hip systems in the United States: Early results. *Clinical Orthopedics and Related Research* 2000; 379: 41-47. See [Evidence Table](#).

The use of ceramic on ceramic hips in total hip replacement surgery does not meet the *Group Health Medical Technology Assessment Criteria*.

### 10/06/2008 MTAC REVIEW

#### Ceramic TRANSCEND® Articulation Hip System

**Evidence Conclusion:** There are RCTs published since 2003 comparing ceramic-on-ceramic hip implants to metal-on-metal or metal-on-polyethylene systems. Two had a safety/durability measure as their primary outcomes. Zhou et al., 2006 did not find a significant difference in cup migration with a ceramic-on-ceramic vs. a metal-on-polyethylene implant system. In the Grubl et al. (2006) study, serum levels of aluminum and cobalt, the primary outcomes, did not appear to differ with a ceramic-on-ceramic versus a metal-on-metal implant, although p-values were not reported. The third study (D'Antonio et al., 2005) did not list its primary outcome measure. The D'Antonio study, conducted by the team with substantial financial links to Stryker, found a significantly lower rate of revision in the group receiving ceramic-on-ceramic implants compared to metal-on-polyethylene systems after a mean follow-up of 5 years. However the absolute difference in revision rate was small (8% vs. 6%). All of the studies reported pain and functioning as secondary outcomes, so these were likely underpowered. None found significantly better pain or patient functioning with the ceramic systems, as measured by the Harris Hip Score and/or SF-36. One of the case series reviewed focused on fracture (Koo et al., 2008) and found 5 ceramic head fractures out of 367 hip implants (1.4%) after a mean of 23 months. In the Murphy et al. (2006) series, there were 3 implant-related complications in 174 hips (1.7%) after a mean of 4 years. Both of these series found statistically significant improvement in patient functioning after the THA compared to baseline, but there was no comparison group that received a different type of implant. Two studies (case series and case-control) were identified that specifically investigated the issue of noise or squeaking associated with ceramic hip implants. The study funded by Stryker found a lower rate of squeaking than the study without industry funding (28/999, 2.8% versus 9/42, 21%). The study finding the higher rate required objective verification of the squeaking noise. In conclusion, there is insufficient evidence on the safety and efficacy of ceramic hip implant systems compared to other types of systems. Studies tended to be small, assess different safety variables, and be underpowered to measure differences in pain and function. The prevalence of squeaking differed across studies (3-28%) and needs additional investigation. Although this is largely a nuisance side effect, it is a reason for revision surgeries. The evidence base is limited by relatively small sample sizes. The largest studies have been conducted by investigators associated with Stryker, which may lead to bias.

**Articles:** Three randomized controlled trials evaluating ceramic-on-ceramic hip implants were identified and critically appraised. All had at least some industry funding, but the research group led by James D'Antonio, which published the largest RCT, has substantial financial links with the implant manufacturer. Several authors are paid consultants to Stryker. The two other RCTs were smaller, and focused on potential adverse effects associated with ceramic implants. Several case series were also identified. Two series with larger sample sizes, no reporting of industry funding and using FDA-approved ceramic implants were critically appraised (Koo et al., 2008; Murphy et al. 2006). In addition, the findings of the two series that specifically addressed squeaking are included (Keurentjes et al., 2008; Restrepo et al., 2006). *References for the studies critically appraised are as follows:* **RCTs** D'Antonio J, Capello W, Manley M et al. Alumina ceramic bearings for total hip arthroplasty. *Clin Orthop Rel Res* 2005; 436: 164-171. See [Evidence Table](#). Grubl A, Weissinger M, Brodner W et al. Serum aluminum and cobalt levels after ceramic-on-ceramic and metal-on-metal total hip replacement. *J Bone Joint Surg (Br)*; 2006; 88-B: 1003-1005. See [Evidence Table](#). Zhou Z, Li MG, Borlin N et al. No increased migration in cups with ceramic-on-ceramic bearing. *Clin Orthop Rel Res* 2006; 448: 39-45. See [Evidence Table](#).

The use of ceramic on ceramic hips in total hip replacement surgery does not meet the *Group Health Medical Technology Assessment Criteria*.

#### Criteria

##### For Medicare Members

##### Local Coverage Determination (LCD)

[Non-Covered Services \(L35008\)](#)

And for facility-based services billed using a UB form, see [Non-Covered Services \(L34886\)](#)

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Multiple sclerosis is an autoimmune inflammatory disease of the central nervous system that affects approximately 250,000 to 500,000 people in the United States. Although the cause of multiple sclerosis is unknown, evidence suggests it may be caused by the interplay of genetic and environmental factors. However, it has recently been hypothesized that a phenomenon known as chronic cerebrospinal venous insufficiency (CCSVI) may also play a role in the etiology, pathogenesis, and/or disease progression of multiple sclerosis. This theory suggests that abnormal drainage of venous blood due to stenosis or malformation of the internal jugular and/or azygous veins may be a cause of multiple sclerosis (Ghezzi 2011, Khan 2010, Vedantham 2010).

The evidence pertaining to the association between CCSVI and multiple sclerosis is inconsistent. Depending on the study, the frequency of CCSVI in patients with multiple sclerosis ranged from 0 to 100%. The frequency of CCSVI in controls ranged from 0 to 23%. Different methods of assessing CCSVI may explain some of the variability among these studies. Doppler sonography, venous MRI, and venous angiography have all been used to assess CCSVI; however, it is not clear which is the gold standard (Ghezzi 2011). Additionally, it is not clear if CCSVI is a cause of multiple sclerosis, an effect of multiple sclerosis, or an unrelated finding (Singh 2009, Vedantham 2010). Based on the CCSVI hypothesis balloon angioplasty has been proposed as a treatment for multiple sclerosis patients with CCSVI.

#### Medical Technology Assessment Committee (MTAC)

##### *Chronic Cerebrospinal Venous Insufficiency Treatment*

##### **06/10/2011: MTAC REVIEW**

**Evidence Conclusion:** A recent open-label, prospective case-series evaluated the safety of CCSVI endovascular treatment and its influence on clinical outcomes in 65 consecutive patients with multiple sclerosis. No operative or postoperative complications were recorded. After the endovascular treatment, disease severity significantly improved for patients with relapse remitting multiple sclerosis, but not for patients with primary progressive or secondary progressive multiple sclerosis. In patients with relapse remitting multiple sclerosis, significantly more patients were relapse free during the 18 months posttreatment compared to the year preceding endovascular treatment; however, there was no significant difference in annualized relapse rate. Quality of life improved significantly for subjects with relapse remitting and primary progressive multiple sclerosis, but not for subjects with secondary progressive multiple sclerosis. Results from this study should be interpreted with caution as this is a small, open-label study with no comparison group (Zamboni 2009). Another prospective case-series evaluated the safety of endovascular treatment for CCSVI in 331 patients with multiple sclerosis. Overall, three patients experienced major complications. Two patients (1.2% of implanted stents) experienced stent thrombosis and one

patient (0.3%) required surgical opening of the femoral vein to remove the angioplastic balloon. Minor complications included: local bleeding from the groin (4 patients, 1.2%), minor gastrointestinal bleeding (1 patient, 0.3%), transient cardiac arrhythmia (2 patients, 0.6%), difficulty removing the angioplastic balloon or delivery system (4 patients, 1.2%), problems with proper placement of the stent (4 patients, 2.3% of implanted stents), unsuccessful catheterization of the stenosed internal jugular vein (4 patients, 1.3%). Long-term complications were not addressed (Ludyga 2010). *Conclusion:* Currently, there is insufficient evidence to determine the safety and efficacy of balloon angioplasty for the treatment of CCSVI in patients with multiple sclerosis. In a recent position statement, the Society of Interventional Radiology also concluded that the current published literature was inconclusive on whether CCSVI is a clinically important factor in the development and/or progression of multiple sclerosis and on whether balloon angioplasty is clinically effective in patients with multiple sclerosis (Vedantham 2010).

**Articles:** To determine the safety and efficacy of balloon angioplasty for the treatment of multiple sclerosis patients with CCSVI. No randomized controlled trials were identified that assessed the safety or efficacy of balloon angioplasty for the treatment of multiple sclerosis patients with CCSVI. The best evidence came from an observational study. This study was selected for review. The following study was critically appraised: Zamboni P, Galeotti R, Menegatti E, et al. A prospective open-label study of endovascular treatment of chronic cerebrospinal venous insufficiency. *J Vasc Surg* 2009; 50:1348-1358. See [Evidence Table](#).

The use of chronic cerebrospinal venous insufficiency treatment for multiple sclerosis does not meet the *Group Health Medical Technology Assessment Criteria*.

National Coverage Determinations (NCD)	<a href="#">Inpatient Hospital Stays for Treatment of Alcoholism (130.1)</a> <a href="#">Outpatient Hospital Services for Treatment of Alcoholism (130.2)</a> <a href="#">Chemical Aversion Therapy for Treatment of Alcoholism (130.3)</a> <a href="#">Electrical Aversion Therapy for Treatment of Alcoholism (130.4) – (Note: Not currently a Medicare covered benefit)</a> <a href="#">Treatment of Alcoholism and Drug Abuse in a Freestanding Clinic (130.5)</a> <a href="#">Treatment of Drug Abuse (Chemical Dependency) (130.6)</a> <a href="#">National Coverage Determination (NCD) for Withdrawal Treatments for Narcotic Addictions (130.7)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare members

Group Health has elected to use the following MCG\* guidelines for medical necessity determinations:

- Substance-Related Disorder, Inpatient Behavioral Health Level of Care, Adult (B-903-IP)
- Substance-Related Disorder, Inpatient Behavioral Health Level of Care, Child/Adolescent (B-907-IP)

##### Medical Necessity Criteria for Coverage of Admission:

An Inpatient Hospital Stay for Substance Detoxification is medically necessary when **ALL** of the following have been met:

- 1) MCG\* Admission Guidelines are met.
- 2) There is a reasonable expectation that the member's illness, condition, or level of functioning will improve as a result of the treatment plan or that stabilization is possible.
- 3) Services must be provided in a state-licensed facility for the proposed level of care.

##### Medical Necessity Criteria for Coverage of Continued Stay:

Continued Inpatient Hospital Stay for Substance Detoxification is medically necessary when **ALL** of the following have been met:

- 1) Continued inpatient substance abuse treatment is medically necessary based on MCG Ongoing Care Guidelines and Discharge Criteria.
- 2) All the criteria for coverage of an admission continue to be met as well as both of the following:
  - a) The patient cannot be treated safely at an alternative level of care, and
  - b) There is a reasonable expectation that the member's illness, condition, or level of functioning will improve as a result of the treatment plan or that stabilization is possible.

##### Exclusions

Inpatient detoxification services will not be authorized or reimbursed if any contract exclusion criteria are met.

**\*MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed by our Behavioral Health Department, you may request a copy of the criteria that is being used to make the coverage determination. Call the Behavioral Health Unit for more information regarding the case under review.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

In January 2006, Group Health adopted and integrated into its clinical review criteria the MCG for determining appropriate levels of care based on symptoms and functional impairment. These criteria are independently developed and based on a review of the scientific literature, expert input, and clinical practice. In addition, the MCG criteria are updated yearly. Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning."

Inpatient detoxification services are provided or authorized with the overall goals of assessing and stabilizing the member's acute symptoms of substance withdrawal, in order that treatment can be continued effectively in a less restrictive and disruptive level of care.

Inpatient detoxification treatment is utilized when it is the most appropriate and effective level of care that can safely be provided for the member's immediate condition. Service authorization is based on the member's contract and the MCG for inpatient substance abuse, dependence and withdrawal care. When treating children or adolescents, the parents or guardians must be included in both the evaluation and treatment planning processes, except for children age 13 or older who refuse to have a parental/guardian figure involved.

## Clinical Review Criteria

### Chemical Dependency Treatment – Suboxone/Opioid Agonist Treatment

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Non-Medicare members

To qualify for office based opioid agonist treatment – admission, continued stay or discharge **ONE** of the following must be met:

- I. Admission: **All of the following** must be met for authorization for admission to a provider for office-based agonist treatment (e.g. buprenorphine/naloxone (Suboxone), buprenorphine (Subutex):
  - A. Patient must be a minimum of 18 years old.
  - B. Patient must obtain a Chemical Dependency (CD) Evaluation\* by a state licensed chemical dependency provider and the evaluation must reflect a primary diagnosis as Opioid Use Disorder, Moderate or Severe, DSM code 304.00 (DSM 5 Diagnostic and Statistical Manual of Mental Disorders.)
  - C. Patient is assessed by the prescribing physician as meeting the diagnostic criteria for Opioid Use Disorder, Moderate or Severe (DSM 5 diagnosis code 304.00) and is assessed to be an appropriate candidate for office-based agonist detoxification or maintenance treatment.
  - D. Patients administratively discharged or voluntarily discontinuing engagement in methadone treatment program in the past 6 months are not eligible for opioid agonist treatment unless a physician associated with a state licensed Chemical Dependency opiate treatment program has recommended this medication as an adjunct to out-patient chemical dependency treatment.
  
- II. Continued Stay Criteria: **ALL of the following** must be met:
  - A. Patient is meeting office-based opioid agonist treatment provider requirements for ongoing refills.
  - B. Patient is adhering to their treatment plan, as determined by the physician.
  - C. Pharmacotherapy has been an important part of treatment, reducing addiction symptoms including relapse. The withdrawal of office-based opioid agonist treatment is likely to lead to a recurrence of addiction symptoms.
  
- III. Discharge Criteria: **ALL of the following** must be met:
  - A. Patient is failing office-based opioid agonist treatment provider treatment requirements, as defined by the individual provider.
  - B. Patient voluntarily discontinues office-based opioid agonist treatment.

*\*A CD Evaluation is not required if a patient is currently enrolled and actively participating in a state licensed Chemical Dependency Treatment Program for opiate dependence (written verification required).*

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

In 2007, Group Health Pharmacy and Therapeutics Committee approved the use of Suboxone for the maintenance treatment of opiate dependence (previously only approved for short-term opiate detoxification). In 2008 Group Health made the decision that Behavioral Health Services would manage the referral pathway for Suboxone treatment which is largely provided in an external delivery system.

As with other addiction pharmacotherapy interventions, it is recommended that Suboxone medication be prescribed as an adjunct to chemical dependency treatment for optimal treatment outcomes. Physicians

prescribing Suboxone will determine if chemical dependency treatment (by a licensed WA State Chemical Dependency Treatment Program or independent provider with chemical dependency expertise) is required based upon their clinical/medical assessment and the patients progress while on Suboxone.

###### ADMISSION CRITERIA

[Chemical Dependency Treatment - Adult \(≥18 years old\) Residential Treatment](#)

[Chemical Dependency Treatment – Adolescents \(13-17 years old\) Residential Treatment](#)

###### CONTINUED STAY CRITERIA

[Chemical Dependency Treatment - Adult \(≥18 years old\) Residential Treatment](#)

[Chemical Dependency Treatment – Adolescents \(13-17 years old\) Residential Treatment](#)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

The purpose of the behavioral health medical necessity criteria is to provide a guide to coverage. Behavioral health policy is not intended to dictate to providers how to practice medicine. Providers are expected to exercise their clinical judgment in providing the most appropriate care. To qualify for the chemical dependency benefit, members must have a DSM-IV diagnosis of substance dependence that is the primary reason for placement at the residential level of care.

Group Health Behavioral Health Services operationally defines clinically indicated services as "services for mental health conditions that are having a clinically significant impact on an individual's social, medical, and/or occupational functioning."

##### Adult Residential Treatment

Substance use disorders are chronic medical problems associated with changes in the nervous system that require months of abstinence for recovery. Clinically, these diseases require long-term engagement in care to have the best outcomes for patients. Outcomes research over the past 27 years consistently finds that longer treatment duration leads to improved outcomes. This has led the Department of Veterans Affairs to set performance measures for substance use disorders treatment to continuing treatment for 90 days or more.

The National Institute on Alcohol Abuse and Alcoholism (NIAAA) of the National Institutes of Health (NIH) considers outpatient treatment to be the most promising course for those that are chemically dependent and, thus, the preferred care strategy. However, residential care does have a role in the continuum of treatment for patients with addictive diseases. When severe addictive disease and other co-morbidities are present, we believe it is important to provide residential care as a covered benefit for those patients who may need more intensive treatment. It should allow them to better engage in and benefit eventually from continued outpatient treatment, which is central to their recovery. As with other chronic health conditions, relapse is expected. Therefore, effective care plans include relapse prevention strategies as well as actions to take in the event of a relapse. Relapse does not constitute a need for residential treatment; rather, it supports the need for engagement or re-engagement in outpatient care and other support activities.

Current data reflects that 50% – 75% of patients with substance use disorders seeking treatment have co-occurring mental health conditions. Patients with co-occurring conditions are more likely to benefit from residential care. Effective treatment should optimally address both disorders via an integrated care plan. The care plan will help guide treatment in residential care and will inform transition and discharge planning related to follow-up needs.

Medical evaluation is often an important component of care. In addition to general medical conditions, attention needs to be given to assessing the patient's need for detoxification. Medical assessment ideally includes evaluation of the patient's eligibility for medications to assist with the medical management of cravings and/or opiate replacement treatment (if applicable).

### **Adolescent Residential Treatment**

Residential treatment services are provided or authorized with the overall goals of assessing and stabilizing the member's severe symptoms, in order that treatment can be continued effectively in a less restrictive and disruptive level of care. Since substance use disorders are chronic disorders, treatment is optimally provided over longer periods of time. Residential treatment may serve as the level of care needed to help youths to stabilize and engage in treatment with the ultimate goal of transitioning to longer term treatment at a lower level of care.

Residential chemical dependency treatment is utilized when it is the most appropriate and effective level of care that can safely be provided for the member's immediate condition. Service authorization is based on the member's contract and these clinical review criteria. When treating children or adolescents under the age of 18 in a residential treatment program, the parents or guardians must consent for the treatment and be included in both the evaluation and treatment planning processes, except for youths who have been living outside of the family home and the parents are unavailable, unable, or unwilling to provide consent to treatment. Admitting a self-consenting youth is a determination made by the program to which the youth applies, based on information obtained by the program, and the program must document efforts to locate and engage the parents in the treatment process.

Medical evaluation is often an important component of care. In addition to general medical conditions, attention needs to be given to assessing the youths need for detoxification, and ideally includes evaluation of the patients eligibility for medications to assist with the medical management of cravings, and/or opiate replacement treatment (if applicable).

### **ASAM placement criteria for both adult and adolescents**

Washington State requires the use of ASAM criteria by State-certified chemical dependency treatment providers, when determining placement of patients with substance use disorders (criteria includes placement recommendations related to residential treatment). Clinical recommendations must be documented in writing and must contain objective clinical information. Clinical criteria do not factor in family, employer or legal mandates or requests for treatment. Clinical criteria are intended to evaluate the impact of the substance use disorder on the affected individual (via a bio-psychosocial assessment) and to guide decision making related to care strategies.

## **Evidence and Source Documents**

### **References for Adult Residential Treatment:**

1) Mojtabai R, Graff Zivin J. "Effectiveness and Cost-Effectiveness of Four Treatment Modalities for Substance Disorders: A Propensity Score Analysis" Health Services Research. 38(1):233-259, 2003.

This study was a data analysis from the Services Research Outcomes Study, surveying 3,047 clients in 99 drug treatment facilities across the United States. No long-term differences in abstinence or reduced drinking between outpatient treatment and residential treatment. Outpatient treatment was the most cost-effective treatment modality.

2) Weisner C, Mertens J, Parthasarathy S, Moore C, Hunkeler EM, Hu T, Selby JV. "The Outcome and Cost of Alcohol and Drug Treatment in an HMO: Day Hospital Versus Traditional Outpatient Regimens" *Health Services Research*. 35(4):791-812; 2000.

This study was a randomized controlled trial of 668 adults entering drug treatment in an HMO (Kaiser) randomized to day hospital treatment or to outpatient treatment. Patients randomized to either outpatient or day hospital treatment fared equally well. Patients with mid-level psychiatric severity did fare better with the higher level of care.

3) Witbrodt J, Bond J, Kaskutas LA, Weisner C, Jaeger G, Pating D, Moore C. "Day Hospital and Residential Addiction Treatment: Randomized and Nonrandomized Managed Care Clients" *Journal of Consulting and Clinical Psychology*. 75(6):947-959; 2007.

This study was a randomized controlled trial of 293 adults entering substance abuse treatment in an HMO (Kaiser) randomized to day hospital treatment or to residential treatment. Despite differences in baseline severity between groups, patients randomized or non-randomized fared equally well in either treatment intensity. 12 month outcomes were most closely related to continued 12-step participation.

4) Kaskutas LA, Witbrodt J, French MT. "Outcomes and costs of day hospital treatment and nonmedical day treatment for chemical dependency." *Journal of Studies on Alcohol*. 65(3):371-382; 2004.

This study was a randomized controlled trial of adults entering substance abuse treatment in an HMO (Kaiser) randomized to hospital-based day treatment or to one of two community-based day treatment programs. Patients randomly assigned to either hospital-based day treatment or community-based treatment fared equally well, while costs were lower in community-based programs.

5) Guydish J, Sorensen JL, Chan M, Werdegard D, Bostrom A, Acampora A. "A Randomized Trial Comparing Day and Residential Drug Abuse Treatment: 18-Month Outcomes" *Journal of Consulting and Clinical Psychology*. 67(3):428-434; 1999.

This study extends similar findings from a report on 6-month outcomes from a randomized trial assigning 188 clients entering a therapeutic community to either day treatment or residential treatment. Both groups had similar improvements over time with those in residential treatment having greater improvement for psychiatric symptoms and social problems.

6) Moos RH, Moos BS. "Long-term influence of duration and intensity of treatment on previously untreated individuals with alcohol use disorders." *Addiction*. 98:325-337; 2003.

This study was a naturalistic study following 473 alcoholic adults over 8 years following SUD identification. Rapidly entering treatment and duration of treatment (i.e., longer duration being better) were related to better short and long-term (i.e., 3 and 8 year) alcohol-related outcomes. In general, intensity of treatment was not related to better outcomes.

7) Chen S, Barnett PG, Sempel JM, Timko C. "Outcomes and costs of matching the intensity of dual-diagnosis treatment to patients' symptom severity." *Journal of Substance Abuse Treatment*. 31:95-105; 2006.

This study evaluated a patient-treatment matching strategy for dual-diagnosis patients in the VA (N=230). Patients with high severity dual disorders had better alcohol, drug and psychiatric outcomes and higher health care costs. Moderate severity patients generally had similar outcomes whether they were matched to low-intensity treatment or not.

#### **References for Adolescent Residential Treatment:**

1) Sussman S, Skara S, Ames SL. "Substance Abuse Among Adolescents". *Substance Use & Misuse*. 43:1802-1828; 2008.

This paper summarizes the findings in adolescent substance abuse treatment with occasional comparisons to adult substance abuse and treatment. There is little evidence to guide selection of treatment modality or setting in adolescents. There are some differences between substance use disorders in adolescents and adults, notably, adolescents typically have less motivation for abstinence than adults.

2) Hser YI, Grella C, Hubbard RL, Hsieh SC, Fletcher BW, Brown BS, Anglin MD. "An Evaluation of Drug Treatments for Adolescents in 4 US Cities." *Archives of General Psychiatry*. 58:689-695; 2001.

This was a naturalistic study of 1167 adolescents who were treated in one of three different treatment settings and followed for one year. This study did not compare treatment settings with one another, but in general, found treatment in all settings to lead to improvements in most substance use and overall functioning domains and that length of time in treatment is associated with better outcomes.

3) Grella C, Hser YI, Joshi V, Rounds-Bryant J. "Drug Treatment Outcomes for Adolescents with Comorbid Mental and Substance Use Disorders." *Journal of Nervous and Mental Disease*. 189(6): 384-392; 2001.

A naturalistic study of 992 adolescents treated in three different treatment settings compared those with and without comorbid psychiatric disorders. Psychiatric comorbidity was associated with greater substance use problems entering treatment, which was associated with less favorable treatment outcomes. Compared to those without comorbidity, comorbid youth were more likely to use cannabis and hallucinogens and were more likely to engage in illegal acts a year after treatment.

## Clinical Review Criteria

### Chemical Dependency Treatment – Adolescents (13-17 years old) Residential Treatment Admission

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

Admission of an adolescent to an approved facility for chemical dependency residential level of care is medically necessary when **All of the following** are satisfied: qualification for the benefit, treatment elements and dimensional criteria.

- 1) Qualification for the benefit – to qualify for the benefit **ALL of the following** must be true:
  - a) Members must have a DSM-5 diagnosis of substance use disorder, moderate or severe, as the primary reason for placement at the residential level of care.
  - b) A reasonable expectation that either the patient is capable of making changes due to the treatment (i.e. active treatment will improve the member's level of functioning) or that stabilization is possible.
  - c) The proposed medical treatment includes **All of the following**:
    - i) must involve a level of care with appropriate resources to assess and treat the client's condition according to its severity, the member's health and level of functioning.
    - ii) must involve the most appropriate level of service which can be safely provided to the member.
    - iii) could not have been provided in a provider's office, the outpatient department of a hospital or a non-residential facility without affecting the member's condition or quality of health services rendered.
  - d) The proposed level of care is not solely for the convenience of the member, his/her family or the provider of the services or supplies.
- 2) Admission is indicated to a facility where **ALL of the following** treatment elements are provided:
  - a) Individualized, developmentally appropriate treatment plan with clear and measurable treatment goals, including plans related to co-morbidity, if applicable.
  - b) Staff monitoring 24 hours a day.
  - c) Clinical assessment of progress toward treatment goals is routinely conducted and documented; treatment plan is reviewed a least once per week.
  - d) Daily individual and / or group counseling (optimally two times per day).
  - e) Weekly educational groups (optimally daily).
  - f) Weekly Family education and counseling.
  - g) Transition / Discharge plan initiated at admission. Transition plan to include **ALL of the following**:
    - i) date returning to intensive outpatient treatment for chemical dependency,
    - ii) follow-up appointment time with mental health care provider, if applicable, and
    - iii) medical appointments (including appointments for medication to reduce cravings, if applicable).
  - h) At least one hour per day for 5 days per week of supervised academic tutoring or instruction by a certified teacher or tutor, obtaining school work from youth's home school when possible.
  - i) At least 7 hours per week structured and staff supervised recreational activities.
- 3) Dimensional Criteria - Admission is appropriate when **ALL of the following** exclusionary and indicating factors are satisfied.
  - i) **ACUTE INTOXICATION/WITHDRAWAL DIMENSION** - Youth is stable, not requiring medical management for intoxication or withdrawal
  - b) Indicating factors: There are indicating factors present in at least **ONE of the following** dimensions
    - i) **BIOMEDICAL CONDITION DIMENSION** -  
Youth is at risk for significant medical complications related to continued substance use during the current episode of illness as evidenced by recent hospital admissions or multiple acute medical presentations for medical problems other than substance withdrawal (e.g. acute asthma attack exacerbated by cannabis use requiring hospitalization, abscess from IV drug use requiring inpatient treatment, diabetic ketoacidosis related to continued alcohol use impairing ability to perform diabetic self-care).
    - ii) **COGNITIVE, BEHAVIORAL, AND EMOTIONAL CONDITION DIMENSION**

Youth has at least **ONE of the following** behaviors usually associated with mental illness/personality traits present that significantly interferes with the youth's ability to engage in treatment and cannot be managed at lower levels of care:

- (1) Emotionally labile/frequent mood swings/social isolation/withdrawal with likely significant psychiatric co-morbidity (e.g., behavior interferes with focus of group activity, liability causing disruption in treatment milieu, anxiety prevents engagement in group activity).
  - (2) Interpersonal conflict or poor/inappropriate boundaries (e.g. consistent conflictual or otherwise disrupted relations with others, runaway behavior, dramatic behavior drawing attention of treatment groups away from focus on recovery, poor boundaries prevent appropriate engagement in treatment or disruptive to treatment milieu).
  - (3) Youth is not taking psychiatric medications properly (taking too much or too little) with risk of harm, or impacts treatment participation and abstinence.
  - (4) Recklessness/impulsivity/disinhibition behaviors (weapons, destructive, high-risk sexual activity, self-harm, gambling).
  - (5) Suicidal ideation related to substance use.
- iii) **READINESS/MOTIVATION DIMENSION** - Youth is unable to follow through with treatment recommendations related to limited readiness for change despite serious consequences of use to his/her life, youth does not believe that there is any problem in daily substance use.
- iv) **RELAPSE/CONTINUED USE DIMENSION**  
Evidence substance use is so persistent that youth has been unable to remain abstinent despite significant efforts to engage in a lower level of care with **ONE of the following**:
- (1) In spite of active participation in treatment at appropriate lower level of care, youth continues to abuse substances daily or regularly.
  - (2) Severe progression of substance use disorder (e.g. advanced from abuse of one substance to *dependence on more than one substance* with significant school/legal/health consequences in the last 6 months).
  - (3) Continued use despite severe adverse consequences.
  - (4) Recent history of overdose, severe intoxication/poisoning, requiring medical treatment.
  - (5) School – in or out of school suspensions (more than one), expulsion, declining performance (e.g. failing more than one course).
  - (6) Continued intense cravings to use and has had one or more attempts trying outpatient treatment and medications to reduce cravings (if clinically appropriate).
- v) **RECOVERY ENVIRONMENT DIMENSION** — must meet **ALL of the following**:
- (1) Family is in agreement that treatment is necessary and is willing to participate.
  - (2) Home environment is not safe or stable to promote recovery at a lower level of care (no structure, high risk of neglect, physical or sexual abuse, exposure to active users/triggers or continued enabling in the home environment).

## Clinical Review Criteria

### Chemical Dependency Treatment – Adolescents (13-17 years old) Residential Treatment

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

**Continued stay of an adolescent in an approved Chemical Dependency Residential Treatment Facility is medically necessary when treatment elements and dimensional criteria are satisfied:**

1. **Treatment Elements - ALL of the following** are still being provided:
  - a. Individualized, developmentally appropriate treatment plan with clear and measurable treatment goals, including plans related to co-morbidity, if applicable.
  - b. Staff monitoring 24 hours a day.
  - c. Clinical assessment of progress toward treatment goals is routinely conducted and documented; treatment plan is reviewed a least once per week.
  - d. Daily individual and / or group counseling (optimally two times per day).
  - e. Weekly educational groups (optimally daily).
  - f. Weekly Family education and counseling.
  - g. Transition / Discharge plan initiated at *admission*. Transition plan to include the following:
    - i. date returning to intensive outpatient treatment for chemical dependency,
    - ii. follow-up appointment time with mental health care provider, if applicable, and
    - iii. medical appointments (including appointments for medication to reduce cravings, if applicable).
  - h. At least one hour per day for 5 days per week of supervised academic tutoring or instruction by a certified teacher or tutor, obtaining school work from youth's home school when possible.
  - i. At least 7 hours per week structured and staff supervised recreational activities.
2. **Dimensional Criteria** – continued stay is appropriate when **ALL of the following** have been met:
  - a. Youth has the capacity to make needed changes,
  - b. The current setting is providing the most appropriate spectrum of services to address the problem
  - c. The present condition cannot be safely and effectively managed in a lower level of care
  - d. The present condition can reasonably be expected to be managed at the current level of care with planned interventions.
  - e. Dimensional Criteria – Continued stay is appropriate when exclusionary and indicating factors for i and ii are satisfied
    - i. **ACUTE INTOXICATION/WITHDRAWAL DIMENSION**
      1. Youth is stable, not requiring more intensive treatment of intoxication or withdrawal

#### AND

- ii. **Indicating factors:** There are indicating factors present in at least **ONE of the following** dimensions:
  1. **BIOMEDICAL CONDITION DIMENSION**
    - a. Youth is continues to be at significant risk for serious medical complications related to continued substance use during the current episode of illness as evidenced by recent hospital admissions or multiple acute medical presentations for medical problems other than substance withdrawal. (e.g. acute asthma attack exacerbated by cannabis use requiring hospitalization, acute pancreatitis requiring hospitalization, abscess from IV drug use requiring inpatient treatment, diabetic ketoacidosis related to continued alcohol use impairing ability to perform diabetic self-care).
  2. **COGNITIVE, BEHAVIORAL, AND EMOTIONAL CONDITION DIMENSION** - At least **ONE of the following** behaviors usually associated with mental illness/personality traits

present that significantly interferes with the youth's ability to engage in treatment and cannot be managed at a lower levels of care:

- a. Emotionally labile / frequent mood swings / social isolation / withdrawal with probable cause being significant psychiatric co-morbidity that *impacts treatment participation and abstinence* (e.g., behavior interferes with focus of group activity, liability causing disruption in treatment milieu, anxiety prevents engagement in group activity).
  - b. Interpersonal conflict, poor/inappropriate boundaries that *impacts treatment participation and abstinence* (e.g., consistently conflictual or otherwise disruptive in relations with others, runaway behavior, dramatic behavior drawing attention of treatment groups away from focus on recovery, poor boundaries prevent appropriate engagement in treatment or disruptive to treatment milieu).
  - c. Youth is not taking psychiatric medications properly (taking too much or too little) with *risk of harm or impact on treatment participation and abstinence*.
  - d. Reckless/impulsive/disinhibited behaviors (weapons, destructive, high risk sexual activity, self-harm, gambling) that *impact treatment participation and abstinence*
  - e. Suicidal ideation related to substance use.
3. **READINESS/MOTIVATION DIMENSION** – Youth is unable to follow through with treatment recommendations related to limited readiness for change:
- a. Despite serious consequences of use to his/her life, youth does not believe that there is any problem in daily substance use and does not intend to continue any treatment after discharge.
4. **RELAPSE/CONTINUED USE DIMENSION**
- a. Despite recent, active participation in treatment at a less intensive level of care (including medication assisted treatment if appropriate, e.g. buprenorphine or methadone maintenance with counseling for opioid use disorder), the member continues to use alcohol or other drugs or deteriorates psychiatrically, with imminent serious consequences and is at high risk of continued substance use or mental deterioration in the absence of close 24-hour monitoring and structured treatment.
5. **RECOVERY ENVIRONMENT DIMENSION** – Both of the following are satisfied:
- a. Family is in agreement that treatment is necessary and remain willing to participate
  - b. Home environment is not safe or stable to promote recovery at a lower level of care (no structure in the home, high risk of neglect, and/or recent/ongoing physical or sexual abuse, exposure to user/triggers or continued enabling in the home environment).

## Clinical Review Criteria

### Chemical Dependency Treatment – Adult (≥18 years old) Residential Treatment Admission

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

Admission to an approved facility for chemical dependency residential level of care is medically necessary when qualification for the benefit, treatment elements, AND dimensional criteria are satisfied:

- 1) **Qualification for the benefit** – to qualify for the benefit **ALL of the following** must be true:
  - a) The member must have a DSM-5 diagnosis of Substance Use Disorder, moderate or severe, that is the primary reason for placement at the residential level of care.
  - b) There must also be a reasonable expectation that either the member is capable of making changes (i.e. active treatment will improve this person's level of functioning) as a result of the treatment plan or that stabilization is possible.
  - c) The proposed medical treatment must meet **ALL of the following**:
    - i) Must involve a level of care with appropriate resources to assess and treat the patient's condition according to its severity and the consumer's health and level of functioning.
    - ii) Must involve the most appropriate level of service which can be safely provided to the patient.
    - iii) Could not have been provided and both safely and effectively managed at a lower level of care such as a provider's office, the outpatient department of a hospital or a non-residential facility without affecting the patient's condition or quality of health services rendered.
  - d) The proposed level of care is not solely for the convenience of the patient, his/her family or the provider of the services or supplies.
- 2) **Treatment Elements** – Admission is indicated to a facility when **ALL of the following** treatment elements are provided:
  - a) Individualized treatment plan with clear and measurable treatment goals, including plans related to co-morbidity, if applicable.
  - b) Staff monitoring 24 hours a day.
  - c) Review of Treatment Plan and clinical assessment of progress toward treatment goals is routinely conducted and documented at a least once per week.
  - d) Daily individual, group and / or family counseling (optimally two times per day).
  - e) Weekly educational groups (optimally daily).
  - f) Transition / Discharge plan initiated at admission. Transition plan to include **All of the following**:
    - i) date returning to intensive outpatient treatment for chemical dependency,
    - ii) follow-up appointment time with mental health care provider, if applicable, and
    - iii) medical appointments (including appointments for medication to reduce cravings, if applicable).
- 3) **Dimensional Criteria** - Admission is appropriate when **ALL of the following** exclusionary and indicating factors for a), b), and c) are satisfied.
  - a) **ACUTE INTOXICATION/WITHDRAWAL DIMENSION**
    - i) Member is stable, not requiring more intensive treatment of intoxication or withdrawal
  - b) **READINESS/MOTIVATION DIMENSION**
    - i) It is expected that the member has verbalized **ALL of the following**:
      - a. Interest in recovery with identification of desired goals / outcomes related to request for residential treatment, including a desire/willingness to abstain from all substances of abuse (exception made for nicotine), including cannabis and abused prescription drugs.
      - b. Willing to continue outpatient treatment post discharge.
      - c. Willing to obtain additional clinical (chemical dependency or mental health) or medical work-ups, if necessary, to promote an integrated care plan.
      - d. Willing to address post-treatment housing needs during treatment, if applicable.
  - c) **Indicating factors**: There are indicating factors present in at least **ONE of the following** dimensions:
    - i) **BIOMEDICAL CONDITION DIMENSION**

- a. Member is at risk for significant medical complications related to continued substance use during the current episode of illness as evidenced by recent hospital admissions or multiple acute medical presentations for medical problems other than substance withdrawal. (e.g. acute pancreatitis requiring hospitalization, abscess from IV drug use requiring inpatient treatment, diabetic ketoacidosis related to continued alcohol use impairing ability to perform diabetic self-care).
- ii) **COGNITIVE, BEHAVIORAL, AND EMOTIONAL CONDITION DIMENSION** - At least **ONE** of the **following** behaviors usually associated with mental illness/personality disorder are interfering with the member's ability to achieve and sustain abstinence and engage in lower levels of care:
  - a. Emotionally labile / frequent mood swings / social isolation / withdrawal with probable cause being significant psychiatric co-morbidity that impacts treatment participation and abstinence (e.g., behavior interferes with focus of group activity, liability causing disruption in treatment milieu, withdrawal/anxiety prevents engagement in group activity).
  - b. Interpersonal conflict, poor/inappropriate boundaries or severe personality disorder that impacts treatment participation and abstinence (e.g., consistently conflictual or otherwise disruptive in relations with others, frequently aggressive, dramatic and drawing attention of treatment groups away from focus on recovery, poor boundaries prevent appropriate engagement in treatment or disruptive to treatment milieu).
  - c. Member is not taking psychiatric medications properly (taking too much or too little) with risk of harm or impact on treatment participation and abstinence.
  - d. Reckless/impulsive behaviors (weapons, destructive, sexual, self-mutilation, gambling, anger) that impact treatment participation and abstinence
  - e. Difficulty following instructions due to chronic and persistent intoxication and/or effects of prolonged substance abuse that impact treatment participation and abstinence (e.g., repeated drinking and driving despite significant consequences).
  - f. Suicidal ideation related to substance abuse.
- iii) **RELAPSE/CONTINUED USE DIMENSION**

Despite recent, active participation in treatment at a less intensive level of care (including medication assisted treatment if appropriate, e.g. buprenorphine or methadone maintenance with counseling for opioid dependence), the member continues to use alcohol or other drugs or deteriorates psychiatrically, with imminent serious consequences and is at high risk of continued substance use or mental deterioration in the absence of close 24-hour monitoring and structured treatment.
- iv) **RECOVERY ENVIRONMENT DIMENSION**

Environment not conducive to abstinence as evidenced by at least **ONE** of the **following**, which interfere with engagement in lower levels of care:

  - I. Family/significant others undermine efforts to maintain abstinence (may include home environment exposure to active users/triggers or continued enabling in the home environment).
  - II. Recovery environment is not safe as evidenced by recent/ongoing physical or sexual abuse.

## Clinical Review Criteria

### Chemical Dependency Treatment – Adult (≥18 years old) Residential Treatment Continued Stay

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

**Continued stay for chemical dependency residential level of care is medically necessary when treatment elements AND dimensional criteria are satisfied:**

**1) Treatment Elements - ALL of the following are still being provided:**

- a) Individualized treatment plan with clear and measurable treatment goals, including plans related to co-morbidity, if applicable.
- b) Staff monitoring 24 hours a day.
- c) Review of Treatment Plan and clinical assessment of progress toward treatment goals is routinely conducted and documented at least once per week.
- d) Daily individual, group, and / or family counseling (optimally two times per day).
- e) Weekly educational groups (optimally daily).
- f) Transition / Discharge plan initiated at admission. Transition plan to include the following:
  - date returning to intensive outpatient treatment for chemical dependency,
  - follow-up appointment time with mental health care provider, if applicable, and
  - medical appointments (including appointments for medication to reduce cravings, if applicable).

**2) Dimensional Criteria – continued stay is appropriate when ALL of the following have been met:**

- a) The member has the capacity to make needed changes,
- b) The current setting is providing the most appropriate spectrum of services to address the problem
- c) The present condition cannot be safely and effectively managed in a lower level of care
- d) The present condition can reasonably be expected to be managed at the current level of care with planned interventions.
- e) Dimensional Criteria – Continued stay is appropriate when exclusionary and indicating factors for i, ii, and iii are satisfied
  - i) **ACUTE INTOXICATION/WITHDRAWAL DIMENSION**
    - a. Member is stable, not requiring more intensive treatment of intoxication or withdrawal
  - ii) **READINESS/MOTIVATION DIMENSION**
    - a. It is expected that the member has verbalized ALL of the following:
      - Interest in recovery with identification of desired goals / outcomes related to request for residential treatment, including a desire/willingness to abstain from all substances of abuse (exception made for nicotine), including cannabis and abused prescription drugs.
      - Willing to continue outpatient treatment post discharge.
      - Willing to obtain additional clinical (chemical dependency or mental health) or medical work-ups, if necessary, to promote an integrated care plan.
      - Willing to address post-treatment housing needs during treatment, if applicable.
  - iii) **AND** There are indicating factors present in at least ONE of the following dimensions:
    - a. **BIOMEDICAL CONDITION DIMENSION**
      - I. Member continues to be significant risk for serious medical complications related to continued substance use during the current episode of illness as evidenced by recent hospital admissions or multiple acute medical presentations for medical problems other than substance withdrawal. (e.g. acute pancreatitis requiring hospitalization, abscess from IV drug

use requiring inpatient treatment, diabetic ketoacidosis related to continued alcohol use impairing ability to perform diabetic self-care).

- b. **COGNITIVE, BEHAVIORAL, AND EMOTIONAL CONDITION DIMENSION** - At least ONE of the following behaviors usually associated with mental illness/personality disorder *continues to interfere with the member's ability to achieve and sustain abstinence* and engage in lower levels of care:

- a) Emotionally labile / frequent mood swings / social isolation / withdrawal with probable cause being significant psychiatric co-morbidity that *impacts treatment participation and abstinence* (e.g., behavior interferes with focus of group activity, liability causing disruption in treatment milieu, withdrawal/anxiety prevents engagement in group activity).
- b) interpersonal conflict, poor/inappropriate boundaries or severe personality disorder that *impacts treatment participation and abstinence* (e.g., consistently conflictual or otherwise disruptive in relations with others, frequently aggressive, dramatic and drawing attention of treatment groups away from focus on recovery, poor boundaries prevent appropriate engagement in treatment or disruptive to treatment milieu).
- c) Member is not taking psychiatric medications properly (taking too much or too little) with *risk of harm or impact on treatment participation and abstinence*.
- d) Reckless/impulsive behaviors (weapons, destructive, sexual, self-mutilation, gambling, anger) that *impact treatment participation and abstinence*
- e) Difficulty following instructions due to chronic and persistent intoxication and/or effects of prolonged substance abuse that *impact treatment participation and abstinence* (e.g., repeated drinking and driving despite significant consequences).
- f) Suicidal ideation related to substance use

- c. **RELAPSE/CONTINUED USE DIMENSION**

- a) Despite recent, active participation in treatment at a less intensive level of care (including medication assisted treatment if appropriate, e.g. buprenorphine or methadone maintenance with counseling for opioid dependence), the member continues to use alcohol or other drugs or deteriorates psychiatrically, with imminent serious consequences and is at high risk of continued substance use or mental deterioration in the absence of close 24-hour monitoring and structured treatment.

- d. **RECOVERY ENVIRONMENT DIMENSION**

- a) Environment not conducive to abstinence as evidenced by at least ONE of the following, which interfere with engagement in lower levels of care:
  - Family/significant others undermine efforts to maintain abstinence (may include home environment exposure to *active users/triggers or continued enabling* in the home environment).
  - Recovery environment is not safe as evidenced by recent/ongoing physical or sexual abuse.

## Clinical Review Criteria

### Chemical Dependency - General

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

Indications for chemical dependency services within the limits of the coverage benefit:

- 1) All of the following conditions must be met:
  - a) The patient must have a current chemical dependency diagnosis and symptoms from the Diagnostic and Statistical Manual of Mental Disorders V (DSM-V).
  - b) The symptoms are significantly interfering with the individual's ability to function in at least one life area.
  - c) There must also be a reasonable expectation that either the patient is capable of making changes (i.e. active treatment will improve this person's level of functioning) as a result of the treatment plan or that stabilization is possible.
  - d) The proposed medical treatment must involve a level of care with appropriate resources to assess and treat the client's condition according to its severity and the consumer's health and level of functioning.
  - e) All consumer decisions are reviewed and based upon the most recent edition of The American Society of Addiction Medicine Patient Placement Criteria for the Treatment of Substance-Related Disorders (ASAM – PPC), as a clinical guide to be used in matching patients to the appropriate level of care.
  - f) The following six dimensions (as defined by the 2R Edition of the ASAM-PPC) must be evaluated in the process of making placement decisions and in the formulation of an individualized treatment plan:
    - Acute intoxication and/or withdrawal potential;
    - Biomedical conditions and complications;
    - Emotional, behavioral, or cognitive conditions and complications;
    - Readiness to change;
    - Relapse, continued use or continued problem potential; and
    - Recovery/living environment.
  - g) The proposed medical treatment must involve the least intensive level of care necessary to accomplish the treatment objectives in a clinically appropriate manner.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Group Health Behavioral Health Services (GH BHS) defines medically necessary chemical dependency services as "those services necessary to treat a chemical dependency condition that is having a clinically significant impact on an individual's emotional, social, medical, and/or occupational functioning." An adaptation by GHC of the American Society of Addiction Medicine's Patient Placement Criteria for the Treatment of Substance-Related Disorders – 2R Edition is used to guide placement decisions and to meet the medical necessity standard.

[National Coverage Determination \(NCD\) for Inpatient Hospital Stays for Treatment of Alcoholism \(130.1\)](#)

[National Coverage Determination \(NCD\) for Outpatient Hospital Services for Treatment of Alcoholism \(130.2\)](#)

[National Coverage Determination \(NCD\) for Chemical Aversion Therapy for Treatment of Alcoholism \(130.3\)](#)

[National Coverage Determination \(NCD\) for Electrical Aversion Therapy for Treatment of Alcoholism \(130.4\)](#)

[National Coverage Determination \(NCD\) for Treatment of Alcoholism and Drug Abuse in a Freestanding Clinic \(130.5\)](#)

[National Coverage Determination \(NCD\) for Treatment of Drug Abuse \(Chemical Dependency\) \(130.6\)](#)

[National Coverage Determination \(NCD\) for Withdrawal Treatments for Narcotic Addictions \(130.7\)](#)

##### For Non-Medicare Members

**A - One of the following** must be met for either admission or continued stay for CD adult partial hospitalization:

- 1 – **Admission:** According to the Group Health Clinical Review Criteria for Chemical Dependency Treatment, **ALL of the following** must be met for admission chemical dependency services:
  - The patient must have a current chemical dependency diagnosis and symptoms from the Diagnostic and Statistical Manual of Mental Disorders-5 (DSM-5).
  - The symptoms are significantly interfering with the individual's ability to function in at least one life area.
  - There must also be a reasonable expectation that either the patient is capable of making changes (i.e. active treatment will improve this person's level of functioning) as a result of the treatment plan or that stabilization is possible.
  - The proposed medical treatment must involve a level of care with appropriate resources to assess and treat the client's condition according to its severity and the consumer's health and level of functioning.
  - All consumer decisions are reviewed and based upon the American Society of Addiction Medicine Patient Placement Criteria (ASAM-PPC) for the Treatment of Substance-Related Disorders, as a clinical guide to be used in matching patients to the appropriate level of care.
  - **ALL of following** six dimensions\* (as defined in the 2R Edition of the ASAM-PPC) must be evaluated in the process of making placement decisions and in the formulation of an individualized treatment plan:
    1. Acute intoxication and/or withdrawal potential;
    2. Biomedical conditions and complications;
    3. Emotional, behavioral, or cognitive conditions and complications;
    4. Readiness to change;
    5. Relapse, continued use or continued problem potential; and
    6. Recovery/living environment.
  - According to the ASAM Patient Placement Criteria, the requested service would be medically necessary if the patient meets specifications in Dimension 2 as well as one of Dimensions 4, 5 or 6. **All of the following** must be met:

1. For Dimension 2 (Biomedical) , biomedical conditions are severe enough to distract from recovery efforts and require medical monitoring or management that can only be done at a partial hospital level of care.
2. **ONE of the following** must be met:
  - a. In Dimension 4 (Readiness to Change), motivational interventions at lower levels of care have been unsuccessful, the patient has little awareness of his/her co-occurring mental illness, or follow-through with treatment at lower levels of care has been so poor that treatment has not been successful.
  - b. In Dimension 5 (Relapse/Continued Use), although the patient has been engaged in care at a lower level of care, symptoms are intensifying or his condition is deteriorating.
  - c. In Dimension 6 (Recovery Environment), continued exposure to his work or living environment will make recovery unlikely or patient's family are not supportive of recovery goals.

2 – **Continued Stay:** According to the ASAM Patient Placement Criteria, continued stay at Partial Hospital Program level of care would be medically necessary when **ALL of the** following is met:

- The patient is making progress, but has not yet achieved clearly articulated goals that requires treatment at the current level of care to meet.
- The patient is not yet making progress in spite of working on his or her problems, but has the capacity to resolve these problems and requires treatment at this level of care to do so.
- New problems have been identified since admission, which would be most appropriately treated at the current level of care.

\*Dimensions are as defined by the current edition of the ASAM Patient Placement Criteria

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Group Health Behavioral Health Services defines medically necessary chemical dependency services as "those services necessary to treat a chemical dependency condition that is having a clinically significant impact on an individual's emotional, social, medical, and/or occupational functioning." An adaptation by GHC of the American Society of Addiction Medicine's Patient Placement Criteria for the Treatment of Substance-Related Disorders – 2R Edition is used to guide placement decisions and to meet the medical necessity standard.

## Clinical Review Criteria

### Spinal Manipulations – Chiropractic and Osteopathic

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	<a href="#">LCD L34009, Chiropractic Services.</a>
Local Coverage Article	<a href="#">Medicare Coverage for Chiropractic Services – Medical Record Documentation Requirements for Initial and Subsequent Visits</a>

##### For Non-Medicare Members

When considering clinical information submitted for medical necessity review, the following data elements and corresponding details are evaluated to ensure correlation to the presenting diagnosis and proposed care plan\*:

- Chief Complaint(s)
- Past Medical History
- Mechanism of Onset
- Duration of Symptoms (acute or chronic)
- Examination Findings
- Results of Diagnostic Testing
- Diagnostic Impression
- Complicating Factors (conditions or circumstances that may affect the patient's response to care)
- Prior and/or Concurrent History of Treatment
- Prognosis and Provider Comments

Coverage is typically not provided for those categories of services commonly described as “custodial care”, “maintenance care”, “wellness care”, “supportive care”, “palliative care”, or “preventive care”. For instance, when the status of a patient has remained stable for a given illness/condition/injury over approximately four (4) weeks, without functional improvement in a patient's net health outcome or expectation of additional objectively measurable clinical improvement, further treatment is considered non-covered care. Ongoing care after a patient's condition has stabilized or reached a clinical plateau, called Maximum Medical Improvement (MMI), does not qualify for coverage. Such care may be described as “custodial care”, “maintenance care”, “wellness care”, “supportive care”, “palliative care”, or “preventive care”.

Determination of medical necessity is also dependent upon the following:

- The diagnosis should be substantiated by history, symptoms and objective clinical information;
- The diagnosis should be for a condition, which the provider of record can effectively treat, based on scope of license.
- That all body regions of treatment must coincide with a diagnosis established and supported within the clinical record.

When a provider determines that additional or continued treatment is indicated within an episode of care, the following criteria are reviewed:

- Initial and current symptoms as described by the patient including severity, frequency, and character;
- Quantifiable examination and re-examination findings, results of diagnostic tests, daily office notes, and other objective data submitted by the provider;
- The complete initial and current diagnostic impression.

Determination of medical necessity for requested services is based upon review of a member's overall clinical improvement (i.e., response to care) following a course of treatment or authorized trial of care. A comprehensive review of the clinical outcomes specific to the condition for which services are requested is considered in making this decision.

In determining the clinical outcome of a prescribed course of treatment for a specific condition and episode of care, the following factors, as indicated in a Problem Oriented Medical Record (POMR), are evaluated:

1. Clinically significant reduction in symptom severity, frequency, and/or changes in the character of the symptoms to indicate positive clinical results, confirmation of the healing process, and stabilization of the condition.
2. Clinically significant improvement as established by a reduction in the actual number of positive orthopedic tests and neurologic signs.
3. Clinically significant improvement in range of motion as established through valid objective measurement methods; reduction in movement related pain findings (severity and/or character); and reduction in movement induced area of radiation if present.
4. Clinically significant reduction in palpable muscle spasm with associated improvement in muscle strength metrics for the affected spinal region or extremity joint.
5. Clinically significant reduction of tenderness on palpation of the involved spinal or extremity joint and surrounding soft tissue support structures.
6. Clinically significant reduction of paresthesia as established by severity and/or extent of radiation from the spinal nerve root.
7. Clinically significant improvement in the ability to perform a previously identified and specific functional task and/or activity of daily living (ADL) which was quantified during the initial evaluation and/or in a subsequent re-evaluation. For example: an improvement of at least 3 points in a single activity score using the Patient Specific Functional Scale (PSFS).
8. Clinically significant improvements in patient reported scores as demonstrated on appropriately applied outcome-assessment questionnaires. For example: A minimal detectable change of at least 2 points in the average score of all activities or at least a 3 point change in a single activity score using the Patient Specific Functional Scale (PSFS) in a follow-up score over the reported baseline within a 2 to 4 week time frame.
9. Measurable clinically significant improvements from chiropractic procedural care are reasonably expected within a 4-week period from the onset of care for an acute condition or an acute exacerbation of a chronic condition.
10. In the event an individual patient's response or lack of response to chiropractic care or other manual and physical medicine treatment for their condition is less than expected based on the clinical presentation, additional consideration will be given to best practices for management of that condition. In cases where best practices include medical, rehabilitative, or psychological management, the clinical records should indicate that there has been consideration of these other treatment modalities and/or referral for additional evaluation by the patient's primary care physician or medical specialty source of care for coordinated management of that condition.

Clinically significant improvement is defined as objectively measurable clinical and functional improvement in a patient's net health outcome as reflected by a decrease in symptoms, positive correlation in improvement of objective findings, and an increase in function. Each patient and each case is uniquely different, but in general, improvement is recognized by a corresponding reduction in subjective symptoms as measured by PSFS scores; measured improvement in objective findings (i.e., orthopedic tests, neurologic signs, range of motion, muscle strength metrics); and a qualitative and/or quantifiable improvement in the patient's ability to perform functional tasks and/or activities of daily living.

The expected level of improvement, rate of change, and required duration and frequency of care vary by diagnosis in concert with the age of the patient, participation and effort of the patient, mechanism of onset, duration of condition, contributing past history, and the presence or absence of complicating factors.

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Spinal manipulation is defined by chiropractors as “a specific form of direct articular manipulation utilizing a short lever and characterized by a dynamic, forceful, high velocity thrust of controlled amplitude” (Janse, 1975, as cited by Coulehan. 1985, p. 355). Chiropractors distinguish between chiropractic adjustments and spinal manipulation. Spinal manipulation is a generic term that refers to techniques used by osteopathic physicians, physiatrists (rehabilitation specialists), physiotherapists, or orthopedic surgeons. Spinal adjustment therapy usually involves more frequent visit than medical treatment for the same condition. (Coulehan, 1985).

Manual manipulation of the spine is composed of four elements: patient positioning, location of applied load, peak velocity of the load that is achieved, and peak load developed. The total displacement of the body segments is believed to be properly controlled by a combination of patient positioning and peak load. Techniques used by chiropractors to augment the manipulation may include mobilization, manual traction, soft-tissue massage, and pressure-point techniques (Haldeman, 1983).

Spinal manipulation and adjunct therapies (physical therapy) have been demonstrated to be effective when delivered alone, but no therapy has been consistently demonstrated to be more effective than the other modalities. A 2011 Cochrane Back Group review of 26 randomized controlled trials with 6070 participants (9 studies with low bias) found high quality evidence that spinal manipulative therapy for low back pain indicates provides clinically relevant, statistically significant short term effect on pain relief as compared to other interventions, including exercise therapy, standard medical care or physical therapy. (Rubinstein, 26Feb2011) The reviewers note that spinal manipulation appears to be no better or no worse than other existing therapies for pain relief. This review affirms the 2008 Cochrane Database Review of Spinal Manipulative Therapy for low-back pain results indicating no evidence that spinal manipulative therapy is superior to other standard treatments (physical therapy, exercises, back school, general physician care) for pain relief or improved functional outcomes. (Assendelft, et al., Cochrane Library Review, 8Oct2011)

There is mixed evidence on the clinical effectiveness of adjunct modalities, including physical therapy and rehabilitative services and durable medical equipment and supplies, when delivered concurrently with spinal manipulation.

An April 2010 Cochrane Back Group Review of combined chiropractic interventions demonstrated slightly improved pain and disability for patients with acute and subacute back pain in the short term. No difference was demonstrated for combined chiropractic interventions for chronic lower back pain and for studies that had a mixed population of lower back pain. Any demonstrated differences were small and were only seen in studies with a high risk of bias. For acute and subacute LBP, chiropractic interventions improved short- and medium-term pain (SMD -0.25 (95% CI -0.46 to -0.04) and MD -0.89 (95%CI -1.60 to -0.18)) compared to other treatments, but there was no significant difference in long-term pain (MD -0.46 (95% CI -1.18 to 0.26)). Short-term improvement in disability was greater in the chiropractic group compared to other therapies (SMD -0.36 (95% CI -0.70 to -0.02)). However, the effect was small and all studies contributing to these results had high risk of bias. There was no difference in medium- and long-term disability. (Walker, 14APR2010)

In a randomized controlled trial of chiropractic care (flexion distraction) or physical therapy (exercise program), Cambron found that subjects in both groups had decreased pain and disability regardless of which therapy was utilized (p<.002). During the year after care, chiropractic subjects had significantly lower pain scores (p=.002) and received fewer visits but experienced no difference in timing of care following intervention when compared to than those in physical therapy treatment. Physical therapy subjects attended significantly more health care visits than subjects who received chiropractic care only. (Cambron, Cochrane Register of Controlled Trials, Chiropractic care vs medical care for low back pain: Assessment of long-term follow-up data, 2005).

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

A cochlear implant is an electronic device that can enable patients with severe to profound hearing loss to perceive sound. Cochlear implants have two main parts:

- 1) An internal device that is implanted under the skin behind the ear; and
- 2) A speech processor that is worn or carried (externally) by the individual.

Sounds are detected by a microphone and transformed into an electrical signal. The speech processor codes the signals into a particular pattern of electrical pulses. The pulses are sent to the implant, which in turn transmits them via the auditory nerve to the brain, which recognizes them as sound. Use of a cochlear implant requires both a surgical procedure to implant the device, and substantial post-implantation therapy to learn or re-learn the sense of hearing. In the United States, approximately 22,000 adults have cochlear implants and about 15,000 children have received them (NIDCD, 2006).

Provision of unilateral cochlear implants is currently standard practice. Although results are often positive, particularly in the ability to understand speech in a quiet situation, normal hearing is not restored. There is increasing interest in bilateral cochlear implants to further improve the ability to patients to detect sound. Potential advantages of bilateral implantation include improvements in:

- Hearing in noise, due to the ability to benefit from a “head shadow effect”;
- Speech perception, due to the availability of sound information from both ears;
- Sound localization, the ability to correctly identify the directional location of sounds surrounding the listener (Litovsky et al., 2006; Tyler et al., 2003).

A potential problem with bilateral cochlear implants is that bilateral coordination of pulsed signals is not yet possible. Instead, the two implants function independently. This is not likely to be as effective as normal binaural hearing which takes advantages of the integration of binaural acoustical cues. In addition, patients with severe hearing loss may have different patterns of loss on each side, and also may have developed abnormal binaural brain maps (Tyler et al., 2003). Response to bilateral cochlear implants, especially localization ability, may also depend on previous experience with hearing. Adults who have had exposure to binaural stimulation early in life appear to perform better with bilateral cochlear implants than adults who were born without hearing or lost hearing at a very young age (Litovsky et al., 2006).

Experts have pointed out that a challenge in studying the effectiveness of bilateral cochlear implants is that learning may influence an individual’s ability to detect aural cues, either unilateral or bilateral. Studies that evaluate users of bilateral implants without comparing them to experienced users of unilateral users may be limited because they do not include patients who have been able to adapt to listening through one device.

## Medical Technology Assessment Committee (MTAC)

### ***Bilateral Cochlear Implants***

#### **10/13/2004: MTAC REVIEW**

**Evidence Conclusion:** There is insufficient evidence to determine the effect of bilateral cochlear implants on health outcomes compared to unilateral cochlear implants, in patients with severe to profound hearing loss.

**Articles:** The search yielded 19 articles. The empirical studies were small (sample sizes ranged from one to 20 patients) and laboratory-based. They consisted of conducting speech tests of patients with bilateral cochlear implants, sometimes comparing results to one-ear only in the same patients. There were no studies that compared bilateral cochlear implants to experienced users of unilateral implants. There were also no studies that examined functional outcomes with bilateral vs. unilateral implants, such as the ability to use the telephone or perceive speech in a real world setting.

The use of bilateral cochlear implants for severe to profound hearing loss does not meet the *Group Health Medical Technology Assessment Criteria*.

### ***Bilateral Cochlear Implants***

#### **10/02/2006: MTAC REVIEW**

**Evidence Conclusion:** The evidence base consists of small laboratory-based case series and one small randomized controlled trial. The RCT (Summerfield et al., 2006) compared quality of life outcomes in adults who received a second cochlear implant to a delayed treatment group. All participants were successful users of unilateral implants. The study found statistically significant improvement in spatial hearing and quality of hearing subscales of a QOL questionnaire in the bilaterally implanted group compared to the control group. However, there were no significant differences on six other quality of life measures and if the p-values had been corrected for multiple comparisons, none of the between-group comparisons would have been statistically significant. The study suggests that bilateral cochlear implants may be beneficial for improving some aspects of hearing in experienced adult users of unilateral implants but findings are inconclusive. There is insufficient evidence on the effectiveness of bilateral cochlear implants compared to unilateral implants in children.

**Articles:** The evidence base consists of small laboratory-based case series and one small randomized controlled trial. The RCT (Summerfield et al., 2006) compared quality of life outcomes in adults who received a second cochlear implant to a delayed treatment group. All participants were successful users of unilateral implants. The study suggests that bilateral cochlear implants may be beneficial for improving some aspects of hearing in experienced adult users of unilateral

implants but findings are inconclusive. There is insufficient evidence on the effectiveness of bilateral cochlear implants compared to unilateral implants in children.

The use of Bilateral Cochlear Implants in the treatment of severe hearing loss does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Hybrid Cochlear Implant**

#### **BACKGROUND**

Sensorineural hearing loss (SHL) is the most common form of hearing loss occurring when there is damage to the inner ear or the nerve pathway from the inner ear to the brain. Causes are variable and range from aging and heredity, all the way to exposure to loud noises and drugs toxic to the inner ear. SHL typically results in difficulty hearing faint sounds, understanding people with higher-pitched voices, hearing certain speech sounds, and in some cases, hearing high-pitched emergency vehicle sirens or common safety alarms, such as smoke detectors. Any type of hearing loss can be debilitating and can affect people in various ways.

Conventional treatment options for hearing loss are dependent on the type and source of hearing loss. While hearing loss cannot be fully restored, a wide variety of technologies are currently available to improve hearing. These technologies utilize either air or bone conduction to transmit sound. Air conduction hearing aids (ACHA), for example, receive sound waves through a microphone which are then converted to electrical signals and amplified through a speaker in the ear. Alternatively, bone anchored hearing aids (BAHA) transmit sound vibrations directly to the inner ear through the skull, bypassing the outer and middle ear completely. In any case, both technologies come with strengths and limitations.

The Nucleus® Hybrid™ L24 Cochlear Implant System, developed by Cochlear® (Centennial, CO), combines the functions of both ACHA and BAHA in a single device. The device specifically uses acoustic amplification to amplify low frequency hearing, while taking advantage of cochlear implant technology to restore access to the high-frequency hearing allowing a near normal hearing experience. The hybrid technology requires surgical implantation, similar to that of a standard cochlear implant with the main difference being that the array is shorter and therefore not inserted as far into the cochlear.

The United States Food and Drug Administration (FDA) approved the first hybrid cochlear implant in March of 2014. The Medical Technology and Assessment Committee (MTAC) has not previously assessed hybrid cochlear implants and is currently reviewing the topic to support a coverage decision.

#### **08/17/2015: MTAC REVIEW**

##### **Hybrid Cochlear Implant**

**Evidence Conclusion:** *Effectiveness:* A multi-centered European study, carried out by Lenarz and colleagues, investigated hearing conservation in 66 patients with significant low-frequency residual hearing using the Nucleus Hybrid L24 cochlear implant. The investigators compared pre- and post-operative performance in speech recognition scores in both quiet and noisy environments were significantly improved for 65% and 73% of subjects, respectively. In addition, the mean speech spatial and quality subscale ratings were significantly improved by 1.2, 1.3 and 1.8 points, respectively ( $p < 0.001$ ). Ultimately, the investigators concluded that the hybrid cochlear implant preserved low-frequency residual hearing and improved speech perception (Lenarz, James et al. 2013). [Evidence Table 1] A similar study, conducted by Roland et al. in multiple centers across the US, included 50 individuals with severe to profound high-frequency hearing loss. In the same way as the European trial, pre- and post-operative performance was measured on consonant-nucleus-consonant words, AzBio sentence noise as well as self-assessment. At six months, the investigators reported that a majority of the patients had statistically significant improvements in word and sentence recognition leading the investigators to conclude that the Nucleus Hybrid L24 cochlear implant provides significant improvements to hearing (Roland, Gantz et al. 2015). [Evidence Table 2]

*Safety:* The safety profile on these devices is not entirely clear. Both of the included studies detail a number of adverse effects including dizziness, irritation and tinnitus to name a few. Beyond that, the literature reports risk of permanent damage to residual hearing fibers from the surgery and placement of the electrode itself. A larger long-term concern is associated with future changes in hearing in the implanted ear. Specifically, should the patient experience additional hearing loss, will they need additional surgery using a longer standard electrode.

Collectively, the evidence is limited by small sample sizes, lack of randomization and inadequate comparison groups. To add to this, neither of the studies provide a sufficient follow-up period. Finally, both of the studies are sponsored by the device manufacturer leaving the studies open to potential bias. Ultimately, the evidence does not adequately support the safety and effectiveness of the hybrid cochlear implant. The evidence base would benefit from large RCTs with extended follow-up to establish long-term performance and safety.

**Conclusions:** There is insufficient evidence to support the effectiveness of a hybrid cochlear implant with external hearing aid compared with a standard cochlear implant. There is insufficient to establish the safety of hybrid cochlear implant with standard cochlear implant.

**Articles:** The search returned a small variety of publications including retrospective analyses, small single arm prospective studies and one cross-sectional study (Golub, Won et al. 2012; Nguyen, Mosnier et al. 2012; Reiss,

Turner et al. 2012; Szyfter, Wróbel et al. 2013; Jurawitz, Büchner et al. 2014). The literature was specifically screened for randomized controlled trials (RCTs) with the overall aim to compare hybrid cochlear implants with conventional cochlear implants. In the absence of RCTs with appropriate comparators, the best available evidence came from two prospective, single arm studies (one of which supported the 2014 FDA approval) were selected for critical appraisal. The following articles were selected for review: Lenarz T, James C, Cuda D, et al. European multi-centre study of the Nucleus Hybrid L24 cochlear implant. *International Journal of Audiology*. 2013;52:838-848. [See Evidence Table 1](#). Roland JT, Gantz BJ, Waltzman SB, et al. United States multicenter clinical trial of the cochlear nucleus hybrid implant system. *Laryngoscope*. 2015. [See Evidence Table 2](#).

The use of hybrid cochlear implants does not meet the *Group Health Medical Technology Assessment Criteria*.

National Coverage Determinations (NCD)

[Collagen Meniscus Implant \(150.12\)](#)

##### For Non-Medicare Members

Group Health has elected to use the Collagen Meniscus Implant (A-0643) MCG\* for medical necessity determinations.

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

The knee meniscus is a fibrocartilagenous crescent-shaped structure that plays an important part in the biomechanics of the joint. It functions as load-bearing, shock absorption, lubrication, and stabilization of the joint. The avascular nature of the articular cartilage and its hypocellular composition make it incapable of self-repair after injury. In the past, total or subtotal meniscectomy was routinely performed for patients with meniscal tears. This was based on the assumption that removal of the meniscus did not lead to adverse effects. More recently however, repair of the meniscus has become the standard treatment for tears, after studies have shown that total or even partial removal of the meniscus is associated with increased joint pressure, mechanical changes, and ultimately hyaline cartilage degradation and irreversible joint damage. If the meniscus is irreparable, arthroscopic partial meniscectomy of only the torn segments is recommended. In cases of substantial damage, subtotal or total meniscectomy may be inevitable. Researchers have evaluated different materials to substitute for the removed meniscus in order to avoid the joint deterioration that may occur after its removal (Rodkey 1999, Yoldas 2003).

The first meniscal transplantation was performed in the early 1990s. Over the years, different graft types were used including autogenous tissue, allograft tissue, and artificial material. More recently, a group of scientists used tissue engineering techniques to develop a collagen meniscus implant which serves as a scaffold to support the production of a new meniscus-like tissue rather than artificially replacing it. Collagen meniscus implants (collagen scaffold) are fabricated from type I collagen derived from bovine Achilles tendons. The bovine collagen fibers undergo several chemical treatments and techniques to purify them, after which they are swelled in hyaluronic acid and chondroitin sulphate, homogenized, precipitated, dehydrated and manually oriented in a mold which undergoes other processes and sterilization before they are ready for use. Collagen meniscus implants are provided as a semi-lunar shaped device with a triangular cross-section. The surgeon assesses the defect and trims the implant to the size necessary for repair of the damaged or weakened soft tissue (Rodkey 1999, Steadman 2005, Rodkey 2008).

Collagen meniscal implant is not intended to replace the entire meniscus as it requires a meniscal rim for attachment. In a routine arthroscopic surgical procedure, partial meniscectomy is performed to remove only damaged or pathological tissue, leaving the native meniscus intact. A specially designed arthroscopic measuring device is then used to determine the dimensions of the total meniscus and the defect. On the surgical field the collagen implant is trimmed to fit the lesion then delivered into the joint through a cannula, manipulated into the

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

prepared lesion and fixed to the host meniscus rim with nonabsorbable sutures (Rodkey 1999, Steadman 2005, Rodkey 2008).

ReGen Collagen Scaffold (CS), now called Menaflex, was cleared by the FDA in December 2008 to be used in surgical procedures for the reinforcement and repair of soft tissue injuries of the medial meniscus. The patient must have an intact meniscal rim and anterior and posterior horns for attachment of the mesh. In addition, the surgically prepared site for the CS must extend at least into the red/white zone of the meniscus to provide sufficient vascularization. The CS reinforces soft tissue and provides a resorbable scaffold that is replaced by the patient's own soft tissue. CS is not a prosthetic device and is not intended to replace normal body structure. It is contraindicated in patients allergic to bovine or other animal derived products, with an overly sensitized immune system, systemic or local infection, evidence of osteonecrosis in the targeted area, medical history of severe degenerative osteoarthritis, or without an intact meniscal rim and anterior and posterior horns (<http://www.fda.gov/cdrh/pdf8/K082079>).

## Medical Technology Assessment Committee (MTAC)

### Collagen Meniscus Implant

#### 04/06/2009: MTAC REVIEW

**Evidence Conclusion:** The published literature to date, does not provide sufficient evidence to determine the short-term or long-term safety and efficacy of collagen meniscus implants in reducing pain, restoring the knee function, and preventing degenerative osteoarthritis in patients with irreparable damage to the medial meniscus. The only published randomized controlled trial on collagen meniscal implants had several threats to its validity which make it hard to draw any conclusion on the benefits and harms associated with the implant. In addition to the relatively small size, short follow-up duration, and industry funding, the trial had potential selection and observational biases including; the inappropriate randomization process, unblinding of the patients and surgeons, vast differences in the postoperative rehabilitation programs received by the two treatment groups, performing follow-up arthroscopy only among the meniscal transplant group, and assessing improvement in activity level based on historical data subject to recall bias. Overall, the results of the trial show insignificant differences between patients receiving the collagen meniscus implant and the controls in reducing their pain and improving and/or restoring function.

**Articles:** To determine whether using collagen meniscus implants in patients with medial meniscus defects would lead to better clinical outcomes than total meniscectomy or implanting an allograft. To determine if using collagen meniscus implants is safe for the patient and whether it leads to long-term joint damage. The search yielded 14 articles. There was one RCT that compared collagen meniscus implant with partial meniscectomy and 4 very small case series with less than 15 patients each. All studies were conducted by the same group of investigators who developed the implant, except for a small case series with 8 patients. The RCT was selected for critical appraisal: Rodkey WG, DeHaven KE, Montgomery WH, et al. Comparison of the collagen meniscus implant with partial meniscectomy. *J Bone Joint Surg Am* 2008;90:1413-1426. See [Evidence Table](#).

The use of Collagen Meniscus Implants for the reinforcement and repair of soft tissue injuries of the medial meniscus does not meet the *Group Health Medical Technology Assessment Criteria*.

Services	Criteria
Diagnosing Small Intestinal Bacterial Overgrowth	Covered only when ordered by gastroenterologist for possible SIBO
Glucose hydrogen breath test Lactulose hydrogen breath test	There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Small intestinal bacterial overgrowth (SIBO) is characterized by a malabsorption syndrome due to abnormally large amounts of bacteria within the small intestine (Gasbarrini, et al. 2007). Symptoms include diarrhea, abdominal pain or cramps, nausea, constipation, acid reflux, bloating, flatulence, dehydration and fatigue. SIBO can also cause more severe symptoms including steatorrhea, anemia, bleeding or bruising, night blindness, bone pain, fractures, leaky gut syndrome, autoimmune reactions, weight loss and "failure to thrive". Due largely to uncertainty with regard to definition and detection, the true prevalence of SIBO and its relationship to a number of clinical disorders remains unclear (Dukowicz, et al. 2007).

Direct aspiration and culture of jejunal fluid have traditionally been considered the "gold standard" for SIBO diagnosis. With results expressed as colony-forming units per milliliter of jejunal fluid (cfu/ml), a SIBO diagnosis is most commonly defined as >10<sup>5</sup> cfu/ml, however, the thresholds vary throughout the literature (Abu-Shanab and Quigley 2009; Dukowicz, et al. 2007). To add to this, aspiration and culture is expensive, invasive and difficult to perform requiring the passage of a tube under fluoroscopic guidance through the nose, throat, esophagus and stomach. Breath tests, on the other hand, escape these limitations and have been proposed as a simple tool for diagnosing SIBO. Based on the fact that only bacteria in the gastrointestinal tract can ferment unabsorbed carbohydrates and metabolize them into hydrogen and/or methane, the gases are absorbed into the bloodstream and subsequently excreted in the breath (Levitt, et al. 2006; Simren and Stotzer 2006). Put simply, breath tests measure the levels of hydrogen and/or methane gas in a breath (Ghoshal, et al. 2006).

Breath tests can be performed at home or in a clinic and require that the patient fast for 12 hours prior to testing, after which, the patient provides a baseline sample breath. After establishing a baseline measurement, the patient ingests a small amount of substrate, either lactulose or glucose, and subsequently, provides breath samples every 15 minutes for three to five hours. At this time, hydrogen/methane breath tests have not been standardized with protocols differing in dose and concentration of the test substrate, and duration of test time intervals (Bures, et al. 2010). In the same way, there have been no accepted criteria for what constitutes a positive result.

Hydrogen/methane breath tests have not been approved by the Food and Drug Administration (FDA).

## Medical Technology Assessment Committee (MTAC)

### Combined Hydrogen/Methane Breath Test

#### 6/16/2014: MTAC REVIEW

**Evidence Conclusion:** Evidence on the validity of the lactulose breath test for the diagnosis of SIBO is conflicting. In 1990, Corazza and colleagues performed complete microbiological analyses of jejunal aspirates in 77 patients thought to have SIBO. Those results were then compared to glucose and lactulose breath tests. In the results, the investigators reported sensitivities of 62% and 68% for glucose and lactulose, respectively and specificities of 44% and 83% (Corazza, et al. 1990). See [Evidence Table](#) More recently, however, Ghoshal and colleagues performed both glucose and lactulose breath tests on 83 patients on two separate days and reported that, when compared to culture of small bowel aspirate, both glucose and lactulose breath tests had lower sensitivities (glucose 44%, lactulose 31%) and higher specificities (glucose 80%, lactulose 86%). The authors propose several theories to explain the low sensitivities, including non-hydrogen producing patients, and patients with high basal breath hydrogen levels despite adequate preparation (Ghoshal, et al. 2006). See [Evidence Table](#) While none of the studies measured safety outcomes or recorded adverse events, most of the literature identifies breath tests as simple, safe, and lacking invasiveness (Dukowicz, et al. 2007). Despite these advantages, there is a lack of uniformity regarding their protocol and interpretation. Furthermore, hydrogen and methane levels are affected by a number of factors including smoking, exercise, chewing gum, breath mints, and antibiotic use. Above all else, differences in bacterial flora among patients can determine responses to breath testing with about 10-15% of patients lacking bacteria capable of producing hydrogen. Ultimately, the absence of an established interpretation of the gold standard, limits the ability to firmly establish the diagnostic accuracy of breath tests for diagnosing SIBO leaving the validity of the test in question. Conclusion: There is insufficient evidence to establish the diagnostic accuracy of the combined hydrogen/methane breath test for diagnosing SIBO. There is insufficient evidence to conclude that the hydrogen breath test is not harmful to patients. There is insufficient evidence to determine the impact of the test on patient management.

**Articles:** There is extensive literature on the use of breath testing to diagnose SIBO with many publications addressing the prevalence of SIBO among patients with irritable bowel syndrome. Generally speaking, there is a greater body of published literature on the use of hydrogen breath testing with less literature specifically addressing the use of methane breath tests and combination hydrogen and methane breath tests. Two studies were identified that assess the utility and accuracy of SIBO. The following studies were selected for critical appraisal: Corazza GR, Menozzi MG, Strocchi A, et al. The diagnosis of small bowel bacterial overgrowth: reliability of jejunal culture and inadequacy of breath hydrogen testing. *Gastroenterology*. 1990;98(2):302-309. See [Evidence Table](#) Ghoshal UC, Ghoshal U, Das K et al. Utility of hydrogen breath tests in diagnosis of small intestinal bacterial overgrowth in malabsorption syndrome, and its relationship with oro-cecal transit time. *Indian J Gastroenterology*. 2006;25(1):6-10. See [Evidence Table](#).

The use of Combined Hydrogen/Methane Breath Test for Diagnosing Small Intestinal Bacterial Overgrowth (SIBO) does not meet the *Group Health Medical Technology Testing Criteria*.

## Complications of Non-Covered Services

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	<a href="#">Benefit Manual Chapter 16. 180 - Services Related to and Required as a Result of Services Which Are Not Covered Under Medicare</a>
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	<a href="#">Non-Covered Services (L35008)</a> . And for facility-based services billed using a UB form, see <a href="#">Non-Covered Services (L34886)</a>
Local Coverage Article	None

#### For Non-Medicare Members

Services to treat or to correct complications or negative outcomes that are a direct result of a non-covered service are not covered.

The examples below are provided to help define the following terms and are not inclusive of all possible situations that would define the term:

- Complications:
  - An adverse drug reaction
  - A splenic injury or bowel injury during abdominal surgery
  - A postoperative wound infection
  - A postoperative pulmonary embolism
- Negative Outcomes:
  - A nasal obstruction after rhinoplasty
  - The desired cosmetic outcome not achieved
  - The scarring of surgical wound
- Direct Result:
  - An adverse drug reaction during surgery
  - An uncontrolled postoperative hemorrhage
- Indirect Result:
  - The formation of gallstones due to rapid weight loss after bariatric surgery

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Most Group Health contracts state "Excluded: complications of non-covered surgical services." In applying this exclusion guidance was requested by staff making coverage determinations. The above criteria were developed to provide guidance.

Group Health has elected to use the Graduated Compression Stockings (GHC-0336) MCG\* for medical necessity determinations.

Elastic stockings are generally stockings of 18-20 mm or less and can be purchased over the counter.

**\*The MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 12 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Compression garments are usually made of elastic material, and are used to promote venous or lymphatic circulation. Compression garments worn on the legs can help prevent deep vein thrombosis and reduce edema, and are useful in a variety of peripheral vascular conditions. Compression garments can come in varying degrees of compression. The higher degrees require a physician's prescription.

### Evidence and Source Documents

#### 2/12/1986: LITERATURE SEARCH

**Articles:** The use of JOBST products for the treatment of burns is medically appropriate.

#### 12/31/1999: LITERATURE SEARCH

**Articles:** Effective Health Care, NHS Centre for Reviews and Dissemination, University of York, August 1997, Volume 3:4, ISSN: 0965-0288.

Twenty randomized controlled trials evaluated different forms of compression bandaging on venous ulcer healing in a wide range of age groups. Two of these incorporated economic evaluations, 2 compared compression stockings with compression bandages and 2 evaluated intermittent pneumatic compression. Overall the quality of trials is poor. Six RCT's assessed whether compression therapy was better than no compression. These showed that compression provided by either Unna's boot, 2 layer, 4 layer or short stretch bandages improve healing rates compared to treatment using no compression. One study showed that compression was more cost effective because of faster healing rates saving nursing time. High compression showed the best healing rates. A combination of 2 compression stockings has been shown to increase the rate of healing compared to a short stretch bandage.

Compression stockings have been found to be more effective than drug therapy in the prevention of recurrence of leg ulcers.

White Paper - Kaiser on Benefits of Compression Therapy:

Venous ulcers can be healed and recurrence prevented through the use of compression therapy (not TED hose). Recommend coverage of two pair a year and patients must wear all day every day. Compression therapy can prevent serious complications of venous insufficiency and reduce treatment costs.

Federal Post-Mastectomy Reconstructive Surgery Mandate: December 21, 1998 AAHP memo:

The Federal post-mastectomy reconstructive surgery mandate was contained in the Women's Health and Cancer Rights Act of 1998 that was included in the FY99 omnibus appropriations act (P.L., 105-277, enacted October 21, 1998). Under the new law most plans and insurers that provide coverage for medical and surgical benefits in connection with a mastectomy are required to provide reconstructive surgery benefits. Coverage includes reconstruction of the breast on which the mastectomy was performed, surgery and reconstruction of the other breast to produce symmetrical appearance, and prostheses and treatment of physical complications at all stages of the mastectomy, including lymphedemas.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Glaucoma is the second leading cause of blindness worldwide. It is a chronic optic neuropathy characterized by the loss of retinal ganglion cells and its axons. If left untreated, the condition progresses leading to reduction of the visual field and eventually loss of sight. Elevated intraocular pressure (IOP) is the only proven modifiable risk factor for the development and progression of glaucoma. Results of a pivotal glaucoma trial suggest that a 1 mmHg increase in IOP is associated with an 11% increase in the hazard ratio for the progression of glaucoma. Thus, the accurate measurement of IOP and its efficient control are essential in the management of glaucoma (De Smedt 2012, Freiberg 2012, Lorenz 2013, Mansouri 2012, 2013).

Some investigators reported that IOP fluctuates throughout the day (defined as nyctohemeral rhythm) in healthy and glaucomatous eyes and that understanding the IOP behavior over time is important for the management and treatment decisions. However, the role of IOP fluctuation as an independent predictive factor for glaucoma progression is still controversial. The current gold standard for measuring IOP is the Goldmann Applanation Tonometry (GAT), but it only provides a snapshot of IOP at a given moment and is normally used in the office by an ophthalmologist. The 24-hour IOP profiles are of increasing interest, and the repeated IOP measurements over 24-hour period may be performed using portable tonometry, but this can only provide multiple static and non-continuous snapshots for the IOP; up to one measurement per hour at the best. This also requires awakening the patient during the nocturnal sleep period which may potentially lead to stress-related artifacts and sleep disturbances. The 24-hour continuous use of GAT for assessing the IOP profile is only possible in specialized centers with a sleep laboratory (Mansouri 2013, Lorenz 2013, and Mottet 2013).

The SENSIMED Triggerfish® telemetric contact lens sensor (CLS; Sensimed AG, Lausanne, Switzerland) was recently developed to continuously monitor the IOP pattern in glaucoma in an ambulatory setting. The device does not directly measure IOP, but is based on the assumption that there is a correlation between IOP and the corneal curvature. Its key element is a soft disposable silicone contact lens with an embedded microsensor that captures spontaneous circumferential changes at the corneoscleral area, allowing the measurement of changes in corneal curvature which are considered by investigators to be representative for IOP changes. The adhesive SENSIMED Triggerfish® Antenna, which is placed around the eye, wirelessly receives the information from the contact lens. Three hundred data points are acquired during a 30-second period every 5 minutes providing a total of 288 measurements over a 24 hour period. The data is transmitted through a thin flexible cable from the antenna

to a portable recorder worn on the patient's waist. This stores the acquired data during the monitoring session. At the end of the recording period, the data is transferred via Bluetooth from the recorder to the software previously installed on the practitioner's computer for analysis. The CLS measurement is made automatically for a maximum of 24 hours (Frieberg 2012, Lorenz 2013, Mottet 2013, Hollo 2014, Manufacturer's webpage).

As indicated earlier, the CLS is based on an assumption that there is a correlation between IOP and the corneal curvature and it can only provide indirect measurement of the IOP through changes in the corneal curvature. In addition, CLS does not display the output signal in mmHg, but in arbitrary units (au) that are proportional to the electric signal generated by the contact lens-embedded strain gauge. Calibration of the CLS output to mmHg is a challenge as the simultaneous use of CLS and tonometry on the same eye is not feasible. Another limitation is that CLS provides 288 IOP data points instead of a single one measurement (or 8 measurements typically obtained in a diurnal tension curve) which poses a challenge to the clinician. Since the output signal of the CLS is dependent on changes occurring at the corneoscleral junction, non-IOP-related changes in the corneal shape, hydration, or thickness may potentially affect the device output. It is also reported that information on the clinical meaning and practical value of the CLS curves is limited (Mansouri 2012, 2013, Mottet 2013, Hollo 2014).

The contact lens sensor (CLS) may lead to similar side effects caused by the classic vision correction contact lenses. Among the reported adverse effects were innocuous superficial corneal staining, corneal edema, superficial keratitis, and others (Mansouri 2012).

SENSIMED Triggerfish® was approved for use by the European regulatory authorities. It has not been approved by the US Food and Drug administration to date.

## Medical Technology Assessment Committee (MTAC)

### Continuous 24-hour monitoring of Intraocular Pressure

#### 6/16/2014: MTAC REVIEW

**Evidence Conclusion:** The role of IOP fluctuation as an independent predictive factor for glaucoma progression is still controversial and has not been proved in large, well-designed prospective studies, to date. Also, the assumption that there is a correlation between IOP and the corneal curvature is not universally accepted. The SENSIMED Triggerfish® telemetric contact lens sensor was not validated in humans, only in ex vivo in enucleated porcine eyes. The largest published study on continuous 24-hour monitoring of IOP patterns with contact lens sensor was conducted by Mansouri and colleagues (2012). They examined the safety, tolerability, and reproducibility of the device among 40 patients with established (n = 19) or suspected (n = 21) glaucoma in 2 study sessions conducted approximately 1 week apart. After a baseline ophthalmic examination, the patients were fitted with the CLS and re-examined after a 24-hour monitoring session. All participants underwent a second 24-hour monitoring session approximately 1 week later. Complete ophthalmic examinations were performed after each monitoring session, and any change from the baseline ophthalmic examination was reported as an adverse event (AE). Complete data recording was obtained from 37 patients in the first session and 39 patients in the second session. Data were not available for 4 patients due poor battery or disconnection of the device or other unknown reason. The calculated Pearson correlation was (r = 0.59, P = .12) indicating fair to good agreement between the 2 sessions. Patient comfort level was assessed by visual analog scale, which showed moderate to good tolerability of the device (mean score 27.2 + 18.5mm in the first monitoring session and 23.8 + 18.7mm in the second session). 49 device-related adverse events occurred among 38 study participants (Table). All AEs were transient and resolved within 24 hours of CLS removal. Adverse events (AEs) in patients undergoing 24-hour intraocular monitoring with CLS

Adverse events	No. of even	No. (%) of patients with AEs
<b>Mild</b>		32 (80)
Blurred vision	58	30 (75)
Conjunctival hyperemia	52	13 (32)
Eye complications associated with device	17	5 (12)
Superficial punctate keratitis	5	3 (8)
Eye irritation	3	3 (8)
Eye pruritus	3	1 (2)
Ocular discomfort	2	1 (2)
Conjunctival edema	1	1 (2)
Device intolerance	1	1 (2)
<b>Moderate</b>		
Superficial punctate keratitis	1	1 (2)
Blurred vision	1	1 (2)
<b>Severe</b>		
Conjunctival edema.	5	2 (5)

A more recent very small study (Hollo 2014) evaluated 24-hour continuous intraocular pressure (IOP) monitoring with a CLS to detect prostaglandin-induced IOP reduction. The study included nine ocular hypertensive and

primary open-angle glaucoma patients. After a washed-out from IOP-lowering medication for 6 weeks, one study eye per patient underwent 3 baseline 24-hour measurement curves 4 days apart: 2 curves with Sensimed Triggerfish CLS and 1 curve with standard tonometry (GAT). The patients then received travoprost monotherapy for 3 months. The 24-hour CLS and tonometry curves were repeated on the study eyes after 3 months. The results showed that a significant decrease in IOP measured by the 24-hour GAT, but no significant difference was observed in the means of the 3 CLS curves. There was a high correlation between the 3 CLS curves but no correlation was seen between the CLS and GAT values either at baseline or under treatment. The authors concluded that these results suggest that the current CLS technique cannot be clinically used to monitor IOP decrease induced by topical medication in glaucoma, and has limited value in identification of transient IOP elevation periods. Impact on management was studied in a small case series (Mansouri 2011) with 15 glaucoma patients with worsening disease despite the controlled IOP values as measured by office GAT. The 24-hour monitoring with CLS found that 9/13 (69%) of the patients who completed the 24-hour monitoring had the highest IOP during sleep. Based on the CLS findings, the management plan was changed in 11 (73%) patients. There is a lack of published literature on 24-hour IOP monitoring using contact lens sensors.

**Articles:** The literature search did not reveal any validation study of the CLS or any other study that compared its accuracy with the gold standard of 24-hour GA, or trial that evaluated its clinical utility in managing patients with glaucoma. There was only a limited number of very small observational nonrandomized studies or case series that examined the safety and tolerability of the CLS. The population sizes varied between 5-15 subjects with only one study involving 40 individuals. The published studies were mainly conducted in Europe, particularly in Switzerland, mostly by the same group of authors, and sponsored by the SENSIMED the manufacturer of the SENSIMED Triggerfish® telemetric contact lens sensor.

The use of Continuous 24-hour monitoring of intraocular pressure does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Commercial Members

Group Health has elected to use the Continuous Glucose Monitor (GHC-0126) MCG\* for medical necessity determinations.

**MCG\* are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed for heart transplant eligibility, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (endocrinology, primary care)
- Last 6 months of lab work
- Last 3 months of home monitoring logs

#### ORDER FORM

[Request for Approval of Patient-Use Continuous Glucose Monitoring System \(CGMS\)](#)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Diabetes mellitus is one of the leading causes of death in the United States. If poorly controlled, it causes accelerated both large and small artery diseases that predispose patients to a number of late secondary complications including heart disease, stroke, renal, disease, peripheral vascular disease, retinal damage, peripheral nerve damage, and others. Management of diabetes involves maintaining blood glucose levels close to the normal range. Currently, self-monitoring of capillary blood glucose (SMBG), and laboratory testing of HbA1c, to measure longer term glycemic control, are the standard methods for glucose testing. Blood glucose values are influenced by a number of changing variables, including food choices and portions, stress, insulin doses, physical activity, and rate of nutrient absorption. SMBG is important for monitoring and treating fluctuations in blood glucose level, but it provides only a snapshot of glucose status at a given moment, and even compliant diabetics do not do perform it frequently enough to identify all the fluctuations in the blood glucose level, especially those that occur at night (Evert 2009).

In hopes of gaining a more complete picture of blood glucose level, researches have thus developed technologies for monitoring blood glucose concentrations on a continuous basis. Among these are the continuous glucose monitoring systems (CGMS) which are capable of monitoring interstitial glucose levels every 1-5 minutes. These systems consist of a small needle which is inserted in the abdominal subcutaneous fat. On the tip of the needle there is a glucose sensor that measures the glucose levels in the fluid surrounding the fatty tissue. There are two

types of CGMS: retrospective systems and real-time systems. Both systems measure glucose concentration during a certain time span; however, these systems differ with regards to when the information is accessed. With the retrospective system data is stored in a monitor to be downloaded for later use while the real-time system continuously provides the actual glucose concentration on a display. It is thought that CGMS may help diabetic patients reach a near normal blood glucose pattern, assist in preventing hypoglycemic events, reduce emergency room visits, and decrease long-term complications by improving glycemic control (Cemeroglu 2010, Chetty 2008, De Block 2008, Girardin 2009, Langendam 2012).

Early generations of CGMS e.g. the GlucoWatch Biographer, and the physician use device MiniMed Continuous Glucose Monitoring System were uncomfortable and difficult to use. In addition, their results could only be determined in a physician's office and when graphed provided useful, but retrospective information about within- and between-day blood glucose variations and the frequency of unrecognized hypoglycemia. When compared with venous plasma glucose values, the interstitial fluid glucose sensor yielded lower values when blood glucose concentrations were rapidly rising. More recent devices were developed to overcome some of the earlier limitations, and several products that provide real-time information on glucose levels to patients rather than requiring data download in a providers' office are now available. These newer systems, however, still measure glucose in the interstitial space, and it takes time for interstitial glucose to achieve equilibrium with blood glucose (Reach, 2008, Cox 2009).

All continuous glucose monitoring devices consist of the same basic components: 1. A disposable short-term glucose sensor (a fine wire about the diameter of two hairs) which is placed under the skin and is worn for 3-7 days depending on the system (3 days for Guardian RT, 5 days for FreeStyle Navigator, or 7 days for DexCom Seven), 2. A reusable transmitter that is wirelessly attached to the sensor and conveys data to a receiver within a 5-10 foot range of the sensor, and 3. A pager-size receiver that displays current glucose values and recent trends. The receiver can be worn on the belt or carried in a pocket or purse. The process is very fast with measurements made every 10 seconds and then aggregated to give a value on the glucose monitor every 1-5 minute. High and low glucose value thresholds can be customized for individual patients and fed into the system. When these thresholds are exceeded, an alarm will sound. The receiver displays directional arrows to show the rate of change in glucose levels, allowing the patient to predict and possibly prevent hypoglycemic episodes. CGMS can be used continuously, as long as the sensors are replaced according to manufacturer recommendations. Continuous readings over a 24-hour period for up to seven days allow the user to detect variations and identify trends. Patients must initialize and calibrate the system whenever a new glucose sensor is inserted. They also need to calibrate it every 8-12 hours and before adjusting insulin therapy (Peters 2009).

Continuous glucose monitors are intended to be used as an adjunct, not a replacement, for self-monitoring of blood glucose. They should not be used to make therapeutic decisions; any readings that indicate hypo- or hyperglycemia events must be verified by SMBG before taking action. CGM systems have several limitations including:

1. They are not suitable for use by all patients and those who are likely to benefit from them are the motivated patients who know the importance of strict metabolic control, participate in the care of their diabetes, and are able to use the technology. Those who have poor control because of reluctance to perform SMBG would not comply with CGMS and will not benefit from its use.
2. Patients need to learn how to use the large amount of data generated by the real-time CGMS.
3. The patients also need to be aware of the limitations of the systems as regards the lag time and calibration issues, and check with a standard blood glucose meter before making medication adjustments. They also need to understand the time of onset and peak of their insulin so that they make appropriate adjustments.
4. The insertion of the sensor under the skin is at times painful, and if it fails to calibrate another one has to be placed. Moreover, it needs to be firmly attached to the skin using tape, which may cause skin irritation or infection, and may become loose especially with sweating and exercise.
5. The functional operability of CGMS is limited to 2-7 days which might not be sufficient to detect recurrent glycemic patterns throughout the day or night.
6. Providers will have to find ways to incorporate the technology into their already busy clinical practice (De Block 2008, Hrabchak 2010, Ives 2010).

As of the current review the FDA-approved CGM real-time systems include:

- Medtronic Guardian Real Time Glucose Monitoring System that records glucose values for up to 3 days.
- Medtronic MiniMed Paradigm Real-Time System which integrates real-time CGM with an insulin delivery device and records glucose values for up to 3 days.
- DexCom SEVEN PLUS records glucose values for up to 7 days.
- Abbott FreeStyle Navigator provides continuous measurement for up to 5 days.

- The iPro Continuous Glucose Monitor (Medtronic, Inc) used only by the health provider and provides an average blood sugar measurement every 5 minutes for 3 days at a time.

The SEVEN PLUS and the FreeStyle Navigator are FDA approved for adults only. Pediatric versions of MiniMed Paradigm and Guardian systems are approved for use in patients 7-17 years. All systems require a prescription.

## Medical Technology Assessment Committee (MTAC)

### Continuous Glucose Monitoring

#### 06/07/2001: MTAC REVIEW

**Evidence Conclusion:** The published evidence is insufficient to draw conclusions about the effect of continuous glucose monitoring on health outcomes. According to MiniMed, a multicenter outcome study is underway.

**Articles:** The literature search yielded 20 articles. Excluding review articles and opinion pieces, articles on other types of glucose monitoring or other aspects of diabetes control, there were two empirical articles, both of which were case series. One article had a sample size of 11 children and the other had a sample size of 9 adults. Due to the small sample sizes, evidence tables were not created.

Continuous Glucose Monitoring for the management of unstable diabetes is approved by the FDA, but does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 02/11/2004: MTAC REVIEW

### Continuous Glucose Monitoring

**Evidence Conclusion:** *Pediatric population* - Three studies with the pediatric population were reviewed. The DirecNet study, a relatively large study with nearly 100 patients, evaluated the accuracy of the CGMS in children during a 24-hour hospital stay. It did not specifically include children with diabetes management problems. The authors found a relatively low accuracy. According to Clarke error grid, 61% of the decisions using the CGMS would lead to clinically correct treatment decisions (Zone A). Newer modified sensors appeared to be more accurate (78% of measurements were in Zone A compared to 58% with older original sensors). The newer sensors were also more reliable than the original sensors, but measurement taken by two new sensors differed from one another by more than 20% about one-fourth of the time. The Ludvigsson study, a randomized cross-over design, focused on changes in HbA1c during three months with the benefit of data from the CGMS and three months without CGMS data. Eligibility included an initial HbA1c  $\geq 6.8\%$ . When each time period was examined separately, there was not a statistically significant benefit from having CGMS data available. When data from both periods were combined, there was a significant decrease in mean HbA1c in the study arm using CGMS data, but not the other arm. The authors did not compare the change in HbA1c in the arm using CGMS data versus the other arm and had several threats to validity including lack of a wash-out period. The Kaufman study included patients with glucose management problems. The study found that data from the CGMS leads to changes in the recommendation for patient management. However, the authors did not discuss the impact of these changes on health outcomes. In summary, the limited evidence suggests that the accuracy of the CGMS in children may not be sufficiently high. The evidence is insufficient to determine the effect of continuous glucose monitoring on improving health outcomes. *Adult population* - There is less published empirical evidence in the adult population and no high-quality studies on accuracy. The best available study (Yogev) was on pregnant women with type 1 diabetes (not on patients with uncontrolled diabetes). In this sample, continuous glucose monitoring detected hyperglycemia that was not detected by self-blood glucose monitoring in all 34 patients and nocturnal hypoglycemia in 26 (76%) patients. Recommendations to change insulin treatment were made for 24 out of the 34 (70%) patients. However, the authors did not present data on how the change in recommendations affected maternal or neonatal outcomes.

**Articles:** The Medline search yielded 52 articles, some of which were reviews or opinion pieces, were on technical aspects of glucose monitoring or had outcomes unrelated to the accuracy of the glucose monitor e.g. changes in blood glucose with a low glycemic diet. *Pediatric population* - The search yielded 5 empirical articles. One had a sample size of only 9 patients (Caplin, 2003). Another was a case series with 28 patients and appeared to be relatively weak methodologically (e.g. only included 28 out of the 44 children who used the monitor in the analysis, did not discuss management changes following use of the monitor) (Salardi, 2002). The remaining 3 studies, one of which was a randomized cross-over trial, were critically appraised: Diabetes Research in Children Network (DirecNet) Study Group. The accuracy of the CGMS in children with type 1 diabetes: Results of the diabetes research in children network (DirecNet) accuracy study. *Diabetes Technol Ther* 2003; 5: 781-789. See [Evidence Table](#). Kaufman FR, Gibson LC, Halvorson M. A pilot study of the continuous glucose monitoring system. *Diabetes Care* 2001; 24: 2030-2034. See [Evidence Table](#). Ludvigsson J, Hanas R. Continuous subcutaneous glucose monitoring improved metabolic control in pediatric patients with type 1 diabetes; A controlled crossover study. *Pediatrics* 2003; 111: 933-938. See [Evidence Table](#). *Adult population* - The search yielded 4 empirical articles. One was specifically on diabetic patients needing dialysis and included only 8 patients. Two other studies each

included only 18 patients. The remaining study, which studied pregnant women with type 1 diabetes, was critically appraised: Yogev Y, Chen R, Ben-Haroush A. Continuous glucose monitoring for the evaluation of gravid women with type 1 diabetes mellitus. *Obstet Gynecol* 2003; 101: 633-638. See [Evidence Table](#).

The use of continuous glucose monitoring in the management of diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **08/30/2005: MTAC REVIEW**

##### **Continuous Glucose Monitoring**

**Evidence Conclusion:** The new studies published after our last review of 2/11/2004 were evaluated. There was only one RCT with just over 100 patients (Tanenberg 2004), that compared the hemoglobin A1c values between patients who used the CGMS to those who underwent self-monitoring. The difference between the two groups in the HBA1c was not statistically significant.

**Articles:** Tanenberg R, Bode B, Lane W et al. Use of the continuous glucose monitoring system to guide therapy in patients with insulin-treated diabetes: A randomized controlled trial. *Mayo Clin Proc* 2004; 79: 1521-1526. See [Evidence Table](#).

The use of continuous glucose monitoring in the management of diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **08/07/2006: MTAC REVIEW**

##### **Continuous Glucose Monitoring**

**Evidence Conclusion:** There are no published studies to date that evaluate the impact of real-time glucose monitor use on diabetic complications. There are also no published studies evaluating the accuracy or effectiveness of the Medtronic Minimed Guardian RT device, or the consistency of measurements of either the Guardian RT or DexCom STS when multiple devices are worn. One published empirical study on the DexCom STS system was identified. The study evaluated both device accuracy compared to self-monitoring of glucose measurements and impact on short-term glycemic control. In 47 patients, 95% of paired sensor-home monitoring data points over nine days were in Clarke error grid regions A (clinically accurate) or B (acceptable). In addition, compared to a control group (n=44) that used devices but did not receive display information, there was a statistically significant improvement in glycemic control (more time in target glucose range, less time in hypoglycemic and hyperglycemic ranges). Conclusions cannot be drawn about the intermediate or long-term impact of the DexCom STS on glycemic control-- patients were only followed during the nine days devices were worn. Another remaining issue is the 15-30 minute lag time between interstitial glucose readings and blood glucose levels when the blood glucose is rising or falling quickly.

**Articles:** No published empirical studies evaluating the Guardian RT were identified. One published empirical study on the subcutaneous DexCom STS was identified. This was a randomized controlled trial with 91 patients and was critically appraised: Garg S et al. Improvement in glycemic excursions with a transcutaneous, real-time continuous glucose sensor. *Diabetes Care* 2006; 29: 44-50. See [Evidence Table](#).

The use of continuous glucose monitoring in the management of diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **08/04/2008: MTAC REVIEW**

##### **Continuous Glucose Monitoring**

**Evidence Conclusion:** *Accuracy/Reliability* The Garg et al. (2006) study, previously reviewed by MTAC, found that the DexCom STS device was reasonably accurate compared to self-monitoring of blood glucose. >95% of 6,767 paired sensor-SMBG data points were in Clarke error grid regions A or B (clinically accurate or acceptable, respectively). An issue identified was the 15-30 minute lag time between interstitial glucose readings and blood glucose levels when the blood glucose is rising or falling quickly. Weinstein et al. (2007) also found >95% of paired sensor-venous blood sample data points were in Clarke error grid regions A or B when the FreeStyle Navigator was tested in an inpatient setting in adults. A smaller study of the FreeStyle Navigator in children (Wilson et al., 2007) identified a lag time, with Navigator readings lagging behind reference values during times of rapid rates of change in glucose levels. Impact: There is insufficient evidence on the impact of real-time continuous glucose monitor use on diabetic complications, hospitalizations and ER visits. There is fair evidence from one RCT (Deiss et al., 2006) that there are greater improvements in HbA1C levels of children and adults when a Guardian RT is worn continuously, but not intermittently, compared to self-monitoring of blood glucose. Limitations of the RCT were that it was sponsored by Medtronic, the device manufacturer, and the process for using glucose monitor data to make changes to patient treatment was not well described. There is insufficient evidence that other commercially available real-time continuous glucose monitors, the DexCom STS or Seven, and the Abbott

FreeStyle Navigator, impact glycemic control. Only case series were available. A series of 140 patients (Bailey et al., 2007) found a significant reduction in HbA1c level after 12 weeks of continuous glucose monitoring with the DexCom STS. Significant reductions in HbA1c over 13 weeks were also found in small case series with children who were managed with the FreeStyle Navigator. The available evidence is insufficient to evaluate the impact of real-time continuous glucose monitors on detection of hypoglycemic episodes, larger sample sizes and longer follow-up are required.

**Articles:** No published empirical studies evaluating the Guardian RT were identified. One published empirical study on the subcutaneous DexCom STS was identified. This was a randomized controlled trial with 91 patients and was critically appraised: Garg S et al. Improvement in glycemic excursions with a transcutaneous, real-time continuous glucose sensor. *Diabetes Care* 2006; 29: 44-50. See [Evidence Table](#).

The use of continuous glucose monitoring in the management of diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

## 06/21/2010: MTAC REVIEW

### Continuous Glucose Monitoring

**Evidence Conclusion:** The CGMS technology was previously reviewed by MTAC for several times between 2001 and 2008 and did not pass the diagnostic test evaluation criteria due to the lack of evidence on the impact of any of the commercially available devices on health outcomes as diabetic complications, hospitalization, and ER visits. The 2006 MTAC review on real-time monitors concluded that DexCom system was reasonably accurate. An issue identified was the 15-30 minute lag time between interstitial glucose readings and blood glucose levels when the blood glucose is rising or falling quickly. Impact of CGMS on health outcomes: To date the best available evidence on the effects of CGMS on health outcomes in patients with diabetes uses HbA1c as a surrogate outcome. Several studies also evaluated the level of duration hyperglycemia and hypoglycemic events. The 2006 review concluded, "There is fair evidence from one trial (Garg 2006) that patients managed using the DexCom system, spent more time in target glucose range and less time in hypoglycemic and hyperglycemic ranges over the 9-day study period, when compared to those managed without CGMS. An issue identified was the 15-30 minute lag time between interstitial glucose readings and blood glucose levels when the blood glucose is rising or falling quickly". The 2008 re-review of real time CGMS conclusion was: "There is fair evidence from one RCT (Deiss et al, 2006) sponsored by Medtronic the device manufacturer, that there are greater improvements in HbA1c levels of children and adults when a Guardian RT is worn continuously, but not intermittently, compared to self-monitoring of blood glucose". The recent Juvenile Diabetes Research Foundation Continuous Glucose Monitoring (JDRF CGM) study (2008) was a RCT that evaluated the use of CGM in the management of type 1 diabetes. The study randomized 322 adults and children receiving treatment for type 1 diabetes to a group with continuous glucose monitoring (using DexCom Seven, FreeStyle Navigator, or Mini Med Paradigm Real-Time systems) or a control group performing blood glucose self-monitoring. The participants were stratified into three age groups and the primary outcome was change in HbA1c level at 26 weeks. The results of the trial showed that adults with type 1 diabetes achieved significantly better HbA1c levels with 6 months of real-time CGM use than with point-in-time self-monitoring of blood glucose. This improved control was associated with fewer episodes of hypoglycemia. The observed change in HbA1c in the two study groups varied markedly according to age group with a statistically significant difference among patients 25 years of age or older favoring CGM use. There was a smaller nonsignificant benefit for patients in the 15-24 years age group, and no benefit for those in the age group 8-14 years. The results of the study however, may have limited generalizability as it included highly selected group of patients who tested their blood sugar levels six times a day, were able to log their data, and the majority were on insulin pumps. In addition, during the trial the participants had access to top diabetic educators and were provided with complex algorithms for adjusting their insulin doses. Adherence to sensor use may be much lower outside the investigational setting. Moreover, the study used three different CGMS which have variable accuracies, performance and reproducibility. **Conclusion:** There is insufficient evidence to determine the accuracy and reliability of the 7-day continuous glucose monitoring systems. There is fair evidence that the use of CGMSs including the 7 day is associated with a significant reduction in HbA1c levels among highly selected motivated 25 years of age or older patients with type 1 diabetes. There is insufficient evidence to determine whether use of the 7-day real-time continuous glucose monitoring systems leads to better patient-oriented health outcomes (e.g. hospitalizations, ER visits, and microvascular and macro vascular diabetic complications). Long-term studies are needed to confirm the potential benefits of CGMS in preventing hypo- and hyperglycemic episode, improving the patient's quality of life and potentially reducing the likelihood of complications that may develop.

**Articles:** Accuracy/Reliability of CGMS: The literature search revealed the STAR 1 trial (2008) evaluating the MiniMed Paradigm Real-Time System which is sensor augmented insulin pump, the Real Trend study (2009) on the Medtronic MiniMed Paradigm Real-Time System, the MITRE trial (2009) that used the MiniMed CGMS and GlucoWatch which is no longer available commercially and a small study (N=14) by Garg and colleagues (2010)

that compared the SEVEN and FreeStyle Navigator CGMS, as well as a meta-analysis of studies published up to March 2007. Impact of CGMS on health outcomes:

The ideal study would be a randomized trial comparing health outcomes in patients managed using a real-time CGMS compared to standard self-monitoring. The literature search did not identify any published RCTs that evaluated the impact of CGMS on hospitalizations, ER visits, microvascular or microvascular diabetic complications. There was a relatively large trial by the Juvenile Diabetes Research Foundation Continuous Glucose Monitoring Group (2008) that used change in the HbA1c as a surrogate outcome for diabetes control. This study was selected for critical appraisal. The Juvenile Diabetes Research Foundation Continuous Glucose Monitoring Group. Tamborlane WV, Beck RW, Bode BW, et al. Continuous glucose monitoring and intensive treatment of type 1 diabetes. *N Engl J Med* 2008;359:1464176 See [Evidence Table](#).

The use of continuous glucose monitoring in the management of diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

**08/20/2012: MTAC REVIEW**

**Continuous Glucose Monitoring**

**Evidence Conclusion:** Results from a recent meta-analysis that included 22 RCTs and evaluated the effects of CGMS compared to SMBG found that there was limited evidence on the efficacy of CGMS in children, adolescents, and adults with type 1 diabetes. The mean difference in HbA1c using real-time CGMS compared to SMBG was -0.2% after 6 months of follow-up (Langendam 2012). A recent RCT followed 176 subjects for 12 months to assess the effects of two modes of continuous glucose monitoring (patient led and physician driven) compared with SMBG in patients with poorly controlled type 1 diabetes. Results from this study suggest that both patient led and physician delivered CGM resulted in significantly greater reduction in HbA1c compared to SMBG [patient led (-0.50%); physician delivered (-0.45%), SMBG (0.02%)] (Riveline 2012). A recent observational study that included 19 subjects compared the accuracy of multiple glucose sensors worn simultaneously with the accuracy of a single sensor. Results from this study suggest that the use of multiple sensors decreased large (25% above or below the reference blood glucose value) and very large errors (at least 50% above or below the reference blood glucose value) and improve overall accuracy (Castle 2012).

**Sensor errors by degree of error and venous blood glucose value (Castle 2012)**

			<10%	10 to 24%	25 to 50%	>50%
<b>&lt;70 mg/dL</b>	Single	N=156	26.9%	38.5%	29.5%	5.1%
	Avg of 2	N=58	41.0%	33.3%	21.8%	3.8%
	Avg of 4	N=39	38.5%	38.5%	19.9%	5.1%
<b>70–180 mg/dL</b>	Single	N=2,938	41.9%	38.0%	17.1%	3.1%
	Avg of 2	N=1,478	46.5%	37.9%	14.3%	1.3%
	Avg of 4	N=739	50.6%	37.6%	11.2%	0.5%
<b>&gt;180 mg/dL</b>	Single	N=2,000	46.6%	39.3%	12.6%	1.6%
	Avg of 2	N=1,012	48.3%	42.7%	8.5%	0.5%
	Avg of 4	N=506	54.0%	39.3%	6.5%	0.2%

*Children:* A recent RCT assessed the benefits of CGM with SMBG compared to SMBG alone in 146 children aged 4 to 9 years with type 1 diabetes. The mean change in HbA1c was -0.1% in both groups. Results from this study suggest that CGM does not reduce HbA1c in children aged 4 to 9 years old (Mauras 2012).

*Conclusion:* For CGM to be considered a useful technology, it needs to be accurate, reliable, and reproducible for reflecting a patient’s plasma glucose values, especially in the lower glucose range to help avoid hypoglycemia and allow patients to achieve lower HbA1c with less hypoglycemia. However, current data do not allow this conclusion. Even when taking the average of four sensors worn simultaneously (an impractical approach for everyday use) results vary from the true plasma glucose value by 25 – 50% almost 20% of the time when patients true blood glucose values were less than 70 mg/dL. Additionally, most studies show no or only trivial improvement in HbA1c, that is not sustained overtime. Results from current data suggest that it is unlikely that everyday use of CGM will result in decreased hypoglycemia or lower HbA1c.

**Articles:** No studies were identified that addressed patient-oriented health outcomes. Several meta-analyses and three randomized controlled trials (RCTs) published after the meta-analyses were identified that addressed the effects of CGMS on glycemic control. The most recent meta-analysis, two RCTs, and an observational study published after the meta-analysis were selected for review. The other RCT was not selected for review due to methodological limitations (i.e., not stated if an intent-to-treat analysis was performed, power was not assessed, and baseline characteristic were not similar). The following studies were selected for critical appraisal: Langendam MW, Luijf YM, Hoof L, Devries JH, Mudde AH, Scholten RJ. Continuous glucose monitoring systems for type 1 diabetes mellitus. *Cochrane Database Syst Rev*. 2012;1:CD008101. See [Evidence Table](#)

## Clinical Review Criteria

### Restorative and Cosmetic Procedures

- Abdominoplasty
- Panniculectomy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	<a href="#">Medicare Benefit Policy Manual Chapter 16 - General Exclusions from Coverage</a>
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	<a href="#">Non-Covered Services (L35008)</a>
Local Coverage Article	<a href="#">Cosmetic vs. Reconstructive Surgery (A52729)</a>

##### For Non-Medicare Members

**Cosmetic Surgery** is performed to reshape normal structures of the body in order to improve appearance in the absence of a specific functional improvement. Surgery performed to improve on "natural" appearance or performed purely for the purpose of enhancing one's normal appearance is not considered reasonable and necessary.

**Reconstructive Surgery** is performed to restore bodily function or to correct a deformity resulting from disease, injury, trauma, birth defects, congenital anomalies, infections, burns or previous medical treatment, such as surgery or radiation therapy. The primary goal is to restore function. Reconstructive surgery is reasonable and necessary to improve the functioning of a malformed body part.

#### I. Abdominoplasty

1. Abdominoplasties are not covered as they are considered cosmetic.  
i.e. Repair of diastasis recti

Excision of excessive skin (thigh, leg, hip, buttock, or upper arm): is covered when **ALL of the following** criteria are met:

1. Documentation in the medical record of the presence of infections that:
  - a. Have been refractory to systemic treatment for bacterial infection control with oral or parenteral antibiotics.
  - b. Have required at least two serial office visits for the same occurrence.
    - i. If the procedure is being performed following significant weight loss, in addition to meeting the criteria noted above, there should be evidence that the individual has maintained a stable weight for at least six months. If the weight loss is the result of bariatric surgery, procedure should not be performed until at least 18 months after bariatric surgery.
    - ii. Excess skin is impairing normal function

Panniculectomy is covered when **ALL of the following** criteria are met:

1. Must meet criteria for excision of excessive skin (above)
2. Panniculus hangs below the level of the pubis (documented by photographs)
3. Interferes with activities of daily living
4. Not covered when performed in conjunction with abdominal or gynecological procedures (e.g., abdominal hernia repair, hysterectomy, obesity surgery) unless criteria for panniculectomy are met separately
5. Not covered to minimize the risk of hernia formation or recurrence

See individual links below for the following potentially cosmetic procedures:

- [Blepharoplasty](#)
- [Dermatological Procedures](#)
- [Poly-L-Lactic Acid Injection \(Sculptra\)](#)
- [Reduction Mammoplasty](#)
- [Rhinoplasty](#)
- [Breast Reconstruction](#)
- [Skin Lesions](#)
- [Vein Procedures](#)

The following are considered cosmetic in nature and non-covered under members contact:

- Cervicoplasty (“neck lift”)
- Collagen injection
- Hair Transplant
- Canthoplasty (“outer eyelid lift surgery”)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Group Health coverage contracts exclude cosmetic procedures. However, some procedures may be medically necessary when certain clinical criteria have been met. This document has been created to provide guidance to physicians reviewers when reviewer requests to cover potentially cosmetic services.

## Clinical Review Criteria

### Collagen Cross-Linking for the Treatment of Keratoconus

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	L35008 Non-Covered Services
Local Coverage Article	None

##### For Non-Medicare Members

- A. To qualify for photochemical cross-linkage using riboflavin and Ultraviolet A light **ALL** of the following must be met:
1. Has a diagnosis of keratoconus
  2. Patient is not older than 40 years old
  3. Treatment is limited to a once in a lifetime

##### Notes:

GH considers epithelium-off photochemical collagen cross-linkage using riboflavin and ultraviolet A medically necessary for keratoconus. All other diagnosis such as keratectasia is considered experimental and investigational, as the effectiveness has not been established. Epithelium-on (transepithelial) collagen cross-linkage and performance of photochemical collagen cross-linkage in combination with other procedures (CXL-plus) (e.g., intrastromal corneal ring segments, PRK or phakic intra-ocular lens implantation) is considered experimental and investigational.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Keratoconus is a disease of the cornea that is characterized by a gradual thinning and protuberance of the cornea resulting in visual damage. The cause of keratoconus is not known; its prevalence varies from 50 to 230 per 100,000 (Kennedy, Bourne et al. 1986, Heidecke, Burkert et al. 2008) and the association between African Americans and Latinos and keratoconus has been described (Woodward, Blachley et al. 2016). Several risk factors have been identified; these include eye-rubbing, contact lens use, systemic disorders (Down syndrome, Ehlers-Danlos syndrome, and osteogenesis imperfecta), family history, and environment (asthma, atopic disease) (Gasset, Houde et al. 1978, Rabinowitz 1998, Sugar and Macsai 2012, Woodward, Blachley et al. 2016).

Clinical characteristics include bilateral or unilateral visual impairment, sudden decrease in visual acuity, and/or astigmatism. Patient may also present with difficulty with visual correction and protrusion of the cornea with an indentation of the lower eyelid on downgaze. Disease progression is marked by corneal hydrops. Diagnosis can be done by slit lamp examination when the disease progresses. The mainstay of treatment is the correction of the vision which can be performed with spectacle correction, contact lens, surgical treatments or intrastromal corneal ring, keratectomy, keratoplasty (corneal implantation) and collagen crosslinking (CXL).

Corneal collagen crosslinking aims to slow the progression of keratoconus by increasing covalent bonds in the cornea. During the corneal crosslinking treatment, riboflavin drops saturate the cornea, which is then activated by ultraviolet light. In laboratory and clinical studies this procedure has been shown to strengthen the cornea. CXL is

not a cure for keratoconus. The goal of this treatment is to stop the progression of keratoconus, and prevent further deterioration in vision. The procedure consists of applying riboflavin every 3-5 minutes for 25-30 minutes and irradiating the cornea with UVA light after removal of the corneal epithelium. Then bandage lens are applied and assessment of re-epithelialization is performed about one week after the treatment. The intervention lasts one hour to 90 minutes. Although no approval statement was found on the Food and Drug Administration website, Avedro, the manufacturer of Photrexa® Viscous, Photrexa® and KXL® System indicated that in 2016, the US Food and Drug Administration approved corneal collagen cross-linking using riboflavin and UV for progressive keratoconus (Avedro 2016). Collagen crosslinking is believed to flatten the cornea and improve vision.

## Medical Technology Assessment Committee (MTAC)

### Collagen Cross-Linking for the treatment of Keratoconus

#### 09/19/2016: MTAC REVIEW

**Evidence Conclusion:** Two randomized trials were critically appraised. These studies assessed the efficacy and effectiveness of CXL. Comparison was made between CXL and no treatment or between CXL and riboflavin only. Baseline characteristics were similar between the groups and patients were followed up for one year. The results showed that CXL led to positive outcomes by reducing corneal steepness and asphericity. Adverse events were reported and these include corneal opacity, eye pain, punctate keratitis, blurry vision, corneal striae and corneal epithelial defect. However, the open label nature of the design, the lack of clarification on how the sequence generation was performed, the lack of information of allocation concealment, the short follow-up (1 year), the small sample size, and the fact that the sponsor of one of the trials was the manufacturer compromise the validity of the studies. The body of evidence is also constituted of prospective and observational studies. The sample size in these studies varied from 13 to 97 and a reduction in keratoconus progression was globally observed. It is worth noted that the follow-up period varied from 6 to 24 months. No meaningful conclusion can be reached because these studies are non-comparative studies.

#### Conclusion:

The body of evidence is of low quality and there is insufficient evidence to determine whether CXL is effective and safe in stopping the progression of keratoconus as compared to the use of alternative treatments.

#### Articles:

The literature revealed a number of articles; the following articles were selected for critical appraisal:

Safety and Effectiveness of the UV-X System for Corneal Collagen Cross-Linking in Eyes with Progressive Keratoconus (NCT00647699)

<https://clinicaltrials.gov/ct2/show/results/NCT00647699?term=corneal+collagen+crosslinking&rank=19&sect=X016>

See Evidence Table 1 (not peer reviewed). Corneal collagen crosslinking for progressive keratoconus in Saudi Arabia: One-year controlled clinical trial analysis (Khattak, Nakhli et al. 2015) See Evidence Table 2.

The use of Collagen Cross-Linking for the treatment of Keratoconus does not meet the *Group Health Medical Technology Assessment Criteria*.

### Background

Cryosurgery has been known for years, but the recent changes in the technology and the development of improved cryosurgery units are permitting its clinical use. Cryoablation is a technique that uses liquid nitrogen or argon gas to freeze and ablate tissues. Cryoablation is mainly performed laparoscopically under real time ultrasound guidance.

It is reported that the critical temperature that leads to cancer cell destruction is approximately  $-40^{\circ}\text{C}$ . Normal and neoplastic tissues are ablated and rendered necrotic at temperatures of  $-20^{\circ}\text{C}$  (Chosy, 1996). During cryosurgery, the temperature is lowest at the center of the iceball with an incremental increase towards the periphery. Thus with a cryoprobe tip temperature of  $-185^{\circ}$  to  $-195^{\circ}\text{C}$ , the temperature will be approximately  $0^{\circ}\text{C}$  at outer edge of the ice ball,  $-20^{\circ}\text{C}$  at a distance of 4mm, and  $-40^{\circ}\text{C}$  at a distance of 6mm towards the center of the iceball. It is important that the edge of the cryolesion be 1 cm beyond the margin of the tumor to make sure that a lethal temperature of  $-40^{\circ}\text{C}$  or less was achieved throughout the tumor. The effect of cryosurgery occurs in two phases, freezing and thawing. The freezing phase is performed rapidly, and passive thawing is performed more slowly for a maximum

effect. A double freeze-thaw cycle is usually performed to ensure the extension of the iceball to approximately 1 cm beyond the tumor edge.

The size of the cryolesion depends on several factors, including the temperature at the tip of the cryoprobe, area of tissue contact, freeze time, and tissue vascularity. The response of a tumor to cryoablation depends on its biological characteristics e.g. density, specific heat, thermal conductivity, and rate of blood flow (Gage 1992).

## Medical Technology Assessment Committee

### *Cryoablation for Breast Cancer or Benign Fibroadenomas of the Breast*

#### BACKGROUND

Cryoablation has been used to treat liver and prostate tumors. It is also proposed a treatment for small breast cancers and benign fibroadenomas of the breast. Cryoablation kills tumor cells by alternately freezing and thawing a target tissue. Freezing injures individual cells at the time of treatment. In addition, the tissue as a whole is affected because microcirculation is damaged. Cell necrosis during cytoablation depends on the lowest temperature achieved and the hold time at subzero temperatures. It is believed that uniform ablation can be achieved when tissue is exposed to at least -40oC during two consecutive freeze thaw cycles (Whitworth & Rewcastle, 2005). The procedure for using cryoablation to treat breast tumors is as follows: Using ultrasound guidance, a cryoprobe is inserted through a 3mm skin incision into the center of the tumor. Ultrasound is used to guide the cryoprobe, and also to monitor the treatment. Once appropriate placement of the cryoprobe is confirmed, the machine it turned on "high." When set to "high," argon gas, the cooling agent, is allowed to flow continuously through the cryoprobe. The probe is cooled to -160oC which freezes the tumor, forming an "ice ball" around it. After the iceball is formed, the cryoablation unit set on "low" setting which allows argon gas to flow intermittently into the cryoprobe for 1 of every 10 seconds to preserve freezing temperatures. Generally, two freeze-thaw cycles are used. Helium is used as the warming agent between freezing cycles (Nurko et al., 2005; Visica, manufacturer's Web site). Benign breast fibroadenomas are common, especially among young women. Approximately 10% of women will experience a breast fibroadenoma during their lifetime. Currently accepted treatments include excisional biopsy and conservative management. Conservative management may be a reasonable choice for this benign condition, particularly smaller fibroadenomas. Moreover, women may choose to avoid immediate intervention since an estimated 30% of breast fibroadenomas resolve spontaneously within several years. Excisional biopsy provides a definitive diagnosis, but a disadvantage is morbidity including possible cosmetic and/or ductal damage. Cryoablation is less invasive than excisional biopsy and is done on breast fibroadenomas after confirmation that the tumor is benign, generally with needle biopsy (Whitworth & Rewcastle, 2005; Houssami et al. 2001). A minimally invasive procedure, such as cryoablation, may also be useful for treating early breast cancers treated with breast-conserving therapy rather than mastectomy. Other thermal methods have been used to treat breast tumors. These include radiofrequency ablation, interstitial laser therapy and high intensive focused ultrasound (Pfleider et al., 2005).

#### 08/07/2006: MTAC REVIEW

#### Cryosurgery – Breast Cancer

**Evidence Conclusion:** There is insufficient evidence to permit conclusions the efficacy of cryoablation for treating benign breast tumors including fibroadenomas. No studies were identified that compared cryoablation to conservative management, an accepted approach for managing fibroadenomas. The available studies were case series. A limitation of the published series was that there was likely overlap among patients in the studies. The degree of overlap could not be determined. In addition, two of the three studies reviewed (not the registry) were funded by the manufacturer of the cryoablation system. The Kaufman et al. and Caleffi et al. studies found that a higher proportion of larger (>2.5cm) fibroadenomas than smaller fibroadenomas were palpable at 12 months. This suggests that the usefulness of cryoablation may be limited because there is likely more demand for intervention, rather than conservative management, with larger fibroadenomas. There is insufficient evidence to permit conclusions on the efficacy of cryoablation for treating early breast cancer. No studies were identified comparing cryoablation to other treatments such as radiofrequency ablation or interstitial laser therapy. The available studies were relatively small case series with sample sizes of 30 or fewer patients. In the series, cryoablation was followed by surgery 1-4 weeks later, at which time the tumor cells were evaluated. In one study, there was residual DCIS in 5 out of 30 patients and in the other study, there was residual invasive cancer or DCIS in 6 out of 27 patients. In the latter study, cryoablation was successful in all of the 10 patients with tumors <1.5 cm and with ductal or medullary cancer and no extensive intraductal component. Number of patients were too small to draw conclusions about sub-groups that might benefit from cryoablation for early breast cancer.

Cryoablation appears to be safe, although data on adverse effects are limited. No major complications were reported in any of the series that were reviewed.

**Articles:** No randomized controlled trials or other controlled trials were identified. Empirical studies were all case series. Three series on benign breast tumors, including fibroadenomas, were identified. Findings from one of the series, written by Kaufman and colleagues, were reported in three articles. Sample sizes were 63 patients in the Kaufman study and 102 and 29 in the other series. In addition, a registry of fibroadenomas treated by cryoablation was identified. The registry included 444 fibroadenomas (the number of patients was not reported, some patients contributed more than one fibroadenoma). The registry study and the two largest case series were critically appraised. All of the Kaufman et al. studies were included in the same evidence table. Four studies on cryoablation for breast cancer were identified. All included patients with small breast tumors  $\leq 2.0$  cm. Sample sizes in the studies were  $n=30$ ,  $n=29$ ,  $n=15$  and  $n=9$ . The two larger case series were critically appraised. The series with  $n=15$  appeared to report preliminary data for one of the larger studies. The studies reviewed were as follows: Kaufman CS, Bachman B, Littrup PJ et al. Cryoablation treatment of benign breast lesions with 12-month follow-up. *Am J Surg* 2004; 188: 340-348. (Kaufman CS, Littrup PJ, Freeman-Gibb LA et al. Office-based cryoablation of breast fibroadenomas with long-term follow-up. *Breast J* 2005; 11: 344-350. Kaufman CS, Littrup PJ, Freeman-Gibbs LA et al. Office-based cryoablation of breast fibroadenomas: 12-month follow-up, *J Am Coll Surg* 2004; 198: 914-923) v See [Evidence Table](#). Caleffi M, Filho DD, Borghetti K et al. Cryoablation of benign breast tumors: Evolution of technique and technology. *The Breast* 2004; 13: 397-407. See [Evidence Table](#). Nurko J, Mabry CD, Whitworth P et al. Interim results from the FibroAdenoma Cryoablation Treatment Registry. *Am J Surg* 2005; 190: 647-652. See [Evidence Table](#). Pfleiderer SOR, Marx C, Camara O et al. Ultrasound-guided, percutaneous cryotherapy of small ( $\leq 15$ mm) breast cancers. *Invest Radiol* 2005; 40: 472-477. See [Evidence Table](#). Sabel MS, Kaufman CS, Whitworth P et al. Cryoablation of early-stage breast cancer: Work-in-progress report of a multi-institutional trial. *Ann Surg Oncol* 2004 11: 542-549. See [Evidence Table](#).

The use of Cryoablation in the treatment of breast cancer or benign fibroadenomas of the breast does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Cryosurgical Ablation (CSA) for Liver Tumors**

#### **BACKGROUND**

The liver is a common site for primary and secondary malignancies. Hepatocellular carcinoma (HCC), the most common primary tumor, is the fifth most common cancer in the world, and the third most common cause of cancer-related mortality. It is responsible for more than half a million deaths across the globe each year. Treatment options for patients diagnosed with primary and secondary malignancies are limited. Less than 15% are candidates for surgical resection at presentation because of inadequate liver functional reserve, extrahepatic disease, anatomic constraints of the tumor, or medical co morbidities. The use of external beam radiation is limited due to the intolerance of normal liver parenchyma to tumoricidal radiation doses ( the dose required to destroy solid tumors ( $>70$  Gy) is much higher than the liver tolerance dose of 35 GY). In addition, systematic chemotherapy was found to have little impact on survival, and negative impact on the health-related quality of life due to the toxicity to other organs and systems. These limitations have led to the emergence of other therapies, such as radiofrequency ablation (RFA), cryosurgical ablation (CSA), percutaneous ethanol injections (PEI), hepatic arterial infusion chemotherapy, transarterial chemo-embolization (TACE), and selective intrarterial radioembolization therapy (Steel 2003, Salem 2005, Ibrahim 2008, Bult 2009, Riaz 2009, Bhardwaj 2010). Ablative techniques, such as RFA and CSA, improve the ability to treat patients with unresectable hepatic tumors. Thermal ablative techniques destroy tumors via a source that changes temperature to levels that are associated with cell death while causing minimal damage to adjacent, normal tissue. The choice of technique depends on equipment availability and physician preference. The most commonly used ablative technique in the United States is RFA. RFA causes tumor destruction through the use of alternating high-frequency electric current in the radiofrequency range (460-500 kHz). This current is delivered through an electrode placed in the center of a lesion. Ions within the cell follow the alternating current creating frictional heat producing local tissue temperatures that can exceed  $100^{\circ}\text{C}$ . This ionic agitation leads to tissue destruction via tissue boiling and creation of water vapors. Once temperatures greater than  $60^{\circ}\text{C}$  are reached, protein denaturation, tissue coagulation, and vascular thrombosis result in a zone of complete ablation. Partial tissue destruction can occur up to 8 mm in diameter from the zone of complete ablation. RFA can be delivered either percutaneously, laparoscopically, or through open approaches (laparotomy). Complications from RFA include: pleural effusion, hepatic abscess, biliary injury, liver failure, intra-abdominal hemorrhage, pneumothorax, and hypoxemia. The most troubling complications arise when a probe is placed too close to the diaphragm or intra-abdominal organ, resulting in ablation of the surrounding viscera with the accompanying complications of perforation, diaphragmatic injury, or pulmonary damage. Limitations of RFA include: treating lesions in perihilar areas or near large vascular structures, and real time monitoring of the ablative zone is difficult due to air released during heating (Yamane 2009, Arciero 2006). CSA is another ablative technique. CSA uses repetitive freezing and thawing to produce irreversible tissue destruction. One or more cytoprobes are inserted at the site of the diseased tissue and liquid nitrogen or argon gas is delivered through the

probe to freeze the tissue. Rapid freezing of the tissue results in the formation of intercellular ice crystals. At temperatures of about -40°C lethal ice crystals begin to form in the cell. Ice crystals also form in the fluid outside the cell leading to cell dehydration. The combination cause tumor cells to burst. Additionally, ice crystals form in small vessels and block blood supply to the tumor. Normally, two freeze-thaw cycles are used. CSA is easy to monitor and the area treated can be accurately visualized with ultrasound. This allows for accurate real-time visualization; however, it does not guarantee that there has been cell death. Two devastating complications that are associated with CSA are cryoshock, a complex of severe coagulopathy and multi-organ failure, and intra-operative hypothermia. Other complications include: hemorrhage from cracking of the frozen liver, subphrenic abscesses, bilomas, and biliary fistulae (Bhardwaji 2010, Arciero 2006). The cryoprobe that is used in CSA has received FDA approval for ablation of cancerous or malignant tumors, benign tumors, and as a palliative intervention. RFA has received FDA approval for generic tissue ablation and the ablation of unresectable colorectal cancer metastases. This technology is being reviewed based on a request from gastroenterology.

## **06/21/2010: MTAC REVIEW**

### **Cryosurgery – Liver Tumors**

**Evidence Conclusion:** It is difficult to compare the results of CSA with surgery or other ablative techniques, as most authors report data from studies where a variety of different treatment modalities were used in conjunction with CSA. Differences in patient selection, follow-up duration, types of tumors, and treatment approaches also make studies difficult to compare.

**CSA vs. RFA:** The empirical evidence comparing CSA to RFA consists of nonrandomized, case series, and cohort studies that examined multimodal therapies rather than CSA alone. The Pearson study was selected for critical appraisal as it was the largest prospective study (N=146). The objective of this study was to compare complication and local recurrence rates in patients treated with RFA or CSA. Patients with either primary or secondary hepatic malignancies were included in the study. Compared to patients treated with RFA, patients treated with CSA appeared to have higher local recurrence rates (22% vs. 3%). However, data was not adjusted for confounding factors that may influence the rate of recurrence. With regard to complications, a total of 27 complications occurred in 22 CSA patients, while a total of 3 complications occurred in 3 RFA patients. Patients treated with CSA had a higher incidence of intrahepatic abscess and symptomatic pleural effusion than patients treated with RFA. It is not clear who these results are generalizable to as only very limited demographic information is presented. There is a high probability of selection bias in the study, as it is not stated how patients were recruited for the study and treatment choice was based on preference and training of the individual surgeon. Additionally, a subset of patients underwent resection in combination with CSA or RFA.

**CSA vs. CSA + resection:** The Niu study was selected for critical appraisal as it was a large prospective study (N=315) that compared long-term results of resection combined with CSA with resection alone in patients with colorectal liver metastases. The study found that the combined treatment group (CSA + resection) had higher recurrence rate, but survival rates were not statistically different between the two groups. Results from this study should be interpreted with caution as treatment groups were not comparable at baseline, more patients in the combined treatment group were treated with chemotherapy, and results were not controlled for confounding factors. It is not clear who these results are generalizable to as only very limited demographic information is presented. Conclusion: There is insufficient evidence to determine the relative safety and efficacy of CSA compared to RFA. There is insufficient evidence to determine whether CSA combined with hepatic resection will improve recurrence and survival rates compared to resection alone in patients with liver metastases from colorectal carcinomas.

**Articles:** No published randomized controlled trials or meta-analyses were found pertaining to the use of cryosurgical ablation for liver cancer. The literature consisted mainly of case series and cohort studies. Two prospective cohort studies were selected for critical appraisal. One study (Pearson 1999) assessed the relative safety and efficacy of CSA versus RFA and one study (Niu 2007) evaluated recurrence and survival rates of CSA combined with resection versus resection alone in patient with liver metastases from colorectal carcinomas. The following studies were critically appraised:

Pearson SA, Izzo FI, Declan RY, Delrio P et al. Intraoperative radiofrequency ablation or cryoablation for hepatic malignancies. *Am J Surg* 1999; 178:592-599. See [Evidence Table](#). Niu R, Yan TD, Zhu JC et al. Recurrence and survival outcomes after hepatic resection with or without cryotherapy for liver metastases from colorectal carcinoma. *Ann Surg Oncol* 2007; 14:2078-2087. See [Evidence Table](#).

### **Cryosurgery for Prostate Cancer**

#### **BACKGROUND**

Radical prostatectomy and external beam radiation therapy are considered standard treatments for localized prostate cancer. Both can result in significant morbidity such as incontinence and impotence. There is interest in other treatments that are of similar or greater effectiveness and have less morbidity. Cryosurgery (also known as cryoablation) was first used to treat prostate cancer in the last 1960s. Originally, clinicians used an open perineal approach that had high morbidity. The procedure was re-introduced in 1993 by Onik and colleagues using

transrectal ultrasound (Onik, 1993). The technique continued to evolve and is now performed with modifications to the procedure introduced by Onik. In the basic modern technique, six to eight 3.4 mm diameter cytoprobes are inserted transperineally into the prostate guided by transrectal ultrasound. Temperature probes are placed in the right and left neurovascular bundles and the apex of the prostate gland to ensure that temperatures reach optimal levels in the margins of the gland. In addition, temperature probes are placed in the Denonvilliers fascia and the external sphincter and are used to make sure that sensitive areas adjacent to the prostate are not frozen. A urethral warming catheter is used to prevent the urethra from being frozen. Patients are treated with one or two freeze-thaw cycles (two is used more often in recent procedures) using a target temperature of  $-40^{\circ}\text{C}$ . When the target temperature is attained, the ice ball is maintained at a static size for up to 10 minutes if this is possible without endangering the rectal wall (Bahn et al., 2002). Cryosurgery is also used as salvage therapy to treat recurrent prostate cancer after radiation therapy. Salvage prostatectomy is the standard treatment, but about half of patients have positive surgical margins and there is significant associated morbidity (Cespedes et al., 1997).

#### **06/11/2003: MTAC REVIEW**

##### **Cryosurgery – Prostate Cancer**

**Evidence Conclusion:** Primary treatment of clinically localized prostate cancer - Only case series data were available, the lowest grade of evidence because there is no control or comparison group. In addition, the case series did not evaluate a standard intervention; instead, the procedure changed over time. Both case series reported an intermediate outcome, biochemical success, as their primary health outcome. Conclusions about the effectiveness of cryosurgery compared to standard treatments for prostate cancer (e.g. radical prostatectomy, external beam radiation therapy) or no treatment can be drawn. Randomized controlled trials testing cryotherapy as primary treatment for prostate cancer should be feasible. The case series data suggest that cryosurgery is associated with a high-rate of impotence. Among men potent before surgery, in Bahn, 95% became impotent after cryosurgery and 90% remained so at follow-up (a mean of 5.4 years) and in Donnelly, 100% became impotent after cryosurgery and 53% remained so at 3 years, even with the use of sildenafil.

Salvage treatment for recurrent prostate cancer- Only case series data were available, the lowest grade of evidence because there is no control or comparison group. In addition, the procedure was inconsistent and changed over time. In a series of 131 patients (Izawa), 5-year disease-specific survival was 79% and 5-year disease-free survival was 40%. The long-term post-cryosurgery incontinence rate was 29%. Conclusions about the effectiveness of cryosurgery as salvage therapy after radiation treatment for patients with recurrent prostate cancer, or associated morbidity, compared to an alternate treatment such as salvage prostatectomy cannot be drawn.

**Articles:** *Primary treatment of clinically localized prostate cancer:* There were no randomized or non-randomized controlled trials. The only empirical data were from case series. The two largest case series that had data both on outcomes and adverse effects were critically appraised: Bahn DK, Lee F, Badalament R et al. Targeted cryoablation of the prostate: 7-year outcomes in the primary treatment of prostate cancer. *Urology* 2002 (Suppl 2A): 3-11. See [Evidence Table](#). Donnelly BJ, Saliken JC, Ernst S et al. Prospective trial of cryosurgical ablation of the prostate: Five-year results. *Urology* 2002; 60: 645-649. See [Evidence Table](#).

*Salvage treatment for recurrent prostate cancer:* Three case series were identified. Two were from the same institution and reported different outcomes on virtually the same group of patients. These studies were critically appraised. The other case series, which had a smaller sample size and a shorter follow-up, was excluded. Cespedes RD, Pisters LL, von Eschenbach AC et al. Long-term follow-up of incontinence and obstruction after salvage cryosurgical ablation of the prostate: Results in 143 patients. *J Urol* 1997; 157: 237-240. See [Evidence Table](#). Izawa JI, Madsen LT, Scott SM et al. Salvage cryotherapy for recurrent prostate cancer after radiotherapy: Variables affecting patient outcome. *J Clin Oncol* 2002; 20: 2664-2671. See [Evidence Table](#).

The use of cryosurgery in the treatment of prostate cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

##### **Cryoablation of Renal Tumors**

###### **BACKGROUND**

With the widespread use of body imaging techniques as magnetic resonance imaging (MRI) and computed tomography (CT), there is an increasing number of incidentally detected small renal masses or lesions with unclear clinical significance. The standard treatment for renal masses is radical nephrectomy. Other available treatment options include watchful waiting or partial nephrectomy. Recently, with the current trend of minimally invasive surgery, nephron-sparing approaches have gained more acceptance. Open, percutaneous, and laparoscopic renal cryoablation, radiofrequency ablation, and high intensity focused ultrasonography (HIFU) have been performed but are still under development. These techniques only target selected, small renal tumors with a diameter of 4 cm or less. Cryosurgery has been known for years, but the recent changes in the technology and the development of improved cryosurgery units are permitting its clinical use. Cryoablation is a technique that uses liquid nitrogen or argon gas to freeze and ablate tissues. Cryoablation is mainly performed laparoscopically under

real time ultrasound guidance. It is reported that the critical temperature that leads to cancer cell destruction is approximately  $-40^{\circ}\text{C}$ . Normal and neoplastic renal tissues are ablated and rendered necrotic at temperatures of  $-20^{\circ}\text{C}$  (Chosy, 1996). During cryosurgery, the temperature is lowest at the center of the iceball with an incremental increase towards the periphery. Thus with a cryoprobe tip temperature of  $-185^{\circ}\text{C}$  to  $-195^{\circ}\text{C}$ , the temperature will be approximately  $0^{\circ}\text{C}$  at outer edge of the ice ball,  $-20^{\circ}\text{C}$  at a distance of 4mm, and  $-40^{\circ}\text{C}$  at a distance of 6mm towards the center of the iceball. It is important that the edge of the cryolesion be 1 cm beyond the margin of the tumor to make sure that a lethal temperature of  $-40^{\circ}\text{C}$  or less was achieved throughout the tumor. The effect of cryosurgery occurs in two phases, freezing and thawing. The freezing phase is performed rapidly, and passive thawing is performed more slowly for a maximum effect. A double freeze-thaw cycle is usually preformed to ensure the extension of the iceball to approximately 1 cm beyond the tumor edge. The size of the cryolesion depends on several factors including the temperature at the tip of the cryoprobe, area of tissue contact, freeze time, and tissue vascularity. The response of a tumor to cryoablation depends on its biological characteristics e.g. density, specific heat, thermal conductivity, and rate of blood flow (Gage 1992). Potential complications of renal cryosurgery include post-thaw hemorrhage, urine leakage due to caliceal cryoinjury, and fistula formation.

**04/09/2003: MTAC REVIEW**

**Cryosurgery – Renal Tumors**

**Evidence Conclusion:** There is insufficient published evidence to determine the efficacy, safety, and long-term outcome of cryoablation for the treatment of renal tumors. No randomized controlled trials or non-randomized comparative studies were conducted to compare the procedure to surgery or other alternatives and assess its long-term benefits. All studies were either case reports or case series with very small sample sizes. The case series reviewed included small numbers of patients, were subject to selection and observation biases, and had short follow-up durations. These series showed that after a mean follow-up of 9 months in Shingleton’s study, 14 months in Lee’s study and 16 months in Gill’s study the ablated renal tumor was no longer detectable in 25-40% or reduced in size in 20-75% of the patients with available follow-up data. Large randomized controlled studies with long-term follow up duration will be needed to compare cryoablation to other alternatives, and to determine its efficacy, safety, and long-term benefits.

**Articles:** The search yielded 48 articles. Many were reviews or tutorials that dealt with the technical aspects of the procedure. There were no meta-analyses or randomized controlled trials. There were 13 case reports (with 1-9 patients), and 9 case series with a small number of patients (10 to 32 patients). The 3 largest series were selected for critical appraisal: Gill IS, Novick AC, Meraney AM, et al. Laparoscopic renal cryoablation in 32 patients. *Urology* 2000;56:748-753. See [Evidence Table](#). Lee DI, McGinnis DE, Feld R, et al. Retroperitoneal laparoscopic cryoablation of small renal tumors: intermediate results. *Urology* 2003;61: 83-88. See [Evidence Table](#). Shingleton WB and Sewell PE. Percutaneous renal tumor cryoablation with magnetic resonance imaging guidance. *J Urol* 2001;165:773-776. See [Evidence Table](#).

The use of cryoablation in the treatment of renal tumors does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Chest CT Angiography (CTA) Cardiac CT Angiography (CTA)

- Cardiac CT Angiography
- Cardiovascular Computed Tomography (CVCT)
- Cardiovascular Multislice CT (MSCT)
- Contrast Enhanced Computed Tomographic Angiography
- Multidetector Row Spiral Computed Tomography (MDCT Scan)
- Multislice Detector Computed Tomography
- Multislice Tomography

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	05/13/2016 Noridian retired <a href="#">LCD Multidetector Computed Tomography of the Heart and Great Vessels (L34137)</a> These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an article. Most LCDs are not retired because they are incorrect. Therefore, continue to use LCD L34137 for determining medical necessity.

#### For Non-Medicare Members

##### Cardiac CT Angiography (CTA) (CPT 75574)

Group Health has elected to use the MCG\* (A-0483) for medical necessity determinations.

##### Chest CT Angiography (CTA) (CPT 71275)

Group Health has elected to use the MCG\* (A-0471) medical necessity determinations.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.)

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (cardiology)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Coronary artery disease (CAD) is one of the leading causes of morbidity and mortality worldwide. Currently invasive coronary angiography is the gold standard for coronary artery lumen assessment. It provides high spatial resolution and accurately determines the location, extent, and severity of coronary obstructive lesions. It also allows immediate intervention if needed. Coronary angiography however, is an invasive procedure, has a small risk of serious complications, and requires a period of observation for several hours in a monitoring unit. Moreover, it was reported that nearly 40% of these procedures result in normal findings. This has led to a growing interest in the development less invasive methods for evaluating coronary anatomy, especially in stable patients at low to moderate risk of disease (Vembar 2006, Miller 2008).

Numerous anatomic and functional noninvasive tests for detecting CAD have emerged and are rapidly developing. Among these are stress echocardiography, nuclear perfusion studies, SPECT, magnetic resonance angiography, and others. More recently, computed tomography has been used for the evaluation of CAD. Electron beam computed tomography (EBCT) was initially used to assess coronary artery calcium as a marker of atherosclerosis. The first generation of multislice computed tomography (MSCT), also known as multidetector computed tomography (MDCT) scanners were introduced in the 1990s. The 4-slice scanner was developed to provide noninvasive direct visualization of the coronary arteries, and led to significant improvements in spatial resolution compared to EBCT. However, it had motion artifacts, low resolution, long acquisition time, and up to 22% of the segments were non-assessable. The 4-slice CT thus rapidly evolved to 16, 32, 40, and 64-slice CT scanners. The 16-slice scanner has better spatial resolution, faster gantry rotation, and larger coverage resulting in significantly shorter breath hold and less motion artifacts than those with 4-slice. The 64-slice scan generation, introduced in 2004, further improved the resolution, decreased the slice thickness, and reduced the acquisition time to less than 10 seconds. The entire procedure can be performed in approximately ten minutes. Systems with 256 and 320 slices and others with 64 slices but with 2 x-ray tubes (dual –source CT or DSCT) have recently been introduced (Gertz 2006, Vembar 2006, Berman 2006, Min 2009).

With the newer scanners, electrocardiographically synchronized images can be taken through the entire heart in the time of one breath hold. Synchronizing the location of the peak of QRS complex in the ECG with the projection data allows the reconstruction and visualization of anatomy at various phases of the cardiac cycle thus making functional imaging possible (Cademartiri 2005, Vembar 2006, Budoff 2008).

MDCT technology however, has its limitations; it does not have the ability to correctly identify and differentiate between functionally significant and nonsignificant stenosis, or allow for intervention during the examination if needed. Positive findings frequently require confirmation with selective cardiac catheterization angiography, or stress myocardial perfusion to evaluate the functional significance. One of the difficulties in imaging the coronary vessels is the constant motion of the heart, which leads to artifacts and influences the image quality even with the significant improvements in the technology. Reducing the heart rate to 50-60 bpm with beta-blockers, now routinely used by most investigators, increases the cardiac rest period and reduces, but does not eliminate motion artifacts. To date, it is not possible to perform CT angiography in patients with atrial fibrillation unless it is highly regular.

One other significant problem, even with the most recent generations, is the inability of the MDCT to assess the degree of luminal obstruction within a calcified zone when there is dense calcification of the coronary arteries. This may lead to relatively high rate of false positive results and overestimate the severity of the disease. The use of MDCT is also limited for in-stent visualization, for evaluation of distal anastomosis among patients with previous bypass graft surgery, and for patients with higher body mass index. Moreover, MDCT requires the administration of contrast material and exposure to ionizing radiation. The radiation dose used is equivalent to 2-3 times the dose typically used during an invasive angiogram. This may be considered a low radiation exposure, but might be of concern among women in childbearing age, or younger individuals who may use the test repeatedly. History of severe allergic reactions to an iodinated contrast material or of impaired renal function (creatinine level >1.5 mg/dL) are contraindications to CT coronary angiography (Garcia 2005, De Roos 2006, Leber 2006, Berman 2006, Hoffmann 2006, Rixe 2009, Min 2009).

## Medical Technology Assessment Committee (MTAC)

### *Virtual Coronary Angioscopy*

**04/03/2006: MTAC REVIEW**

**Evidence Conclusion:** All published studies on MSCT scanners investigated the accuracy of MCST in patients with known or suspected CAD, who was referred for evaluation with catheter angiography. None of the studies evaluated the technology for screening healthy, asymptomatic, or low risk individuals. Schuijff and colleagues'

meta-analysis (2006) included 24 studies with 1,300 participants that compared MSCT scans head to head with invasive catheter angiography in patients with known or suspected CAD. The studies used one of the 4, 8, or 16 slice CT scanners. Those evaluating the 64-slice CT scans were not published to the date of analysis. The results of the meta-analysis show that the 4,8, and 16 MSCT scan generations had an overall high specificity (95%) and negative predictive value (97%) but lower sensitivity (85%) and positive predictive value (76%) compared to invasive angiography as the gold standard. Published studies evaluating 64-slice CT scanners had some differences in the methodology and patient characteristics, but all used invasive catheter angiography as the gold standard, included only patients with known or suspected CAD, excluded those with cardiac arrhythmias and unstable conditions, defined significant coronary stenosis as >50% lumen narrowing, and the majority used beta-blockers to reduce the heart rate. The trials ranged in size from 35 to 84 patients, used the same Sensation 64 CT Siemens Medical Solutions scanners, and almost all reported analysis of sensitivity, specificity, positive and negative predictive values. Analysis of MSCT performance was limited to coronary segments > 1.5 or 2 mm in diameter, and most studies used individual coronary vessels or vessel segments as the unit of analysis. Not all studies reported on the performance characteristics of MSCT using the patient as a unit of analysis. The results of the studies critically appraised show that 4-13% of the coronary segments were non-evaluable due to motion artifacts, severe calcified plaques, and/or other technical imaging problems. The sensitivity and specificity of MSCT for detecting >50% diameter reduction in the evaluated coronary segments ranged from 73% to 95% and from 80% to 97% respectively. Only two studies reported on the performance characteristics of MSCT using the patient as a unit of analysis showing a sensitivity of 95-96% and specificity of 90-91%. The negative predictive values ranged from 92-100% when segments were used as the unit of analysis and 93% to 98% when analyses were per patients. The positive predictive value on the other hand was much lower (as low as 56 % per segment and 83% per patient). Leber et al (2005) went a step beyond assessment of stenosis and evaluated the 64-MSCT scan for detecting and quantifying coronary atherosclerotic plaque compared to intravascular ultrasound (IVUS), and reported a 84% sensitivity and 91% specificity. This however, was studied on a very small subgroup of only 18 patients with stable angina. The overall results of the published studies may indicate that MSCT scanning may have a high sensitivity of diagnosing CAD, and a high NPV that would accurately rule out CAD among the selected symptomatic patients with a negative MSCT scan result. However, all studies were small, conducted in single, highly specialized centers, conducted among selected intermediate to high risk patients, with stable conditions, regular heart rhythm, and a high prevalence of CAD. These factors in addition to analyzing the diagnostic performance of the technology based on the evaluable segments of the vessels only, would overestimate the calculated accuracy and predictive values of the test, and in turn the results may not be generalizable to a broader population. In conclusion: There is insufficient evidence to support the use of MSCT as a method of screening for CAD among healthy, low risk populations, or asymptomatic patients with known risk factors. There is insufficient evidence that the technology is as beneficial as catheter angiography in the diagnosis of CAD. There is insufficient evidence to support the use of MSCT scanning in monitoring progress of the disease and its outcome after an intervention, in patients with confirmed disease. There is insufficient evidence that the technology improves health outcomes. A multicenter study (CorE 64), and study with long-term healthcare outcomes conducted by the Medical College of Wisconsin are underway.

**Articles:** The search yielded around 170 articles. Many were review articles, opinion pieces, or dealt with technical aspects of the scan. The search revealed several studies using 4, 8, and 16-slice CT scanners for the detection of coronary artery lesions. A recent meta-analysis of 24 of these studies was also identified, as well as seven studies that used the 64-slice CT angiography for detecting CAD stenosis and comparing the technology with invasive coronary angiography. The meta-analysis and four of the studies on the 64-slice scanners were critically appraised. Fine JJ, Hopkins CB, Ruff N, et al. Comparison of accuracy of 64-slice cardiovascular computed tomography with coronary angiography in patients with suspected coronary artery disease. *Am J Cardiol.* 2006;97:173-174. The use virtual coronary angioscopy of in the evaluation of coronary artery disease does not meet the *Group Health Medical Technology Assessment Criteria*.

## 02/05/2007: MTAC REVIEW

## MDCT in the Treatment of Coronary Heart Disease

**Evidence Conclusion:** *Use of MDCT for the diagnosis of coronary artery stenosis* - The published studies evaluating the use of MDCT scanners in the diagnosis of coronary artery stenosis are all relatively small trials mainly conducted in single specialized centers, and among selected patients with stable conditions who were referred for invasive coronary angiography for a known or suspected CAD. The technology was not assessed for screening healthy, asymptomatic, or low risk individuals. The studies evaluated MDCT angiography in respect to its accuracy in identifying coronary stenosis (per segment, per-vessel and per-patient), but not its effect on the treatment decisions, patient management, and health outcomes. Certain segments or whole patients were excluded from the analysis due to nonassessable images, which would overestimate the accuracy of the test. Three recently published meta-analyses (Hamon 2006, Sun 2006, and Stein 2006) pooled the results of published individual small studies. There were some variations between the three meta-analyses in the inclusion/exclusion criteria, but many of the same studies were included in all three analyses. Hamon and colleagues' analysis included more up-to date studies, and only those using 16 or more slice MDCT scans. The other two meta-analyses included older studies with 4, 8, 12 as well as the newer 16 and 64-slice scans. The authors of all three meta-analyses performed per-segment, per-vessel, and per-patient analyses. The per-patient analysis would be the most relevant if the MDCT is intended for use as a substitute for invasive angiography. Overall the results of the three meta-analyses show that MDCT angiography had a sensitivity ranging from 81-94%, and specificity ranging from 93-94% for the per-segment analysis. Analyses based on patients showed a sensitivity of 91-95%, and specificity of 74-84%. The per-patient pooled positive likelihood ratios were 5.4 and 6 and negative likelihood ratios were 0.05 and 0.07 in the two analyses that reported them. Hamon and colleagues also pooled the results of the positive and negative predictive values which were 83% and 94% respectively for the per-patient analysis. Nikolaou and colleagues, 2006 evaluated the clinical value of the 64-slice computed tomographic (MDCT) in the diagnosis of coronary artery disease among 72 patients with and without a history of a known coronary artery disease (CAD) in a cardiology center in Germany. 40% of the participants had already been diagnosed with CAD and angiographically verified. Invasive coronary angiography was the gold standard, and was evaluated by an independent observer blinded to the MDCT results. Scan results were analyzed by two independent experienced observers blinded to the invasive angiography results, and patients' history. 6% of patient-based and 10% of the segment-based CT angiograms were nonassessable. 64% of the assessable CT angiograms had a high image quality, 30% had moderate quality and 6% were poor. The results of this study showed a sensitivity of 86% and specificity of 94% for the per-segment analysis. These were 97% and 79% respectively for the per-patient analysis. The negative predictive value was 100% for patients with known CAD, and 93% for those with a suspicious disease. These rates were computed from very small number of patients with a high prevalence of CAD and would not necessarily apply to populations at a lower risk. *Use of MDCT to evaluate patients presenting to emergency rooms with acute chest pain:* The few studies that evaluated the use of the technology in the emergency room did not compare it to the gold standard of catheter angiography, but used a combination of noninvasive tests and observations as a surrogate gold standard. Gallagher and colleagues, 2006 evaluated the diagnostic accuracy of the 64-slice multidetector computed tomographic (MDCT) coronary angiography compared to stress nuclear imaging for the detection of an acute coronary syndrome (ACS) or 30 day major cardiac adverse events. The study included 92 low-risk chest pain patients seen in the emergency department of a teaching hospital in Michigan USA. The participants had negative serial ECG and cardiac marker results at presentation to the ER. They were admitted to the emergency department observation unit for the chest pain diagnostic protocol (cardiac monitoring, serial ECG and cardiac marker tests) 4 hours after arrival. Those with abnormal markers had repeat tests and ECG at 8 hours. If these latter tests were negative the patients received a stress nuclear imaging test followed by MDCT coronary angiography using 64-slice multidetector CT scanners. Patients were treated based on the findings of both tests, and then followed up for evidence of ACS or major adverse events within 30 days of their initial visit. Those with positive tests suggesting unstable angina underwent cardiac catheterization to confirm the diagnosis. The authors used clinical markers and outcomes as a surrogate gold standard, and 7 (7.6%) of the study participants were not included in the analysis due to uninterpretable MDCT images. The numbers were too small and show a MDCT sensitivity of 86% specificity of 92%, NPV of 99% and a PPV of 50%. Hoffmann et al, 2006 also assessed MDCT angiography among 103 patients presenting to the ER with acute chest pain in a university hospital in Massachusetts. The participants had no ischemic ECG changes and negative initial biomarkers. They all underwent contrast enhanced 64-slice MDCT coronary angiography before admission. The results were not compared to the gold standard of catheter angiography. The diagnosis of acute coronary syndrome was made by an expert panel blinded to the results of MDCT, based on the results of serial ECGs, cardiac biomarkers, and subsequent cardiac testing including exercise testing, stress perfusion imaging, or cardiac catheterization during the index hospitalization and 5-months follow-up. The results of the study showed that MDCT had a sensitivity of 100%, specificity of 82%, negative predictive value of 100%, and a positive predictive value of 47% in detecting a significant stenosis. These however, were not verified with catheter angiography for all patients. Two other studies (White et al 2005, and Sato et al 2005) also evaluated MDCT use in small numbers of patients (N=69 and 31 respectively) admitted to ER with chest pain. They used the older 4 and 16 row CT

detectors. Patients included also had non-diagnostic ECGs and normal cardiac enzymes. Invasive angiography was not used as a gold standard. The reference standards used were similar to those discussed earlier. The sensitivities and specificities were 83% and 96% respectively in White's study, and 95.5% and 88.9% respectively in Sato's study. This relatively moderate accuracy indicates that some cases might be missed and others may undergo unnecessary invasive angiograms based on the results of the MDCT.

**In conclusion:** The patient-based analysis of the results of the studies, as presented individually or pooled in meta-analyses show high sensitivity and negative predictive values, but lower specificity and positive predictive value of the MDCT angiograms in the diagnosis of CAD in selected patients. This indicates that the test may be useful in excluding CAD and avoiding a conventional angiography among some patients, but at the expense of up to 25% false positive tests among population groups with a high prevalence of CAD. The latter would overestimate the calculated accuracy and predictive values of the test, and in turn the results may not be generalizable to a broader lower-risk population. There is insufficient evidence to determine whether using the technology to diagnose coronary artery stenosis improves the net health outcomes. The published literature on the use of MDCT angiography in an ER does not provide sufficient evidence to determine the benefits and harms of the test in diagnosing patients presenting with acute chest pain. There are no published data to date on the effect of the using the technology on patient treatment or management decisions. A multicenter study (CorE 64) and a study with long-term healthcare outcomes conducted by the Medical College of Wisconsin are underway.

**Articles:** The search yielded around 55 articles. Many were review articles, opinion pieces, or dealt with technical aspects of the scan. Three meta-analyses published after the last review were identified, as well as several small studies on MDCT with patient sizes ranging from 51 to 129. Four studies (Nikolaou 2006, Plass 2006, Schuijff 2006, and Muhlenbruch 2006) compared the technology with invasive coronary angiography, Dewey et al, compared the 16-slice scanner with exercise electrocardiography, in one study and MRI in another study using the invasive angiography as the gold standard. Four published studies evaluating the use of MDCT for patients presenting to the ER with acute chest pain were identified. None of the latter studies compared the technology to the gold standard of invasive angiography, and only two used the 64-slice CT scans. All meta-analyses and recent studies were reviewed. The meta-analysis that included the most recent studies that used the newest generations of MSCT (> 16 slices), compared MDCT to invasive coronary angiography, and had a valid methodology was critically appraised. A recent study comparing the 64-slice MDCT with invasive angiography, and another evaluating its use in patients presenting to the emergency room with acute chest pain were also selected for critical appraisal. Hamon M, Biondi-Zoccai GG, Malagutti P, et al. Diagnostic performance multislice spiral computed tomography of coronary arteries as compared with conventional invasive coronary angiography. *J Am Coll Cardiol.* 2006;48:1896-1910. Gallagher MJ, Ross MA, Raff GL, et al. The diagnostic accuracy of 64-slice computed tomography coronary angiography compared with stress nuclear imaging in emergency department low-risk chest pain patients. *Ann Emerg Med.* 2006; See [Evidence Table](#).

The use of MDCT in the treatment of coronary heart disease does not meet the *Group Health Medical Technology Assessment Criteria*.

## **06/01/2009: MTAC REVIEW**

### **MDCT in the Treatment of Coronary Heart Disease**

**Evidence Conclusion:** Use of 64-multidetector computed tomography (MDCT) for the diagnosis of coronary artery stenosis in nonemergent settings: The published studies that evaluated the use of MDCT scanners in the diagnosis of coronary artery stenosis had generally valid methodology but were relatively small and mainly conducted among selected patients with stable conditions who were referred for invasive coronary angiography for a known or suspected CAD. The technology was not assessed for screening healthy, asymptomatic, or low-risk individuals. The meta-analyses that pooled the results of the published studies had some variations in their inclusion/exclusion criteria, but a large number of same studies were included in all. The participants in ACCURACY (Budoff 2008) and CORE-64 (Miller 2008) studies, not included in the meta-analyses, were also patients with suspected symptomatic CAD referred for conventional coronary angiography. ACCURACY excluded patients with a known history of CHD, but no exclusions were made based on coronary artery calcium scoring or BMI. On the other hand CORE 64 included patients with or without a history of CAD, and excluded those with coronary artery calcium score >600 or BMI >40. Only coronary artery segments >1.5 mm were included in the analysis. These two studies as well as the other included in the meta-analyses performed patient-based and vessel-based analyses. Per-segment analyses were also performed in several studies. Accuracy of 64-slice MDCT. The patient-based analysis of the results of the studies, as presented individually or pooled in meta-analyses show high sensitivity (85-99%) and negative predictive values (95-100%), but lower specificity (83-91%) and positive predictive value (64-91%) of the MDCT angiograms in the diagnosis of significant (>50%) stenosis of CAD in selected patients. The technology was less sensitive (75-85%) but more specific (90-96%) in detecting

stenosis per vessel. The accuracy of the test varied widely by artery and was highest for the left main artery followed by the left circumflex artery. These results indicate that the test may be useful in excluding CAD and avoiding a conventional angiography among some patients with a suspected disease. This however could be at the expense of more than 20% false positive tests among population groups with a high prevalence of CAD. Impact on management and health outcomes: There was insufficient evidence to determine the effect of 64-slice on patient management or net health outcomes. The published studies to date evaluated MDCT angiography in respect to its accuracy in identifying coronary stenosis, but not its effect on the treatment decisions, patient management, and health outcomes. Use of MDCT to evaluate patients presenting to emergency rooms with acute chest pain. The published literature on the use of MDCT angiography in emergency departments (ED) does not provide sufficient evidence to determine the benefits and harms of the test in diagnosing patients presenting with acute chest pain. Hoffmann 2009 (ROMICAT study), as well as earlier smaller studies that evaluated the use of the technology in the ED, did not compare it to the gold standard of catheter angiography, but used a combination of noninvasive tests and observations as a surrogate gold standard. The ROMICAT study aim was to determine the usefulness of MDCT angiography in patients with acute chest pain who presented to an emergency department and were admitted with low to intermediate risk for acute coronary syndrome. However the results of the CT angiography findings were not provided to the physicians managing the patients, and thus it is not possible to determine whether the management or outcomes would have been altered based on the CT angiography findings. It is uncertain whether the clinicians would have performed less stress tests, more invasive angiograms, treated the patients more or less aggressively, or discharged the patients earlier had they known the results of the CT angiograms.

**Articles:** The search yielded around 325 articles on CT angiography. Many were review articles, opinion pieces, or dealt with technical aspects of the scan. Six meta-analyses published after the last review were identified. Four evaluated the diagnostic performance of the 64-slice CT scanners, one compared the performance of the 16 vs. the 64-slice scanners and another evaluated all 4, 16-slice, and 64 slice CT scanners. Two of the four meta-analyses on 64-slice scanners were performed by the same group of investigators (Mowatt and colleagues), and included the same studies. The literature search also identified two more recent multicenter studies (ACCURACY, and CORE 64) on the accuracy of the 64-slice CT scans in non-emergent settings, and one study on patients presenting to an emergency department (ROMICAT study). None was included in the meta-analyses. There were no published studies that prospectively compared MDCT to other noninvasive stress testing. The most recent valid meta-analysis that compared the performance of 64-slice scanners to invasive coronary angiography was selected for critical appraisal, as well as the newer studies ACCURACY, CORE 64, and ROMICAT. The references for the studies reviewed are: Mowatt G, Cook JA, Hillis GS, et al. 64-slice computed tomography angiography in the diagnosis and assessment of coronary artery disease: systematic review and meta-analysis. ## Clinical Review Criteria

### Cardiovascular Risk Panel

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

**Effective May 1, 2017**

There is insufficient evidence in the published medical literature to show that Cardiovascular Risk Panels provide better long-term outcomes than current standard services/therapies.

Cardiovascular risk panels, consisting of multiple individual biomarkers intended to assess cardiac risk (other than simple lipid panels\*) are considered **not medically necessary**. Some examples of commercially available cardiovascular risk panels include but are not limited to the following:

- Applied Genetics Cardiac Panel
- Atherotech® Diagnostics Lab CVD Risk Panel and VAP Lipid Panel
- Berkeley Heart Lab (a Quest Diagnostics service) Cardio IQ® Lipid Panel
- Health Diagnostics Cardiac Risk Panel
- Boston Heart Diagnostics
- Genova Diagnostics CV Health Plus Genomics Panel
- Genova Diagnostics CV Health Plus Panel
- Metamatrix Cardiovascular Health Profile
- Cleveland HeartLab CVD Inflammatory Profile
- Applied Genetics Cardiac Panel
- Genetiks Genetic Diagnosis and Research Center Cardiovascular Risk Panel
- Quest Diagnostics 4myheart
- Singulex Cardiac Related Test Panels
  - Cardiac Dysfunction panel
  - Vascular Information and Dysfunction panel
  - Dyslipidemia panel
  - Cardiometabolic

\* A simple lipid panel is generally composed of the following lipid measures:

- Total cholesterol
- LDL cholesterol
- HDL cholesterol
- Triglycerides

Certain calculated ratios, such as the total/HDL cholesterol may also be reported as part of a simple lipid panel. Other types of lipid testing, i.e., apolipoproteins, lipid particle number or particle size, lipoprotein (a), etc., are not considered to be components of a simple lipid profile.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

## Background

Cardiovascular risk panels refer to different combinations of cardiac markers that are intended to evaluate risk of cardiovascular disease. There are numerous commercially available risk panels that include different combinations of lipids, noncardiac biomarkers, measures of inflammation, metabolic parameters, and/or genetic markers. Risk panels report the results of multiple individual tests, as distinguished from quantitative risk scores that combine results of multiple markers into one score. While the individual risk factors have in most cases been associated with increased risk of CV disease, it is not clear how the results of individual risk factors impact management changes, so it is also not certain how the panels will impact management decisions. Given the lack of evidence for clinical utility of any individual risk factor beyond simple lipid measures, it is unlikely that the use of CV risk panels improve outcome.

2010 American College of Cardiology Foundation (ACCF)/American Heart Association (AHA) Guideline for Assessment of Cardiovascular Risk in Asymptomatic Adults: Recommendation for Assessment of Lipoprotein Concentrations, Other Lipoprotein Parameters, and Modified Lipids: "Measurement of lipid parameters, including lipoproteins, apolipoproteins, particle size, and density, beyond standard fasting lipid profile is not recommended for cardiovascular disease risk assessment in asymptomatic adults."

## Codes

**The following is a list of codes that will not be covered when billed on a Cardiovascular Risk Panel. This is not an all-inclusive list.**

- 0111T Long-chain (C20-22) omega-3 fatty acids in red blood cell (RBC) membranes
- 0126T Common carotid intima-media thickness (IMT) study for evaluation of atherosclerotic burden or coronary heart disease risk factor assessment
- 0337T Endothelial function assessment, using peripheral vascular response to reactive hyperemia, non-invasive (eg, brachial artery ultrasound, peripheral artery tonometry), unilateral or bilateral
- 0423T Secretory type II phospholipase A2 (sPLA2-IIA)
- 81229 Cytogenomic constitutional (genome-wide) microarray analysis; interrogation of genomic regions for copy number and single nucleotide polymorphism (SNP) variants for chromosomal abnormalities [not covered for cardiovascular disease risk]
- 81240 Prothrombin coagulation factor II
- 81241 Factor V Leiden
- 81225 CYP2C19
- 81291 MTHFR
- 81400 Molecular pathology procedure, Level 1(eg, identification of single germline variant [eg, SNP] by techniques such as restriction enzyme digestion or melt curve analysis)
- 81401 Molecular pathology procedure, Level 2 (eg, 2-10 SNPs, 1 methylated variant, or 1 somatic variant [typically using nonsequencing target variant analysis], or detection of a dynamic mutation disorder/triplet repeat)
- 81479 Unlisted molecular pathology procedure (when utilized with a description of KIF6, 9p21, 4q25-AF, LPA-Aspirin, LPA-Intron 25)
- 82172 Apolipoprotein, each
- 82163 - Angiotensin II
- 82306 Vitamin D; 25 hydroxy, includes fraction(s), if performed
- 82652 Vitamin D; 1,25 dihydroxy, includes fraction(s), if performed

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

82397 Chemiluminescent assay (Leptin)  
82542 Column chromatography, includes mass spectrometry, if performed (eg, HPLC, LC, LC/MS, LC/MS-MS, GC, GC/MS-MS, GC/MS, HPLC/MS), non-drug analyte(s) not elsewhere specified, qualitative or quantitative, each specimen [not covered for cardiovascular disease risk]  
82610 Cystatin C  
82664 Electrophoretic technique, not otherwise classified  
82725 Fatty acids, nonesterified [not covered for cardiovascular disease risk]  
82777 Galectin-3 [not covered for cardiovascular disease risk]  
83006 Growth stimulation expressed gene 2 (ST2, Interleukin 1 receptor like-1)  
83090 Homocysteine  
83520 Immunoassay for analyte other than infectious agent antibody or infectious agent antigen; quantitative, not otherwise specified [adiponectin] [leptin] [interleukin-6 (IL-6)] [tumor necrosis factor alpha (TNF-a)] [Oxidized phospholipids] [interleukin 17] [toll-like receptor 4 (TLR4)]  
83525 Insulin, total [not covered for cardiovascular disease risk]  
83695 Lipoprotein (a) enzyme immunoassay  
83698 Lipoprotein-associated phospholipase A2 (Lp-PLA2)•83700 Lipoprotein, blood; electrophoretic separation and quantitation  
83701 high resolution fractionation and quantitation of lipoprotein subclasses when performed (e.g., electrophoresis, ultracentrifugation)  
83704 quantitation of lipoprotein particle numbers and lipoprotein particle subclasses (e.g., by nuclear magnetic resonance spectroscopy)  
83719 - Lipoprotein, direct measurement; VLDL cholesterol  
83876 Myeloperoxidase (MPO)  
83880 Natriuretic peptid  
85384 Fibrinogen activity  
85385 Fibrinogen antigen

Review not required for Medicare members

#### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Movement disorders are neurological conditions that affect the speed, fluency, quality, and ease of movement. They include a wide range of disorders including, but not limited to, Parkinsonian syndromes (PS) and essential tremor (ET). ET, the most common movement disorder, typically involves involuntary shaking movement with no cause. PS, on the other hand, is a group of neurodegenerative disorders that have similar features and symptoms, of which, the most frequent form is idiopathic Parkinson's disease (PD) accounting for 80% of all PS. Although ET and PS have different underlying etiologies, they present with similar clinical features, especially in the early stages of disease progression, thus complicating diagnostic differentiation. Accurate diagnosis of patients with suspected PS is critical for patient management because the disease course, therapy and prognosis greatly differ from non-degenerative diseases (Dauer and Przedborski 2003; de Lau and Breteler 2006).

Currently, the gold standard for the diagnosis of PS is post-mortem neuropathological examination. In practice, however, diagnosis is based on the presence of two or more classical motor features including bradykinesia, rigidity, tremor, and postural instability which can be atypical or mild in the early stages of the disease. Long-term clinical follow-up and good response to dopaminergic drugs have also been used to support clinical diagnosis (de la Fuente-Fernández 2012). Pathologic studies have shown that the lack of an objective diagnostic tool has resulted in an error rate of 10-30% (Rajput, Rozdilsky et al. 1991). Misdiagnosis can lead to unnecessary disability if effective treatment options are not initiated, and inappropriate therapies may unnecessarily expose patients to the potential side effects thus warranting an early and accurate diagnostic tool to ensure appropriate management.

DaTscan™ is a recent advance in imaging technology that supports the clinician in the differential diagnosis of PS and ET. While there is limited knowledge on the etiology of ET, the main pathological hallmark of PS is the loss of dopaminergic neurons in the substantia nigra, leading to striatal dopamine depletion (Dauer and Przedborski 2003). The DaTscan™ technology is able to determine the location and measure the amount of dopamine transporter (DaT) in the brain. More specifically, through small amounts of a contrast agent called (<sup>123</sup>I)ioflupane and using a single photon emission computerized tomography (SPECT) scanner, DaTscan™ is able to demonstrate reduced striatal uptake of DaT where PS is present and, in contrast, normal striatal uptake in patients with ET. The results of DaTscan™ are not intended to differentiate between different PS disorders, but instead, should be used when diagnosis is inconclusive to rule out other movement disorders with similar presenting symptoms.

In January 2011, the U.S. Food and Drug Administration (FDA) approved the DaTscan™ for striatal dopamine transporter (DaT) visualization using SPECT brain imaging to assist in the evaluation of adult patients presenting with symptoms or signs suggestive of dopaminergic neurodegeneration. In these patients, DaTscan may be used

to help differentiate ET from tremor due to PS and is intended for use as an adjunct to other diagnostic evaluations.

## Medical Technology Assessment Committee (MTAC)

### DaT-SPECT

#### 02/10/2014: MTAC REVIEW

**Evidence Conclusion:** Marshall and colleagues conducted a prospective, longitudinal study. Among 102 patients with an early Parkinsonian syndrome with or without tremor (possible and probable) vs. a combination of patients with non-PD tremor (essential or dystonic tremor) and healthy volunteers. Clinical and DaTscan assessments were made at baseline, 18 month, and 36 month follow-up. The primary endpoint was the baseline DaTscan image assessment by three independent blinded readers as normal or abnormal. The standard of truth was the clinical diagnosis established by two independent movement disorder specialists in consensus, based on the assessment of patients clinical examination videos at 36 months of follow-up. The standard of truth was used to judge whether or not a subject had a striatal dopaminergic deficit (Marshall, Reininger et al. 2009). Ultimately, the study concluded that in the 99 patients who completed all three assessments, on-site clinical diagnosis over-diagnosed degenerative parkinsonism at baseline (sensitivity was 93% and specificity was 46%) compared with the standard of truth clinical diagnosis (sensitivity 78% and specificity 97%). See [Evidence Table](#). Vlaar and colleagues meta-analysis included eight studies that specifically assessed the diagnostic differentiation between PD and ET and concluded that SPECT with presynaptic tracers may accurately differentiate between patients with PD and ET with a reported sensitivity ranging from 88-100% and specificity of 80%-100%. Two of the included studies compared the diagnostic accuracy of the treating physician with the SPECT in its capacity to delineate PD from ET. Initial clinical diagnosis in these trials reached a sensitivity of respectively 76% and 87% and a specificity of 50% and 80%. More often than not, the included studies compared DaTscan diagnoses with clinical diagnoses, and it is not known how often the clinical diagnosis was wrong. Ideally, a study would follow patients until death to confirm diagnosis with autopsy (Vlaar, van Kroonenburgh et al. 2007). See [Evidence Table](#)

**Risks of Diagnostic Test:** The Marshall et al. study, recorded adverse events (AE) at each follow-up visit. During the 36-month period, a total of 4 subjects died and 32 subjects (18%) experienced 71 nonfatal serious AEs, none of which were deemed to be related to the DaTscan. Only 24 (6.0%) AEs, reported by 13 subjects were considered to be related to the DaTscan. The most common AEs were headache (3%), nausea (2%), injection site hematoma (1%), dizziness (1%) and dysgeusia (1%) (Marshall, Reininger et al. 2009). Kupsch and colleagues also collected information on AE in their study which only resulted in two patients with AE that were considered related to the DaTscan. Both of the events, sleep disorder and headache, occurred following administration and prior to imaging and required no treatment (Kupsch, Bajaj et al. 2012). **Impact on Diagnosis and Patient Management:** In practice, clinical diagnosis is sufficient and accurate for many patients with advanced and typical manifestations of PD. There is a subset of patients, however, with suspected PS, particularly those with early-stage disease or atypical signs and symptoms, who theoretically may benefit from further diagnostic evaluation. The recently published, and rigorous evaluation of the impact of diagnostic test on clinical outcomes is a randomized, prospective, multicenter, global (US and Europe), controlled clinical trial conducted by Kupsch and colleagues in 2012. The study sought to demonstrate the impact of (<sup>123</sup>I)ioflupane on clinical management, diagnosis and confidence of diagnosis during a one-year follow-up in 273 patients with clinically uncertain PS of whom 138 were randomized to (<sup>123</sup>I)ioflupane and 135 randomized to no imaging. Significantly more patients in the (<sup>123</sup>I)ioflupane imaging group had at least one change in their actual clinical management after 12 weeks (p=0.002) and after 1 year (p<0.001) compared with patients in the control group. In addition, significantly more (<sup>123</sup>I)ioflupane patients had changes in diagnosis and an increased confidence diagnosis at 4 weeks, 12 weeks and 1 year (all p<0.001) compared with control patients (Kupsch, Bajaj et al. 2012). See [Evidence Table](#). Although the literature reports good accuracy with minimal safety concerns, the studies should be interpreted with caution. It is important to remember that throughout the literature, there was no autopsy confirmation of diagnosis, and thus no confirmed "gold standard". The interpretation of the imaging data is controversial due to inter-reader reliability and the target populations are poorly defined with many studies using clearly defined later-stage patients that are obviously not representative of the FDA indication. Even with the use of the DaTscan, the diagnosis of PS remains a clinical judgment based on imaging technology. Finally, it should be noted that the majority of the literature has received some sort of industry sponsoring. **Conclusion:** The evidence supports high sensitivity and specificity but the lack of a gold standard limits the value of these numbers. There is evidence to indicate that the use of DaTscan™ can sometimes result in changes in diagnosis and treatment, however, there is no evidence to support that these changes result in improved health outcomes.

**Articles:** The literature search for studies on the accuracy of DaTscan in patients with suspected PS revealed almost 200 articles that assessed the DaTscan in a variety of differential diagnostic situations. This search was further narrowed down to include studies that specifically addressed diagnostic differentiation between PS and ET. For the most part, the literature was comprised of studies that were small with limited methodology due to a lack of gold standard for diagnosis.

The following articles were selected for critical appraisal:

Marshall VL, Reininger CB, Marquardt M et al. Parkinson’s Disease is overdiagnosed clinically at baseline in diagnostically uncertain cases: A 3-year European multicenter study with repeat [<sup>123</sup>I]-FP-CIT SPECT. *Movement Disorders*. 2009;**24**(4):500-508. See [Evidence Table](#). Vlaar AM, van Kroonenburgh MJ, Kessles AG, et al. Meta-analysis of the literature on diagnostic accuracy of SPECT in parkinsonian syndromes. *BMC Neurol* 2007;**7**:27. See [Evidence Table](#). Kupsch AR, Bajaj N, Weiland F, et al. Impact of DaTscan SPECT imaging on clinical management, diagnosis, confidence of diagnosis, quality of life, health resource use and safety in patients with clinically uncertain parkinsonian syndromes: a prospective 1-year follow-up of an open-label controlled study. *J Neurol Neurosurg Psychiatry*. 2012;**83**:620-628. See [Evidence Table](#).

The use of DaT-SPECT does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Deep Brain Stimulation

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Deep Brain Stimulation for Essential Tremor and Parkinson's Disease (160.24)</a>
Local Coverage Determinations (LCD)	None

##### For Non-Medicare Members

Group Health has elected to use the Deep Brain Stimulation (GHC-0403) (MCG)\* for medical necessity determinations.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (neurology, neuro surgeon)

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies:

- Refractory Obsessive - Compulsive Disorder
- Primary Headache
- Neuropathic Pain (see GHC-0403)

[\(See also Occipital Nerve Stimulation for Primary Headache\)](#)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Deep-brain stimulation (DBS) was first developed in the late 1980's. DBS involves ongoing electrical stimulation of a particular target in the brain and is designed to block the abnormal firing of neurons. The exact mechanism of action of DBS is not known. DBS has been used since the early 1990s to treat movement disorders such as Parkinson's disease, and, in 1999, the first report was published applying DBS to the treatment of refractory obsessive-compulsive disorder.

DBS consists of an insulated wire lead with four electrodes at its end that are surgically implanted into the affected area of the brain. A wire runs under the skin to a battery-operated pulse generator implanted near the collarbone or in abdomen. The generator is programmed to send continuous low voltage electrical pulses to the brain. It can be turned on or off when the patient swipes a special magnet over the generator. (Movement disorders patients typically turn off the device at night, because tremors usually stop during sleep.) The voltage can be adjusted in relation to the symptoms being treated.

To implant the electrodes, a neurosurgeon uses a stereotactic head frame and magnetic resonance or computed tomography imaging to map the brain and pinpoint the problem area. The patient's scalp is anesthetized before

the procedure, but the patient is awake to report side effects while the electrodes are placed. This allows the lead to be placed for maximum effectiveness and minimum side effects.

## Medical Technology Assessment Committee (MTAC)

### **Electrical Stimulation of the Thalamus for Essential and Parkinsonian Tremor**

#### BACKGROUND

Essential tremor is the most common form of tremor that affects more than 1 million patients in the US. It is defined as tremor which is postural, usually involving the upper limbs, absent at rest, not exacerbated by movement and not of cerebellar or extrapyramidal origin. One of the symptoms of Parkinson's Disease is tremor. Treatment for mild cases of tremor involves pharmacologic therapy with propranolol or L-dopa for Parkinsonian tremor. Severe debilitating tremor is usually treated with stereotactic surgical thalamic ablation (thalamotomy). However, thalamotomy can result in clinically significant neurologic side effects and once lesioned, no further tremor control is possible. The beneficial effects of thalamic stimulation on tremor were first identified when stimulation was used to localize the electrode prior to making a lesion in the thalamus for tremor control.

Electrical tremor control systems consist of an electrode implanted in the thalamus connected to an implanted radio-frequency pulse generator. The stimulator is programmed for optimal tremor control by a Neurologist and can be turned on or off by the patient using a magnet.

#### 04/19/1999: MTAC REVIEW

##### **Electrical Stimulation of the Thalamus for Essential and Parkinsonian Tremor**

**Evidence Conclusion:** Several case series have been published examining the role of thalamic stimulation in essential tremor and in Parkinson's disease. It is clear that stimulation reduces contralateral upper limb tremor to a clinically significant extent. In essential tremor improvement was noted when performing activities such as writing, drinking and eating. Although quality of life was not formally assessed the degree of change is likely to be clinically important. In Parkinson's disease the utility of reducing tremor is less clear, with no change in ability to write, dress, cut food, or speak. Perioperative complications occur in approximately 10%, and at 12 months neurologic complications related to stimulus intensity are common, each of the following occurring in 2-4%: dystonia, dysarthria, parasthesia, and disequilibrium.

**Articles:** Koller, W, et al, High Frequency Unilateral Thalamic Stimulation in the Treatment of Essential and Parkinsonian Tremor, *Ann Neurol.* 1997, 42:292-299 See [Evidence Table](#). Limousin, JD et al, Multicentre European Study of Thalamic Stimulation in Parkinsonian and Essential Tremor. *J Neurol. Neurosurg Psychiatry.* 1999;66:289-296 See [Evidence Table](#). Ondo, W et al. Unilateral Thalamic Deep Brain Stimulation for Refractory Essential Tremor and Parkinson's Disease Tremor. *Neurology*, 1998;51:1063-1069 See [Evidence Table](#).

Members noted that patients who had debilitating non-tremor symptoms of Parkinson's disease such as rigidity and cogwheel movements would probably not show clinically significant improvements in their ability to eat, write or drink and therefore the benefits of thalamic stimulation would probably not outweigh the harms of this invasive surgical procedure in this population.

Electrical stimulation of the thalamus for the treatment of essential tremor meets GHC Medical Technology Assessment Criteria 1-5 for effectiveness and 6 for appropriateness and is therefore considered to be medically appropriate for patients who have failed maximal medical therapy for controlling their tremor.

Thalamic stimulation for treatment of Parkinsonian tremor also meets GHC Medical Technology Assessment Criteria 1-6 only for patients whose primary functional disability is tremor despite maximal medical therapy.

#### 10/03/2006: MTAC REVIEW

##### **Electrical Stimulation of the Thalamus for Essential and Parkinsonian Tremor**

**Evidence Conclusion:** The evidence on deep brain stimulation for treating Parkinson's disease consists of two randomized controlled trials. Both studies had results favoring deep brain stimulation. The stronger study methodologically found a statistically significant reduction in motor symptom scores in the group assigned to deep brain stimulation in a double-blind comparison to no stimulation (Deep Brain Stimulation Study Group, 2001).

However, Medtronic, the device manufacturer funded the study and was responsible for data collection and analysis. The other randomized controlled trial found more improvement in quality of life and symptom severity scores in patients assigned to neurostimulation compared to medical management (Deuschl et al., 2006). Limitations of the latter study are the study was not blinded and study participants had already failed medical management. The Deuschl study was not funded by Medtronic, but several authors had financial links with the company.

**Articles:** Deuschl G, Schade-Brittinger C, Krack P et al. A randomized trial of deep-brain stimulation for Parkinson's Disease. *N Engl J Med* 2006; 355: 896-908. See [Evidence Table](#).

Evidence updated but not brought to MTAC as no change from previous review outcome.

### ***Globus Pallidus and Subthalamic Nucleus Stimulator Implant***

#### **BACKGROUND**

Deep brain stimulation (DBS) is a technique that is being used to treat symptoms of Parkinson's disease (PD). The main pharmacotherapy for PD is levodopa. Although levodopa is generally initially effective at reducing symptoms of PD, it eventually leads to side effects such as dyskinesias in many patients. Surgeries such as thalamotomy, pallidotomy are other possible treatments. An advantage of DBS is that, unlike other surgeries, it does not create lesions or destroy brain tissue.

Deep brain stimulation involves implanting an electrode into a specific region of the brain using stereotactic neurosurgical techniques. The electrode is connected to a programmable pulse generator that generates high frequency stimulation (>100 Hz) in a target nucleus. The pulse generator is implanted below the clavicle.

Thalamic stimulation, used to treat tremor, is the most well established application of DBS with Parkinson's patients (thalamic stimulation for tremor met MTAC evaluation criteria in April, 1999). Other targets are the internal globus pallidus and subthalamic nucleus which are believed to be effective for treating a wider range of PD symptoms, including bradykinesia, rigidity dystonia and gait disorder, as well as tremor.

Medtronic, Inc. manufactures the device that provides deep brain stimulation (the Activa System). The FDA approved a version of this device in 1997 for stimulation of the thalamus to control Parkinson's tremor and essential tremor. In March 2000, an FDA panel gave a premarket approval with conditions for bilateral DBS for the treatment of other Parkinson's symptoms.

#### **10/10/2001: MTAC REVIEW**

##### **Globus Pallidus and Subthalamic Nucleus Stimulator Implant**

**Evidence Conclusion:** The highest quality evidence consisted of one study that had a double-blind randomized component. In the double-blind randomized assessment, the study found a statistically significant reduction in motor symptom scores during deep-brain stimulation of the subthalamic nucleus or pars interna of the globus pallidus compared to no stimulation. The case series portion of the study found that symptoms improved significantly with stimulation 3 and 6 months post-implantation compared to pre-implantation. There were a substantial number of adverse effects but no comparison with adverse effects with other treatments or no treatment. A limitation of the study was that Medtronic, the device manufacturer, not only funded the study but also was responsible for data collection and analysis.

**Articles:** The search yielded 146 articles, many of which were review articles, opinion pieces, dealt with technical aspects of the procedures or addressed other, similar treatments. There were a number of small studies (n=25 or less), mainly case series; one was an RCT with n=10. The strongest study was published after the formal search was conducted. This study included a randomized double-blind assessment of outcomes and the sample size was over 100. This partially randomized study was critically appraised: Deep-brain stimulation for Parkinson's disease study group. Deep-brain stimulation of the subthalamic nucleus or the pars interna of the globus pallidus in Parkinson's disease. *N Engl J Med* 2001;345: 956-63. See [Evidence Table](#).

The use of Globus Pallidus and Subthalamic Nucleus Stimulator Implant in treatment of Parkinson's Symptoms does meet the *Group Health Medical Technology Assessment Criteria*.

### ***Refractory Obsessive-Compulsive Disorder***

#### **BACKGROUND**

Obsessive-compulsive disorder is a common psychiatric diagnosis, affecting approximately 3% of people worldwide (Burdick et al., 2009). For initial treatment of OCD, the American Psychiatric Association (APA) recommends cognitive behavioral therapy (CBT), pharmacotherapy with SSRIs, or a combination of the two. For patients who do not respond to monotherapy, the next step is either switching medications, augmenting with another medication, or adding CBT if not already initiated (Harvard Medical Letter, 2009).

Approximately 20-40% of patients have worsening symptoms despite conventional treatment. Surgery is an option for patients who experience severe and incapacitating symptoms in spite of multiple medication trials and/or medication and CBT. Primary surgical approaches are subcaudate tractotomy (creating a lesion beneath the head of the caudate nucleus in the substantial innominata), cingulotomy (radiofrequency ablation of the anterior cingulum), limbic leucotomy (combination of previous two procedures), and anterior capsulotomy (interrupting fibers between the thalamus and the anterior frontal lobe) (Burdwick et al., 2009).

Another potential alternative therapy for treatment-resistant patients is deep brain stimulation (DBS). DBS involves chronic electrical stimulation of a particular target in the brain and is designed to modulate transmission of the neural circuit. The exact mechanism of action of DBS is not known and this is an area of active research. DBS has been used since the early 1990s to treat movement disorders such as Parkinson's disease, and, in 1999, the first report was published applying DBS to the treatment of refractory OCD. The optimal target for DBS in OCD patients is still being determined (Burdwick et al., 2009).

In February, 2009, the FDA approved a humanitarian device exemption for a deep brain stimulator for severe OCD by Medtronic (Reclaim device). The humanitarian device exemption is an FDA classification signifying that the technology is used to treat conditions that affect fewer than 4,000 new patients per year. The FDA reviews the safety of the device, but does not require that efficacy is established before approval. The FDA decision stipulates that deep brain stimulation is indicated for treatment of OCT in adult patients who have failed at least three SSRIs, and it can be used as an adjunct to medication. DBS is contraindicated in patients exposed to diathermy or MRIs, or who are unable to properly operate the brain stimulator. Medtronic plans to release the product commercially in the United States in mid-2009 (Medtronic website; FDA documents).

The Reclaim device by Medtronic includes a neurostimulator that is implanted subcutaneously in the upper abdominal region. The neurostimulator produces electrical stimulation pulses that are carried to an implanted set of leads via a lead extension. The leads are stereotactically introduced into the target area of the brain, and are fixed at the skull with a burr hole cap and ring. The neurostimulator is battery-powered. There are sparse clinical data on battery life. According to Medtronic, the battery is expected to last 6-16 months, or longer depending on the neurostimulator setting used. When the battery is depleted, it can be replaced surgically. The primary clinical data submitted by Medtronic for FDA approval was a case series of 26 patients treated at 3 centers in the US and one in Europe (FDA and Medtronic documents).

#### **06/01/2009: MTAC REVIEW**

##### **Deep brain stimulation for the treatment of refractory obsessive-compulsive disorder**

**Evidence Conclusion:** There is insufficient evidence to draw conclusions about the safety and effectiveness of deep brain stimulation for patients with refractory obsessive-compulsive disorder. The empirical literature consists of case series with 10 or fewer patients.

**Articles:** The Medline search limited to a range of clinical trials yielded 10 articles. No additional articles were identified on the manufacturer's Web site. There were no randomized controlled trials or non-randomized comparative studies. The empirical literature consisted of small case series, with sample sizes ranging from 4 to 10. The studies do not meet MTAC criteria for reviewable evidence which requires that studies are published and, for case series, has a minimum sample size of 25.

The use of Deep brain stimulation for the treatment of refractory obsessive-compulsive disorder does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **Primary Headache**

##### **BACKGROUND**

Headache is a major worldwide health problem disabling millions of people and resulting in considerable economic burden. Up to 40% of patients seen in major headache clinics suffer from chronic daily headache. Chronic headache disorders include migraine, cluster headache, cervicogenic headache, occipital neuralgia, and others types of primary headache (Maizels 1998, Jasper 2008).

Cluster headache (CH), an excruciating headache syndrome, is the most common type of trigeminal autonomic cephalalgias, and is thought to be the most severe primary headache disorder. 10-20% of CH patients develop a chronic form in which the attacks persist for more than one year without remissions, or with remissions lasting less than a month. Acute treatment for the attacks includes injectable or intranasal triptans or oxygen inhalation. About one percent will become refractory to medical treatment and fulfill the criteria of intractable headaches. These patients may get some relief with attack treatments, but the disorder could be disabling and may be associated with depression and suicidality (Magis 2007, Leroux 2008).

Migraine headache is a chronic headache that affects about 15% of the population and is one of the most common problems seen in emergency departments and doctors' offices. Migraine is believed to result from changes in the brain and surrounding blood vessels. The attacks typically last from 4-72 hours and vary in frequency from daily to less than one per year. Transformed migraines are chronic daily or almost daily headaches (>15/month) that lasts more than 4 hours. There is no cure for migraine, and medications can only help reduce the frequency and severity of disorder (Bigal 2008).

Cervicogenic headache is a chronic hemicranial pain that usually occurs daily. It usually begins at the suboccipital region and spreads anteriorly to the ipsilateral orbital, frontal, and temporal areas. It is typically unilateral but occasionally affects the two sides. It is believed to be due to convergence of upper cervical and trigeminal sensory pathways allowing pain signals to refer from the neck to the trigeminal sensory fields of the head and face. Treatments with pain medication, physical therapy, manipulative treatment, and surgical interventions may provide only some inconsistent temporary relief of pain (Naja 2006).

Various ablative surgical procedures targeting the trigeminal nerve or the cranial parasympathetic outflow have been tried to treat these patients with intractable headaches. These include gamma knife surgery or root section of the trigeminal nerve, trigeminal tractotomy, microvascular decompression of the trigeminal nerve, glycerol injection of the Gasserian ganglion, and others. However, none of these procedures has a consistent effect, and many are associated with serious complications (Magis 2007).

Electrical stimulation of the brain was first attempted late in the 19th century, but its application for pain control began in the 1960s with spinal cord stimulation. The neurostimulation technique for ablating pain is based on the theory that peripheral nerve stimulation can produce specific focal analgesia and anesthesia. In addition, the technique may alter perception of pain by blocking cell membrane depolarization and axonal conduction with directly applied current (Shealy 1967, Lim 2007, Trentman 2008).

In the early 2000s, neurostimulation therapy emerged as a potential treatment option for a variety of different intractable primary headache disorders. This is an invasive device-based approach that has two broad types:

1. Peripheral therapy that involves branches of the occipital nerve: occipital nerve stimulation (ONS), and supraorbital nerve stimulation.
2. Central which refers to deep-brain stimulation (DBS) approaches e.g. hypothalamic deep brain stimulation used for chronic cluster headache (Schwedt 2009).

The occipital nerve stimulators (ONS) are implanted surgically in a 3 phase procedure: Phase 1. An incision is made over the occipital region at the level of the first cervical vertebra for the subcutaneous implantation of bilateral electrodes. These are tunneled in a cephalad direction so that they come to lie across the path of the greater occipital nerve on each side of the head. Phase 2. Confirmation of the electrode position by testing each separately by an external stimulator. The operator gradually increases the amplitude delivered to the electrodes from 0 to 4 v, and the patient is asked to locate and describe any sensation he /she feels. Correct placement is confirmed by the patient describing a vibrating sensation that radiates at least 4 cm cephalad from the base of the skull, on the side of the tested electrode, and Phase 3. Implantation of the stimulator battery in the pectoral, abdominal, or gluteal region, and connecting it to the electrodes via subcutaneously tunneled leads. The procedure is performed under sedation or general anesthesia, however during the second phase the patients are required to be awake and to be able to identify the position of the occipital electrodes when the electric stimulus is applied. Potential complications of the procedure include lead migration, infection, localized pain, muscle spasm, and lack or loss of effect (Lim 2007, Trentman 2008).

The deep brain stimulation (DBS) of the posterior hypothalamus has been investigated in patients with chronic cluster headaches or SUNCT (short-lasting, unilateral, neuralgiform headache attacks with conjunctival injection and tearing). DBS involves MRI guided stereotactic placement of an electrode into the brain (e.g. thalamus, globus pallidus, or subthalamic nucleus). It is typically implanted unilaterally on the side corresponding to the most severe symptoms. The use of bilateral stimulation using two electrodes has been investigated in patients with bilateral, severe symptoms. Initially, the electrode(s) is/are attached to a temporary transcutaneous cable to validate treatment effectiveness and, if effective, the patient returns to surgery several days later for permanent subcutaneous implantation of the cable and a radiofrequency-coupled or battery-powered programmable stimulator. After implantation, noninvasive programming of the neurostimulation can be adjusted to control the patient's symptoms. The procedures can be performed only by a highly experienced neurosurgeon and may be associated with a small risk of mortality due to intra-cerebral hemorrhage. Before implantation, all patients must undergo complete preoperative neuroimaging to exclude disorders associated with increased hemorrhagic risk (Leon 2006, Bartsch 2008).

Neither the occipital nerve stimulation nor the deep brain stimulators are approved to date by the U.S. Food and Drug Administration for the treatment or prevention of primary headaches.

**08/03/2009: MTAC REVIEW**

**Deep Brain Stimulation for the Treatment of Primary Headache**

**Evidence Conclusion:** The literature on brain stimulation for the treatment of chronic primary headache is limited and does not provide sufficient evidence to determine the efficacy or safety of either occipital or deep brain stimulation therapy for the prevention or treatment of chronic headache. There are no published randomized or nonrandomized controlled trials on the intervention to date. The empirical studies consist of a few very small case series with no comparison groups and a number of case reports. The outcome measures varied between studies as some reported change in pain and others reported on headache frequency intensity, disability and/or medication use. To date all published studies on hypothalamic deep brain stimulation are small case series and case reports with a combined total of 55 participants with refractory chronic cluster headache. Leone et al’s series had the largest size (N=16) and follow-up duration (mean 23 months). The results of this study and other case series indicate that this invasive procedure has potential serious complications, and is not always effective. Deep brain stimulation was not compared to another treatment or intervention to determine that the benefit observed was no a placebo effect.

**Articles:** The search yielded almost four hundred articles. The majority was review articles, opinion pieces, or dealt with technical aspects the procedure. DBS: The search identified 12 small case series and reports with a total number of 57 patients on deep-brain stimulation for chronic cluster headache. Leone M, Franzini A, Broggi G, et al. Hypothalamic stimulation for intractable cluster headache; long-term experience. Neurology 2006;67:150-152. See [Evidence Table](#).

The use of Deep brain stimulation for the treatment of primary headache does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Defecography for Diagnosing Defecation Disorders

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

##### National Coverage Determination (NCD)

[Magnetic Resonance Imaging \(220.2\)](#)

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Defecation is a highly complex physiologic process that requires normal colonic transit, ano-rectal sensation, expulsion force, and coordinated function of the pelvic floor for successful evacuation. A disturbance at any level of this process can lead to a defecation disorder (DD) ([Maccioni 2013](#)). DDs encompass a variety of clinical conditions including obstructed defecation syndrome, rectocele, rectal intussusception, rectal prolapse and enterocele. Patients typically report symptoms such as excessive straining, sensation of blockage, and a feeling of incomplete evacuation. Some patients even report a need to use digital maneuvers to defecate, and frequent use of enemas or suppositories. While the true prevalence of DD is unknown, the symptom of constipation is extremely common in the United States with a reported 5.7 million constipation-related physician visits in 2006 alone. While not life threatening, DDs can cause a considerable amount of morbidity and, in some cases, have devastating impacts on quality of life.

In most cases, diagnosis of DDs can be established accurately based on physical examination and detailed history. However, symptoms can be nonspecific and overlapping. While there is no gold standard for pinpointing the cause of DD, current practice guidelines from national bodies recommend physiological testing such as anorectal manometry (ARM) and rectal balloon expulsion tests (BET). In the event of equivocal results, however, direct visualization of the pelvic floor and lower bowel may be necessary ([AGA 2013](#); [Wald, Bharucha et al. 2014](#)). Defecography, first described in 1952 by Wallden, was initially developed for the evaluation of outlet obstruction ([Wallden 1952](#)). Since then, however, defecography has evolved to not only detect structural abnormalities, but also to assess functional parameters. Although it has been recognized as a useful diagnostic technique, methods and interpretation of defecography have not yet been standardized. Conventionally, the technique involves placement of a contrast medium into the rectum, similar to the consistency of stool, and laterally imaging activity throughout defecation using fluoroscopy. Alternatively, defecography can also be performed in the supine or upright position with magnetic resonance imaging (MRI). In any case, interpretation of the imaging focuses on the anal rectal angle (ARA) at rest and during straining providing an indirect measurement of the function of the puborectalis muscle. Additionally, imaging can provide information about perineal descent, anal diameter, indentation of the puborectalis, and the amount of rectal and rectocele emptying.

#### Medical Technology Assessment Committee (MTAC)

##### Defecography for Diagnosing Defecation Disorders

##### 10/20/2014: MTAC REVIEW

**Evidence Conclusion:** A 2011 study conducted in France by Vitton and colleagues compared the accuracy of both MRI defecography and dynamic anal endosonography (DAE) using conventional defecography as the gold standard. The study involved 56 female patients with a history of dyschezia. Patients received each procedure randomly over a one month period. Using conventional defecography as the criterion standard, the investigators calculated a range of sensitivities and specificities for detecting rectoceles, perineal descent, and enterocele. For

both DAE and MRI, the sensitivities were highest in detecting rectoceles at 73.5% and 81.6%, respectively. For detecting perineal descent and enterocele the sensitivities were 61% and 58.3% for DAE and 46.3% and 66.7% for MRI. Specificities were 100% in both DAE and MRI for identifying enteroceles. The specificities were lower for perineal descent 73.3% (DAE) and 86.7% (MRI) and rectoceles 85.7% (DAE) and 85.7% (MRI). Although MRI defecography performed better than DAE no significant differences were observed between the diagnostic techniques and both correlated well with conventional defecography under the Youden index and the Yule correlation coefficient. Regardless, conventional defecography is an imperfect gold standard limiting the value of these results (Vitton, Vignally et al. 2011). Foti and colleagues also prospectively compared conventional and MRI defecography. In this study, 19 consecutive patients with outlet obstruction syndrome (OOS) underwent both conventional and MRI defecography. With the overall aim to develop a protocol for MRI defecography the comparisons between the two techniques showed no significant differences in sphincter hypotonia, dyssynergia, rectocele and rectal prolapse. Significant differences were, however, seen in descending perineum. Ultimately, the authors concluded that while MR imaging provides morphological and functional study of pelvic floor structures it cannot replace CD and may offer benefit if offered as a complementary tool to CD in evaluating OOSs (Foti, Farina et al. 2013). In a meta-analysis that sought to estimate the prevalence of abnormal findings associated with dyssynergic defecation across testing modalities, 79 studies including 7,581 patients were pooled and analyzed. The overall prevalence of any single abnormal dynamic pelvic floor test ranged from 14.9% to 52.9% with a median of 37.2%. The investigators note that the prevalence of abnormal tests tended to be lower in defecographic studies accounting for the lower end of this range. In addition to identifying a high prevalence of dyssynergic defecation in patients with chronic constipation, the investigators suggest that the lower prevalence of abnormalities found with defecography supports the use of ARM and BET for initial evaluation (Vidlock, Lembo et al. 2013). None of the selected studies overtly assessed the safety and harms of defecography however, theoretically, the harms of conventional defecography include all those that we know to be associated with radiation exposure. In the study by Vitton and colleagues, patient tolerance and preference for assessment procedures was examined using a visual analogue scale. Tolerance was rated "high" or "very high" more frequently in the MRI defecography group (44.9%) than in the conventional defecography group (36.7%), although this difference was not significantly significant ( $P=0.9$ ). This partiality was mirrored in a 2012 study, by Pilkington and colleagues, assessing patient acceptance of conventional and MRI defecography. In this study, the investigators administered questionnaires to 42 patients undergoing defecography (of these patients 25 patients completed for both conventional and MRI defecography). Over half of patients (62%) who underwent both procedures identified MRI proctography as the preferred technique. When asked why, all of these patients cited 'less embarrassing' as the reason for preference (Pilkington, Nugent et al. 2012). The clinical utility of diagnostic tests for constipation in adults was examined in a 2005 systematic review by Rao and colleagues. The investigators were able to identify ten case series related to the use of defecography. Although the results of the included studies did not allow for meta-analysis, the investigators found the results of the included studies to be conflicting citing significant overlap of findings between patients and healthy controls and poor correlation of symptoms with defecographic findings. Ultimately, defecography was recognized as a useful source of information regarding the anatomical and functional changes of the anorectum but concluded that the technique should only be regarded as an adjunct to clinical assessment and not relied upon as a sole diagnostic test. This study was not critically appraised due to lack of meta-analysis (Rao, Ozturk et al. 2005). Overall, the literature should be interpreted with caution. Beyond the heterogeneous nature of the populations across the literature, an inherent difficulty of evaluating the accuracy of defecography is that there is the lack of a true gold standard. To add to this, diagnostic criteria are continually changing inhibiting the ability to establish a standard technique or interpretation. Without adequately defined ranges for quantified measures and parameters interpretation relies on opinion rather than objective findings. Beyond that, no studies have been able to demonstrate that defecography contributes to improved diagnosis and more appropriate patient management.

**Conclusions:** There is insufficient evidence to conclude that defecography is accurate in the evaluation of DD. There is insufficient evidence to conclude that defecography is not harmful to patients. There is insufficient evidence to conclude that defecography contributes to improved diagnosis of DD. There is insufficient evidence to conclude that defecography leads to more appropriate management of patients with DD.

**Articles:** The literature search revealed just over 200 publications addressing defecography, the majority of which were continuing medical educational materials, manuscripts or editorials. The remainder was comprised of small studies either describing various techniques or attempting to establish standards for interpretation. No studies were identified that aimed to assess the accuracy of conventional defecography by comparing the technique to other available techniques. The best available evidence came from two prospective studies comparing conventional defecography with MRI defecography and one meta-analysis comparing different testing modalities in the assessment of chronic constipation. The following articles were selected for critical appraisal: Vitton V, Vignally P, Barthet MB, et al. Dynamic anal endosonography and MRI defecography in diagnosis of pelvic floor disorders: comparison with conventional defecography. *Diseases of the colon & Rectum* 2011;(54)11:1398-1404. See [Evidence Table 1](#). Foti PV, Farina R, Riva G, et al. Pelvic floor imaging: comparison between magnetic resonance imaging and conventional defecography in studying outlet obstruction syndrome. *Abdominal Radiology*

2013;(118)1:23-39. See [Evidence Table 2](#). Videlock EJ, Lembo A, Cremonini. Diagnostic testing for dyssynergic defecation in chronic constipation: meta-analysis. *Neurogastroenterology & Motility* 2013;(25)6:509-519. See [Evidence Table 3](#).

The use of Defecography for Diagnosing Defecation Disorders does not meet the *Group Health Medical Diagnostic Test Assessment Criteria*.

## Clinical Review Criteria

### Dermatology Services

Cosmetic vs Medical for the following:

- Alopecia, Keloids, Laser Treatments, Benign Lesions
- Broad Band UVB Therapy
- Excimer Laser for Vitiligo
- Home Narrow Band UVB Therapy for Psoriasis
- Narrow Band UVB Therapy
- PUVA Therapy
- UV Lights

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Laser Procedures (140.5)</a> <a href="#">Treatment of Psoriasis (250.1)</a> <a href="#">Treatment of Actinic Keratosis (AKs) (250.4)</a> <a href="#">Scalp Hypothermia During Chemotherapy to Prevent Hair Loss (110.6)</a> <a href="#">Skin Lesion Removal (Excludes AK and Excludes MOHS) (L33979)</a>
Local Coverage Determinations (LCD)	<a href="#">Non-Covered Services (L35008)</a> . And for facility-based services billed using a UB form, see <a href="#">Non-Covered Services (L34886)</a>

#### For Non-Medicare Members

- 1) The following treatments are considered cosmetic and are therefore not covered:
  - a) Botulinum injections for treatment of wrinkles and facial imperfections (for covered indications for botulinum injections see the pharmacy prior authorization criteria)
  - b) Tattoo removal CPT 15783
  - c) Laser treatment of pigmented lesions, rosacea, superficial leg and face veins, cherry angiomas, telangiectasias, spider angiomas, or spider veins/venous ectasias
  - d) Chemical peel (CPT 15788, 15789, 15792, 15793, 17360)
  - e) Micro-dermabrasion (No codes specific for this service)
  - f) Dermabrasion (CPT 15780, 15781, 15782, 15783, 15786)
  - g) Acne scar repair (CPT 15780)
  - h) Tattooing, depigmentation, and melanocyte transplant for vitiligo
  
- 2) The following treatments are covered and are not considered cosmetic when conditions are met:
  - a) **Alopecia treatment** when the alopecia results from:
    - Infection (treatment is for the infection)
    - Autoimmune disorder
    - Discoid lupus
    - Low iron stores
    - Folliculitis decalvans
  - b) **Laser treatment for ONE of the following:**
    - Port wine stain on head or neck
    - Telangiectasias scarring when caused by removal of skin cancer or radiation therapy

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

- Facial angiofibromas secondary to tuberous sclerosis
  - Vascular lesions with history of spontaneous bleeding as documented in the patient's medical record
  - Actinic Keratoses (AK) for chemosensitive agents
- c) **Excimer Laser** (CPT code 96920, 96921, 96922 ) is covered when **ALL of the following** are met:
1. Member must have **one** of the following conditions:
    - a. Vitiligo dx 709.01 - vitiligo on the face, neck and hands.
    - b. Psoriasis: scalp, face, neck & hands
  2. There must be documentation of the failure of medical management with topical therapy
- d) **Scar/keloid revision:** Group Health has elected to use the Scar Revisions (GHC-0495) MCG\* for medical necessity determinations.
- e) Removal of **benign skin lesions** (seborrheic keratoses, skin tags, milia, molluscum contagiosum, sebaceous (epidermoid) cysts, moles (nevi), acquired hyperkeratosis (keratoderma) and viral warts (excluding condyloma acuminatum)) as medically necessary and not cosmetic is covered when **ONE or more of the following** criteria are met:
- The clinical diagnosis is uncertain, particularly where malignancy is a realistic consideration based on lesional appearance (non-responsive to conventional treatment or change in appearance).
  - The lesion has **ONE** or more of the following characteristics:
    1. Bleeding
    2. Intense itching
    3. Pain
    4. Has physical evidence of inflammation (purulence, oozing, edema, erythema, etc.)
    5. Clinically restricts an orifice or vision
    6. Is in an anatomical region subject to recurrent physical trauma and there is documentation of resulting pain, itching, or bleeding
    7. The lesion is infectious (e.g. warts [verruca vulgaris])
- f) Laser/intense **pulse light treatment** is covered for hair removal when the excess hair is a result of a documented endocrine abnormality confirmed by blood test.(may be billed with CPT 17999)
- g) **PUVA:** Group Health has elected to use the Skin Phototherapy (GHC-0253) MCG\* for medical necessity determinations. CPT code 96912, 96913
- h) **UVA:** Group Health has elected to use the Skin Phototherapy (GHC-0255) MCG\* for medical necessity determinations. CPT code 96900
- i) **Home narrowband UVB phototherapy** for psoriasis is covered to the benefit limit when:
- The member has durable medical equipment coverage and the light is ordered by a Dermatologist
- \*Dx of eczema will be reviewed on a case-by-case basis

### Electronic Brachytherapy for non-melanoma skin cancer

\* **MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

### **If requesting this service, please send the following documentation to support medical necessity:**

- Last 6 months of clinical notes from requesting provider &/or specialist (dermatology, surgery notes)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## **Background**

Dermatology services include a wide array of therapies. Some therapies are purely cosmetic, others are considered from a benefits standpoint to be "medically necessary" and relate to function and/or have an impact on an individual's physical, social and/or mental well-being.

The purpose of expanding the criteria set is to distinguish between dermatology services that are considered purely cosmetic versus those which are seen as medically necessary and are covered in part or whole. The creation of the criteria set incorporated what was previously found in coverage policy and other reference documents.

## **Medical Technology Assessment Committee (MTAC)**

### **Home Narrowband UVB Phototherapy**

Date Sent: February 28, 2017

## BACKGROUND

Psoriasis is a chronic skin disease that affects 1-3% of the population. With psoriasis, the life cycle of skin cells are shortened from about a month to a few days. Consequently, cells build up rapidly on the outer layer of skin, forming thick erythematous plaques that are often pruritic. (Mayoclinic.com; BMJ clinical evidence). Treatments for psoriasis include: 1) self-care: baths, avoidance of alcohol, moisturizer; 2) topical medications: corticosteroids, vitamin D analogues, anthralin, retinoids; 3) oral medications: retinoids, methotrexate, azathioprine, cyclosporin, immunomodulator drugs (biologics); 4) phototherapy; 5) combination therapy e.g. phototherapy and oral medications. The biologic Etanercept is current covered by GHC for patients with extensive, severe psoriasis who meet the following criteria: failed topical treatments, failed at least one systemic agent (e.g. methotrexate), and failed a 12-week course of phototherapy. Phototherapy is one of the more commonly used treatments for psoriasis. The rationale behind phototherapy is that it causes photochemical reactions of endogenous absorbing molecules results in reduction of DNA synthesis that leads to a treatment effect. The therapy was first proposed in the 1920s by Dr. Goeckerman at the Mayo clinic who found a beneficial effect of natural sunlight in combination with coal tar. In the 1970s, it was shown that broadband ultraviolet B (UVB) radiation alone could treat milder clinical forms of psoriasis. After experimentation with different wavelengths, it was found that wavelengths between 311-313 nm were best at balancing the clearing of psoriasis while at the same time minimizing the adverse effect of erythema. The first well-designed lamp that emitted narrow-band radiation at 311-313 nm, the Phillips TL-01 fluorescent lamp, was introduced in 1984 (Kist, 2005; Honigsmann, 2001). The main treatment-limiting side effect of narrowband UVB is erythema, reported by 10-94% of patients depending on treatment regimen and definition of erythema. Other short-term side effects include dry skin with pruritis, blistering, and increased frequency of recurrent herpes simplex outbreaks. Long-term side effects, as with other types of phototherapy, include photoageing and skin cancer. However, the incidence of skin cancer in patients with psoriasis treated with narrowband UVB is not well known (Kist et al., 2005, Naldi et al., 2005). The recommended initial treatment dose of narrowband UVB is 50-80% of a patient's minimal erythema dose (MED), established through phototesting. This is followed by increases of 10-40%, depending on the aggressiveness of the treatment and the patient's response (Kist, 2005; Honigsmann, 2001). The American Academy of Dermatology guidelines recommend giving up to 20-25 treatments of narrowband UVG, 2-3 times a week (Menter et al., 2008).

### 10/06/2008: MTAC REVIEW

#### Home Narrowband UVB Phototherapy

**Evidence Conclusion:** There is insufficient evidence to draw conclusions about the safety and effectiveness of home narrowband UV-B phototherapy for patients with psoriasis. There are no published randomized or non-randomized trials that use modern home phototherapy equipment. Findings from an RCT are expected to be published within the next 3-6 months.

**Articles:** A 2006 review article (Koek et al., 2006) on home ultraviolet B phototherapy for psoriasis identified 7 empirical clinical studies, 5 of which were published in English. 3 of the 5 studies in English were published between 1979-1983, before the introduction of the Phillips TL-01 fluorescent lamp. Thus, they did not use currently available phototherapy technology. Both of the more recent studies (Cameron et al., 2002; Feldman et al., 1996) were case series with fewer than 25 patients. One of the 3 older studies (Paul et al., 1983) had a comparison group, the others were case series. The Paul et al. study, which included 40 patients, compared the efficacy of a Metec-Helarium unit emitting low-intensity selective UV phototherapy (LISUP) at home to 3 times/week in-office UVB therapy. In-office UVB therapy was found to be more effective than home LISUP treatment; 90% (18/20) of patients in the UV-B group experienced clearing of psoriasis compared to 40% (8/20) of patients in the home LISUP group. No additional completed studies were identified that compared home UVB phototherapy to in-office UVB phototherapy or to a different type of treatment. A published protocol for an RCT was identified (Koek et al., 2006). This trial, called the PLUTO study, is a multi-center trial comparing home UVB treatment to in-center UV-B phototherapy in 196 patients with psoriasis. The home phototherapy treatments is Waldmann UV-100 unites with TL-01 lamps. According to the lead author (personal communication), a manuscript on the study outcomes is currently under review by the BMJ.

The use of Home narrowband UVB phototherapy in the treatment of psoriasis does not meet the *Group Health Medical Technology Assessment Criteria*.

### 10/05/2009: MTAC REVIEW

#### Home Narrowband UVB Phototherapy

**Evidence Conclusion:** PLUTO study (Koek 2009) on home versus outpatient ultraviolet B phototherapy for psoriasis randomized 196 patients (in the Netherlands) with mild to severe psoriasis and clinically eligible for narrowband ultraviolet B phototherapy, to receive the treatment at home or in an outpatient setting. The trial had valid methodology and design as a noninferiority study. The patients and providers were not blinded, however assessment of the severity of and extent of the disease were evaluated by an independent research nurse blinded

to the treatment arms. The results of the trial indicate that home phototherapy was not inferior to that provided in outpatient department, mainly for the self-administered psoriasis area and severity index (SAPASI) 50, 75, and 90 (i.e. proportion of patients achieving at least 50%, 75%, or 90% decline of baseline SAPASI at the end of therapy) as well as the psoriasis area and severity index (PASI) 90. However, the possible inferiority of home ultraviolet phototherapy to that provided in an outpatient setting, could not be entirely excluded for the primary outcome of PASI 50, or PASI 75, as the lower limits of the 95% confidence intervals were slightly lower than -15% preset noninferiority margin. The differences observed in SAPASI and PASI results may indicate a bias in the patients self-assessment. The results of the trial also showed that patients in the home therapy group had a significantly higher mean number of irradiations, but an insignificantly higher cumulative dose at the end of therapy. 87% of the all participants had at least one occurrence of mild erythema, 58% a burning sensation, and 39% severe erythema with no significant differences between the two study groups. No significant differences were observed in the disease specific or generic quality of life among patients treated on outpatient setting or at home. The home therapy however, was associated with a lower burden of treatment and greater patient satisfaction.

**Articles:** A study on home versus outpatient ultraviolet B phototherapy for psoriasis was recently published in BMJ in 2009. Koek MB, Buskens E, vanWeelden H, et al. Home versus outpatient ultraviolet B phototherapy for mild to severe psoriasis: pragmatic multicenter randomized controlled non-inferiority trial (PLUTO study). *BMJ* 2009; 338:b1542 doi 10.1136/bmj.b1542

The use of Home narrowband UVB phototherapy in the treatment of psoriasis does meet the *Group Health Medical Technology Assessment Criteria*.

### Medical Technology Assessment Committee (MTAC)

#### Diabetes Sentry Monitor

##### BACKGROUND

There is evidence that tight glycemic control is associated with a lower incidence of diabetic complications including reduced rates of retinal, neurologic, and renal damage. Strict control of blood glucose, however, is associated with an increased risk of hypoglycemia (DCCT Research Group, 1993).

Hypoglycemic episodes commonly occur at night. Mild episodes of nocturnal hypoglycemia are generally asymptomatic, but may affect mood and well-being the following day. Recurrent exposure to nocturnal hypoglycemia may impair cognitive function. Severe episodes can cause convulsions and coma and may lead to cardiac arrhythmias resulting in sudden death. Strategies to reduce nocturnal diabetes include regular blood glucose monitoring, eating appropriate bedtime snacks, and use of short- and long-acting insulin analogues (Allen & Frier, 2003).

The Diabetes Sentry monitor is designed to monitor hypoglycemia and alert patients when they are experiencing physiological symptoms. The device was originally developed as the Sleep Sentry monitor in approximately 1980s. The device was later taken off the market and a re-designed version received FDA approval in 2003. In 2005, the FDA approved the name change to Diabetes Sentry. The device is manufactured by Diabetes Sentry Products in Bellingham, WA.

According to manufacturer's materials, the Diabetes Sentry monitors two symptoms of hypoglycemia: perspiration and drop in skin temperature (decrease of 2o F). Either of these symptoms will trigger an audible alarm loud enough to awaken most people. Patients are instructed that, when the alarm sounds, they need to verify whether they are in fact experiencing hypoglycemia with a blood glucose monitor. The company acknowledges that there are false-positive alarms since there are other reasons for nocturnal perspiration and temperature drop, for

example, change in room temperature or a shift in blankets. The manufacturer estimates that there will be an approximately one false alarm per night. The device is designed for people with insulin-dependent diabetes who have a severe enough problem with nocturnal hypoglycemia that they are willing to accept false-positives.

Other potential limitations of the Diabetes Sentry monitor are that patients may forget to turn on the device and some individuals may not awaken when the alarm sounds. In addition, the device is not useful for patients with hypoglycemia unawareness since they may not perspire or experience a drop in temperature during mild hypoglycemic episodes.

Unlike the GlucoWatch, which is intended to measure blood glucose levels, the Diabetes Sentry measures symptoms of hypoglycemia (perspiration and temperature).

This is the first time that MTAC has reviewed the Diabetes Sentry.

Assessment objective: To evaluate the accuracy of the Diabetes Sentry for detecting hypoglycemic events. To evaluate the impact of device use on health outcomes (e.g. reduction in morbidity from hypoglycemia).

## **08/07/2006: MTAC REVIEW**

### **Diabetes Sentry Monitor**

**Evidence Conclusion:** There is no published evidence on the Diabetes Sentry approved by the FDA in 2003.

**Articles:** The search yielded 3 articles; all of these were small case series (n<25 each) and were published in the 1980s on the original Sleep Sentry device. There were no published articles evaluating the re-designed Diabetes Sentry device approved by the FDA in 2003.

The use of Sleep Sentry Monitor in the treatment of Diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

## **GlucoWatch**

### **BACKGROUND**

Intensive glucose control to maintain a lower level of blood glucose has been associated with fewer long-term complications of diabetes (e.g. UKPDS, 1998). Self-monitoring of blood glucose is an important part of a program to maintain tight glucose control. The standard procedure for self-monitoring of blood glucose involves frequent finger-stick measurements which can be painful and/or inconvenient for patients.

The GlucoWatch Biographer (Cygnus Inc., Redwood City, CA) is proposed as a non-invasive blood glucose self-monitoring device. The GlucoWatch Biographer was approved by the FDA to supplement (not replace) the information provided by standard finger-stick, glucose monitoring devices. The theoretical advantages of the GlucoWatch over standard self-monitoring procedures are increased convenience and less pain since patients could take fewer finger-stick measurements, increased accuracy of blood glucose levels through continuous monitoring and increased safety since the GlucoWatch has the capacity to sound an alarm when blood glucose reaches a dangerous level.

The GlucoWatch is worn on the forearm and has the appearance of a wristwatch. It extracts extracellular fluid by applying a low level electrical current to the skin, a process known as reverse iontophoresis. The fluid is collected in gel discs on a single use component of the device, called the Autosensor. The fluid undergoes a chemical reaction after being catalyzed by glucose oxidase and. The GlucoWatch calculates a blood glucose level using the electrical signal produced by this chemical reaction, the strength of which is proportional to the glucose level.

After a 3-hour warm-up period and calibration with a blood glucose level, the Autosensor provides up to 12 hours of glucose readings produced every 20 minutes. The GlucoWatch displays the most recent glucose level and stores the remaining readings. It can be set to produce an audible alarm if the glucose level is above or below pre-specified limits. The alarm will also sound if the glucose level falls more than 35% compared to the last measurement, or if the device senses perspiration, which can interfere with functioning of the device and is also associated with hypoglycemia.

The FDA approved the GlucoWatch Biographer in March 2001 for individuals, age 18 and older. In August 2002, the GlucoWatch was approved for use by children between the ages of 7 and 17 years.

## **02/13/2003: MTAC REVIEW**

### **GlucoWatch**

**Evidence Conclusion:** *Children:* There is no published evidence on the efficacy of the GlucoWatch Biographer for monitoring blood glucose levels among children with diabetes.

*Adults:* There is no published evidence on whether use of the GlucoWatch Biographer improves health outcomes or glucose control among people with diabetes compared to standard self-monitoring techniques. The evidence on the accuracy of the GlucoWatch suggests that measurements are reasonably accurate compared to fingerstick measurements (approximately 70% of measurements would lead to clinically correct decisions and about 95%

would lead to clinically acceptable decisions). However, the data may be biased because all studies were conducted by investigators affiliated with the device manufacturer, and most data were collected in a controlled clinical environment and accuracy may differ in a “real-life” setting.

**Articles:** The search yielded nine articles. One was an article reviewing several glucose monitoring devices, one was a report announcing the new technology, and the remaining seven were authored by the Cygnus Research Team. There were no studies reporting on the effect of glucose self-monitoring with the GlucoWatch on health outcomes e.g. macrovascular or microvascular complications of diabetes. There were also no studies reporting on the effect of glucose self-monitoring with the GlucoWatch on the ability to maintain tight glucose control. The empirical data all addressed the accuracy of the GlucoWatch to detect current blood glucose levels. All of the studies were conducted among adults. The two studies on accuracy with the strongest methodology were critically appraised. Features examined for study selection were sample size, thoroughness of methods description, setting (controlled environment vs. home setting) and comparison with finger-stick measurements. The following articles were reviewed: Tierney MJ, Tamada JA, Potts et al. Clinical evaluation of the GlucoWatch biographer: a continual, non-invasive glucose monitor for patients with diabetes. *Biosensors & Bioelectronics* 2001; 16: 621-629. See [Evidence Table](#)

The use of GlucoWatch in the evaluation of diabetic control does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Home A1c Tests**

### **BACKGROUND**

A1c (also known as hemoglobin HbA1c or HbA1c) gives information about the average blood glucose level over the previous 2-3 months and is the best measure of overall blood glucose control for patients with diabetes (Group Health diabetes guideline). The A1c test measures the concentration of glycosylated hemoglobin in the blood. A1c forms when some of the glucose circulating in the blood binds irreversibly to hemoglobin A, forming a stable glycated hemoglobin complex. The A1c level is proportional to the amount of glucose in the blood over the life span of red blood cells. It does not fluctuate with daily blood glucose levels.

An HbA1c target of <7% is recommended for most patients with type 1 or type 2 diabetes. Research has found that, if a patient's HbA1c level is higher than 8%, reducing it by one-tenth (e.g., from 10% to 9%) will slow down damage to their body by about 50% from the current rate (DCCT Research Group 1997). The Group Health diabetes glycemic control guideline recommends that people with diabetes routinely monitor their HbA1c every 6 months. For patients who have elevated blood glucose and are attempting to reduce their blood glucose levels, Group Health recommends checking HbA1c every 3 months until the target level is reached.

HbA1c tests have traditionally been conducted in a health-care setting. Several in-home HbA1c tests have been cleared by the FDA. The FlexSite A1c At-Home test was FDA-approved in 1997 and is available over-the-counter. It includes a blood sample collection kit that uses treated filter paper for spotting blood. The patient provides one or two drops of blood to each of two target areas on the filter paper and lets the sample dry overnight. The dried blood sample is then mailed to the FlexSite lab where it is evaluated. Results are available by phone or mail. The manufacturer claims that its sample collection technique allows a dried blood sample to be transported for up to 12 days without significant artifactual in vitro glycation (manufacturer's website; Parkes et al., 1999).

Another home A1c test was approved by the FDA in 2002 under the name Metrika A1cNow. It was cleared both for prescription and over-the-counter use. Beginning in 2004, the test has been distributed exclusively by Bristol-Meyers Squibb and it is now called the ChoiceDM A1c Home test. Unlike the FlexSite test, the Metrika A1cNow/Choice DM A1c Home test provides results at home. The test comes as a disposable, one-use device about the size of a pager. It incorporates microelectronics, optics and dry-reagent chemistry strips. Individuals collect a sample of whole blood via fingerstick or venipuncture, place the sample in a cartridge and mix it with the dilution solution provided by the manufacturer. The diluted sample is added to the monitor which activates the device (there are no buttons or switches, the device is self-activated). Activating the device causes blue microparticles conjugated to an anti-HbA1c antibody to migrate along the reagent strips. The amount of blue microparticles captured on the strips is proportionate to the amount of HbA1c in the sample. After about eight minutes, the results are displayed in numeric form on the digital display. Total hemoglobin in the sample is also measured (manufacturer's website; Kordella, 2002).

## **02/05/2007: MTAC REVIEW**

### **Home A1c Test**

**Evidence Conclusion:** No published evidence was identified on the Metrika A1cNow/Choice DM A1c Home test, the test that provides results to patients within minutes at home. In addition, there was no published evidence the ability of home A1c testing to improve clinical outcomes. One published study was identified on the FlexSite at-home A1c sampling kit, which requires mailing samples to a centralized laboratory. This study found that A1c levels using the usual method for analyzing in-home samples was highly correlated with two standard methods of

establishing A1c levels. However, the accuracy e.g. sensitivity and specificity of any of the tests was not reported. In addition, the study involved having patients and staff collect blood samples, but the test results for the two types of samples were not reported in the analysis. The authors of the study had links to the test manufacturer which may have introduced bias.

**Articles:** No published studies were identified on the Metrika A1cNow/Choice DM A1c Home test. An FDA talk paper from 2002 states that the Metrika device was cleared for non-prescription use based on a study by the manufacturer comparing test results obtained by lay users to those obtained by medical professionals. The Medline search did not identify a published version of this study and the company did not respond to a request for the manuscript. One published study was identified on the Flexsite at-home test. This study was critically appraised: Parkes J, Ray R, Kerestan S et al. Prospective evaluation of accuracy, precision, and reproducibility of an at-home hemoglobin A1c sampling kit. *Diab Tech Ther* 1999; 1: 411-419. See [Evidence Table](#).

The use of Home A1c tests in the treatment of diabetes does not meet the *Group Health Medical Technology Assessment Criteria*.

### **I-Port™ Injection Port**

#### **BACKGROUND**

The I-Port is a device that is placed on the skin, and through which patients can self-administer subcutaneous injections of prescription medications using a standard syringe and needle. A removable insertion needle allows placement of the body of the I-Port device on the skin. The device is held in place by an adhesive pad and a soft cannula. The I-Port body is 1.5" (38mm) in diameter and 1/3" (9mm) tall. The disposable I-Port can be worn for up to 72 hours and, during this time, up to 75 needle sticks can be made through the soft cannula. During an injection of medication, the needle of the syringe remains above the surface of the skin. Medication is delivered through the cannula into the subcutaneous tissue. The I-Port is manufactured by Patton Medical Devices, a company founded by K.K. Patton, the inventor of the device. The I-Port was approved by the FDA in September 2005 as a class II device judged to be substantially equivalent to predicate devices. It is approved for marketing to adults and children who require multiple daily injections of prescription medication, including insulin.

The manufacturer materials warns consumers to use as specified by a health care provider and not to re-use the I-Port, not to use the same I-Port for longer than 72 hours and not to use a needle longer than 8mm or thicker than 28 gauge when injecting into the I-Port. In addition, the I-Port website Q&A section states that irritation, inflammation and infection are rare, but the potential for these exist, especially when the skin surface is not adequately cleaned before application or when the device is improperly applied to the body.

There was one adverse event report on the FDA Manufacturer and User Facility Device Experience Database (MAUDE) database. This was a device malfunction that occurred on July 24, 2007 with a life-threatening patient outcome. Details of the event were not included in the report.

#### **10/01/2007: MTAC REVIEW**

#### **I-Port™ Injection Port**

**Evidence Conclusion:** There is no published evidence to support the use of the I-Port and no published information on the safety of the device.

**Articles:** No published articles were identified.

The use of iPort in the delivering of prescription medications does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Frequent Dialysis - Greater Than 3 Days a Week

- Facility
- In Home
- Nocturnal
- Short Daily

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	<a href="#">Medicare Benefit Policy Manual, Chapter 11 - End Stage Renal Disease (ESRD).</a>
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

Internet Only Manual (IOM), Publication 100-04, Chapter 8, Section 50.6.2  
 Noridian Coverage Article – [HemoDialysis Frequency](#)

#### For Non-Medicare Members

**Standard dialysis 3 days a week** is covered for members with end stage renal disease. For home dialysis the following additional criteria must be met:

1. The member is stable on dialysis.
2. The member is free of complications and significant concomitant disease that would render home dialysis unsuitable or unsafe.
3. The member or caregiver is capable of completing a home dialysis training program and adhering to a prescribed treatment regimen.
4. Adequate caregiver is available during dialysis
5. Back-up arrangements have been made with the facility-based dialysis center.

#### Frequent (Greater Than 3 Days a Week) Dialysis, Nocturnal or Short Daily, In Home or Facility

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

End-stage renal disease (ESRD) is defined as an irreversible decline in kidney function that is severe enough to be fatal without treatment. In 2008, the prevalence of ESRD in the United States was 547,982 (Collins 2011). Treatment options for patients with ESRD include kidney transplantation and dialysis. Kidney transplantation is the preferred treatment for ESRD; however, the demand for kidney transplant exceeds the supply of transplantable organs (Pauly 2009). Of the 547,982 patients with ESRD, approximately 382,343 patients received dialysis (Collins 2011).

Dialysis filters blood to rid the body of harmful wastes, extra salt, and water. There are two types of dialysis peritoneal dialysis and hemodialysis. The majority of patients are treated using hemodialysis; however, there is no

consensus on the optimal dose and frequency of hemodialysis. Difference hemodialysis regimens include: conventional hemodialysis, nocturnal hemodialysis, and short-daily hemodialysis (Toussaint 2010).

There are two types of dialysis: 1) Peritoneal dialysis: Removes waste products via the peritoneum, the membrane that lines the inside of the abdomen. The membrane is bathed in a special fluid called dialysate that is placed into the abdomen through a small tube, and after a designated period of time, the fluid is drained and replaced by new fluid. 2) Hemodialysis: Access is through surgical placement of an arteriovenous fistula, generally in the forearm, and less commonly by a venous catheter. After access is established, the fistula is connected to a hemodialysis machine that drains the blood, bathes it in dialysate solution and returns it to the bloodstream.

Conventional hemodialysis consists of three treatment sessions per week, with each session lasting 3 to 5 hours. Treatments can be performed in a dialysis center, hospital, or at home. Although this is a life-saving treatment, mortality in patients with ESRD is still remarkably high. Compared to the general population, mortality is four times higher in patients under 30 receiving dialysis and six times higher in patients over 65. Additionally, patients receiving dialysis often experience hypertension, fluid overload and the attendant cardiac sequelae, anemia, mineral and bone disorders, inflammation, poor nutritional status, poor functional status, and psychological disorders (Bayliss 2009, Ng 2010). Moreover, this approach to dialysis is inconvenient for patients receiving treatment in a dialysis center or hospital, who must travel to a dialysis unit several times a week.

Both nocturnal hemodialysis (typically 6-8 hours, 3-7 nights per week) and short-daily hemodialysis (typically 1.5-3 hours, 4-6 days per week) can take place at home or at a dialysis center. It is thought that increasing the frequency and duration of hemodialysis will lead to less fluid gain leading to improved blood pressure control, increased hemodynamic stability, and increased efficiency of solute clearance. A potential harm is an increased risk of vascular access complications due to more frequent use (Ng 2010, Toussaint 2010).

There are several hemodialysis devices approved by the FDA for home use. Some are large, non-portable devices that require modifications to the home electrical and plumbing systems. These include the Fresenius 2008K and the B. Braun Dialog Plus. Others are smaller and portable. The NxStage System One is specifically designed for home use; it does not require infrastructure changes.

## Medical Technology Assessment Committee (MTAC)

### Frequent Home Dialysis

#### 08/04/2008: MTAC REVIEW

**Evidence Conclusion:** on home nocturnal or short daily dialysis versus in-center dialysis 3 times a week:

One RCT and two cohort studies were identified that compared nocturnal home dialysis to in-center dialysis 3 times a week. The RCT (Culleton et al., 2007) found statistically significant improvement in the primary outcome, LV mass, a surrogate marker for cardiovascular disease. Among other secondary outcomes, phosphate level was significantly lower in the nocturnal home dialysis group, and there was no significant between group differences in calcium level and anemia. Two cohort studies matched patients who received nocturnal dialysis to similar patients receiving conventional in-center dialysis 3 times a week. Bergman et al. (2008) found significantly lower dialysis-related or cardiovascular-related hospital admissions (the primary outcome) in the group converted to nocturnal dialysis, but no significant difference in all-cause hospitalization. Schwartz et al., (2005) also had significant findings for the primary study outcomes, increase in hemoglobin concentration and increase in the proportion of patients who were EPO-free after 12 months. None of the studies had mortality as an outcome.

There are fewer published studies on short-daily dialysis. A statistical analysis (Blagg et al., 2006) found a lower mortality rate in 117 patients who received short-daily dialysis either in-center or at home compared to national rates on patients receiving conventional hemodialysis (standardized mortality ratio=0.39). Patients who received short-daily dialysis may have differed from those in the national database, and there were financial links between the authors of this study and the home dialysis device used in the study.

Evidence on home nocturnal or short daily dialysis versus home dialysis 3 times a week:

No randomized controlled trials were identified, and there were no comparative studies with mortality as an outcome. The highest grade of evidence comparing different frequencies of home nocturnal dialysis is a retrospective cohort study by Mahadevan and colleagues (2006). The investigators evaluated biological parameters in 13 patients receiving nocturnal dialysis 6 nights a week and 21 patients receiving nocturnal dialysis every other night (3-4 times a week). After 3-6 months of follow-up, levels of urea, creatinine and PTH were all significantly lower in the group treated 6 nights/week, and there were no significant differences between groups in phosphate, calcium, albumin and homocystine levels, or in use erythropoietin or phosphate binders. There were no significant differences at follow-up in the proportion of patients taking phosphate binders, calcitrol, blood pressure medications or erythropoietin. The evidence is limited due to lack of randomization (there may have been pre-existing differences between groups) and the small sample size (may be underpowered).

There is no high-grade evidence on health outcomes associated with short daily dialysis at home versus home hemodialysis 3 times a week.

Conclusions:

Objective 1:

- There is insufficient evidence that home nocturnal dialysis improves important health outcomes compared to in-center dialysis. An RCT found improvement in LV mass and phosphate level, intermediate outcomes, and mixed findings in QOL. There is weak evidence from a single cohort study that nocturnal dialysis lowers the rate of dialysis-related or cardiovascular-related hospitalizations. In this cohort study, all-cause hospitalizations did not decrease significantly.
- There is insufficient evidence that home short-daily dialysis improves health outcomes compared to in-center dialysis. One statistical analysis found a lower mortality rate with short daily dialysis compared to national rates, but patients may have differed in ways that affect outcomes, and there was potential financial bias.

Objective 2:

- There is insufficient evidence that home nocturnal dialysis 6 nights a week improves important health outcomes compared to home hemodialysis 3 times a week.
- There is insufficient evidence that home short-daily dialysis 5 or more times a week improves important health outcomes compared to home hemodialysis 3 times a week

**Articles:** Assessment objectives:

- 1) To determine whether frequent home nocturnal or home short daily dialysis leads to better health outcomes in patients with end-stage renal disease compared to conventional in-center dialysis 3 times a week.
- 2) To determine whether frequent home nocturnal or home short daily dialysis leads to better health outcomes in patients with end-stage renal disease compared to home dialysis 3 times a week.

Important health outcomes are survival, hospitalizations and quality of life.

**Objective 1: Comparison with in-center hemodialysis** One randomized controlled trial (Culleton et al., 2007) and two cohort studies (Bergman et al., 2008; Schwartz et al., 2005) comparing frequent nocturnal home hemodialysis to in-center hemodialysis were identified and critically appraised. Case series were not reviewed due to the availability of higher-grade evidence. The studies on short-daily hemodialysis were all case series. Most were small (<15 patients) and or included patients who primarily received dialysis in-center and thus were not suitable for critical appraisal. The strongest study identified compared outcomes in 117 patients on short-daily dialysis (84% at home) to outcomes of patients from a national database receiving conventional dialysis (Blagg et al., 2006). The Blagg study was critically appraised. **Objective 2: Comparison with home hemodialysis 3 times a week** One comparative study was identified, and critically appraised (Mahadevan et al., 2006). This was a small retrospective cohort study comparing outcomes in patients who received home nocturnal dialysis either six nights per week or on alternate nights (3-4 times a week). An RCT by the Frequent Hemodialysis Network (FHN) is underway comparing nocturnal home hemodialysis 3 versus 6 times a week. The study is currently recruiting patients; the estimated completion date is January 2010 (Clinicaltrials.gov). **Studies reviewed include:** Blagg CR, Kjellstrand CM, Ting GO, Young BA. Comparison of survival between short-daily hemodialysis and conventional hemodialysis using the standardized mortality ratio. *Hemodialysis International* 2006; 10: 371-374. See [Evidence Table](#) Culleton BF, Walsh M, Klarenbach SW et al. Effect of frequent nocturnal hemodialysis vs conventional hemodialysis on left ventricular mass and quality of life. *JAMA* 2007; 298: 1291-1299. See [Evidence Table](#) Bergman A, Fenton SSA, Richardson RMA, Chan CT. Reduction in cardiovascular related hospitalization with nocturnal home hemodialysis. *Clin Nephrol* 2008; 69: 33-39. See [Evidence Table](#) Schwartz DI, Pierratos A, Richardson RMA et al. Impact of nocturnal home hemodialysis on anemia management in patients with end-stage renal disease. *Clin Nephrol* 2005; 63: 202-208. See [Evidence Table](#) Mahadevan K, Pellicano R, Reid A et al. Comparison of biochemical, hematological and volume parameters in two treatment schedules of nocturnal home hemodialysis. *Nephrology* 2006; 11: 413-418. See [Evidence Table](#).

The use of home dialysis in the treatment of kidney disease does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Nocturnal Dialysis**

### **04/18/2011: MTAC REVIEW**

**Evidence Conclusion:** *Short-daily dialysis compared to conventional dialysis:* A recent RCT that included 245 patients and evaluated whether short-daily dialysis (1.5 to 2.75 hours, six times per week) would improve patient outcomes compared to conventional dialysis (2.5 to 4 hours, three times per week). There were two composite primary outcome variables: death or 12-month change in left ventricle mass as assessed by cardiac MRI, and death or 12-month change in physical-health composite score from the RAND 36-item health survey. Compared to conventional dialysis, frequent dialysis was associated with favorable changes in both of the primary composite outcomes. As the mortality rate in both groups was low, the bulk of the treatment effect was seen in intermediate outcomes. The sample size was insufficient to determine the effects of frequent versus conventional dialysis on overall mortality, cause-specific mortality, or hospitalizations (FHN Trial Group 2010). *Nocturnal dialysis compared*

*to conventional dialysis*: There is no high-quality evidence on health outcomes associated with nocturnal dialysis versus conventional dialysis. The majority of studies identified assessed intermediate outcomes such as mineral metabolism. Very few studies had mortality as an outcome. Results from these studies are inconsistent due to the low-quality of the studies. **Conclusion**: There is insufficient evidence to determine whether nocturnal dialysis leads to better health outcomes in patients with end-stage renal disease compared to conventional dialysis 3 times a week. There is fair evidence that short-daily dialysis leads to improvements in intermediate outcomes such as left ventricle mass and physical-health composite score compared to conventional dialysis 3 times a week. **Articles**: Studies were selected for review if they included at least 25 subjects and assessed the effect of nocturnal or short-daily dialysis on health outcomes. The majority of studies identified were non-randomized, observational studies. As these studies are more prone to bias, they were not selected for review. A RCT that compared the quality of life of patients receiving nocturnal dialysis to conventional dialysis was not selected for review as it did not have adequate power. A recent RCT comparing short-daily dialysis to conventional dialysis was selected for review. The following study was critically appraised: FHN Trial Group. In-center hemodialysis six times per week versus three times per week. *N Engl J Med* 2010; 363:2287-2300. See [Evidence Table](#)

The use of nocturnal dialysis in the treatment of kidney disease does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Frequent Home Dialysis**

**08/20/2012: MTAC REVIEW**

#### **Evidence Conclusion:**

**Survival** – There is lower quality evidence upon which to draw conclusions about survival with home versus in-center hemodialysis. Three observational studies specifically reported on death or measures of mortality and survival with home hemodialysis compared to in-center hemodialysis. One study had no deaths and therefore found no difference. The two other studies favored home hemodialysis, but were either small or had a higher likelihood of residual confounding (Kaiser 2011).

Since the Kaiser review, a recent matched-cohort study was identified that included 11,508 subjects assessed the relative mortality between daily home hemodialysis and thrice-weekly in-center hemodialysis. Results from this study suggest that home hemodialysis may be associated with a reduction in all cause mortality compared to thrice-weekly in-center hemodialysis (HR 0.87, 95% CI 0.78-0.97, P=0.01). Limitations of the study include: residual confounding, approximately 1 in 4 home hemodialysis patients switched to in-center hemodialysis, more patients in the in-center treatment group were dually eligible for Medicare and Medicaid, and the cause of death was unknown in 10-20% of cases (Weinhandl 2012).

**Hospitalizations** – There is lower quality evidence upon which to draw conclusions about hospitalizations with home versus in-center hemodialysis. One nested-case control study favored home hemodialysis in terms of hospitalizations per patients and two additional studies appeared to possibly favor home hemodialysis, but were underpowered (Kaiser 2011).

**Quality of life** – The evidence is of insufficient quantity and quality to draw conclusions on quality of life with home versus in-center hemodialysis. Two small observational studies did not find differences in quality of life with home versus in-center hemodialysis. One study reported that both groups had about the same number of subjects working (Kaiser 2011).

**Change in left ventricular mass** – No studies were identified that evaluated this outcome (Kaiser 2011).

**Blood pressure control** – There is lower quality evidence upon which to draw conclusions. Two studies reported significant decreases in blood pressure measures with home hemodialysis compared to in-center hemodialysis. One study also appeared to favor home hemodialysis in terms of need for antihypertensive medications (Kaiser 2011).

**Nutritional status and serum albumin** – There is lower quality evidence upon which to draw conclusions. Three observational studies reported mixed results on measures of serum albumin, with one study significantly favoring home as compared to in-center hemodialysis. One study found no difference in intradialytic weight gain with home versus in-center hemodialysis (Kaiser 2011).

**Vascular access complications/ Safety** – The studies evaluating vascular access complications have been very small and the results were somewhat mixed. One study evaluated the operations (per patient) due to vascular access and found no significant difference, but the data tended toward favoring home hemodialysis. Another small study appeared to favor in-center, but the study was not adequately powered to evaluate this outcome. In terms of other safety reports, one small study appeared to have more machine malfunctions with home hemodialysis, another study reported that a composite measure of intradialytic adverse events appeared to favor home hemodialysis, but this was not significant (Kaiser 2011).

**Articles**: In March 2011, Kaiser reviewed alternative approaches to hemodialysis. Since the Kaiser review three observational studies were identified. Two studies were excluded as they did not compare in-center hemodialysis to home hemodialysis. The remaining observational study was selected for review.

Several studies were identified that reanalyzed results from the FHN trial; however, they were not selected for review since the FHN trial evaluated whether short-daily in-center hemodialysis improved patient outcomes compared to conventional in-center hemodialysis, and whether nocturnal home hemodialysis improved patient outcomes compared to conventional home hemodialysis. The following article and medical technology assessment were selected for review: Kaiser Permanente. Alternative approaches to hemodialysis: short “daily” and nocturnal. March 2011. The committee voted to accept the Kaiser technology assessment. The studies were insufficient to draw conclusions on clinical benefit as compared to standard forms of dialysis.

The use of frequent home dialysis in the treatment of kidney disease does not meet the *Group Health Medical Technology Assessment Criteria*.

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

The diaphragm is a musculotendinous sheet separating the thoracic and abdominal cavities. Supplied by the phrenic nerve from the neck, it contracts rhythmically during respiration and is essential for adequate ventilation (Marieb, Mallatt et al. 2005). Interruptions to the diaphragms physiology from spinal cord injuries (SCI) or amyotrophic lateral sclerosis (ALS or Lou Gehrig's disease) can be devastating leading to chronic hypoventilation. In many cases, mechanical ventilation has been used to generate a controlled flow of gas into a patient's airways which often times, adds a degree of complexity to care due to associations with a number of undesirable side effects such as infection and increased need for assistance. In addition, mechanical ventilation inhibits mobility and speech and can be expensive. Unfortunately, many patients cannot be weaned, and consequently, will require chronic mechanical ventilation.

Diaphragm pacing (DP; Synapse Biomedical, Oberlin, OH) was developed to reduce or eliminate the use of a mechanical ventilator allowing patients to breathe and speak more naturally. In addition, DPS also decreases the risk of complications associated with mechanical respirators such as infection. To a certain degree, DPS allows for an improved quality of life as the device does not inhibit the sense of smell and taste, reduces the reliance on external power source and allows the patient increased mobility making everyday activities such as bathing easier.

The diaphragm pacing system (DPS) requires a minimally invasive procedure to implant four electrodes on the diaphragm where the phrenic nerves connect and an additional electrode just below the skin. The electrodes are then connected to an external battery powered system that provides ongoing electrical stimulation causing the diaphragm to contract and assist with breathing. With the overall goal to produce a training effect by repeated stimulation the DPS is advertised to have the potential of preventing progression of respiratory dysfunction.

The NeuRx DPS™ is manufactured by Synapse Biomedical, Inc. and received approval from the U.S. Food and Drug Administration (FDA) under the humanitarian device exemption in 2008 for treatment of respiratory insufficiency in high-level SCIs. More recently (2011), the indications for the device have been expanded for use in patients with ALS.

## Medical Technology Assessment Committee (MTAC)

### Diaphragmatic/Phrenic Pacing

04/21/2014: MTAC REVIEW

**Evidence Conclusion:** In 2008, Alsheklee and colleagues evaluated 36 SCI patients who had chronic ventilation for more than a year. Prior to surgical implantation of the device, phrenic nerve conduction studies were conducted to confirm nerve viability. While successful implantation of DPS occurred years after injury, 96% of patients were able to pace and tolerate being off the ventilator for more than four hours per day. Fourteen of the patients (56%) were able to pace full time (24 hours/day) and six were able to pace part-time (12-24 hours/day). The remaining 5 patients (20%) were still in the conditioning phase (4+ hours/day) and had only been implanted within 2-5 months of final analysis. Only, one patient was unable to initiate conditioning due to muscle cramps. The authors concluded that DPS can help patients with cervical SPI to breathe unassisted by a ventilator. (Alsheklee, Onders et al. 2008). [\[Evidence Table 1\]](#). Most recently, Onders and colleagues published a final analysis of the pilot trial of diaphragm pacing in patients with ALS. Aimed to assess the safety and effectiveness of DPS in ALS patients the prospective open-label evaluation provided long-term analysis of DP in ALS patients. In this study, patients were their own controls with outcome measures being obtained at several visits before and after implantation. While not statistically significant, the efficacy endpoint of respiratory decline was promising with a  $-2.38 \pm 2.84\%$  per month slope for decline pre-implant and a  $-1.34 \pm 1.49\%$  per month slope following implant. In the same way, diaphragm thickness following surgery was greater than the thickness measured prior to implantation. The investigators concluded that long-term use of DP had no safety issues and can positively influence diaphragm physiology and survival (Onders, M et al. 2014). [\[Evidence Table 2\]](#). Thus far, the body of evidence has flaws that complicate interpretation. All reports include small sample sizes and are not randomized. Given that the intervention involves surgery, selection bias may play a role with overall healthier patients referred for intervention limiting the generalizability of the results. Furthermore, methodological details on how some of the outcomes were measured and validated have not been well described. Lack of a comparator group is also a limiting factor in these studies. In terms of safety, while there were no reports of serious adverse effects attributable to the device, DPS relies on surgical implantation exposing patients to any risks associated with surgery including. Finally, it should be noted that Raymond Onders, MD, one of the primary investigators of both selected studies, is the developer of the DPS device. Conclusions: There is insufficient evidence to support the safety of DPS in carefully selected patients with SCI and ALS.

**Articles:** The search revealed numerous case reports and retrospective case series. The majority of the evidence focused on the use of DPS in patients with SCI or ALS. No randomized trials were identified. The initial FDA trial that led to the approval under the humanitarian device exemption was selected as well as the pivotal trial that led to the FDA approval of DP as a therapeutic option in ALS patients. The following studies were selected for review: Alsheklee A, Onders RP, Syed TU et al. Phrenic nerve conduction studies in spinal cord injury: applications for diaphragmatic pacing. *Muscle & Nerve*. 2008;38:1546-1552. [\[Evidence Table 1\]](#). Onders RP, Elmo M, Kaplan C et al. Final analysis of the pilot trial of diaphragm pacing in amyotrophic lateral sclerosis with long-term follow-up: diaphragm pacing positively affects diaphragm respiration. *The American Journal of Surgery*. 2014;207:393-397. [\[Evidence Table 2\]](#).

The use of diaphragmatic/phrenic pacing does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Mammography is the gold-standard for population-based breast cancer screening. The sensitivity of mammography in randomized trials is in the range of 68-88% (Elmore 2005). However, mammography is less sensitive in women with dense breasts (Brem 2008; Killela 2009). Because of this new technologies are being developed to improve detection and characterization of breast lesions. One of these technologies is digital breast tomosynthesis (Helvie 2010).

Digital breast tomosynthesis is a modified form of digital mammography. With digital breast tomosynthesis, multiple views of a stationary compressed breast are taken at different angles. These images are then reconstructed using an algorithm to create 3D radiographic images of the breast. It has been hypothesized that this technology may be able to decrease the number of false positive and false negative results and decrease recall rates. One limitation of digital breast tomosynthesis is that the specifications of many parameters including the number of projections, dose, angle, and post-processing algorithm differ across manufactures making clinical comparisons between manufactures difficult (Helvie 2010, Holloway 2010).

The Selenia Dimensions 3D System (Holistics, Inc.) has received approval from the FDA.

#### Medical Technology Assessment Committee (MTAC)

##### Digital Breast Tomosynthesis

##### 12/19/2011: MTAC REVIEW

**Evidence Conclusion:** Based on evidence from observational studies, the Kaiser MTAT concluded that the evidence is of insufficient quantity and quality to conclude that digital breast tomosynthesis is more effective than any other technologies to screen for breast cancer in average-risk or high risk women, in evaluating those with equivocal/indeterminate mammography and/or ultrasound, or evaluating women considering breast conserving therapy. The current evidence base consists primarily of studies reporting diagnostic results of women with

abnormal screening mammograms and is not representative of key populations under consideration. In addition, the sample sizes were too small and not powered to compare accuracy measures (Kaiser 2011). Conclusion: The evidence is of insufficient quantity and quality to conclude that digital breast tomosynthesis is more effective than any other technologies to screen for breast cancer.

**Articles:** The Kaiser Permanente Medical Technology Assessment Team (MTAT) reviewed digital breast tomosynthesis in 2009, 2010, and 2011. No additional studies were identified since the 2011 review. The following technology assessments were selected for review: Kaiser Permanente Interregional New Technologies Committee. Tomosynthesis. 2011; [http://pkc.kp.org/national/cpg/intc/topics/04\\_04\\_116.html](http://pkc.kp.org/national/cpg/intc/topics/04_04_116.html) Kaiser Permanente Medical Technology Assessment Team. Breast Imaging: Digital Breast Tomosynthesis. 2010; See [Evidence Table](#).

The use of digital breast tomosynthesis does not meet the *Group Health Medical Technology Assessment Criteria*.

**04/20/2015: MTAC REVIEW**  
**Digital Breast Tomosynthesis**

**Evidence Conclusion:** The external technology assessments by HTA, INTC, and TEC all concluded that there is insufficient evidence to determine that benefits of using breast tomosynthesis for screening asymptomatic women for breast cancer.

Lorenco, 2014 ‡‡	NR	NR	91.1	94.0
Greenberg, 2014‡	NR	NR	84.3	87.0
McCarthy,2014‡‡	NR	NR	NR	NR

M=mammography, DBT=digital breast tomosynthesis .

\* Prospective studies

‡ Retrospective multicenter study

‡‡ Retrospective single center study

\*\* US study

The majority of the studies compared DBT+DM vs DM alone.

There was population overlap between Greenberg, McCarthy, and Friedwald studies

All the trials had their limitations

*Estimated yield of DBT in combination with digital mammography  
 Vs. digital mammography alone in women presenting for population screening  
 (Table reproduced from HTA review Executive Summary)*

	DM	DBT+DM	Uncertainty
<b>Recall rate /1,000</b>	100-160	80-140	Moderate-high
<b>Biopsy rate /1,000</b>	14-22	12-27	Moderate
<b>Cancer detection rate/1,000</b>	3-5	4-6	Moderate-high
<b>Positive biopsy among total biopsied</b>	20-25%	25-30%	Low-moderate

The HTA review summary indicates that the 9 studies reviewed showed a substantial decrease in the recall rate with DBT vs. mammography and most found an increase in cancer detection. The evidence on biopsy rate was mixed, with the more recent studies showing an increase in the biopsy rate with DBT. Studies reporting on subgroups of women with dense and non-dense breasts found consistent findings.

There were limitations in the studies, including heterogeneity and differences among the screened populations, short follow-up duration, and lack of large prospective studies with patient outcomes. In addition the only 2 prospective studies were conducted overseas, where the patterns of recall differ from that in the US. *Kaiser*

Interregional New Technologies Committee (INTC), November 2014 The evidence reviewed by the committee included 8 published comparative studies of DBT + mammography vs. mammography alone for routine screening (from a previous review) plus four more recent comparative studies. There were no published studies that investigated the impact of DBT screening on mortality or other health outcomes among women at low, average or high risk of breast cancer. The review concluded that there is insufficient evidence to determine that breast tomosynthesis is appropriate for screening asymptomatic women for breast cancer. The estimated absolute benefits in cancer detection and reduction in recall are small and the overall evidence is of low-to moderate quality. The review also concluded that the positive results observed may not translate to outcomes and there is insufficient evidence to determine that DBT prevents mortality or advanced disease from breast cancer, Blue Cross Blue Shield/ Kaiser Permanente Technology Evaluation Center (TEC), January 2014 The addition of DBT to screening or diagnostic mammography did not meet the TEC criteria. The review included six studies that compared the use of mammography versus DBT with or without mammography for screening asymptomatic women. Four of the studies (Rose 2013, HAAS 2013, Skaane 2013, and Ciatto 2013) were also included in the HTA review. The two other studies included in the review were Rafferty et al's study (2013) and Good et al's study 2008 (Gur 2009). The TEC review did not include studies published in 2014 as the literature search was conducted in June 2013. TEC also evaluated the use of DBT for breast cancer diagnosis. The review concluded that the available evidence (at the time) on adding DBT to mammography for screening for breast cancer or to diagnostic mammography is insufficient to permit conclusions regarding the effect on health outcomes, or to determine the comparative benefit of adding DBT to mammography vs. mammography alone. More recent published evidence after the HTA 2015 review The literature search for more recently published studies identified a large (N=7,060) retrospective reading study embedded in a prospective study (TOMMY trial, Gilbert et al, 2015) that compared DBT plus 2D mammography vs. mammography alone, and a small (n=150) retrospective study (Thomassin-Naggara 2015) that evaluated the value of adding one view DBT to mammography to characterize breast lesions. TOMMY trial (Gilbert et al 2015 [Health Technology Assessment, NHS] Evidence table 1). This was a large retrospective reading study conducted by the UK National Institute for Health Research in six UK centers to compare the diagnostic accuracy of DBT in conjunction with 2D mammography or synthetic 2D mammography vs. standard 2D mammography among 6,021 women 47-73 years of age, for further assessment after routine breast screening, and 1,040 women 40-49 years with moderate/high risk of developing breast cancer attending annual mammography screening. All participants underwent a two-view 2D mammography of both breasts and two-view DBT imaging. Image-processing software generated a synthetic 2D mammogram from the DBT data set. Blinded readers reviewed 2D or 2D+DBT, or synthetic 2D+ DBT images for each case without access to the original screening mammograms or prior examinations. Sensitivities and specificities were calculated for each reading arm and by subgroup analyses. Overall, the results indicate that the specificity of DBT plus 2D mammography was statistically significantly higher than that of 2D mammography alone. The improvement in sensitivity by adding DBT to 2D mammography was minimal and statistically insignificant among all participants combined. Subgroup analyses however, showed significantly higher sensitivity with DBT+2D mammography vs. 2D mammography for women in the age range of 50-59 years, women with invasive tumors 11-20mm in diameter, those with breast density >50%, and in women with grade 2 invasive tumors. The analysis suggests that there was no significant difference in specificity of synthetic 2D +DBT versus 2D +DBT. As regards the sensitivity of synthetic 2D+DBT, subgroup analysis suggested that it had higher sensitivity than 2D alone in the detection of 11-20 mm invasive cancers, but lower sensitivity than 2D or 2D+DBT in the detection of microcalcifications and DCIS (ductal carcinoma in situ) 11-20mm in size. The study included women recalled for suspicious lesions on 2D mammography (only 5% of the screened women were recalled) as well as younger women at high risk. DBT was not used for 95% of the women screened by 2D mammography who were not recalled. This inherent selection bias of the study could overestimate the true effect of adding DBT to 2D mammography on the specificity, and underestimate its impact on the sensitivity. The study was not a screening trial and its results cannot be generalized to screening populations. Thomassin-Naggara and colleagues' study (2015) found that adding DBT to mammography improved reproducibility and diagnostic performance especially for radiologists with lower experience in reading mammography. Conclusion: There is insufficient evidence to determine the comparative benefit of screening with DBT versus conventional mammography. The published studies suggest that the addition of DBT to DM has no or minimal effect on improving sensitivity especially with experienced film readers. The studies however, suggest that the addition of DBT to DM may reduce the recall rates, but that would depend on the reading protocol, recall policy and experience of radiologists reading the images. There is no published evidence, to date, to determine the benefit of using DBT alone or in addition to digital mammography on long-term health outcomes.

**Articles:** The literature search revealed over 130 articles on digital breast tomosynthesis published after the last MTAC review. DBT technology was recently assessed by TEC for breast cancer screening or diagnosis in January 2014, by INTC in November 2014, and more recently by HTA in January 2015, for breast cancer screening in patients with dense breasts. The search for additional large screening studies published after the literature search dates of these reviews identified one large retrospective reading study (TOMMY trial) that

compared the diagnostic accuracy of DBT in conjunction with 2D mammography or synthetic 2D mammography vs. standard 2D mammography, a small retrospective study (N=150) on the added value on DBT combined with DM according to reader experience, a post hoc analysis of the STORM study by Ciatto and colleagues' 2013 study (included in the HTA review), and a recent meta-analysis on the use of DBT as a diagnostic not a screening test. The TOMMY trial was selected for critical appraisal. Gilbert FJ, Tucker L, Gillan MG, et al. The TOMMY trial: a comparison of TOMosynthesis with digital MammographY in the UK National Institute for Health Research (NHS) Breast Screening Programme - a multicentre retrospective reading study comparing the diagnostic performance of digital breast tomosynthesis and digital mammography with digital mammography alone. Health Technol Assess. 2015 Jan;19(4):1-136. See [Evidence Table](#).

The use of Digital Breast Tomosynthesis does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Discography (Discogram) for Low Back Pain

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

This service is covered without need for medical necessity review.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Low back pain is a great and growing problem in the Western countries as well as other parts of the world. It is the most common cause of disability in patients younger than 45 years old, and the loss of work, medical and disability costs can add up to at least \$50 billion per year in the United States. Many factors are associated with back pain, but the exact causes of severe pain are unclear especially in the absence of a diagnosed anatomic pathology such as infection, tumor, deformity or instability (Carragee 2001, 2004, Willems 2007).

Currently, there is no clinical test that could be used as a diagnostic gold standard for discogenic pain, and it is not possible to determine with absolute certainty that a particular disc is the spinal pain generator. Imaging methods such as radiography, magnetic resonance imaging (MRI), and computed tomography (CT) may detect disc degeneration but cannot confirm if it is symptomatic and relevant to the patient's pain syndrome. Plain radiographs provide data on bony alignment and deformity, signs of instability, and the general state of lumbar degeneration. Nuclear medicine scans may exclude tumors, fractures and infection, and magnetic resonance imaging (MRI) is used for the diagnosis of lumbar degenerative disorders. MRI is considered the morphological imaging study of choice in patients with low back pain. It is non-invasive and allows assessment of more levels in one test. MRI findings might also provide some information to indicate that a positive test increases the likelihood of the disc as a source of patients' symptoms, yet the current evidence is insufficient to allow making an accurate prediction (Saal 2002, Hancock 2007, Willems 2007). Surgical exposure can confirm the presence of disc degeneration, but cannot definitely confirm that it is the source of discogenic pain.

Lumbar discography was first introduced in the late 1940s as a morphologic test. The term discography used to describe the technology, implies a strictly anatomic evaluation. Discograms do not image pain and hence do not provide insight into which neural pathways mediate discogenic pain. Imaging of intervertebral disc morphology usually does not change within a short interval, but discographic images may change after only 2 weeks. Concerns about the invasiveness of discography, radiation exposure, risk of infection, and the recent advances made in the high resolution multi-detector CT and MRI of the disc, minimized the role of discography as an imaging tool. However, the frequent recurrence of familiar back pain during the discography led to the use of the test in evaluating lumbar discs as the origin of chronic low back pain, as well as pain in the cervical spine. Currently discography is used as a provocative test alleged to correlate symptoms with pathology (Buenaventura 2007).

Provocative discography is an invasive diagnostic procedure performed by the injection of a nonirritating radio-opaque dye, under x-ray guidance, into the nucleus of one or more lumbar discs. The dye is slowly injected into the center of the nucleus pulposus by a 22-25 gauge needle. The patient must be awake and cooperative, and is supposed to be blinded to the time and level of injection. The distribution of the dye is noted and the patient is asked whether each injection seems painful, and if the pain is similar "concordant" to the usual back pain he experiences. The patient is also asked to rate the pain on a visual analogue scale (VAS) or pain thermometer from

0-10 (or 0 to 5), with 0 denoting no pain and the higher end being unbearable pain. A completely intact disc will retain the dye in a central globular pattern, and is usually not very uncomfortable, even at high pressures. With more advanced disc degeneration on the other hand, patients may experience varying degrees of discomfort and pain as the dye is injected. A post discogram CT scan is often performed, and allows for a more thorough visualization, assessment, and identification of disc abnormalities (Saal 2002, Carragee 2001, Cohen 2005, Rowles 2005).

Discography has always been described as one of the most controversial tests in the management of degenerative painful lumbar spine conditions. Unlike MRI or CT scans, discography is used as a provocative test alleged to correlate symptoms with pathology. It seeks to confirm an impression that the back pain is discogenic and originating from a certain intervertebral disc. Some researchers found that healthy, previously pain free, patients can develop both back and leg pain from a provocative discogram as a result of the injection of irritants at different sites in motion segments. They also found that placement of the needle and injecting contrasts in the annulus fibrosus rather than the nucleus pulposus may induce back pain which should be regarded as false positive discography. Also, pain response to the discograms may vary widely among patients with chronic pain and somatization disorders. According to several investigators, psychological distress and pre-existing chronic pain processes may be stronger predictors of low-back pain than painful disc injections (Saal 2002, Carragee 2004, and Lander 2005).

One of the most feared complications of discography is discitis because of the poor blood supply of the intervertebral discs. Other reported adverse events include injury to the intervertebral disc, headache due to neuroaxial leak of the contrast, convulsions, meningitis, subdural or epidural abscesses, intrathecal hemorrhage and others. Also, as indicated earlier discography may cause or worsen low back pain especially in patients with somatization disorder (Cohen 2005).

The suggested clinical indications for discography are wide-ranging and highly individualized (Carragee 2004). Guidelines published by specialized groups recommend that discography be reserved for use in patients with equivocal or inconsistent findings from MRI or other tests. Some investigators suggest its use for the evaluation of patients with chronic back pain for whom a surgical intervention is being considered.

Discography is being reviewed by MTAC based on a request from Dr. Kyle Kim. Considered as a procedure, discography is not regulated by the FDA; however the devices and agents used for the test require FDA approval. Several of these devices and contrast material have been approved by the FDA.

## Medical Technology Assessment Committee (MTAC)

### Discography

#### 10/01/2007: MTAC REVIEW

**Evidence Conclusion:** *Reliability of discography for patients with chronic lumbar disc disease:* There is no current consensus in the spine community of what constitutes a positive disc injection (Carragee & Hannibal 2004). In general a positive discogram depends mainly on the production of the usual or concordant pain, which is a subjective measure and might not be a proper validation tool. Observer variability and bias in reading a discogram, as well as inter and intraobserver validation of pain response were evaluated only in a few studies. In a prospective trial involving 47 patients (Carragee 2000), the authors found that patients with abnormal psychological profiles have significantly higher rates of positive disc injections than either asymptomatic volunteers or symptomatic subjects with normal psychological screening. Agorastides and colleagues (2002) found an excellent interobserver and intraobserver agreement in applying Adams classification for discogram morphology, but did not study the reliability of the test in diagnosing discogenic pain. These, as well as other published studies were small, had methodological flaws, and do not provide sufficient evidence to determine the reliability of discography. Diagnostic accuracy of discography: As indicated earlier there is no clinical test that could be used as a diagnostic gold standard for discogenic pain. Several studies investigated the accuracy of discogram and/or CT discograms in detecting disc disease based on surgical confirmation of the pathology. Other researchers evaluated the technology by comparing, and /or correlating its results with those obtained by various other techniques including CT, myelography, and MRI. Small series where experimental discograms (with no surgical confirmation) were performed on asymptomatic patients showed that the test might be associated with high false positive rates. Accuracy based on surgical confirmation of findings: Results of studies with surgical confirmation of disc degeneration (Jackson 1989, Bernard 1994, and others) showed that CT discography was more accurate than standard discography in identifying disc herniation. CT discography had a sensitivity ranging from 74% to 92% and specificity ranging from 60% to 80%, versus sensitivity around 80% and specificity as low as 31% for standard discography. Compared to other diagnostic modalities, CT discography seemed to be more accurate in identifying disc abnormalities. Combining it with MRI improved its sensitivity, but not the specificity in Bernard's study (See attached appendix table 1). Birney et al, 1992 (See evidence table) compared the findings of

discography with MRI using surgical confirmation of disc herniation/degeneration as a gold standard among 90 patients (264 discs). All participants underwent an awake discogram by one radiologist and an MRI exam by another radiologist. 57 patients with 76 discs underwent surgical intervention. The study had its advantages and limitations. The authors evaluated discography as a morphologic test to examine the disc abnormality, but not as the cause of discogenic pain. The results of the study show 86% agreement between MRI and discogram. MRI was found to be more accurate in detecting disc herniation, while discogram was more accurate in detecting disc degeneration. The authors concluded that MRI and discography are equivalent in detecting degenerative disc disease; however the study was not designed nor powered to detect equivalence. These studies determined the accuracy of discography in diagnosing disc pathology, but did not confirm that the disc is the source of discogenic pain. Identifying a disc abnormality is not equal to identifying the cause of pain or that the disc is suitable for surgical intervention. Correlation of discography with MRI without surgical confirmation:

Studies that compared discography with MRI showed a varying agreement between the two tests. (See appendix table 2) Lim and colleagues (2005) studied the correlation between MRI and CT discography findings with pain response at provocative discography in 47 patients with discogenic back pain. MRI and discogram findings were analyzed based on concordant pain at discography. The study was small and had several limitations. Overall the authors reported a 68-89% accuracy of MRI in predicting pain, vs. 61% for discograms. Earlier in 1998, Ito and colleagues showed a 57% correlation between the two technologies in predicting pain. Several other investigators e.g. Gibson 1986, Linson 1990, Simmons 1991, Osti 1992, (See appendix table 2) as well as others studied the correlation between MRI and discograms in diagnosing a disc abnormality. The studies were small and had their limitations. Agreement rates were reported per patients, and/ or per discs. For patients it ranged from 55-75%, and for discs it ranged between studies from 71-94%. It is hard to determine if the lack of agreement between the tests was due lack of sensitivity (false negatives) or lack of specificity (false positives) in one or the other test.

Diagnostic and therapeutic impact of discography on health outcomes: There were a number of published prospective and retrospective studies that aimed at correlating discography findings to surgical outcomes. The population sizes in these studies were small, and the mean duration of follow-up ranged from <2-6 years. Abnormal discogram was the basis for surgery which was mainly spinal fusion, a procedure which is considered by many investigators as a controversial treatment. Willems and colleagues' (2007) study (see evidence table) evaluated whether preoperative status of the adjacent discs, as determined by provocative discography, had an impact on the clinical outcome of lumbar fusion in patients with chronic low back pain (LBP). The study included 209 patients with chronic LBP. They underwent outpatient routine diagnostic tests including radiography, MRI, CT, and provocative discography to determine the levels considered for lumbar fusion. The patients then underwent temporary external transpedicular fixation trial which was the final decisive factor for fusion. The latter was performed on 82 patients. They were followed up for a mean of 80 months and the primary outcome was the individual changes in pain on a visual analog scale (VAS), and patient satisfaction. A successful outcome was defined as 30% or more pain reduction. This rate was arbitrary, and according to the authors debatable. The study had other methodological flaws, and its overall results indicate that provocative discography had no significant impact on the clinical outcome after lumbar fusion. Carragee (2006) compared 5 year outcomes of two cohorts: 1 Discography (presumed discogenic pain) cohort, n=30, and 2: Unstable spondylolithesis cohort of 32 patients used as a control group. The gold standard used for the diagnosis of discogenic pain by discography was clinical outcome after surgical intervention. Outcome measures included VAS for back and leg pain, Modems Lumbar Questionnaires, analgesic usage, work status, reoperation, and complications. The results show a surgical success rate of 27% among the patients with discography positive test, compared to a 72% success rate in the control group. The calculated positive predictive value of discography for achieving at least the minimum acceptable outcome was 43%. Earlier in 2002, Madan and colleagues studied the outcome of spinal arthrodesis among 73 patients with discogenic low back pain refractory to nonoperative management. Chronologically the first 41 patients had not undergone discography while the following 32 patients underwent surgery based on discographic findings. The primary outcome was satisfactory clinical outcome based on a visual analogue scale and other questionnaires including the Oswestry Disability Questionnaire after a mean follow-up of 2.4-2.8 years. The results showed that 75.6 % of the patients in the discography group had satisfactory outcomes versus 81% of those who did not have a preoperative discography. This observed difference in improvement was not statistically significant. The other published studies had their limitations, had potential selection, spectrum and observation bias, and used subjective measures as their outcomes. They also had conflicting results all of which makes it hard to determine if preoperative discography is of value in selecting patients for surgical intervention and/or predicting surgical outcomes. Conclusion: There is insufficient evidence to determine the reliability of discography in the diagnosis of discogenic pain among patients with chronic low back pain. There is insufficient evidence to determine that that discography is accurate for the diagnosis of discogenic pain. There is insufficient evidence to conclude whether or not the use of discography can improve selection of patients, predict or improve surgical outcomes in those with discogenic chronic low back pain.

**Articles:** The search yielded over 500 articles some of which dated back to 1966. There were three systematic reviews of the literature with no meta-analyses, and several small prospective or retrospective studies that aimed at determining the reliability, calculating the diagnostic accuracy, comparing, or correlating the findings of

discography with MRI, CT scanning, myelograms or radiographs in symptomatic or asymptomatic patients. The search also revealed several relatively small studies that utilized health outcomes as a method for assessing the efficacy of discography. The ideal study would be a blinded independent comparison of discogram with a gold standard. However, to date, there is no known gold standard for discogenic pain. Some researchers determined the accuracy of discography by comparing it to other diagnostic modalities. Others used surgical findings and pathological disc morphology as their standard to confirm discographic results. These can confirm the presence of disc degeneration but cannot definitely confirm that it is the source of discogenic pain. Other groups suggested using clinical results of fusion as a gold standard to confirm whether the positive discogram injections were in fact true positives. Still many disagree on using a “controversial” treatment as the spinal fusion as a gold standard for a diagnostic test. One study that correlated discogram findings with MRI, and another that sought to measure its efficacy based on health outcomes were presented in evidence tables. Several others studies were grouped in table forms (see appendix tables 1 and 2) and/or discussed in the reviewer’s evidence summary section. The studies critically appraised in evidence tables are: Birney TJ, White JJ, Berens D, et al. Comparison of MRI and in the diagnosis of lumbar degenerative disc disease. J Spinal Disord 1992;5:417-423 See [Evidence Table](#). Willems PC, Elmans L, Anderson PG, et al. Provocative discography and lumbar fusion. Is preoperative assessment of adjacent discs useful? Spine 2007;32:1094-1099 See [Evidence Table](#).

The use of discography in the treatment of lower back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

## Discography

### 12/14/2011: MTAC REVIEW

**Evidence Conclusion:** In 2007 we reviewed the evidence for lumbar provocative discography, and there was insufficient evidence to determine the benefits of the procedure. A quick literature search did not reveal any good quality or large studies on analgesic discography. The only more recent study discussed in that article is the Cooper et al's study presented in a meeting and not published in a peer reviewed journal.

There was an systematic review with no meta-analysis of studies on lumbar discography (Manchianti 2009) that concluded that the level of evidence on the technology is II-2 ( i.e. evidence obtained from at least one properly designed small diagnostic accuracy study). The review indicated that there is a lack of literature, poor methodological quality and very few studies using IASP criteria. Carragee (2006) compared 5 year outcomes of two cohorts: 1 Discography (presumed discogenic pain) cohort, n=30, and 2: Unstable spondylolithesis cohort of 32 patients used as a control group. The gold standard used for the diagnosis of discogenic pain by discography was clinical outcome after surgical intervention. Outcome measures included VAS for back and leg pain, Modems Lumbar Questionnaires, analgesic usage, work status, reoperation, and complications. The results show a surgical success rate of 27% among the patients with discography positive test, compared to a 72% success rate in the control group. The calculated positive predictive value of discography for achieving at least the minimum acceptable outcome was 43%.

**Articles:** A quick literature search did not reveal any good quality or large studies on analgesic discography. The only more recent study discussed in that article is the Cooper et al's study presented in a meeting and not published in a peer reviewed journal. There was an systematic review with no meta-analysis of studies on lumbar discography (Manchianti 2009) that concluded that the level of evidence on the technology is II-2 ( i.e. evidence obtained from at least one properly designed small diagnostic accuracy study). The review indicated that there is a lack of literature, poor methodological quality and very few studies using IASP criteria.

The use of discography in the treatment of lower back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Device, Equipment and Supplies

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Durable Medical Equipment Reference List (280.1)</a> .
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

[Noridian Jurisdiction D DME Supplier Manual](#)

[Noridian Same or Similar reference Chart, August 2014](#)

##### For Non-Medicare Members

Durable Medical equipment (DME) also known as home medical equipment (HME) may be considered medically necessary when **ALL** of the following criteria are met:

- The patient has a documented physical functional impairment or disability due to disease, trauma, congenital anomaly or prior therapeutic intervention and requires accommodation for basic activities of daily living (ADLs) that can be met by using a DME item; and
- Documentation in the medical record contains a clinical assessment and rationale for the requested DME item (see Required Documentation below); and
- The DME is prescribed by a health care practitioner; and
- It is an item with a published HCPCS code; and
- The piece of equipment meets the definition of DME (see Policy Guidelines) and
- The requested DME item is not considered to be not medically necessary, investigational or unsafe by a regulatory agency, excluded by plan benefits or contract exclusion; and
- When specific criteria exist, the patient has also met those criteria.

The following are considered not medically necessary:

- Accessory add-ons and upgrades when a basic DME item meets the member's functional needs
- Athletic/exercise/physical fitness equipment (e.g. treadmills, stationary bikes)
- Comfort or convenience items added to basic equipment
- Deluxe equipment when basic (standard) equipment is available and meets the member's functional needs
- Duplicate equipment (e.g. a rolling walker, when the member has a properly fitted cane)
- Equipment and modifications/upgrades to equipment when used primarily for leisure or recreational activities (e.g. special wheelchair wheels for sport activities, prosthetic adaptations for beach use, skiing and others)
- Equipment used for environmental control or to enhance the environmental surroundings (e.g. air conditioners, air filters, humidifiers, allergy protective pillow/mattress covers, furniture [e.g. recliner chairs, over-bed tables], and others)
- First aid or precautionary equipment (e.g. automatic external defibrillator (AED), portable oxygen to back up an in-home oxygen system)
- Home modifications (e.g. bath grab bars, electronic door openers, elevators, Jacuzzi/whirlpools, ramps,)
- Institutional equipment (e.g. any DME that is used only in a medical facility and is not suitable for use in the home setting)
- Same/similar or back-up DME item(s) not used as the primary device to meet the member's functional needs (ie more than one of the same item of durable medical equipment).

\*See below for specific exclusions

### **Required Documentation**

Documentation from the clinical evaluation should include the following:

- An order/prescription from the physician/health care provider responsible for the patient's care that states the therapeutic purpose of the DME
- Details of the patient's physical functional impairment related to completing activities of daily living (ADLs) without the home medical equipment/DME; and
- The patient's medical condition that requires DME for long term use (i.e. 6-12 months or more) when applicable; and
- What assistive devices (e.g., canes, walkers, manual wheelchairs) the device has been trialed and found to be inadequate/unsafe or contraindicated to completely meet the patients functional needs (when applicable)

**Note:** Even when a provider orders or prescribes DME and deems the equipment necessary for the patient's functional needs, that does not mean that the item meets the criteria as listed in the policy. It also does not guarantee that the item will be considered medically necessary.

### **Definition of Terms**

**Activities of daily living (ADLs)** – ADLs are self-care activities done daily within a member's place of residence and includes

- Dressing/bathing
- Eating
- Ambulating (walking)
- Toileting
- Transferring
- Hygiene/grooming

**Durable Medical Equipment (DME)** – DME is:

- Primarily and customarily used to serve a medical purpose and
- Not useful to a person in the absence of illness or injury and
- Ordered or prescribed by a physician or other qualified provider and
- Reusable (non-disposable) and
- Designed to withstand repeated use (durable) and
- Not solely for the convenience of the patient or caregiver
- The equipment is not for use exclusively outside the home setting.

Prosthetics are covered if:

1. The device replaces all or part of an internal body organ or
2. Replaces all or part of the function of a permanently inoperative or malfunctioning internal body organ. **AND**
3. When specific medical criteria exist, the patient has also met those criteria.

The following items require review by Clinical Review:

1. Equipment with no HCPCS code
2. Equipment using miscellaneous code \*\*\*\*99, K0108, or L4205 in the absence of specific equipment/prosthetic codes
3. New technology
  - a. Not yet FDA approved
  - b. No specific HCPC for the service
  - c. New FDA approval within 6 months
4. All equipment/prosthetics listed in Clinical Review Criteria
5. Duplicate items of equipment are being requested

Testicular prosthesis is considered medically necessary for replacement of congenitally absent testes, or testes lost due to disease, injury or surgery.

Testicular prosthesis may be covered when associated with transgender services when [clinical criteria](#) is met. Some plans do not cover transgender services.

### **\*Exclusions:**

For non-Medicare members, the items in the following list are not covered in the home setting:

© Group Health Cooperative. All Rights Reserved.

[Back to Top](#)

Code	Description
	Air Conditioners or Cleaners
A9280	Alert or alarm device, not otherwise classified
L3000-L3090	Arch support
E0162	Bath Chair Sitz
E0235	Bath unit, paraffin, portable
E0160 & E0161	Bath, sitz type, portable
E0240	Bath/shower chair, with or without wheels, any size
E0242	Bathroom rail, floor base
E0241	Bathroom wall rail
E0625	Bathtub lift
	Bed Baths (home type)
E0273	Bed board
	Bed Lifters (bed elevators)
	Beds-Lounges (power or manual)
E0270	Beds (oscillating)
E0462	Bed, rocking, with or without side rails
	Dehumidifiers
	Diathermy machines
	Disposable sheets and bags
A4553	Non-disposable underpads, all sizes
A4554	Disposable underpad, all sizes
	Electric air cleaners
	Electrostatic machines
	Elevators
A9300	Exercise equipment
	Face masks (surgical)
E0241	Grab bars
E0218	Heat pad
E0191	Heel or elbow protector, each
E0270	Hospital bed, institutional type includes: oscillating, circulating and Stryker frame, with mattress (not on Exclusions list in the General Criteria)
A9273	Hot water bottle, ice cap or collar, heat and/or cold wrap, any type
	Humidifiers (not associated with PAP equipment, oxygen, IPPB, and Cool Air mist set ups)
A4520	Incontinence garment, any type (e.g. brief, diaper), each
E0221	Infrared heating pad system
E0481	Intrapulmonary percussive ventilation system and related supplies
L8499	Leg cover, realistic
	Leotards (does not include the burn leotards)
	Massage devices
A9270	Non-covered service
E0274	Over-bed table
E0235	Paraffin bath units
	Parallel bars
E0635	Patient lift, electric with seat or sling
E0640	Patient lift, fixed system, includes all components/accessories
E0625	Patient lift, kartop, bathroom or toilet
E0639	Patient lift, moveable from room to room with disassembly and reassembly, includes all components/accessories
E0300	Pediatric crib, hospital grade, fully enclosed
	Portable room heaters
A9281	Reaching/grabbing device, any type, any length, each
E0710	Restraints, any type, body, chest, wrist or ankle
E0700	Safety equipment (belt, harness, vest)
	Sauna Baths
E0172	Seat lift mechanism placed over or on top of toilet, any type
	Spare tanks of oxygen
	Speech teaching machines

Code	Description
	Stairway elevators
E0638 & E0641-E0642	Standing tables
A4490-A4510	Support hose
	Telephone alert systems
E0203	Therapeutic light box
E0243	Toilet rail
E0244	Toilet seat
A4575	Topical hyperbaric oxygen chamber, disposable
E0446	Topical oxygen delivery system, not otherwise specified, includes all supplies and accessories
E0247	Transfer bench for tub or toilet with or without commode opening
E0248	Transfer bench, heavy duty, for tub or toilet with or without commode opening
	Treadmill exercisers
E0246	Tub rail attachment for transfer
E0245	Tub stool or bench
L8510	Voice amplifier
E0218	Water circulating cold pack with pump
E0249	Water circulating heating pad
E0950	Wheelchair tray
E1310	Whirlpool, nonportable (built-in type)
E1300	Whirlpool, portable (over tub type)
	White Canes
A9282	Wigs
A9286	Hygienic item or device, disposable or non-disposable, any type, each

##### For Non-Medicare Members

Medical necessity review is no longer required for this service.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Percutaneous transluminal coronary angioplasty (PTCA) has become the preferred strategy for treating patients with blockage of one or more coronary arteries by atherosclerotic plaques. It is limited however, by the high rate of restenosis that may occur after a successful PTCA. The main processes involved in restenosis include the immediate elastic recoil of the vessel, rapid platelet deposition, late constrictive remodeling and neointimal hyperplasia. This problem stimulated the development of coronary endovascular stents which have been shown to reduce restenosis by preventing the elastic recoil and pathological remodeling. However, researchers found that stents do not prevent the restenosis caused by neointimal hyperplasia, but rather initiate an inflammatory reaction that induces more proliferation than other coronary devices (Surreys 2002).

An effective treatment of restenosis within the stent would be the suppression of neointimal hyperplasia. Investigators studied several modalities of treatment and pharmaceutical agents to inhibit restenosis after coronary interventions. Among these modalities is the local delivery of antiproliferative drugs via drug-coated stents. A drug-eluting stent (DES) is a device that releases single or multiple bioactive agents that can deposit in, or affect tissues adjacent to the stent. Potentially, it has the advantage of using a stent that is similar to that already in use, as well as delivering the drug in a high local concentration with no systemic toxic effects. Different stent designs with different immunosuppressive antimitotic agents including paclitaxel, rapamycin, actinomycin D, and tacrolimus have been developed by the device industry.

Currently two drug eluting stents are FDA approved and available for use; the sirolimus-eluting stent and the paclitaxel eluting stent. Both sirolimus and paclitaxel agents proved experimentally to be capable of significantly reducing or even inhibiting the intimal hyperplasia in animals and humans. Sirolimus is a macrolide antibiotic with a cytotoxic mechanism and an anti-inflammatory effect. The limus-family agents are active immunosuppressant and antiproliferative agents used to prevent graft rejection in kidney and heart transplantation (Hara 2006). They are used for the coronary system to diminish neointimal proliferation of coronary arteries (Marx 1995). Paclitaxel (taxol) and its related taxane compounds are cytotoxic antineoplastic agents used in cancer chemotherapy. They interfere with the proliferation, and migration of smooth muscle cells, thus contributing to the reduction of

neointimal growth. Paclitaxel has a narrow-toxic to therapeutic ratio, i.e. it has dose dependent efficacy and toxicity (the higher the dose, the greater the inhibition of proliferation and the higher the level of toxicity). If the stent does not expand regularly, and the struts are gathered in a curved vessel, the dosing in the vessel could potentially have toxic effects (Hara 2006).

The drug can be linked to the stent surface, embedded and released from within polymer materials, or surrounded by and released through a carrier. The polymers act as a drug reservoir and allow for gradual elution of the drug and delivering it precisely to the target site. The safety and efficacy of the stent depends on the choice of the combination of drug and the polymer, the correct dose, and the kinetics of release. The stent is inserted percutaneously and implanted at the target site in the coronary artery. It is then expanded to fit against the inner lumen of the vessel (stent-vessel wall apposition). The drug will be delivered directly to the wall, and any space between the stent and vessel wall should be avoided, otherwise the eluting drug will be released in the blood flow, go to the systemic circulation, and reduce the appropriate concentration for the vessel wall (Hara 2006). It was reported that the metallic surface of the stent may stimulate thrombosis inside the vessel in the first weeks after insertion before it is completely covered by endothelial tissue. Other potential factors that may increase the risk of subsequent thrombosis include the delay in endothelial healing, impaired re-endothelialization, hypersensitivity due to the stent and its coating, and vascular cytotoxicity of the drug (Ellis 2007, Joner 2006). In order to prevent thrombosis from occurring, the patients receive dual antiplatelet therapy after the procedure. The current recommended duration is 1 month after bare metal stents, 3 months after sirolimus eluting stents, and 6 months after paclitaxel stents.

In April 2003, the Food and Drug Administration approved the first drug-eluting stent in the United States, the sirolimus-eluting Cypher™ stent (Cordis, Johnson and Johnson CYPHER, Warren, NJ, USA) based on experience from the SIRIUS and RAVEL trials. One year later, in March 2004, The FDA approved the second drug eluting stent system, the Boston Scientific TAXUS™ Express2™ Paclitaxel-Eluting Coronary Stent System. The approved indications for the DES use were limited to the treatment of patients with symptomatic ischemic disease due to discrete de novo lesions <28 - <30 mm (<28 for Taxus, < 30 for Cypher) in length in native coronary arteries > 2.5 to < 3.75 mm in diameter. The FDA required that the manufacturers conduct a 2000-patient post-approval study and continue to evaluate patients enrolled in the original clinical trials for 5 years after implantation of the stent to assess its long-term safety and efficacy.

In July 2003, the manufacturer of the Cypher stent in conjunction with the FDA issued a warning letter to the US physicians on the risk of thrombosis that may occur at the time of implantation or within several days. More cases of thrombosis were observed with the use of the drug eluting stents, which led the FDA to convene a meeting of its Circulatory Systems Devices Panel in December 2006, to characterize the risk, timing, and incidence of DES thrombosis (FDA Update January 2007, Report of Advisory Panel, Laskey 2007).

DES was reviewed by MTAC in October 2003 and passed its evaluation criteria. The technology was also approved for coverage without criteria based on the evidence on its short term efficacy. At the time, there was a lack of long-term follow-up data.

Drug eluting stents are being re-reviewed by MTAC due to the concern regarding their long-term safety. Recent reports have suggested that the stents may be associated with an increased rate of the overall and late stent thrombosis and potential fatal complications.

## Medical Technology Assessment Committee (MTAC)

### *Drug-Eluting Stents for Coronary Revascularization*

#### **10/08/2003: MTAC REVIEW**

**Evidence Conclusion:** The trials reviewed had generally valid methodology with some limitations. However, all three trials included selected groups of patients that do not represent the real world patients with CHD that need intervention. Patients with multiple and /or complex coronary lesions were excluded from the trials as well as those at higher risk. The outcomes of the trials reviewed were short-term, and to date there is insufficient data on the long-term effects: benefits, limitations, or harms of the technology. The SIRIUS trial (Moses, 2003) showed that the target vessel failure (primary outcome) at 270 days of follow-up, was significantly lower among patients in the sirolimus stent group (8.6%) versus those in the standard stent group (21.0%) with an absolute risk reduction of 12.4%, and a number needed to treat of eight. The difference observed was mainly due to the higher target lesion revascularization rate among patients who received the standard stent. The RAVEL trial (Morice, 2002) conducted with sirolimus coated stents, showed that at six months, the angiographic rate of restenosis was 26% in the standard stent group compared to none (0%) in the sirolimus stent group. At one year, 23% of the patients in the standard stent group needed repeat revascularization compared to none of those in the sirolimus group, with a number needed to treat of four. The results of TAXUS II trial (Colombo, 2003) using a different drug (paclitaxel) in

their eluting stents, also showed significant reductions in restenosis and need for revascularization among patients in the drug-eluting stent group. Restenosis however was significantly reduced but not completely eliminated. In conclusion, the trials show that compared to the standard stents, the drug-eluting stents significantly reduced the rate of repeat revascularization at nine months to one year of follow-up, among the selected groups of patients included in the trials. They do not provide evidence on the long-term outcomes of the technology.

**Articles:** The search yielded 104 articles. Many were literature reviews and tutorials. There were eight articles on randomized controlled studies, three of which were different publications for the same trials. Two other RCTs compared drug eluting stents using the same coating drug but with different release velocities, and the others were smaller trials and/or with no clinically important outcomes. Few articles reported data on longer follow-up for subsets of population who received the drug-eluting stent with no control or comparison groups. The search also revealed few case series, with no control or comparison groups on subsets of patients treated for in-stent restenosis. SIRIUS (Moses, 2003) and RAVEL (Morice, 2002) trial using the Cypher Sirolimus-eluting stents were selected for critical appraisal. Another large trial (TAXUS II) using a different agent (Paclitaxel) for the drug-eluting stent was also selected for critical appraisal. All three RCTs compared the drug-eluting stents with the standard stents, and had clinically important outcomes. *Evidence tables were created for the following studies:* Moses JW, Leon MB, Popma JJ, et al. for the SIRIUS investigators. Sirolimus-eluting stents versus standard stents in patients with stenosis in a native coronary artery. *N Engl J Med.* 2003;349:1315-1323. See [Evidence Table](#). Morice M-C, Serruys PW, Sousa JE, et al for the RAVEL study group. A randomized comparison of a sirolimus-eluting stent with a standard stent for coronary revascularization. *N Engl J Med.* 2002;346:1773-1780. See [Evidence Table](#). Colombo A, Drzewiecki J, Banning A, et al, for the TAXUS II Study Group. Randomized study to assess the effectiveness of slow and moderate release polymer-based paclitaxel-eluting stent for coronary artery lesions. *Circulation.* 2003;108:788-794. See [Evidence Table](#).

The use of drug-eluting stents for coronary revascularization does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **06/04/2007: MTAC REVIEW**

##### **Drug-Eluting Stents for Coronary Revascularization**

**Evidence Conclusion:** The results of the pivotal trials that led to the FDA stent approval (RAVEL, SIRIUS and TAXUS trials), showed significant reductions in the rate of stenosis and need for revascularization among the patients receiving drug-eluting stents whether sirolimus or paclitaxel coated. The trials however, were short-term and were neither designed nor powered to detect differences between the DES and bare metal stents in the rates of stent thrombosis and the associated MI and death. The technology was first reviewed by MTAC in October 2003. RAVEL and TAXUS II trials were included in the review, SIRIUS trials were not published then. This earlier review concluded that the results of the published trials at the time showed that compared to the standard bare-metal stents, the drug-eluting stents significantly reduced the rate of repeat revascularization at one year of follow-up, among the selected groups of patients included in the trials. It was noted however, that there was insufficient evidence to determine the long-term effects; benefits, limitations, or harms associated with the DES. The technology passed MTAC evaluation criteria, and is currently covered without criteria. It is being re-reviewed due to the publication of several reports suggesting that the stents may be associated with an increased rate of an overall and late stent thrombosis and potential fatal complications. This risk of stent thrombosis is the main safety concern in the current practice. However, it was not uniformly defined in the original trials. Moreover, it was not angiographically confirmed in many of the studies, and secondary stent thromboses occurring after revascularization were excluded in most trials. Some meta-analyses used the original definition of stent thrombosis in the protocol of the trials, while others redefined it or adopted the Academic Research Consortium (ARC) definition of stent thrombosis\*. All these factors and others e.g. differences in the inclusion/exclusion criteria, make it difficult to pool the results for analysis and provide accurate comparisons of risks associated with the stents. Moreover, meta-analyses are conducted to combine moderate sized trials in order to provide sufficient statistical power. In this case, to determine the long-term efficacy and safety of the stents. Based on calculations performed by different investigators, the meta-analyses still lacked the sufficient power to detect significant associations between the DES and the long-term risk of myocardial infarction and mortality. Mauri and colleagues (2007) calculated that an RCT comparing two stents would require a sample size of approximately 8,000 patients to detect a doubling of the risk (from 1% to 2%) of stent thrombosis with 90% power. Spaulding et al (2007) reported that more than 11,000 patients are needed to provide sufficient power to detect a clinically significant difference in mortality. Holmes calculated a number of 4,621 per arm to reach a statistically significant difference in total mortality (211,053 for cardiac mortality) with 80% power. Some of these comparable and conflicting results of the meta-analyses are as follows. Sirolimus-eluting stents: In their meta-analysis of both sirolimus and paclitaxel DES, Stone and colleagues, 2007 (evidence table) pooled the results of 4 RCTs that compared the sirolimus-eluting stents to bare metal stents (RAVEL, SIRIUS, E-SIRIUS, and C-SIRIUS, N= 1,748 participants). The SIRIUS trials included patients with de novo lesions of > 50% stenosis, 15-30 mm in length, in native coronary arteries 2.5-3.5 mm in diameter. The RAVEL study included patients with similar characteristics but with shorter

blockages. In all trials patients with acute MI were excluded. The results of the analysis showed a significantly lower revascularization rate with the DES, but a higher rate of stent thrombosis (as defined in the study protocols) at 1-4 years with the sirolimus-eluting stents vs. bare metal stents with a NNH of 167. The meta-analysis did not show any difference between the stents in the cumulative rates of death or MI at 4 years. The latter might be due to the lack of power to detect a significant difference between the stents, or possibly because higher rates of MI or mortality were offset with the reduction in rate of complications associated with additional revascularization. It is worth noting that the authors of the meta-analysis had financial ties to the manufacturers of both drug eluting stents. Spaulding et al, 2007 (evidence table), pooled the data for the same 4 RCTs on sirolimus eluting stents. The methodology of the analysis was valid, however the principal author also had financial ties to the manufacturer, and data for the individual studies were obtained from the manufacturer, which could lead to more accuracy or to bias. The results of the analysis showed that at 4 years, there were no statistically significant differences in the rates of death, MI, or stent thrombosis (as defined in the study protocols) between the two stent groups. When the authors of the meta-analysis used the ARC definition of stent thrombosis, they found a significantly higher rate for late (31 days-1 year) thrombosis with the bare metal stent (1.3% ) vs. sirolimus-eluting stent (0.3% , p=0.03). A subgroup analysis showed a higher mortality rate among patients with diabetes receiving a sirolimus-eluting stent vs. bare metal stent. Kastrati and colleagues (2007) performed a meta-analysis of 14 trials (N=4,958) that included the four pivotal trials, as well as ten other sirolimus trials with patient sizes ranging from 75-500. These additional trials included off-label use of the DES e.g. acute MI, venous bypass grafts, small vessels, long vessels, and complex lesions. A few of these trials were not published in peer-reviewed journals. The follow-up intervals ranged from 12.0-58.9 months, and the primary outcome of the meta-analysis was death from any cause. The pooled results of the analysis showed a sustained reduction in target lesion revascularization with the sirolimus stents, and no significant difference between the sirolimus and bare metal stents in the combined risk of death or MI, or stent thrombosis. However, after the first year of follow-up, the overall risk of stent thrombosis was significantly higher in the sirolimus vs. bare metal stent (0.6% vs. 0.02%, p=0.02). The author indicated that this was chronologically associated with the discontinuation of the dual antiplatelet therapy, according to the protocol specified duration. They however, did not make a statement but suggested the need for longer duration of dual antiplatelet therapy. In another meta-analysis of the same four pivotal sirolimus trials, Holmes and colleagues (2006), found no significant difference between patients receiving DES or bare metal stents in the rates of stent thrombosis or deaths related to it. They noted however that a sample size of 4, 621 per arm is required to provide sufficient power to detect a statistically significant difference in total mortality.

Paclitaxel-eluting stents: Stone et al (2007) performed a separate analysis for paclitaxel eluting stents (evidence table). The results of their pooled analysis showed that paclitaxel drug eluting stents were associated with significantly less revascularization in the target lesion or target vessel (NNT for four years was 10 and 13 respectively). The results also indicate that the paclitaxel eluting stents were associated with a significantly higher rate of stent thrombosis between 1-4 years vs. the bare metal stent, with a NNH of 167 in 4 years. As regards MI and mortality rates, the only significant difference observed was the higher MI rate at more than 30 days to one year with the paclitaxel stent vs. bare metal stent. The results may only be generalized to patients with characteristics similar to the inclusion criteria of the trials included (on label use as defined by the FDA). Similar to the other meta-analyses on DES, the authors had financial ties to the manufacturers of both drug eluting stents. Ellis and colleagues 2007, conducted a meta-analysis of the Taxus II, IV, V, and VI (N=3,445) for up to 3 years of follow-up (3 years for TAXUS I & II, 2 years for TAXUS VI, and 1 year for TAXUS V). In the entire follow-up period, there was no significant difference in the cumulative stent thrombosis rate between the paclitaxel and bare metal stent. The TAXUS group however showed a statistically significant higher rate of stent thrombosis from 6 months to 3 years, vs. bare metal stent. Univariate and multivariate analysis showed that male gender, smoking, nonuse of clopidogrel, and possibly use of multiple non-overlapping stents were independently correlated to stent thrombosis. Meta-analyses that combined the results for both the sirolimus and paclitaxel-eluting stents: Mauri and colleagues 2007 pooled the follow-up data for the pivotal 4 sirolimus (RAVEL, and 3 SIRIUS trials, and four paclitaxel trials (Taxus I, II, IV and VI). The total number of participants was 4,545, and the median follow-up duration was 1,804 days for the sirolimus trials, and 1,426 days for the paclitaxel studies. In this meta-analysis the authors used pooled data on stent thrombosis based on the definition in the trials' protocol, and according to the ARC, and found no increase in the stent thrombosis risk with either of the DES compared to the bare metal stent. They however noted that the power of the analysis was insufficient to detect statistically significant differences. Bavry et al (2006), performed a meta-analysis of 14 trials (N=6,675) that compared drug eluting stents (sirolimus and paclitaxel) to bare metal stents. The primary endpoint was angiographic stent thrombosis. However, those presumed by the trial investigators as stent thrombosis, without angiographic confirmations were also included. The results of the analysis showed no significant difference in the rates of early stent thrombosis. The incidence of very late stent thrombosis (> 1 year after the procedure) was 5.0 events/1000 patients receiving DES stents, compared to no events in the bare metal stents (RR=5.02, 95% CI 1.29-19.52, p=.02). Analyzed by the type of DES, the relative risk was 3.99 (95% CI .45-35.62, p=.22) for the sirolimus stents, and 5.72 (95% CI 1.08-32.45, p=0.49 for the paclitaxel stents). It is to be noted however, that the SIRIUS and RAVEL trials enrolled half as many patients as the TAXUS trials. Nordmann et al (2006) conducted a meta-analysis of 17 trials with 8,221 participants

(seven sirolimus trials n=2,487, nine paclitaxel trials n=4,908, and one on both n=826). The duration of follow-up was at least 1 year for all trials, was 2 years in 12 trials, 3 years for 9 trials, and 4 years for two trials. The pooled results of the meta-analysis showed no significant differences between the DES and bare metal stents in the total mortality rate. However, the rate of non-cardiac mortality at 2 years was significantly higher among patients randomized to the DES vs. bare metal stents. A subanalysis for each of the sirolimus and paclitaxel stents showed a significant difference associated with the sirolimus but not with the paclitaxel eluting stents when compared to the bare metal stents. The authors did not find a significant difference in the rate of stent thrombosis between the DES in general and the bare metal stents. The meta-analysis was well conducted; however the authors noted that the trials did not report on the rate of follow-up completion, and that there were no published data on cardiac and cardiac mortality for the TAXUS studies. The data analyzed were obtained from the manufacture. Moreno and colleagues (2007) conducted a meta-analysis of 25 RCTs (N=9,791) that compared DES to bare-metal stents to determine the risk of acute MI associated with each. They did not report on the quality of the trials included, how the patients were selected, and whether the studies were randomized and blinded. The results of the pooled analysis showed that the DES were associated with a decreased need for subsequent revascularization as well as a decreased incidence of acute myocardial infarction in the first 12 months after stent implantation. The authors noted that this could be due to a decrease in the incidence of non-Q-wave acute myocardial infarction. A subanalysis showed an odds ratio of 1.20 (95 % CI 0.65-20.2) for Q wave MI, and 0.79 (95 % CI 0.60-1.06) for non Q-wave MI. The authors did not analyze data on stent thrombosis, nor did they evaluate the effect of very late thrombosis on the risk of MI. Comparison between the Sirolimus and paclitaxel stents:

The REALITY trial (Morice 2006) compared the safety and efficacy of sirolimus-eluting vs. paclitaxel-eluting coronary stents. The trial randomized 1,386 patients with angina, and 1 or 2 de novo lesions in native arteries (2.25-3.00 mm in diameter) from 90 hospitals in Europe, Latin America, and Asia, to receive one of the two DES. The primary outcome was in-lesion binary stenosis (stenosis >50% of the luminal diameter) confirmed angiographically at 8 months. The secondary outcome was the rate revascularization and composite endpoint of cardiac death, MI (Q-or non-Q wave), and CABG surgery or repeat target revascularization at 12 months. The authors concluded that the results of the trial showed no difference between the two DES in the rate of binary stenosis or major adverse cardiac events. The trial was powered to prove there is no difference in rate of restenosis but not to detect equivalence between the stents in the event rates. Off-label use: Two more recently published observational studies (Win et al, 2007 and Boehar et al, 2007) assessed the effectiveness and safety of DES for off-label use and untested indications. The studies were relatively large but were only observational, with no control group, and only 12 months of follow-up. These observational studies may only show if there is an association but cannot determine if it is causal. The analysis of the results of these studies indicated that the off-label and untested use of the DES was associated with higher rate of stent thrombosis and adverse outcomes. Dual antiplatelet therapy: Basal Stent Kosten Effektivitata Trial (BASKET) was a randomized controlled trial (N= 826) conducted in Switzerland to compare the 6-month clinical outcomes and cost effectiveness of the sirolimus and paclitaxel-eluting stents versus the bare metal stents. It included on/off label use of the DES. The BASKET-LATE (Pfisterer, 2006), was an observational study that followed-up a series of 746 patients (with 1,133 stented lesions) from BASKET, who survived 6 months without major events (nonfatal MI, or repeat revascularization) for one year after the discontinuation of clopidogrel. The primary outcome was cardiac death and MI. The results of this observational study suggest that after discontinuation of clopidogrel (between 7 and 18 months after implantation) the rates of cardiac death and MI were higher with the drug eluting stents than with bare metal stents (4.9% vs. 1.3% respectively). Thrombosis related events (88% MI or death) occurred between 15 and 362 days after the discontinuation of clopidogrel. **Conclusion:** The results of the published meta-analyses are conflicting in many cases, even for those that pooled the results for the same trials. This could be attributed to different definitions used by the investigators for stent thrombosis, the inclusion and exclusion criteria of the meta-analyses, differences in the clinical protocols of the studies, characteristics of patients and their lesions, and/or different approaches used to analyze the same data. The overall results of these analyses indicate that DESs are associated with a significant decrease in the need for revascularization after the implantation of the stent. They also point towards an increased risk of late stent thrombosis with the drug eluting stents. The analyses do not provide sufficient power to determine if this stent thrombosis is associated with increased risk of acute myocardial infarction and /or mortality. There are also insufficient data to determine if this late stent thrombosis could be attributed to the early discontinuation of antiplatelet therapy. The evidence on the optimal duration of antiplatelet therapy after the placement of a DES is lacking as well. Findings from non-randomized studies suggest a relation between late stent thrombosis and discontinuation of dual antiplatelet therapy, and suggest more prolonged course of clopidogrel than that the recommended by the stent manufacturers (3 months for Cypher, and 6 months for Taxus stents). The current U.S. and European guidelines, as well the as the Circulatory Systems Devices Advisory Panel for the FDA recommend that antiplatelet therapy be taken for at least 12 months unless a patient is at high risk for bleeding.

**Articles:** The search revealed more than 1,000 articles published after our first review. These included over thirty meta-analyses comparing the drug eluting stents vs. the bare metal-stents, or comparing subgroups of patients. The search also identified more than ninety randomized controlled trials and observational studies that compared

different stents with one another for on and/ or off-label use of the stents. There were also published reports from national registries that recorded long-term data on patients receiving the drug-eluting stents for on and off-label indications.

This report will focus on reviewing meta-analyses of randomized controlled trials rather than individual trials. In order to select those with the most valid methodology for critical appraisal, the published met-analyses were screened to determine whether: The authors conducted a systematic literature search, and addressed possible publication bias; The authors stated the inclusion and exclusion criteria for studies they included in the analysis; Selection of the trials and interpretation of the data were conducted by more than one investigator; The quality of the studies was evaluated, and a quality scores given to each study included; The results were pooled and data interpreted with appropriate statistical methods; Data were published in peer reviewed journals or obtained from manufacturers' database; The meta-analysis was conducted by the manufacturer or by independent experts. Screening the published meta-analyses based on these criteria showed that there was no perfect one that fulfilled all criteria. Some included only the pivotal trials that had specific inclusion criteria and resulted in approval of the DES by the regulatory agencies in United States and Europe. Others performed systematic literature searches and included larger numbers of studies, but did not indicate if they were of good quality and if the stent use was on /off label use in trials included. The inclusion criteria for the individual studies varied and were not provided in the majority of the meta-analyses, neither were the rates of on /off-label use of the DES. Some authors combined the results for the sirolimus and paclitaxel-eluting stents compared to bare-metal stents; others restricted their analyses to one of the two DES. The long-term follow-up data were mainly obtained from the manufacturers' databases. The rates of follow-up as well as the duration of antiplatelet therapy used after stenting were not provided. The authors of many of these meta-analyses had financial ties to the manufacturers. Two of the meta-analyses were selected for presentation in evidence tables to demonstrate how pooling data for the same trials could lead to different results due to differences in defining thrombosis and/or using different approaches in the analysis. These two meta-analyses, as well as seven others are also presented in a table form (attached), and in the reviewer's summary section of this report. *The following meta-analyses are presented in evidence tables:* Stone GW, Moses J W, Ellis SG, et al. Safety and efficacy of sirolimus- and paclitaxel-eluting coronary stents. N Engl J Med 2007;356:998-1008. See [Evidence Table](#). Spaulding C, Daemen J, Boersma E, et al. A pooled analysis of data comparing of sirolimus- eluting stents with bare-metal stents. N Engl J Med 2007;356:989-997. See [Evidence Table](#).

The use of drug-eluting stents for coronary revascularization does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Myofascial pain syndrome (MPS) is a fairly common form of pain that arises from muscles or related fascia. The syndrome is usually characterized by palpable muscle tenderness and trigger points (myofascial trigger points or MTrPs). These are highly localized, hyperirritable spots in a palpable taut band of skeletal muscle fibers. When compressed, MTrPs can cause local and/or referred tenderness and pain, aggravation of existing pain, and /or autonomic phenomena. They can also contribute to impaired range of motion and increased sensitivity to stretch. Active MTrPs are associated with spontaneous local or referred pain and/or pain on movement, while latent MTrPs require direct stimulation to trigger pain symptoms. Palpating a trigger point or inserting a needle into it may elicit a localized twitch response, a brisk contraction of muscle fibers in and around the MTrPs. Trigger points may develop anywhere in the body in response to sudden injury, muscle overload, or repetitive microtrauma. Frequently affected sites include trapezius, supraspinatus, infraspinatus, teres muscle, lumbar paraspinals, gluteus, and pectoralis muscles. It is postulated that the injured muscle fibers shorten forming taut bands in response to the excessive amounts of calcium released from the damaged fibers or to the excessive amounts of acetyl choline released from the corresponding motor end plate. There are no laboratory or imaging tests to establish the diagnosis of MPS or to locate the trigger points. It has been suggested that spot tenderness, taut band, and pain recognition are the three important criteria for the diagnosis of MTrP, and that referred pain and local twitch response can be confirmatory signs for the diagnosis (Chou 2012, Dıraçoğlu 2012, Furlan 2005, Kietrys 2013, Ay 2010, Tekin 2013 Tough 2009).

The primary goal of treating MPS is to inactivate the trigger points and loosen the taut bands. The most important strategy is to treat the underlying etiological lesion that causes activation of MTrPs. If the underlying pathology is not appropriately and completely treated, the MTrP is inactivated only temporarily not completely. Several treatment modalities have been used to alleviate the chronic myofascial pain but no single strategy proved to be universally successful. These include the use of non-steroidal anti-inflammatory drugs (NSAIDs), NSAID gel or patch, thermotherapy, massage, physical therapy, spray and stretch techniques, exercise, ischemic compression, laser therapy, acupuncture, or local injections of substances as steroids or lidocaine. Trigger point injection with local anesthetic, saline, steroid, botulinum toxin, or even dry needling is believed to be the most effective method for treating MPS (Ay 2010, Chou 2012, Kalichman 2010).

Dry needling (DN) was initially developed to treat musculoskeletal disorders. It was widely used for the treatment of MTrPs in the last three decades after some investigators indicated that needling effect is distinct from that of the injected substance. Trigger-point DN (also called biomedical acupuncture) is different from acupuncture and is not

based on the insertion of needles in traditional acupuncture meridian sites. DN is a procedure in which an acupuncture-like needle is inserted into the skin and muscle in the location of an MTrPs without the use of saline or any other liquid agent or medication. The needle is not left in situ but is removed after the muscle has finished twitching and the trigger point inactivated. This should be followed by exercises, usually stretching or ergonomic adjustments, in order to establish a painless full range of motion. It has been suggested that DN is most effective when local twitch responses are elicited, probably because of rapid depolarization of the involved muscle fibers which manifest as local twitches. The actual mechanism by which DN may produce an effect is being debated and several explanations were postulated. Some investigators explain that the localized twitch response that often occurs may interrupt the motor end-plate noise, producing an analgesic effect, while others suggest that eliciting a localized twitch response and stretching exercises relax the actin-myosin bonds in the tight bands. It is also postulated that the mechanical damage of the muscle fibers and nerve terminations leads to an increase of extracellular potassium, depolarization of nerve fibers, inhibition of central feedback mechanisms, local dilution of nerve-sensitizing substances, increasing vasodilatation, and formation of necrosis in trigger point area. A number of other mechanisms were postulated by different researchers. Adverse events associated with the DN include soreness after needling, local hemorrhages at the needling site, and syncopal responses (Ay 2010, Furlan 2005, Kalichman 2010, Kietrys 2013).

Several schools and theoretical models of DN have been developed during the last three decades. The most common are the radiculopathy (also known as intramuscular stimulation) and MTrP models. Dry needling techniques include superficial or deep needling, and needling with or without paraspinal needling. In the superficial needling the needle is only inserted into the tissue overlying the MTrP to a depth of 5-10 mm for 30 seconds. At this level the needle does not necessarily reach the MTrP and local twitches are not expected. In the technique that involved paraspinal needling, needles are inserted at the trigger point as well as in the paraspinal muscle of the same segment that innervates the painful muscles. These last two techniques were the least investigated (Kalichman 2010).

DN is a minimally invasive skilled intervention performed by physical therapists (where allowed by state law) and requires advanced training. The states allowing the procedure have to follow guidelines for education and competency standards for performing it.

## Medical Technology Assessment Committee (MTAC)

### *Dry Needling for Myofascial Pain*

#### **02/10/2014: MTAC REVIEW**

**Evidence Conclusion:** The results of the published randomized controlled trials (RCTs) and meta-analyses do not provide sufficient evidence to determine that DN is superior or equivalent to acupuncture, physical therapy, injections with lidocaine or botulinum toxin in reducing myofascial pain or increasing the range of motion. The published randomized controlled trials that compared the effect of DN to sham injections, injections with lidocaine, botulinum toxin, acupuncture, or physical therapy had small sample sizes, and insufficient power to detect significant differences between the study groups. The majority of trials were unblinded, had methodological limitations, and none was designed as an equivalence trial. The overall results of the studies show some improvement in pain and range of motion with lidocaine or botulinum toxin injections, physical therapy, or acupuncture, and some or no improvement with DN. Improvements were observed when the comparisons were made between pre-and post-treatment within each of the study groups. There were no significant between groups differences in the outcomes studied. Many of the authors interpreted the lack of difference between the study groups as equal effects. As indicated earlier, none of the trials were designed as equivalence study, and a lack of significant differences between study groups cannot be interpreted as equal effects as it might be due to the small sample sizes and insufficient power of the trials. Kietrys et al's (2013) meta-analysis (evidence table 1) pooled the results of 12 trials with a total of 696 participants that compared DN to either sham therapy or other active therapies (lidocaine injection, botulinum toxin injection, or acupuncture) for upper quarter myofascial pain. The pooled results of the analysis indicate that DN may be superior to sham needling but less effective than the other active therapies. Tough and colleagues' (2009) meta-analysis pooled the results of 7 small trials, with significant heterogeneity, that studied the effect of acupuncture and DN of the MTrPs compared to no additional intervention, indirect local DN, or a sham therapy. Four of the included studies were rated to have poor methodological quality. The authors could perform a MA only for 4 (N=134 participants) studies that compared DN to sham needling. The pooled results of these trials showed that DN was not superior to sham therapy in reducing the myofascial pain (standardized mean difference =14.09 (95% CI, -5.81 to 33.99). The results of the two meta-analyses have to be interpreted with caution due to the small number and size of the trials as well as their methodological limitations, and significant heterogeneity between studies.

**Conclusion:** There is insufficient published evidence to determine that dry needling has a superior or equivalent effect as acupuncture, other therapies, or injections in reducing pain and improving range of motion (ROM) in patients with myofascial pain syndrome (MPS). The results of trials comparing DN to sham needling are conflicting, and may only provide weak evidence that DN performed by experienced physiatrists may be superior to sham needling in reducing

the pain, but not improving the ROM. There is insufficient published evidence to determine the appropriate number of points to be injected. There is insufficient published evidence to determine the duration of pain relief after the injection. There is insufficient evidence to determine whether the patients would need to undergo another needling procedure, and the most appropriate interval between re-injections if needed.

**Articles:** The literature search revealed a number of small randomized controlled trials and 4 systematic reviews with or without meta-analyses (MA) on the use of DN in the management of myofascial pain. Kietrys and colleagues' 2013 meta-analysis examined the effectiveness of DN for the treatment of upper quarter myofascial pain. Tough et al's 2009 MA updated an earlier 2001 MA on the effect of DN on MPS in any location in the body. A Cochrane review (Furlan et al, 2005) pooled the results of studies on acupuncture and DN for low back pain. The three meta-analyses included the majority of the published RCTs that compared DN to sham needling, physical therapy, or injection of local anesthesia used for the treatment of myofascial syndrome in different locations in the body. The following most recent and larger meta-analysis and selected RCTs included or not included in the meta-analyses were critically appraised. Selection of the RCTs was based on their size, control groups, and methodological quality. Ay S, Evcik D, Tur BS. ## Clinical Review Criteria

### Radiation Therapy for Palmar Fibromatosis

- Radiotherapy
- Dupuytren's Contracture

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

None

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Dupuytren's contracture (DC) is a fibrotic tissue disorder affecting the hands. It is a benign condition characterized by thickening connective tissue in the palm eventually progressing to the formation of nodules and cords. Symptoms typically occur in both hands and progress gradually over time at variable rates. The lumps or dermal pits can be present for extended periods of time before a cord may develop causing the fingers to contract. The contracture, however, may not become troublesome for years or may never progress at all.

DC has a global prevalence of 3-6% primarily affecting males and Caucasian populations. Most patients will present with symptoms in middle age (Rizzo, Stern et al. 2013). Typically diagnosed upon physical examination, the etiology of DC is unknown, however, there is believed to be a strong genetic component as it most commonly occurs in people of Northern European or Scandinavian ancestry and often runs in families. The literature has also suggested associations with diabetes, seizures, smoking, alcohol, trauma and beta-blockers.

At present, there is no cure for DC. Available treatment options include both invasive and noninvasive modalities and typically focus on managing the disability and preventing progression (NICE 2010). Stretching, massage and splinting are frequently recommended while corticosteroid injections and fasciectomy have been used in more extreme and developed cases. In any case, most treatment options have limited effectiveness as 20% of patients experience recurrence of symptoms.

Radiation therapy or radiotherapy (RT) is a non-surgical treatment option that is reported to halt or slow the progression of DC in its early stages. Aimed to prevent or postpone the need for surgical intervention, the mechanism for action is unclear, but it is thought to affect the development and growth rate of fibroblasts within the palmar fascia. RT treatment of the affected nodules and cords can be performed with either superficial x-rays or electron beams. The technique is typically carried out over several consecutive visits until the intended radiation dose has been achieved.

#### Medical Technology Assessment Committee (MTAC)

##### *Radiotherapy for Dupuytren's Contracture*

##### **10/20/2014: MTAC REVIEW**

**Evidence Conclusion:** The most recent study, published by Zirbs and colleagues in September of 2014, included 355 patients with DC who had undergone soft X-ray between 1999 and 2008 at one of two sites in Germany.

Participants were asked to respond to a structured questionnaire addressing family history, predisposing factors, occupation, disease characteristics, progression, treatments, effects, side-effects, and satisfaction using a visual

analogue scale (VAS). Over half (58%) of patients responded to the questionnaire and, of those, almost 80% reported no progression of symptoms after receiving treatment and were satisfied with therapy. The investigators noted a significantly higher improvement in patients with who had experienced symptoms for less than 20 months, supporting the hypothesis that early stages of DC are treated more effectively. Ultimately, the authors concluded that radiotherapy was well-tolerated and prevented further disease progression in most patients (Zirbs, Anzeneder et al. 2014). In the only RCT identified, Seegenschmiedt and colleagues compared two different radiation techniques with the overall aim of optimizing radiation dose. The study included 129 patients (198 hands) who were randomly assigned to receive one of two RT schedules (30 Gy vs. 21 Gy). Subjective responses, DC stage, nodule number, size and consistency, as well as, cords and finger mobility were assessed at two follow-up appointments. At one year, the investigators reported that objective symptom assessment showed indications of regression in over half (56%) of the hands treated with 30 Gy of radiation. Similarly, of the group treated with 21 Gy of radiation, 53% of hands showed signs of regression. Subjective symptom assessment also indicated regression of DC in both groups with 65% and 53% of patients in groups A and B, respectively. The investigators, however, do not indicate if this difference was significant. Ultimately, the authors conclude that both tested regimens are well accepted and tolerated by patients. (Seegenschmiedt, Olschewski et al. 2001). Betz and colleagues present a case series of 135 patients (208 hands) who were irradiated with orthovoltage in two courses of five daily fractions of 3.0 Gy (total dose of 30 Gy) separated by a six to eight week interval. The investigators were able to follow-up 76% of hands treated at 13 years and reported complete relief of symptoms in 16% of patients, good relief in 18% and minor relief in 32% patients. Ultimately, the investigators concluded that radiotherapy is effective in prevention of disease progression and improves patient's symptoms in early stage DC. (Betz, Ott et al. 2010). In terms of safety, theoretical adverse events could be anything that we already know to be associated with radiation such as skin dryness, scarring/hand stiffness, and long-term potential for developing radiation induced cancer. The included studies list both acute and chronic symptoms such as dryness and desquamation, skin atrophy, lack of sweating, teleangiectasia and sensory affection. Seegenschmiedt and colleagues also detailed a higher acute toxicity in the low-dose group receiving (21Gy) when compared to the medium-dose group (30 Gy) citing the dose-time factor as the cause. In any case, all three studies ultimately concluded that the radiation therapy was well tolerated. On the whole, the body of evidence is limited and should be interpreted with caution. First and foremost, none of the included studies used an adequate comparator. In two of the selected studies no comparison group was used, and in the one study that did make comparisons, no sham group was included. To add to this, each study utilized different radiation doses at different regimens without identifying an ideal or standard dose. The inclusion criteria may also be a limiting factor as all three of the studies included patients who had previously received treatment limiting the ability to exclude the effects of prior treatment. Finally, only one of the studies, by Betz and colleagues, provides adequate follow up (13 years) to assess progression of symptoms and long term safety. Conclusions: There is insufficient evidence to support the effectiveness of radiation therapy for patients with DC. There is insufficient evidence to support the safety of radiation therapy for the treatment of DC.

**Articles:** The literature was searched for publications assessing the safety and effectiveness of RT for DC. Several publications were revealed, many of which were published in languages other than English (primarily German). There were no randomized controlled trials (RCTs) comparing the effectiveness of RT with surgical intervention or any other medical intervention for that matter. One RCT was discovered that compared the effectiveness of two different radiation doses. In addition, two recent case series were included to address safety. The following articles were selected for critical appraisal: Zirbs M, Bruckbauer AH, Hoffman H, et al., Radiotherapy with soft X-rays in Dupuytren's disease – successful, well-tolerated and satisfying. European Academy of Dermatology and Venerology. 2014. See [Evidence Table 1](#). Seegenschmiedt MH, Olschewski T, Guntrum F. Radiotherapy optimization in early-stage dupuytren's contracture: first results of a randomized clinical study. Int J Radiation Oncology Biol Phys. 2001; 49(3):785-798. See [Evidence Table 2](#). Betz N, Ott OJ, Adamietz B, et al. Radiotherapy in early-stage Dupuytren's contracture. Strahlenther Onkol. 2010;186(2): 82-90. See [Evidence Table 3](#).

The use of Radiotherapy for Dupuytren's Contracture does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Dynamic Spinal Visualization

- Cineradiography
- Digital Fluoroscopic Video of the Spine
- Dynamic Motion X-ray
- Spine Digital Motion X-ray

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

There is no policy that limits coverage or payment - except the two CPT codes for cineradiology cannot be billed together.

#### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Dynamic spinal visualization addresses different imaging techniques that allow the simultaneous visualization of movement of internal body structures with corresponding external body movement. These include dynamic or digital motion x-rays and video fluoroscopy (also known as digital fluoroscopic video or cineradiography). These imaging technologies use x-rays to create images either on film, video monitor, or computer screen.

Video fluoroscopy is a procedure that uses fluoroscopy to create real-time video images of internal structures of the body. Unlike standard x-rays that take one picture at a time, fluoroscopy provides motion pictures of the body that can be displayed on a video monitor during the procedure and also recorded for further or later evaluation. Digital motion X-ray is a fluoroscopic x-ray that integrates today's digital and optic technology to produce an x-ray movie of the body while in motion. It involves the use of either film x-ray or computer-based x-ray snapshots taken in sequence as the patient moves; to image the cervical spine; for example, patients are asked to perform flexion, extension, right and left lateral flexion and left and right rotation exercises to document range of motion. The snapshots are then digitized, put in order using a computer program and played on a video monitor creating a moving image of the inside of the body. Both digital motion x-rays and video fluoroscopy can either be examined by the physician with or without using special computer software to evaluate several aspects of the body's structure such as intervertebral flexion and extension, in order to determine the presence or absence of abnormalities.

The technology have been used for decades in the diagnosis of various conditions mainly swallowing disorders, and have been proposed for the evaluation of spinal disorders including low back pain, and segmental lumbar spinal instability to determine the presence or absence of abnormalities.

### Medical Technology Assessment Committee (MTAC)

#### Dynamic Spinal Visualization

##### 10/17/2011: MTAC REVIEW

**Evidence Conclusion:** There is insufficient published evidence, to date, to determine the clinical utility of dynamic spinal visualization for the diagnosis or management of patients with spinal disorders. The published studies mainly evaluated the spine kinematics and motion patterns of the lumbar segments in symptomatic patients and

asymptomatic volunteers. Others studied the correlation of total sequence of movement observed by cineradiography with the conventional radiographs taken at the extremes of spinal motion. No studies examined the effect of using the technology on managing the patients, impact on health outcomes, or an incremental value over conventional imaging methods. Reviews made by other health plans including Blue Cross, Blue Shield, Regence, Anthem, and several others, all came to the same conclusion that dynamic spinal visualization is considered investigational, and that there is insufficient published data to support the use of digital motion x-rays or cineradiography/video fluoroscopy of the spine for any indication.

**Articles:** The literature search revealed a limited number of small studies that compared the spine kinematics in patients with neck or back pain versus asymptomatic controls. No studies evaluating the effect of using the technology on managing the patients with back pain or other spinal disorders were identified.

The use of dynamic spinal visualization does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

Group Health has elected to use the MCG\* Electroconvulsive Therapy (B-GHC-802) for medical necessity determinations.

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Electroconvulsive therapy (ECT) is a procedure where electrodes are positioned on the patient's scalp, and a measured electrical current is passed through to the brain, inducing generalized seizure activity. ECT is typically administered by a psychiatrist, with the patient under general anesthesia (provided by an anesthesiologist or anesthetist). The treatments are performed in either an inpatient or outpatient setting, depending on a variety of factors.<sup>1</sup>

ECT is not typically considered the first-line of treatment. It is most often used to treat patients with treatment-resistant depression, after a failure of a number of adequate medication trials over time. However, it may result in therapeutic effect more rapidly than medications and should be considered as a possible first line treatment in life threatening catatonia (e.g. with risk of death due to severe malnutrition/starvation) or in someone who is at extremely high risk of suicide.<sup>2</sup> Patients with severe medical or psychiatric illness often start ECT on an inpatient basis, and as they improve, might switch to outpatient treatment. Continuation and maintenance ECT are usually provided on an outpatient basis.

The mechanism of action for ECT remains unknown. However, many studies have shown a variety of changes in the central nervous system that might play a significant role in its therapeutic effect, including ECT prompting the release of neurotransmitters, and ECT causing the hypothalamus or pituitary gland to release hormones such as thyroid stimulating hormone and endorphins.<sup>2</sup>

ECT has been found to be an effective and safe mode of treatment for a number of behavioral health disorders/conditions, and is practiced widely in the United States.<sup>1</sup> However, the treatment continues to have some stigma attached because of misperceptions about its use, a lack familiarity with the current treatment procedure and the current level of risk of adverse effects.<sup>2</sup>

There are few contra-indications or relative contra-indications to the treatment, so a pre-treatment medical review is required before initiating treatment.

Risks of ECT are primarily those associated with anesthesia. The mortality rate (about 2 to 4 deaths per 100,000 treatments) is mostly related to cardiopulmonary events, but the mortality rate is less than that reported for normal childbirth, and is associated with the anesthesia risks.<sup>3,4</sup>

Current ECT techniques use anesthesia and brief-pulse electrical stimuli that “virtually eliminate” the past risk of fractures and minimize the risk of developing transient cognitive dysfunction effects. Not all patients who receive ECT will obtain Cognitive dysfunction / memory loss from the treatment; however, when it occurs, it can present during or after the course of ECT. The memory effects from ECT can manifest as an acute confusional state, as anterograde amnesia or as retrograde amnesia.

The acute confusional state is considered a result of both the seizure and the anesthesia. It usually resolves 10-30 minutes after the procedure.<sup>5</sup>

Anterograde amnesia is a decreased ability to retain newly acquired information. It can occur during a course of ECT and usually resolves within 2 weeks after completing the course.<sup>6</sup>

Retrograde amnesia involves forgetting recent memories, forgetting events that occur during the course of ECT and for a period of weeks or months prior to the ECT. Patients tend to retain knowledge about themselves, but might forget public knowledge or information about world events. This retrograde amnesia tends to recover more slowly.<sup>7,8</sup>

ECT is most commonly used to treat severe or treatment-resistant depression. ECT has also been shown to be effective for bipolar mood disorders (depression, mania or mixed states), schizoaffective disorder, schizophrenia and catatonia.<sup>2</sup>

ECT has been found to be particularly effective in treating patients with depression with prominent suicidal ideation or patients with psychotic depression. Response rates have been found to range from 50-80% for patients with treatment-resistant depression, and maintenance medication management or maintenance ECT may significantly decrease the relapse rate.<sup>9,10</sup>

For patients with bipolar disorder, ECT has been used for treatment of severe and psychotic depression, especially if refractory to medication management.<sup>11,12</sup>

For patients with schizophrenia or schizoaffective disorders, ECT may be considered when a rapid global improvement with reduction in symptoms is needed.<sup>13</sup> ECT might also be used in the treatment of catatonia.<sup>14</sup>

ECT may be warranted for patients who are in an acutely life-threatening situation (e.g. high risk for suicide attempt, unremitting self-injury, catatonia, starvation, intractable manic excitement, or neuroleptic malignant syndrome). ECT might also be indicated when patients have a coexisting medical condition, where ECT is considered a safer therapeutic alternative than behavioral medication management (e.g. pregnant or elderly patients), and for patients who have previously responded well to ECT or who are unwilling or unable to take medications.<sup>1,2,15,16,17</sup>

For patients who have obtained a positive therapeutic response with ECT, but who are unable to sustain the response with post-ECT behavioral health medication management, ECT as maintenance treatment may be considered, and is generally administered with decreased frequency (e.g. weekly, biweekly, monthly), and might be provided as long-term maintenance treatment, when discontinuation or further reduction in the treatments is likely to lead to a relapse.<sup>1,18</sup>

## Clinical Review Criteria

### Electrical Stimulation Devices

- Electrical Stimulation for the Treatment of Dysphagia
- Functional Neuromuscular Stimulation Unit (FNS or ENS)
- Galvanic Stimulation Device
- Gastric Electrical Stimulation (Enterra)
- H-wave Stimulation Device
- Hypoglossal Nerve Stimulation
- Microcurrent Stimulation Device (MENS)
- NESS Stimulators for Foot Drop and Paralyzed Hands
- Neuromuscular Electrical Stimulation Unit (NMES)
- Percutaneous Neuromodulation Therapy (PNT) for Back Pain - Vertis
- Pulsed Electrical Stimulation for Treatment of Osteoarthritis of the Knee
- ReBuilder System
- Transcutaneous Electrical Nerve Stimulation (TENS) Unit
- WalkAide System for Patients with Foot Drop

#### A Separate Criteria Document Exists for the Following Devices:

[Central Nervous System Electrical Nerve Stimulator: Dorsal Column Stimulators, Deep Brain Stimulator](#)

[Electrical Stimulation for Treatment of Wounds](#)

[Osteogenic Stimulation](#)

[Sacral Nerve Stimulator for Fecal and Urinary Incontinence](#)

[Thalamic and Sub-Thalamic Stimulator for Essential Tremor or Parkinson's Disease](#)

[Vagal Nerve Stimulator for Partial Seizures \(VNS\)](#)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. ## Background

A transcutaneous electrical nerve stimulator (TENS) is a device that utilizes electrical current delivered through electrodes placed on the surface of the skin to decrease the patient's perception of pain by inhibiting the transmission of afferent pain nerve impulses and/or stimulating the release of endorphins.

These are not the same as neuromuscular electrical stimulators (NMES), which are used to directly stimulate muscles and are used to prevent disuse atrophy (not address pain).

The transcutaneous electrical nerve stimulator is a well-established technique with limited effect and efficacy for the control of chronic painful disorders. Patients with chronic pain are best treated with a multi-disciplinary approach that includes increasing their activity. A TENS unit may be useful for a few weeks to assist a patient in becoming more active. It is not recommended for acute pain management as medication is much more effective and is safe for short-term management. It may be used occasionally to assist with pain control in patients with acute pain.

## Medical Technology Assessment Committee (MTAC)

### *Transcutaneous Electrical Nerve Stimulation (TENS)*

06/30/1998: MTAC REVIEW

**Evidence Conclusion:** Jarzem et al., Transcutaneous Electrical Nerve Stimulation for Patients with Chronic Backpain, presented at the annual meeting of the American Academy of Orthopedic Surgeons, San Francisco, 1997. 350 patients with chronic back pain, randomized into 4 groups; (1) daily treatment with conventional TENS; (2) treatment with nu-wave form TENS; (3) treatment with acupuncture TENS; (4) and treatment with sham TENS. In addition, all underwent an identical exercise program by a single therapist, blinded. 26 patients dropped out. All patients improved over time, but there were no significant differences among treatment groups.

### *Electrical Stimulation for the Treatment of Dysphagia*

#### BACKGROUND

Dysphagia is the subjective sensation of difficulty or abnormality of swallowing. The term is derived from the Greek dys for bad or disorder, and phago for eat. Swallowing is a complex sensory-motor behavior that involves more than 25 pairs of muscles, 6 cranial nerves, and 2 cervical nerve roots to transport saliva, ingested solids, and fluids from the oral cavity to the stomach. It consists of three sequential, physiologically interconnected phases: oral preparatory and propulsive phase, pharyngeal phase, and esophageal phase. Dysphagia occurs when there is a problem with any part of this swallowing process. It can affect any age group, and may result from congenital abnormalities, stroke, head injury, neoplasms, and/or other medical conditions. Its incidence is higher in the elderly, in patients who have had strokes, and in patients who are admitted to acute care hospitals or chronic care facilities. Some may have trouble swallowing food, liquids, or saliva, and others are completely unable to swallow. Dysphagia can be a serious health threat due to the risk of aspiration pneumonia, bronchospasm, airway obstruction, pulmonary fibrosis, malnutrition, dehydration, and death (Leelamanit 2002, Blumenfeld 2006, Shaw 2007, Bulow 2008, Humbert 2012, Tan 2013). Functional dysphagia therapy aims at reducing the risk of aspiration and improving the physiology of the impaired swallowing mechanism to restore function. The traditional therapy incorporates diet modification, position adjustment, speech therapy, and exercise to alter the muscle structure and function. Percutaneous endoscopic gastroscopy tubes are often used in the management of dysphagia. Thermal tactile stimulation by the application of cold to the anterior faucal arch is also being used with some success. Existing treatments for dysphagia are usually unable to restore the complete swallow function among patients with the most severe disorders (Freed, 2001, Miller 2013, Tan 2013). Transcutaneous electrical stimulation (ES) that involves the application of electric current across the skin to stimulate nerve or muscle tissue during a functional task is commonly used in physical and rehabilitation therapy. It is used to strengthen muscles after surgery, prevent disuse atrophy of denervated muscles, decrease spasticity, and accelerate wound healing. There are several variants of electrical stimulation therapy. Transcutaneous electrical nerve stimulation (TENS) is mainly used in an attempt to alleviate neuropathic or chronic musculoskeletal pains. This can be used on atrophied or denervated muscles, but does not cause muscle contraction. Functional electrical stimulation (FES) is the application of electrical current to excitable tissue to supplement or replace function that is lost in neurologically impaired individuals e.g. after spinal cord injury. Neuromuscular electrical stimulation (NMES) therapy is used on innervated muscles to recruit motor units and increase muscle strength. It selectively targets healthy innervated muscle fibers, but does not always stimulate atrophied or denervated muscle. NMES may be considered as a FES in situations when a muscle contraction is facilitated during a functional task (Peckham 2005, Carnaby-Mann 2007, Tan 2013). Over the last 2-3 decades, NMES therapy has been proposed as a treatment option for pharyngeal dysphagia to initiate or re-establish the act of swallowing. The therapy involves the application of electric stimulation through a pair of surface electrodes located on the neck. These are usually placed in one of two configurations: one electrode above the lesser horn of the hyoid bone and the other roughly 4 cm below it, or both electrodes above the lesser hyoid bones bilaterally. Electric pulses are then delivered continuously at 80Hz for duration of 300  $\mu$ s and intensity ranging from 2.5 to 25 mA depending on the patient's tolerance. The therapy is usually given for 60-minutes session every day, 5 days a week until swallowing has been restored or until the patient cannot tolerate it (Steele 2007). NMES has received great interest, and raised much controversy since it was introduced. Over 9,000 speech pathologists in the US have been trained to use the technology. However, the underlying neurophysiologic basis for using the procedure that involves surface electrode placement on the external lateral neck is poorly defined. Challenge in designing a neuromuscular stimulation device for swallowing include selecting which muscles to target in the swallowing sequence, designing a device that triggers a chain of successive muscle excitations and inhibitions similar to normal swallowing process. Some scientists have argued that the current intensity delivered by NMES at the submental region is greatest at the skin surface and diminishes with depth through the platysma underlying the skin and subcutaneous fat. The deeper muscles which would pull the hyoid bone up and toward the mandible, and those that elevate the larynx to the hyoid bone, are much less likely to be activated by surface stimulation (Ludlow 2007, Steele 2007). Potential risks of NMES include arrhythmia, hypotension, laryngospasm, burns, glottic closure, and interference with pacemakers. The therapy is

contraindicated in patients with pacemakers, superficial metal implants or orthotics, skin breakdown, cancer, history or cardiac disorders, seizures, impaired peripheral conduction system, pregnancy, significant reflux due to use of a feeding tube, or dysphagia due to drug toxicity (Leelamanit 2002, Blumenfeld 2006, Huckabee 2007). Two NMES devices, the Freed Bioelectric Dysphagia treatment Device and the Chattanooga VitalStim™ system, were cleared by the FDA for marketing in June 2001 and December 2002 respectively. Both are equivalent external electrical stimulation devices intended for re-education of the throat muscles, necessary for pharyngeal contraction, for the treatment of dysphagia from any etiology other than mechanical causes requiring surgery. The therapy treatment sessions last for 60 minutes, and are most commonly administered by a speech and language pathologist. The FDA approval came with a warning that: 1. The long-term effects of chronic electric stimulation are unknown, 2. Stimulation should not be applied over the carotid sinus nerves, 3. Improper placement of the electrodes or improper use of recommended frequency, intensity or pulse, may cause laryngeal or pharyngeal spasm which may close the airway or cause difficulty in breathing.

#### **04/14/2004: MTAC REVIEW**

##### **Electrical Stimulation for the Treatment of Dysphagia**

**Evidence Conclusion:** The study reviewed provides insufficient evidence on the use of electrical stimulation in patients with dysphagia. It had potential selection and observation bias. The investigators compared electrical stimulation to tactile stimulation in a controlled study where patients were not randomized, but alternately assigned to electric stimulation using the Freed Bioelectric Dysphagia treatment Device, or thermal tactile stimulation. Overall, the results of the study show that both treatment groups improved, but the final swallow scores were higher among the electrical stimulation group. The study has potential selection and observation biases and does not provide sufficient data on the long-term effectiveness of the treatment.

**Articles:** The search yielded 11 articles on electrical stimulation for the treatment of dysphagia. There was a longitudinal study with a control group, on electrical stimulation for swallowing disorders caused by stroke (Freed et al 2001), and another on effects of electrostimulation on salivary function of Sjogren's syndrome patients (Taal 1992). In the latter study, treatment aimed at increasing the production of saliva by an electrostimulation device placed on the tongue, which is different from the transcutaneous electric stimulating of the pharyngeal muscles. The search also revealed one case series with 23 patients, four small case reports, and four review articles. A larger study with 892 patients was submitted to the FDA but has not been published in a peer reviewed medical journal to date. *An evidence table was created for the following study:* Freed ML, Freed L, Chatburn RL et al. Electrical stimulation for swallowing disorders caused by stroke. *Respir Care* 2001;46:466-474. See [Evidence Table](#)

The use of electrical stimulation in the treatment of dysphagia does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **08/04/08: MTAC REVIEW**

##### **Electrical Stimulation for the Treatment of Dysphagia**

**Evidence Conclusion:** VitalStim was reviewed earlier by MTAC in April 2004. The best evidence at the time was the Freed et al (2001) nonrandomized controlled trial that compared electrical stimulation to tactile stimulation for the treatment of 110 patients with swallowing disorders caused by stroke. The study had its limitations and biases and did not provide sufficient evidence on the safety and effectiveness of neuromuscular electrical stimulation in treating dysphagia.

**Articles:** There is still a lack of published literature on the use of NMES for swallowing. The best published evidence to date is a very small (N=25) recent RCT with several limitations and a meta-analysis that included one small controlled trial (Freed, et al 2001), a retrospective study with a control group, and small case series. The results of the published controlled studies and case series are conflicting. Several case series with non-blinded subjective measures reported some improvement in swallowing. This positive effect was however not observed when more objective outcomes were used and blindly measured. The only published randomized controlled trial showed no significant differences between NMES and traditional swallowing therapy in treating patients with swallowing difficulties due to stroke. The trial was too small, unblinded, had insufficient statistical power, and no long-term follow-up. These limitations together with other methodological flaws do not allow making conclusions on the efficacy and safety of the therapy. In conclusion, there is insufficient published evidence to determine: 1. Whether patients treated with VitalStim will show more improvement in the oral and pharyngeal phases of swallowing compared to the traditional therapies used in the management of dysphagia. 2. If patients treated with VitalStim would have fewer dietary consistency restrictions compared to those receiving traditional means for dysphagia management, or 3. If patients treated with VitalStim would progress more rapidly from nonoral to oral nutrition compared to those receiving traditional means for dysphagia management.

The search yielded just over 30 articles on electrical stimulation for the treatment of dysphagia. Many were reviews and opinion pieces. There was one meta-analysis of non-randomized controlled studies and case series studies, a more recent small randomized controlled trial, and a number of case series on the effect of NMES therapy on

improving swallowing. The literature search did not reveal any study on the effect of therapy on dietary restrictions, or progress from nonoral to oral nutrition. The meta-analysis and the RCT were selected for critical appraisal. Carnaby-Mann GD, Crary MA. Examining the evidence on neuromuscular electrical stimulation for swallowing. A meta-analysis. Arch Otolaryngol Head Neck Surg. 2007;133:564-571. See [Evidence Table](#) Bulow M, Speyer R, Baijens L, et al. Neuromuscular electrical stimulation (NMES) in stroke patients with oral and pharyngeal dysfunction. Dysphagia April 2008. See [Evidence Table](#) Bulow M, Speyer R, Baijens L, et al. Neuromuscular electrical stimulation (NMES) in stroke patients with oral and pharyngeal dysfunction. Dysphagia April 2008. See [Evidence Table](#)

The use of electrical stimulation in the treatment of dysphagia does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 06/16/2014: MTAC REVIEW

##### **Electrical Stimulation for the Treatment of Dysphagia**

**Evidence Conclusion:** NMES was reviewed earlier by MTAC in 2004 and 2008 and did not pass the evaluation criteria due to the lack of evidence on its safety and efficacy in the management of dysphagia. The best published evidence at the time was the Freed et al (2001) nonrandomized controlled trial that compared electrical stimulation to tactile stimulation for the treatment of 110 patients with swallowing disorders caused by stroke, a very small RCT with 25 patients (Bulow 2008) and a meta-analysis of small nonrandomized studies comprising 225 patients. More recently a number of randomized or quasi randomized RCTs were conducted to assess the efficacy of NMES in patients with dysphagia due to variable etiologies. The studies were small in size, had short follow-up durations, and varied widely in the patient selection, electrode positioning, stimulation protocols, combination with other therapies, and outcome measures. The results of the published trials as well as a meta-analysis of 7 trials are conflicting (evidence tables 1&2). Baijens, et al (2013) found no additional clinical benefit when submental NMES used in addition to the traditional dysphagia therapy in patients with dysphagia secondary to Parkinson's disease. Kushner, et al (2013) reported significantly better outcomes with NMES combined with traditional therapy vs. traditional therapy alone for patients with dysphagia following stroke. On the other hand Tan and colleagues' 2013 meta-analysis of RCTs suggest that NMES may be more effective than traditional therapy in patients with dysphagia due to different etiologies, except for post-stroke dysphagia. The conflicting results of the published studies, different stimulation protocols used, various underlying pathological conditions, and short follow-up durations, makes it hard to determine whether NMES provides additional therapeutic benefit for patients with dysphagia.

**Articles:** The literature search for studies on NMES published after the last 2008 MTAC review, revealed over 50 articles. There were two meta-analyses, 6 small randomized controlled trials, and a number of observational small studies related to the current review. One of the two meta-analyses (Geeganage et al, 2012) assessed feeding and swallowing treatment strategies including NMES in stroke patients and the other (Tan et al, 2013) evaluated NMES in patients with dysphagia caused by non-stroke conditions. The published RCTs identified by the search examined the effect of NMES on treating dysphagia due to stroke, Parkinson's disease, or cancer. The following meta-analysis and the RCTs were selected for critical appraisal. Baijens LW, Speyer R, Passos VL, et al. The use of electrical stimulation in the treatment of dysphagia does not meet the *Group Health Medical Technology Assessment Criteria*.

##### **Gastric Electrical Stimulation for Treatment of Medically Refractory Diabetic Gastroparesis (Enterra™)**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

## BACKGROUND

Gastroparesis (GP) is a gastric motility disorder characterized by delayed gastric emptying in the absence of mechanical obstruction. The most common etiologies of GP are diabetes mellitus, post-surgical often as the result of damage to the vagal nerve, and idiopathic. Other causes include Parkinson's disease, collagen vascular disorder, and any disease process that interferes with the neuromuscular function of the stomach. The characteristic symptoms of gastroparesis include early satiety, nausea, vomiting, bloating, and abdominal pain. These symptoms are typically driven by meal intake, but can also be present continually at varying degrees of intensity. A severe gastroparesis can result in impaired quality of life, recurrent hospitalizations, malnutrition, and even death (Velanovich 2008, McCollum 2011). The standard medical management of gastroparesis involves dietary modification, glycemic control, and the use of antiemetic therapy combined with prokinetic agents such as metoclopramide and erythromycin. These therapies are generally effective for the symptomatic relief in the majority of patients with GP. However, some patients do not respond to, or cannot tolerate drug treatment, and may require palliative endoscopic or surgical therapies. Surgical options include feeding jejunostomy tubes, decompressing gastrostomy tubes, pyloroplasty, and gastrectomy as a last resort (McKenna 2008, Velanovich 2008, McCallum 2010). In the last decade, high frequency gastric electrical stimulation (GES) emerged as a potential treatment option for patients with medically refractory gastroparesis. The therapy involves delivering low-energy electrical stimuli in the muscularis propria of the stomach at a frequency significantly higher than the normal gastric slow wave frequency. This is different from gastric pacing that delivers high energy stimuli at a frequency slightly above the intrinsic slow wave activity. The Enterra® Therapy System (Medtronic, Minneapolis, MN), a stimulation device delivering high-frequency GES, was granted Humanitarian Device Exemption by the US Food and Drug Administration in 2000 for patient with chronic drug refractory nausea and vomiting secondary to gastroparesis of diabetes mellitus or idiopathic in origin (O'Grady 2009, Chu 2012). The Enterra® system consists of three main elements: a pair of leads, a pulse generator, and a programming system. The leads and pulse generator are implanted surgically via laparotomy or laparoscopically. The two leads are surgically implanted about 1 cm apart in the muscle wall of the greater curvature of the stomach, approximately 10 cm from the pylorus. They are anchored in place then connected to a pulse generator placed in a subcutaneous pocket created in the abdominal wall generally in the superior quadrant of the abdomen. The pulse generator is controlled by an external programmer that allows for interrogation and programming of stimulation via a radio-telemetry link. The battery life of the pulse generator is 5-10 years depending on the neurostimulator setting. It is sealed in the generator and thus the device must be replaced when the battery is depleted. The leads can be left in place and reused with the new pulse generator. The Enterra system produces intermittent bursts of high-frequency (~14 cycles per second) short duration pulses (~ 330 µs) that are three to four times faster than the native gastric slow wave frequency (Chu 2012, Guerci 2012, Soffer 2012). GES therapy is not without complications; researchers reported that 7-10% of the patients treated with the Enterra® system experience an adverse event mainly infection of the subcutaneous pocket. Other events include erosion of the abdominal wall by the device, leads dislodgment or penetration through the gastric wall, or tangling of wires in the generator pocket and formation of adhesions (Soffer 2012). This technology was approved by the FDA as a humanitarian device based on data from one study consisting of 33 patients that was not published in the peer-reviewed literature at the time.

### 02/14/2001: MTAC REVIEW

#### **Gastric Electrical Stimulation for Treatment of Medically Refractory Diabetic Gastroparesis (Enterra™)**

**Articles:** There are currently no peer-reviewed articles on this technology. Therefore, it is not possible for the MTAC committee to review the Gastric Electrical Stimulation Enterra™ Therapy System at this time. No published evidence found.

The use of Gastric Electrical Stimulation Enterra Therapy System in the treatment of chronic, intractable (drug refractory) nausea and vomiting secondary to gastroparesis of diabetic or idiopathic etiology does not meet the *Group Health Medical Technology Assessment Criteria* as there was no published evidence to review.

### 02/11/2013: MTAC REVIEW

#### **Gastric Electrical Stimulation for Treatment of Medically Refractory Diabetic Gastroparesis (Enterra™)**

**Evidence Conclusion:** There is insufficient published evidence to determine that gastric electrical stimulation (GES) may improve refractory nausea and vomiting symptoms in patients with gastroparesis secondary to diabetes mellitus. There is also insufficient evidence to determine that GES improves gastric emptying, or that it is superior to other therapies for the treatment of GP. The three published RCTs on GES had their limitations, had negative results, and could not rule out the placebo effect of the therapy. There was no, or very short washout periods between the ON/OFF modes of the experimental phases of the trials, no comparisons were made between GES and other therapies, medical therapy was tried for only one month in some cases, and the prokinetic/antiemetic agents and other therapies were not discontinued during the study periods. The Worldwide Anti-Vomiting and Electrical Stimulation Study (WAVESS) conducted by Abell and colleagues, 2003 (Evidence table 1) was the first published RCT that evaluated the efficacy of the implanted GES system for highly

symptomatic patients with drug refractory nausea and vomiting secondary to gastroparesis of diabetes or idiopathic etiology. This trial together with two other observational studies were the basis for the US Food and Drug Administration Humanitarian Device Exemption approval of Enterra® Therapy System for patient with chronic drug refractory nausea and vomiting secondary to gastroparesis of diabetes mellitus or idiopathic origin. The study was a very small RCT with limitations. It was powered to enroll 80 subjects but could only recruit 33, and was changed from a RCT to an observational study after 2 months of randomization. After implantation of the device, patients were randomized to an ON or OFF stimulation of the device for one month, after which, they were crossed-over to the alternative ON/OFF mode without a washout period. All patients were kept on the prokinetic, antiemetic and other therapies they were using for the duration of the randomized and observational phases of the study. Overall, the results of the trial showed a significant decrease in the weekly vomiting frequency for all the patients combined, but not for the diabetic or idiopathic subgroups. It is to be noted that the published outcome data are different from the data presented to the FDA where no significant differences were found in the mean or median vomiting episodes between the ON and OFF modes. The total Symptom Scores (TSS) did not improve significantly during the RCT phase, but showed significant improvement in the open-label phase. Side effects included infection, pacemaker migration, and stomach wall perforation. Another crossover RCT conducted by McCallum and colleagues, 2010 (evidence table 2) also had its methodological limitations and did not allow examining the placebo effect of GES. All study participants underwent GES for 1.5 months before randomization. There was no washout period after the initial GES or between the ON and OFF modes in the experimental randomized phases. The results of the study showed no significant difference in the (weekly vomiting frequency) WVF or other symptoms between the ON versus OFF periods, but showed a significant improvement in WVF in the first 6-week unblinded period after implantation vs. baseline, which could have been carried over to the randomized phase, especially with a lack of washout period. There was a high rate of adverse events, many of which were serious, and three patients require surgical intervention for infection requiring removal of the device, lead dislodgement, or device migration. At one year after the implant, when all patients had the device switched on, the WVF remained lower than baseline. One meta-analysis (Grady, 2009) combined the results of the first RCT (Abell 2003) together with 12 case series with no control groups, and a second meta-analysis (Chu 2012) pooled the results of two RCTs (Abell 2003, and McCallum 2010) together with 8 case series with no controls. The pooled results showed significant improvement in gastroparesis symptoms. The authors of the two meta-analyses indicated that the results of the analyses should be interpreted with caution due to the limitations and design of the studies included. The three most important complications reported were infection in the subcutaneous pocket affecting, electrodes detachment or displacement, and pulse generator migration, all of which require surgical intervention. Due to the unpredictable response of patients to GES, Abell and colleagues, 2011 (evidence table 3) investigated the effects of temporary electrical gastric stimulation therapy on gastroparesis symptoms to assess the response after a few days of therapy as a predictor of response to long-term therapy with GES. The trial included 55 patients among whom only 13 had diabetes mellitus as the cause of GP. The study was a crossover RCT with only one day washout period between the two sessions in which the device was alternately turned ON and OFF. In the first 3 days after implantation of the electrodes (session 1) both groups experienced a significant improvement in vomiting, nausea, and all symptom scores, irrespective of stimulation, which may indicate a placebo effect. In conclusion, larger studies with a parallel group design, sufficient power, and long-term follow-up are needed to more accurately determine the efficacy and safety of gastric stimulation therapy for gastroparesis of diabetes mellitus or idiopathic etiology.

**Articles:** The literature search revealed over 100 articles on gastric electrical stimulation in patients with gastroparesis. The majority were review articles, articles on technical aspects of the therapy, or observational studies and case series with no comparison groups. The search identified three randomized controlled trials and two meta-analyses that pooled the results of case series together with the randomized controlled trial. The three RCTs were selected for critical appraisal. Abell T, McCallum R, Hocking M, et al. Gastric electrical stimulation for medically refractory gastroparesis. *Gastroenterol.* 2003;125:421-428. See [Evidence Table](#) McCallum RW, Snape W, Brody F, et al. Gastric electrical stimulation with Enterra therapy improves symptoms from diabetic gastroparesis in a prospective study. *Clin Gastroenterol Hepatol.* 2010 ;8:947-954. See [Evidence Table](#) Abell TL, Johnson WD, Kedar A, et al. A double-masked, randomized, placebo-controlled trial of temporary endoscopic mucosal gastric electrical stimulation for gastroparesis: *Gastrointest Endosc.* 2011;74:496-503. See [Evidence Table](#)

The use of Gastric Electric Stimulation for the Treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Hypoglossal Nerve Stimulation**

#### **BACKGROUND**

Hypoglossal nerve stimulation is a new treatment for obstructive sleep apnea (OSA). It addresses the issue of tongue prolapse into the pharynx which causes airway blockage. Tongue prolapse may be due to decreased neuromuscular activity in the genioglossus muscle, the principal tongue protrusor muscle. Electrical stimulation of

the hypoglossus muscle may result in activation of the genioglossus muscle, increasing tongue protrusion and opening the pharynx (Eisele, 1997). A review article published in 1999 (Loube) mentioned that there is a multicenter clinical trial underway on the feasibility of a hypoglossal nerve stimulator (Inspire system; Medtronic), but that the trial has been slowed due to technical issues. The most recent entry on hypoglossal nerve stimulation on the Medtronic web site was in 1997.

#### **08/08/2001: MTAC REVIEW**

##### **Hypoglossal Nerve Stimulation**

**Evidence Conclusion:** There is insufficient evidence on which to base conclusions about the effect of hypoglossal nerve stimulation on health outcomes associated with obstructive sleep apnea.

The search yielded 113 articles. Most of the articles were on uvulopalatopharyngoplasty or glossectomy.

**Articles:** There was one empirical article on hypoglossal nerve stimulation. This was a small case series which included only 5 patients with sleep apnea (also included were 15 patients that were undergoing a surgical procedure involving the neck). Because of the small number of sleep apnea patients and a dearth of clinical outcomes, this study was not reviewed.

The use of hypoglossal nerve stimulation in the treatment of sleep apnea does not meet the *Group Health Medical Technology Assessment Criteria* for effectiveness.

#### **NESS Stimulators for Foot Drop and Paralyzed Hands**

##### **BACKGROUND**

Foot drop is a motor deficiency caused by partial or total paralysis of the muscles innervated by the peroneal nerve. It is not a disease but a symptom of an underlying problem. It is often caused by an injury to the peroneal nerve, but can also be associated with a variety of conditions such as stroke, dorsiflexor injuries, neuropathies, drug toxicities, or diabetes. The problem may be temporary or permanent depending on the cause. Foot drop is characterized by the lack of voluntary control of ankle dorsiflexion, and subtalar eversion. Patients with foot drop are unable to walk on their heel, flex their ankle, or walk with the normal heel-toe pattern. They usually exhibit an exaggerated or high-stepping walk called steppage gait or footdrop gait in order to compensate for toe drop. This unnatural walking motion may result in subsequent damage to the hip, back or knee (Voigt 2000). Management of patients with foot drop varies and is dependent on the underlying cause. Some patients may be fitted with of ankle-foot orthoses (AFO) brace, which typically limit ankle plantarflexion to enhance foot clearance during swing. Patients may also undergo physical therapy for gait training. Surgery may be an option when the cause of foot drop is muscular or neurologic. Electrical stimulation was first proposed as a treatment for foot drop by Liberson in 1961. Liberson referred to the treatment as "functional electrotherapy" because its purpose was to replace a functional movement that was lost after injury or illness. There has been extensive development of functional stimulation devices since the early 1960s. The first devices were hard-wired surface stimulators, followed by hard-wired implanted electrical stimulators, and then microprocessor-based surface and implanted systems. In the 1990s, artificial and "natural" sensors were developed as a replacement for the foot-switch. More recently, testing has been done on a device in which both the sensor and stimulator are implanted (Lyons et al. 2002). The WalkAide system is an external neuromuscular functional stimulator. It contains a control unit attached to a flexible cuff that contains two electrodes. The unit is placed on the leg below the knee, near the head of the fibula. According to FDA materials, WalkAide stimulates the common peroneal nerve which innervates the muscles that cause dorsiflexion of the ankle. This stimulation is intended to produce a more natural and stable walking stride. It is indicated for individuals with foot drop due to central nervous system conditions including cerebral palsy, multiple sclerosis, traumatic brain injury, and cerebrovascular accident. It is contraindicated for patients with traumatic accidents to the leg, complications of back, hip or knee surgery, sciatica, peripheral neuropathy, spinal stenosis, post-polio syndrome and Guillain-Barre syndrome. In addition, patients with pacemakers or who experience seizures should not use WalkAide (FDA materials; Innovative Neurotronics website). The Innovative Neurotronics WalkAide System for foot drop was approved by the FDA in August, 2005 to address the lack of ankle dorsiflexion in patients who have experienced damage to upper motor neurons or pathways to the spinal cord. The NESS L300 is another electrical stimulation system that received FDA clearance (in 2006) to provide ankle dorsiflexion in individuals with drop foot following an upper motor neuron injury or disease. It has the same intended use and same principal of operation as the WalkAide. The main technological difference however between the two systems, is the RF wireless communications between the components of NESS L300 versus the wired communication in the WalkAide system. NESS L300 is a neuroprosthesis device that consists of four main parts 1. A lower leg orthoses containing electrodes and a controlled stimulation unit, 2. A heel sensor 3. A control unit that is carried in the pocket, mounted on the waist, or on a neck strap, and 4. PDA to be used by the clinician to configurate the control unit with functional parameters as appropriate for every patient. The system is intended to provide ankle dorsiflexion in individuals with foot drop following an upper motor neuron injury or disease. During the swing phase of gait, the NESS L300 electrically stimulates muscles in the affected leg to provide dorsiflexion of

the foot. According to the manufacturer it may also facilitate muscle reduction, prevent/retard disuse atrophy, maintain or increase joint range of motion and increase local blood flow (FDA materials; Ness 300 website). NESS H200 or Bioness is another new muscle stimulation device developed Bioness Inc. to restore function to paralyzed muscles. It is a brace like apparatus, equipped with electrodes to stimulate and activate muscles that have been affected by stroke, injury, multiple sclerosis or cerebral palsy. The H 200 is worn on the forearm and hand, and holds the hand in a functional position. According to the manufacturer, the functional electrical stimulation is used to move affected areas through repetitive exercises which would strengthen the muscles, reduce spasticity, improve blood flow, and increase range of movement. A microprocessor allows the therapist to program the device with a sequence of exercises customized to each patient. The system may be also used in the home setting (Bioness Inc. web page). Stroke is one of the leading causes of disability and impairment in the United States. It is reported that only 12-18% stroke survivors will regain complete functional recovery of the upper extremity, and that about 30% to 66% of those with paretic arms will still have an impaired upper limb function after six months with routine rehabilitation. Arm dysfunction impairs the daily activities of the individual as writing, dressing, bathing, self-care, and in turn reduces the functional independence, occupational performance, and quality of life (de Kroon 2002, Meilink 2008, and Kwakkel 2008). Loss of upper extremity function following stroke is a major rehabilitation challenge. Occupational and physical therapies which are commonly used in the rehabilitation of stroke patients have not always been satisfactory in improving the reaching, grasping, holding, or releasing functions of the paralyzed limb. Investigators are now focusing on therapies that will lead to regaining and improving upper extremity functional activity rather than only minimizing the impairment (Alon 2008). Electrical stimulation (ES) has been studied and used clinically for about 40 years in different neurological conditions such as cerebrovascular accidents, multiple sclerosis, cerebral palsy, and other events. Its use for the upper limb is getting increased attention as a therapeutic modality in poststroke rehabilitation. It provides continuous low voltage stimuli which enable repetitive exercise to the neuromuscular system. ES has two modalities: 1. Therapeutic electrical stimulation (TES) which applies higher frequency (36 Hz) with the aim of activating the reduced muscle strength and preventing or lowering the pain and spasticity of the muscles, and 2. Functional electrical stimulation (FES) which applies lower frequency ES (18 HZ) in order to improve activity during the stimuli. TES includes neuromuscular electrical stimulation (NMES), EMG-triggered electrical stimulation, positional feedback stimulation training (PFST), and transcutaneous electrical nerve stimulation (TENS). These have different indications, mechanisms of action, and are applied by multiple devices with a range of possibilities for the adjustment of stimulation parameter (Berner 2004, Kroon 2002). FES on the other hand, is the application of neuromuscular electrical stimulation concurrently with the training of task specific or functional activity i.e. provoking muscle contraction in order to assist the performance of functional activities during stimulation. In the last decades, several research groups have been working on the development of FES systems for the upper extremity, and currently multiple devices aiming at restoring the upper limb function are commercially available (Snoek 2000, Alon 2008). The NESS H200, formerly known as "The Handmaster", (NESS Ltd Ra'anana, Israel) is a portable, non-invasive, hybrid wrist/hand orthosis and electrical stimulation device that is designed to be used in hemiplegic as well as C5 tetraplegic patients. It provides an instrument for both the treatment at the level of impairment (neuromuscular and articular properties) and disability (functional handgrip with stabilized wrist). The system contains an external control unit connected by a cable to a below the elbow splint. The splint contains a body with front spiral end and a wing which pivots about the body and can be opened by lifting a release handle. Five surface electrodes are attached to the splint and correspond with the motor points in finger and thumb muscles. The control unit allows the user to select from among three exercise modes and three functional modes. The exercise modes provide stimulation to the targeted finger and thumb extensor and flexor muscles. The functional mode provides sequential key grip or palmer grasp and release patterns. The spiral design of the system allows wrist stabilization in a functional position of 10 -20o of extension. The system is also designed to permit reproducible accurate electrode positioning by the patient. Once fitted into the orthosis, the electrodes remain in position for all subsequent applications and allow consistent replication of the grasp, hold and release hand functions. The patient is provided with a progressive home exercise program and is required to follow a conditioning paradigm using the system's exercise modes. Training periods start at 10 minutes twice daily and gradually increase to 45 minutes 2 times a day (Hara 2008, Snoek 2000). The NESS system and the Handmaster device received FDA clearance in September 2002, and August 2003 respectively, to be used to maintain or increase the range of motion, reduce muscle spasm, prevent retardation of disuse atrophy, muscle reduction, increase local blood circulation, and provide hand active range of motion and function in patients suffering from upper limb paralysis due to C5 spinal cord injury, or hemiplegia due to stroke.

## **12/03/2007: MTAC REVIEW**

### **NESS Stimulators for Foot Drop and Paralyzed Hands**

**Evidence Conclusion:** There is insufficient published evidence to determine the efficacy and safety of the Ness L300 system for patients with foot drop. There is insufficient published evidence to determine the efficacy and safety of the Ness H200 system for the restoration of hand movements.

**Articles:** The search did not reveal any published studies, on Bioness, NESS L300, or NESS H200. Information about the devices was obtained from the FDA and/or the manufacturer's Web sites.

The use of the NESS L300 or NESS H200 in the treatment of foot drop or paralyzed hands does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **10/06/2008: MTAC REVIEW**

##### **NESS Stimulators for Foot Drop and Paralyzed Hands**

**Evidence Conclusion:** The two published RCTs (Alon 2007, and Alon 2008) were conducted by the same group of investigators in the same center, using the same eligibility criteria, procedures, and outcome measures. One of the studies (Alon 2007) included patients with mild/moderate paresis (Fugl-Meyer score 11-40), and the other (Alon 2008) included patients with severe motor loss of the upper extremity (Fugl-Meyer score 2-10). The two trials compared the standard physical and occupational therapies plus FES using NESS H200 versus the standard physical and occupational therapies alone. The trials were small, unblinded, and had no extended follow-up after the end therapy. Their overall results showed some improvement in movement and function in the patients randomized to the NESS H200. The observed differences vs. standard therapy were statistically significant in patients with mild/moderate paresis but not in those with severe motor loss (Alon 2008). The lack of statistical power in the latter study, as well as open-label design, short duration, and absence of follow-up do not allow making any definitive conclusion regarding the effectiveness of the therapy or the persistence of the improvements observed in patients with severe motor impairment. Ring and colleagues' trial (2005) was a comparative study with blinded assessment of outcomes, but had the disadvantage of inappropriate randomization, small number of patients, and absence of follow-up after the six weeks of therapy. The authors categorized the participants into those with or without active voluntary motion of the fingers and wrist at baseline. Patients were assigned to receive rehabilitation with or without NESS Handmaster. The overall results of the trial showed significant improvement in spasticity, motion, and function in all participants receiving the NESS Handmaster device vs. those who did not receive the device. The observed differences were statistically significant for all variables studies for patients who had active partial range of movement at baseline. For those with no active voluntary motion in the fingers and wrist at baseline, decrease in finger spasticity was the only statistically significant improvement observed.

Conclusion: There is poor evidence to determine that the use of NESS H200 may improve upper extremity function in patients with mild or moderate paresis/paralysis with similar eligibility criteria as those in the trials, compared to standard physical and occupational therapies. There is insufficient evidence to determine whether the benefits observed would persist after therapy is ended. There is insufficient published evidence to determine that the use of NESS H200 would improve function in patients with severe motor loss in the upper extremity. There is insufficient published evidence to determine if the use of NESS H 200 would lead to a faster motor and functional recovery vs. standard therapy alone. There is fair evidence that NESS H200 is safe to use among patients with upper limb impairment due to stroke, and who has eligibility criteria similar to those of the published studies.

The search revealed a large number of published articles on the use of FES in general, but very limited publications on use the use NESS H200 ( NESS Handmaster) for patients with cervical spinal cord injury or stroke. The majority of studies on NESS H200 were case reports or case series with less than 30 patients. There were two small (N=15, and N= 26) randomized controlled trials and one quasi-randomized study, that compared the outcomes of FES using NESS H200 or NESS Handmaster devices in addition to the standard rehabilitation vs. standard rehabilitation alone in stroke survivors with impaired upper extremity. All three were critically appraised.

The use of the NESS H200 in the treatment of paralyzed hands does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **Percutaneous Neuromodulation Therapy (PNT) for Back Pain - Vertis PNT System**

##### **BACKGROUND**

The Vertis percutaneous neuromodulation therapy (PNT) system, manufactured by Vertis Neuroscience, is a minimally invasive, nonsurgical therapy. It is based on the premise that chronic back pain is caused by increased sensitization of the nerve cells that transmit pain signals. The Vertis PNT system delivers electrical stimulation to the deep tissues near the spine to alter the "hypersensitivity" of nerve pathways that cause persistent pain.

Treatment consists of a series of outpatient treatment sessions performed in a clinic setting. It is intended for use by a physician or other clinician (e.g. physical therapist), not for patient use. The device includes three major components: Control unit - A software driven, five-channel, AC powered nerve stimulator which generates the

electrical stimulus, Sterile, needle electrodes, A cable that connects the needles to the control unit. The FDA approved Verdis PNT in September 2001 for the following indications: Symptomatic relief and management of chronic or intractable low back pain and/or as an adjunctive treatment in the management of post-surgical low back pain and post-traumatic low back pain.

#### **10/09/2002: MTAC REVIEW**

##### **Percutaneous Neuromodulation Therapy (PNT) for Back Pain - Vertis PNT System**

**Evidence Conclusion:** There is insufficient evidence to determine the effect of percutaneous neuromodulation therapy on back pain.

**Articles:** There were no published articles evaluating the effect of PNT on back pain. Two articles that were submitted for publication were identified on the manufacturer's website. The manufacturer indicated that the articles are not yet published.

The use of percutaneous neuromodulation therapy in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **Pulsed Electrical Stimulation for Treatment of Osteoarthritis of the Knee**

##### **BACKGROUND**

There are three main types of arthritis that can affect the knee joint: osteoarthritis, rheumatoid arthritis and post-traumatic arthritis. Osteoarthritis, the most common type, is generally a slowly progressing degenerative disease that involves the gradual wearing away of the joint cartilage. Symptoms include pain and swelling. Pain often increases after activities such as walking and stair climbing and is the principal symptom for which patients with osteoarthritis seek medical attention. The main goal of treatment is pain control, although maintaining and/or improving joint function are also goals. A stepwise approach to management of osteoarthritis of the knee is generally recommended. Initial conservative measures include weight reduction, exercise, and the use of supportive devices. Medications, including anti-inflammatories and corticosteroids, can be used to supplement the conservative approaches. For patients who fail medical management, surgical treatments are available. Pulsed electrical stimulation is a potential non-invasive alternative to surgery for patients who do not respond to medical treatment. The BionCare Stimulator has been approved by the FDA as an adjunctive treatment for osteoarthritis of the knee. It is a portable battery operated device that delivers a low frequency (100 Hz) electrical signal to the knee via skin electrodes. Other types of electrical stimulation including electro-acupuncture, transcutaneous electrical nerve stimulation (TENS) and neuromuscular electrical stimulation (NMES) with the Respond Select device have also been used to treat osteoarthritic knee pain.

#### **08/01/2005: MTAC REVIEW**

##### **Pulsed Electrical Stimulation for Treatment of Osteoarthritis of the Knee**

**Evidence Conclusion:** There was one randomized controlled trial on BionCare for treating osteoarthritis (Zizic et al. 1995). The authors reported that the active treatment group had significantly better outcomes than the placebo group two weeks after completing a 4-week treatment period. However, the statistical analysis may have been biased. The authors used a one-sided p-value at  $p < 0.05$ . If they had used the commonly accepted method of dividing the p-value in half for a one-sided p-value (in this case  $p < 0.025$ ), two of the three primary efficacy variables would not have been significant. Another limitation of the study is that, although the authors reported statistically significant differences, the clinical significance is unclear. There was approximately a 10% difference in the change from baseline in patient perception of pain and patient perception of function (approximately 30% change in the treatment group and 20% change in the placebo group for each outcome variable).

**Articles:** The single RCT was published in 1995 and has not been replicated. In addition, no studies were identified that compared BionCare to other treatments such as medication or TENS. Patients in the Zizic study were not required to have failed other treatments. One empirical study on the BionCare system was identified (Zizic, 1995). This was a placebo-controlled randomized controlled trial and was critically appraised. No studies were identified that compared BionCare to other treatments such as exercise or medication, or to different forms of electrical stimulation such as TENS. *The Zizic study was critically appraised:* Zizic TM, Hoffman KC, Holt PA et al. The treatment of osteoarthritis of the knee with pulsed electrical stimulation. *J Rheumatol* 1995; 22: 1757-1761. See [Evidence Table](#)

The use of Pulsed electrical stimulation in the treatment of osteoarthritis of the knee does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **ReBuilder System**

##### **BACKGROUND**

Peripheral neuropathy is a disorder of the peripheral nervous system characterized by impaired function of sensory, motor and/or autonomic nerves. It results from damage to the cell body, nerve fiber, or to the surrounding

myelin sheath of peripheral nerves. Manifestations include pain, numbness, tingling, extreme sensitivity to touch, lack of coordination, muscle weakness or paralysis, and bowel or bladder problems. Treatment relies on addressing the underlying cause and various treatments for pain. ReBuilder is a handheld, battery-powered nerve stimulator that delivers an electrical impulse, similar to a normal nerve signal, to specific regions of the body to alleviate pain, burning, tingling, and numbness from a variety of conditions. The ReBuilder is an FDA class II, neurologic therapeutic medical device that first received FDA 510(k) approval in 1987 for marketing as a TENS unit for pain relief. In 1989, the FDA cleared ReBuilder for other indications. The FDA approval is for the symptomatic relief of chronic intractable pain, post-traumatic and post-surgical pain relief, relaxation of muscle spasms, prevention or retardation of disuse atrophy, increasing local blood circulation, muscle reeducation, immediate post-surgical stimulation of calf muscles to prevent venous thrombosis, and maintaining or increasing range of motions. The FDA has written warning letters to manufacturer of ReBuilder against marketing the device for any off-label indications, including peripheral neuropathy.

## **12/19/2011: MTAC REVIEW**

### **ReBuilder System**

**Evidence Conclusion:** The literature studies did not identify any studies that evaluated the ReBuilder System for any indication. The search did identify a 2011 technology assessment from Kaiser Permanente. Their literature search also did not identify any studies that evaluated the safety or efficacy of the ReBuilder System (Kaiser 2011). Conclusion: There is insufficient evidence to determine the safety or efficacy of the ReBuilder System for the treatment of chronic intractable pain for any condition.

**Articles:** The literature studies did not identify any studies that evaluated the ReBuilder System for any indication. The search did identify a 2011 technology assessment from Kaiser Permanente. Their literature search also did not identify any studies that evaluated the safety or efficacy of the ReBuilder System (Kaiser 2011). See [Evidence Table](#).

The use of ReBuilder System does not meet the *Group Health Medical Technology Assessment Criteria*.

### **WalkAide System for Patients with Foot Drop**

#### **BACKGROUND**

Foot drop is defined as a significant weakness in the muscles involved in flexing the ankle and toes (dorsiflexion). The specific muscles affected include the tibialis anterior, extensor hallucis longus and extensor digitorum longus. These muscles allow the toes to swing upward during the beginning of a walking stride and the planting of the heel towards the end of the stride. In patients with foot drop, the foot droops or drags along the ground during the swing phase. The condition is also called steppage gait because patients often raise their thigh excessively high to compensate for toe drop, and they appear as though they are walking up stairs. The unnatural walking motion may result in subsequent damage to the hip, back or knee. Foot drop is associated with a number of conditions such as peripheral nerve injuries, stroke, diabetes, neuropathies and drug toxicity. The causes can be divided into three categories, which may overlap: nerve damage, muscle damage, and/or a skeletal or anatomic abnormality. The conventional treatment for foot drop is the use of ankle-foot orthoses (AFO). These typically limit ankle plantar flexion to enhance foot clearance during swing. Disadvantages of AFOs are that they can be uncomfortable and limiting to wear. Surgery is sometimes beneficial when the cause of foot drop is muscular or neurologic. Electrical stimulation was first proposed as a treatment for foot drop by Liberson in 1961. Liberson referred to the treatment as "functional electrotherapy" because its purpose was to replace a functional movement that was lost after injury or illness. There has been extensive development of functional stimulation devices since the early 1960s. The first devices were hard-wired surface stimulators, followed by hard-wired implanted electrical stimulators, and then microprocessor-based surface and implanted systems. In the 1990s, artificial and "natural" sensors were developed as a replacement for the foot-switch. More recently, testing has been done on a device in which both the sensor and stimulator are implanted (Lyons et al. 2002). The WalkAide system is an external neuromuscular functional stimulator. The system contains a control unit attached to a flexible cuff that contains two electrodes. The unit is placed on the leg below the knee, near the head of the fibula. According to FDA materials, WalkAide stimulates the common peroneal nerve which innervates the muscles that cause dorsiflexion of the ankle. This stimulation is intended to produce a more natural and stable walking stride. WalkAide is indicated for individuals with foot drop due to central nervous system conditions including cerebral palsy, multiple sclerosis, traumatic brain injury and cerebrovascular accident. It is contraindicated for patients with traumatic accidents to the leg, complications of back, hip or knee surgery, sciatica, peripheral neuropathy, spinal stenosis, post-polio syndrome and Guillain-Barre syndrome. In addition, patients with pacemakers or who experience seizures should not use WalkAide (FDA materials; Innovative Neurotronics Web site). The Innovative Neurotronics WalkAide System for foot drop was approved by the FDA in August, 2005 to address the lack of ankle dorsiflexion in patients who have experienced damage to upper motor neurons or pathways to the spinal cord.

## **10/02/2006: MTAC REVIEW**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

## WalkAide System for Patients with Foot Drop

**Evidence Conclusion:** There is insufficient published evidence to determine the efficacy and safety of the Innovative Neurotronics WalkAide System for patients with foot drop. A randomized controlled trial comparing WalkAide to ankle-foot orthoses is underway. The only empirical study identified was a case study, reporting on one patient. The patient used a bionic nerve (BION) implant and a portable BIONic foot drop stimulator that the authors called a "WalkAide2". It is not clear whether this is the same technology as the Innovative Neurotronics WalkAide system.

**Articles:** There are no published randomized or non-randomized controlled studies. According to ClinicalTrials.gov and the Innovative Neurotronics website, an RCT is underway comparing the Innovative Neurotronics WalkAide System to an ankle-foot orthosis (AFO) in patients with cerebrovascular accident. No data from this study are available at this time.

The use of the WalkAide system in the treatment of foot drop does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Electromagnetic Navigation Bronchoscopy (ENB)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Medicare has no NCD or LCD for Washington for this service. The CPT codes when billed are reimbursed at the APC level when billed in an ambulatory setting.

##### For Non-Medicare Members

###### Diagnosis of peripheral lesions

When used with endobronchial ultrasound, electromagnetic navigation bronchoscopy is considered medically necessary.

###### OR

###### Fiducial marker placement

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Flexible bronchoscopy (FB) is a minimally invasive procedure that is used for the diagnosis and treatment of lung cancer. Research suggests that the sensitivity of FB is approximately 88% for diagnosing central lesions and 78% for diagnosing peripheral lesions (most commonly defined as lesions that are not visible beyond the visual segmental bronchi). However, the sensitivity of FB is dependent on lesion size. FB does not perform as well for smaller peripheral lesions. It has been estimated that for peripheral lesions less than 2 cm in diameter the sensitivity of FB is approximately 34% (Rivera 2007).

Electromagnetic navigation bronchoscopy (ENB) is a relatively new bronchoscopic tool that combines CT-generated virtual bronchoscopy and electromagnetic tracking of a steerable probe to allow physicians to perform biopsy of peripheral lesion that are not accessible through conventional bronchoscopy. It has also been suggested that mediastinal lymph nodes can be biopsied using ENB. Other uses of ENB include implantation of fiducial markers for radiotherapy, implantation of brachytherapy seeds or catheters, and dye marker placement for surgical resection.

Several ENB systems have received FDA approval. ENB using the superDimensions I Logic™ System (superDimensions, Inc. Minneapolis, MN) is performed in three phases – planning, registration, and navigation and biopsy (Bechara 2011, Schwartz 2010).

1. Planning: A three-dimensional image of the patient's lungs with anatomical landmarks is constructed using previously taken CT scans and proprietary software.
2. Registration: The steerable navigation catheter is inserted through the bronchoscope. The three-dimensional image with anatomical landmarks created in the planning phase is viewed and correlated with the actual image from the video bronchoscope. The position of each landmark is marked using a foot pedal.
3. Navigation and biopsy: The steerable catheter is used to navigate to the lesion. The location of the catheter's tip is displayed on the CT images. Once the catheter reaches the target, it is locked in place, and the working guide is retracted. Once the catheter is in place, any endoscopic tool can be inserted

through the channel. This includes transbronchial forceps to biopsy the lesion or guide wire for the placement of fiducial markers.

## Medical Technology Assessment Committee (MTAC)

### Electromagnetic Navigation Bronchoscopy

08/20/2012: MTAC REVIEW

**Evidence Conclusion: Diagnostic yield** A recent RCT that included 118 subjects with evidence of peripheral lung lesions or solitary primary nodules on CT evaluated the diagnostic yield of endobronchial ultrasound (EBUS), electromagnetic navigation bronchoscopy (ENB), and combined EBUS/ENB. Results from this study suggest that combined EBUS/ENB improves diagnostic yield compared to either method alone. The pneumothorax rate was 5% in the EBUS and ENB alone groups and 8% in the combined group. There was no significant difference in pneumothorax rate between the three groups (Eberhardt 2007).

Diagnostic yield (Eberhardt 2007)		
EBUS	ENB	Combined
69%	59%	88%

A recent meta-analysis also evaluated the diagnostic yield of different guided bronchoscopy methods. Results from this meta-analysis suggest that the diagnostic yield of ENB is approximately 67%. Results from this meta-analysis should be interpreted with caution as the majority of the studies included in the meta-analysis were small case series (Wang Memoli 2012). Since the meta-analysis two additional case-series were identified. The first case-series included 112 subjects and evaluated the diagnostic yield of ENB combined with rapid on-site cytopathologic evaluation (ROSE). Overall, the diagnostic yield in this study was 84%. In lesions less than 2 cm, the diagnostic yield was 75.6% and 89.6% in lesions greater than 2 cm. There were two cases (1.8%) of pneumothorax (Lamprecht 2012). The second case-series included 101 subjects and also evaluated the diagnostic yield of ENB combined with ROSE. The diagnostic yield from this study was 85%. There were 6 cases (5.8%) of pneumothorax (Pearlstein 2012). **Fiducial marker placement** A small observational study evaluated the transcutaneous placement of fiducial markers using either CT or fluoroscopic guidance (N=15) or transbronchial placement using ENB (N=8) in patient with small, early-stage, non-small cell lung cancer. Pneumothorax occurred in 8 patients (53%) who underwent transcutaneous placement and no patients who underwent transbronchial placement. The fiducial markers did not show substantial migration during the course of treatment for either method (Kupelian 2007). Conclusion: Diagnostic yield: Results from a RCT, a meta-analysis of mainly small case-series, and two case-series suggests that the overall diagnostic yield of ENB is approximately 59 to 85%.

Safety: The pneumothorax rate in the studies ranged from 1.8 to 8%.

Fiducial marker placement: There is insufficient evidence to determine the safety and clinical utility of ENB for the placement of fiducial markers.

**Articles:** Several small observational studies, a randomized controlled trial (RCT), and a meta-analysis were identified that evaluated the use of ENB for diagnosing lung cancer. The meta-analysis and the RCT were selected for review. A few small observational studies were identified that evaluated fiducial marker placement using ENB. The number of patients receiving ENB for the placement ranged from 1 to 12. Due to the small sample size none of these studies were selected for review. A summary of the results from one of the more recent studies is presented below. The following articles were selected for review: Eberhardt R, Anantham D, Ernst A, Feller-Kopman D, Herth F. Multimodality bronchoscopic diagnosis of peripheral lung lesions: a randomized controlled trial. *Am J Respir Crit Care Med.* 2007;176:36-41. See [Evidence Table](#). Wang Memoli JS, Nietert PJ, Silvestri GA. Meta-Analysis of Guided Bronchoscopy for the Evaluation of the Pulmonary Nodule. *Chest.* 2011. See [Evidence Table](#).

The use of ENB for diagnosis does meet the *Group Health Medical Technology Assessment Criteria*.

The use of ENB for fiducial marker placement does not meet the *Group Health Medical Technology Assessment Criteria*.

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	<a href="#">Brachytherapy: Non-intracoronary (L24281).</a>
Local Coverage Article	None

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Nonmelanoma skin cancer (NMSC) is the most common malignancy in the Caucasian population and its incidence continues to rise. It is estimated that more than two million Americans are affected by NMSC each year. Basal cell carcinoma (BCC) represents approximately 75% of NMSCs and squamous cell carcinoma (SCC) 25%. These cancers have a low mortality rate and are rarely life threatening, but can be disfiguring when not diagnosed and treated in a timely manner. They also have a significant impact on the health care delivery system (Alam 2011, Bhatnagar 2010 & 2013).

Treatment options for NMSC include surgery, radiation therapy, chemotherapy, and photodynamic therapy. Surgery is considered the gold standard therapy; it provides the highest cure rates and has satisfactory cosmetic results. Surgical techniques include excision, curettage with electrodesiccation, and Mohs micrographic surgery. The choice of procedure depends on the histologic type, size, and location of the lesion. Some patients however, are not suitable candidates for surgery because of their age, health condition, or potential disfigurement due to the location or type of cancer. Radiation therapy has been used for selected skin cancers, typically reserved as a second-line therapy for patients with surgical contraindications or as adjuvant therapy for high-risk lesions. It may also be a good alternative to surgery for lesions located in areas where surgery may be more difficult, lead to disfigurement, or affect structural function e.g. eyelid, ear, or nose. Radiation therapy techniques used for NMSC include superficial x-rays, orthovoltage x-rays and megavoltage photons, electron beam irradiation, and high-dose rate (HDR) brachytherapy with surface applicators or surface molds. HDR brachytherapy works via a precise, radioactive seed that delivers high dose radiation within specialized catheters to a targeted area within a shielded room. It is also commonly used for breast, lung, prostate and gynecologic cancers (Bhatnagar 2010 & 2013, Frakulli 2015, Linos 2015, Safigholi 2015).

Electronic brachytherapy (EBT) is a form of HDR brachytherapy that brings an electronic brachytherapy source in close proximity to the cancerous site. EBT has the potential benefit of providing shorter and more convenient form of radiotherapy without the use of radioactive isotopes, linear accelerators, or dedicated treatment vault, and with

minimal shielding requirements due to the low energy used. Currently there are three different EBT systems available for clinical application: Axxent by Xofig Inc. (Fremont, CA), the Intrabeam Photon Radiosurgery Device by Carl Zeiss Surgical (Oberkochen, Germany), and the Esteya by Elekta (Esteya EBS, Elekta AB-Nucletron, Stockholm, Sweden). The main component in these systems is a miniature X-ray tube that produces bremsstrahlung (electromagnetic) radiation using electron energies ranging from 20-70keV. Treatment of skin cancers by these system is performed using conical applicators developed by the manufacturers and provided in different sizes (1cm, 2 cm, 3.5 cm, and 5 cm) Bhatnagar 2013, Safigholi 2015).

## Medical Technology Assessment Committee (MTAC)

### Electronic Brachytherapy for Non-Melanoma Skin Cancer

#### 04/21/2014: MTAC REVIEW

**Evidence Conclusion:** The published study on EBT for the treatment of NMSC that was identified by the literature search was a small case series with no control or comparison group (evidence table 1). A total of 122 patients with 171 NMSC lesions (from July 2009 to April 2012) received EBT to a dose of 40 Gy in eight fractions, delivered twice weekly. Patients were assessed for acute and late toxicities, cosmesis, and local control. In 2010 Bhatnagar and Loper retrospectively reported on the short-term (median 4.1 months) results of 37 patients (44 lesions); and in 2013, Bhatnagar published the outcomes of 42 patients (46 lesions) with one or more year follow-up data. The author reported that all lesions resolved with treatment, with no recurrences. The early side effects of the therapy were rash dermatitis (83% of the lesions) and pruritus (18%). Late adverse events included grade 1 hypopigmentation in 10% of the lesions, rash dermatitis (6.5%), as well as alopecia, and dry desquamation that occurred at lower rates (2.2%) each. One-year cosmetic evaluation was performed for 42 of the 46 lesions; 39 (92.9%) were graded as excellent, and 3/42 (7.1%) were good. Two-year outcome data for 22 lesions in 21 patients (Bhatnagar 2012) showed that cosmesis was excellent for 20 evaluable lesions, and good for 1. Based on these results the authors concluded that EBT provides a convenient nonsurgical option for NMSC patients. The study was a case series with its limitations and potential biases. EBT was not compared any other surgical procedure or radiation therapy; it had a short follow-up duration, and the authors did not discuss how patients were selected for the procedure, and whether there were any dropouts.

Bhatnagar A, the principal investigator of the study received a research grant from the industry sponsoring the study. Conclusion: There is insufficient published evidence to determine the safety and efficacy of EBT for the treatment of NMSC. There is an ongoing clinical trial "Electronic Brachytherapy for the Treatment of NMSC" (NLM Identifier NCT01016899) with the objective of recording the recurrence in patients treated for nonmelanoma (basal cell and squamous cell carcinomas) skin cancer using the Xofig Axxent Electronic Brachytherapy System. The trial will also evaluate the cosmetic outcomes and skin toxicities related to the treatment.

**Articles:** The literature search for EBT for the treatment of NMSC identified only one study on the use of electronic brachytherapy for the treatment of NMSC. The initial results were reported in 2010 (Bhatnagar A, and Loper A, 2010) and 1 year results were published in 2013 (Bhatnagar A 2013). Bhatnagar A. Nonmelanoma skin cancer treated with electronic brachytherapy: results at 1 year. *Brachytherapy*. 2013; 12(2):134-140. See [Evidence Table](#). Bhatnagar A, Loper A. The initial experience of electronic brachytherapy for the treatment of non-melanoma skin cancer. *Radiat Oncol*. 2010; 5:87. doi: 10.1186/1748-717X-5-87 See [Evidence Table](#).

The use of electronic brachytherapy for non-melanoma skin cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 03/21/2016: MTAC REVIEW

### Electronic Brachytherapy (EBT) for the treatment of non-melanoma skin cancer (NMSC)

**Evidence Conclusion:** There is insufficient published evidence to determine whether the safety and efficacy outcomes of electronic brachytherapy for NMSC are as good or superior to the outcomes of alternative treatment options. There are no published randomized or non-randomized controlled trials that compared EBT to an alternative therapy for the treatment of NMSC. The available published evidence consists of case series that used different systems for the delivery of HDR. The largest series (Bhatnagar 2010 & 2013) that used one of the three commercially available devices (the Axxent system, Xofig Inc. Sunnyvale, CA) was reviewed by MTAC earlier in 2014, and did not provide sufficient evidence on the long-term efficacy or safety of the procedure.

The more recent case series identified by the search were small retrospective series with no comparison groups, and do not provide additional evidence to support the use of EBT for NMSC. In a recently published article, Linos and colleagues (2015), expressed their concern regarding the increase in the use of EBT for skin cancer. The authors analyzed Medicare claims data and found that EBT use for skin cancer is increasing rapidly in the Medicare population. They indicated this may be attributable to marketing by the manufacturers, and that there is insufficient long-term data on the efficacy and safety of the therapy to cover the period during which recurrence and radiation sequelae would be expected (Linos, 2015).

**Articles:** The updated literature search for the use of electronic brachytherapy in the treatment of NMSC did not identify any controlled trial that compared the therapy with an alternative mode of treatment. The search only

identified a number of small retrospective case series and a systematic review of the observational studies reporting on the outcomes of low-dose or high-dose brachytherapy used for the treatment of NMSC of the eyelid (Frakulli 2015).

The use of electronic brachytherapy for non-melanoma skin cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Enteral Formulas for Nutritional Therapy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the member's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### For Non-Medicare Plans

(Excludes Microsoft plans, which have separate criteria)

**The criteria are for formulas only. The pumps and associated equipment are considered durable medical equipment and are covered as part of the durable medical equipment benefit.**

Elemental formulas are composed of amino acids, fats, sugars, vitamins, and minerals and lack whole or partial protein. An example of an elemental formula is Vivonex. Most formulas are not elemental as they contain complete proteins and complex carbohydrates, examples of which are Ensure or Prosoybe.

To qualify for enteral nutritional formula, elemental formula (either replacement or supplemental) or non-elemental formula, the member must meet **ONE of the following**, either I, II or III:

- I. To qualify for Nutritional Replacement Therapy, using an *elemental* formula, members must meet **ONE of the following**:
  - A. Members must have at least **ONE of the following** diagnoses:
    1. Crohn's Disease
    2. Inflammatory Bowel Disease
    3. Short Bowel Syndrome
    4. Eosinophilic gastrointestinal associated disorders
  - B. The member must also meet **ALL of the following**:
    1. Formula is intended for home use
    2. The member is managed by a Gastroenterologist
    3. The member has been evaluated and will be followed by a Registered Dietitian
    4. Elemental total nutritional replacement represents 80 - 100% of diet or 80% or greater of the daily dietary requirements
    5. Alternative approaches, other than use of an elemental formula, have not resulted in adequate nutrition and control of symptoms.
    6. Member must meet **ALL of the following**:
      - a. Able to tolerate oral supplementation
      - b. If unable to tolerate oral supplementation, member must meet **ALL of the following**:
        - The member or caregiver must demonstrate the ability to place a nasogastric tube.
        - The member or caregiver must also be able to demonstrate the ability to regulate flow either via gravity drip or pump.
- II. To qualify for Nutritional Supplementation Therapy using an *elemental* formula, members must meet **All of the following**:
  - A. Members must have at least **ALL of the following** diagnoses:
    1. Crohn's Disease
    2. Inflammatory Bowel Disease
    3. Short Bowel Syndrome
    4. Cystic Fibrosis involving the intestine
    5. Eosinophilic gastrointestinal associated disorders
  - B. Members must also meet **ALL of the following**:
    1. Intended for home use
    2. Growth failure/retardation or cachexia has been documented
    3. The member is managed by a Gastroenterologist

4. The member has been evaluated and will be followed by a Registered Dietitian
  5. Therapy, other than use of an Elemental formula, has not resulted in clinical disease management.
- C. Member must meet **ONE of the following**:
1. Able to tolerate oral supplementation
  2. If unable to tolerate oral supplementation, member must meet **ALL of the following**:
    - a. The member or caregiver must demonstrate the ability to place a nasogastric tube or manage a surgically placed feeding tube.
    - b. The member or caregiver must also be able to demonstrate the ability to regulate flow either via gravity drip or pump.

III. Oral nutrition or supplements using *non-elemental* formula may be considered medically necessary when used for the treatment of inborn errors of metabolism. Member must meet **ALL of the following**:

- A. Must have **ONE of the following** diagnosis:
1. Phenylketonuria [PKU]
  2. Maple syrup urine disease (MSUD)
  3. Homocystinuria,
  4. Histidinemia
  5. Tyrosinemia
  6. Glycogen Storage Type II Syndrome (GSD II or Pompe disease)
- B. Formula is intended for home use (not for use in the hospital or nursing facility)

**The following are not covered:**

Member with a functional intestine and access problems (gastrostomy, jejunostomy or problems with the mechanism of oral feeding requiring tube access to the stomach) are not covered for supplemental therapy unless they meet the criteria above.

## Clinical Review Criteria

### Enteral Formulas for Nutritional Therapy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

[Microsoft Plans](#)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Until 1996, the only Group Health plans that had coverage for enteral therapy were the Medicare plans. In 1996 an appeals case caused Group Health to reevaluate the potential inclusion of enteral therapy for all groups. The reevaluation, which included a special work group and the Cooperative Benefits Committee, concluded that the use of elemental enteral therapy for ineffective GI absorption that represented a major portion of the consumer's calorie intake, should be covered up to the level of replacement of regular cost of food (80% of charges).

This coverage was to be added in 1997 to all plans under dietary formula where enteral nutrition therapy benefit is not in place. Since only subsets of specific consumers are eligible for this coverage, criteria were developed for consistent review of requests.

In 1998, Group Health received a request to consider coverage for Glycogen Storage Type II Syndrome supplemental formula. After review of the case and literature, the decision was made to add the disease to the criteria for coverage.

In July 1998 Group Health received an update of the Healthy Options criteria for coverage of enteral feedings. In October 2005 the MMA program updated the coverage criteria that are applicable to Healthy Options. Group Health criteria were adjusted to reflect the new changes.

#### Evidence and Source Documents

03/1998

**Articles:** Definitions: Inflammatory Bowel Disease includes Crohn's Disease of small intestine or colon, Ulcerative Colitis, and overlap syndromes (Non-Specific IBD, Segmental Colitis) An Elemental Diet contains oligo-peptides as the major protein source. Vivonex (lower fat- 2.5%) and Vital HN (higher fat- 8%) are typical elemental diets. Non-elemental diets contain intact proteins from a defined source (such as milk protein, meat or egg)

Growth Retardation/ Failure requires: A pediatric patient (defined as age<18 years, and epiphyses not fused on radiography) and a height per age <5th percentile, or a decrease in growth velocity of  $\geq 2$ cm/year, or bone age > 2 SD below chronologic age Nutritional Replacement Therapy requires >90% (and preferable 100%) of the caloric intake be provided by the elemental formula Nutritional Supplementation Therapy requires that >50% of the caloric

intake is provided by the elemental formula. The use of elemental enteral nutrition in inflammatory bowel disease has progressed from strictly nutritional to therapeutic. Although the mechanism is not fully understood, disease activity and intestinal permeability decrease in patients "fed" with elemental diets, as compared to regular diet or TPN. The therapeutic role is best documented in the management of Crohn's Disease [especially of the small intestine]. The role of this therapy in Ulcerative Pancolitis, Ulcerative Colitis limited to the left colon, nonspecific IBD, and Segmental Colitis is not supported by these data. Nutritional Therapy (whether Replacement or Supplement) is used only in conjunction with other drug therapy (including 5-ASA compounds, corticosteroids, immunosuppressives and antibiotics) not in lieu of these other therapies. The consideration of surgery as primary therapy must be considered in patients with significant strictures complicating nutrition.

## Clinical Review Criteria

### Enteral Formulas for Nutritional Therapy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Microsoft Plans:

- A. Enteral or oral nutrition may be considered medically necessary for providing nutrition for patients with:
1. Adequate intestinal absorption despite anatomical disorders of the alimentary tract (e.g., head and neck cancer, an obstructing tumor or stricture of the esophagus or stomach, or Crohn's disease); central nervous system disease or injury resulting in interference with neuro-muscular coordination of chewing and swallowing to the extent that a risk of aspiration exists;
  2. Severe hyperemesis gravidarum;
  3. Anorexia or bulimia, when the patient meets criteria;
  4. Metabolic disorders that are recognized as requiring the addition or restriction of specific dietary elements that would otherwise result in physical or neurological injury; and
  5. Failure to thrive.
- B. The following criteria must be met prior to the initial implementation of nutritional support services. In qualifying conditions where enteral nutrition appears appropriate, an attempt must be made to meet the patient's need by enteral nutrition prior to implementing TPN.
1. The patient receives no more than 30% of his/her caloric intake orally OR is unable to maintain estimated nutritional needs even though he may be receiving > 30% orally (e.g., cystic fibrosis or failure to thrive).
  2. The patient must be in a stage of wasting as indicated by one or more of the following:
    - a. Weight is < 90 percent of patient's pre-illness weight
    - b. Serum albumin is less than 2.5 gm
    - c. Patient has had inadequate nutrient intake for 7 days or more (i.e., an average of less than 25% of the caloric requirement)
    - d. The patient is under 75% of IBW
- C. For anorexia or bulimia, the patient must meet the following criteria:
1. The patient is unable to take in or retain adequate amounts orally to correct the applicable abnormalities listed below.
  2. There is objective clinical evidence of malnutrition and/or emaciation (one or more of the following):
    - a. Significantly abnormal Hb (< 10), Hct (<30), Albumin (< 2.5 gm), iron (< 40 µg), B12 (< 140 pg)
    - b. Na < 123 or > 156
    - c. K < 2.5 or > 6.0
    - d. Significant cardiac arrhythmia (EKG confirmed) indicative of an unstable cardiac status
    - e. Volume depletion with azotemia (BUN > 20)
    - f. Significant hypotension that is abnormal for the patient
    - g. Rapid weight loss in a patient with a history of prior rapid weight loss that resulted in serious physiological abnormalities or morbidity.
    - h. Enteral nutrition should be temporary until such time as the patient is able to take in and retain adequate amounts orally to correct the specific physical abnormalities and maintain the corrected state. Within one week of beginning EN, attempts at oral feedings should be made. An additional week may be required to wean off EN. Concomitant psychotherapy to address the underlying psychological reasons for pathological restricting of intake and/or purging is mandatory.
    - i. A physician must specifically order nutrients and the manner of administration for both TPN, and EN, and for oral nutrition supplies.
    - j. Intermittent gravity feeding is sufficient for most patients with nasogastric or gastrostomy tubes.
    - k. Pump-controlled infusions are recommended for jejunal feedings and for gastrostomy feedings given by continuous infusion to decrease gastroesophageal reflux.
- D. Generally, a daily caloric intake of 2000-2200 calories is sufficient to maintain an adult's body weight. Recommended caloric ranges for maintenance by age group are as follows:

1. Infants 115 cal/kg/day
2. Children 80-105 cal/kg/day
3. Adolescents 35-45 cal/kg/day
4. Adults 25-35 cal/kg/day

- E. Greater daily caloric intake may be necessary for patients to regain lost weight.
- F. A medical director evaluates requests for alternative routes of administration and/or infusion of less than 70% of the daily calorie need to TPN and/or EN on a case-by-case basis. Oral nutritional needs due to metabolic disorders are eligible as medical supplies as long as the physician treating the patient indicates the dietary intake is required to prevent physical and/or neurological injury and the dietary requirements cannot be met by management of normal nutritional intake using over-the-counter food sources.

## Clinical Review Criteria

### Epidural Lysis of Adhesions for Chronic Low-Back Pain

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. ##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Estimates for the prevalence of back pain in a lifetime range from 54% to 80%. Chronic persistent back pain is seen in up to 60% of patients five years after the initial episode. Back pain is associated with substantial economic and social costs (Boswell et al., 2005).

Epidural lysis of adhesions (also known as epidural adhesiolysis) is a procedure developed by Dr. Gabor Racz in 1989 to treat chronic low back pain in patients who have failed to respond to conservative treatments. The goals of the procedure are to break down fibrous adhesions in the epidural space and apply medication (i.e. local anesthetics and corticosteroids). Fibrous epidural lesions can develop after surgical laminectomy, or can occur secondary to annular tear, hemotoma or infection. The adhesions prevent free movement of structures in the intervertebral foramen and the bony vertebral canal, and prevent direct application of medications to structures believed to be the source of pain. The role of fibrous epidural adhesions in causing chronic spinal pain, however, remains controversial (Belozer & Wang, 2004; Manchikanti et al., 2004).

The basic procedure for epidural lysis of adhesions is as follows: A 16-gauge RK needle enters the epidural space and contrast material is injected. Next, an epidurogram is performed to visualize spread of contrast medium and identify filling defects. If the filling defect corresponds to the area of pain, a specially designed spring-guided reinforced catheter (Racz catheter) is threaded into the filling defect. Lysis of adhesions is carried out by intermittent injections of normal or hypertonic saline through the catheter. After adhesiolysis, local anesthetic and corticosteroids are injected. The original procedure, as described by Racz, requires the catheter to stay in place for 3-days, with additional injections of local anesthetic and steroid occurring on days 2 and 3. The procedure was modified to a 1-day protocol by Manchikanti and colleagues (Heavner et al., 1999).

Patients often undergo multiple adhesiolysis treatments. The American Society of Interventional Pain Physicians (ASIPP) suggests that with a 3-day protocol, patients should be limited to 2 interventions per year and with a 1-day protocol, patients should be limited to 4 interventions per year. Spinal endoscopic adhesiolysis procedures should be limited to a maximum of 2 per year, provided that the patient experienced at least a 50% reduction in pain for at least 2 months (Boswell et al., 2005).

Epidural adhesiolysis can be conducted with a spinal endoscope (called a myeloscope). This allows a 3-dimensional view of the contents of the epidural space. Proponents believe that spinal endoscopy improves the

ability to perform appropriate adhesiolysis and provide targeted administration of medications (Belozer & Wang, 2004).

Possible side effects of epidural lysis of adhesions include dural puncture, spinal cord compression, infection and administration of high volumes of fluids which would potentially result in excessive epidural hydrostatic pressures (Boswell et al., 2005). In addition, the FDA has received multiple reports of catheter shearing or unraveling, as recently as April, 2005. In most of these cases, sheared catheter pieces were left inside the patient (FDA website).

The Racz epidural catheter received premarket approval from the FDA in 1996.

## Medical Technology Assessment Committee (MTAC)

### Epidural Lysis of Adhesions

#### 04/03/2006: MTAC REVIEW

**Evidence Conclusion:** One RCT evaluated the 3-day procedure for epidural lysis of adhesions. Conclusions cannot be drawn about effectiveness of this treatment from the study because there was no control group that did not receive the treatment. The study compared three alternate ways of performing the procedure. In addition, conclusions cannot be drawn about the relative effectiveness of different ways of performing the procedure since a between-group statistical analysis was not reported. Study validity was limited by a high drop-out rate and no intention to treat analysis, and lack of details about randomization and blinding procedures. Two RCTs evaluated the 1-day procedure for epidural lysis of adhesions. Both were conducted by Manchikanti and colleagues, the group that developed the shortened procedure. One of these was on percutaneous adhesiolysis (Manchikanti et al., 2004) and the other was on spinal endoscopic adhesiolysis (Manchikanti et al., 2005). The studies had similar methodology, and similar findings. Manchikanti et al., 2004 found significantly lower pain in each of two groups receiving epidural adhesiolysis (one received normal saline and the other, hypertonic saline) compared to a no treatment control group at 3, 6 and 12 months. Manchikanti et al., 2005 found significantly lower pain in a group receiving spinal endoscopic adhesiolysis compared to a no treatment control group at 3, 6 and 12 months. In both studies, the authors reported multiple outcomes without specifying primary outcomes or adjusting their p-value for multiple comparisons. Actual p-values were low enough that most of the differences would still have been statistically significant if the p-value had been adjusted. The clinical significance of outcomes using the VAS scale is not clear, but a substantially higher proportion of patients experienced ~50% pain reliefs. A limitation of the two studies was that patients could choose to be unblinded at 3 months, which could bias responses at 6 and 12 months. 25% of patients in the control group in the Manchikanti et al., 2004 study and 33% of all patients in the Manchikanti et al., 2005 study chose to be unblinded at 3 months.

**Articles:** Three randomized controlled trials were identified and critically appraised. One was on the original 3-day procedure and two were on the 1-day procedure. In addition, one non-randomized controlled trial and several case series were identified. The non-randomized controlled trial was not evaluated further because there were two later RCTs by the same research group on the 1-day procedure. The RCTs were: Heavner JE, Racz GB, Raj P. Percutaneous epidural neuroplasty: Prospective evaluation of 0.9% NaCl versus 10% NaCl with or without hyaluronidase. *Reg Anesthesia Pain Med* 1999; 24: 202-207. See [Evidence Table](#). Manchikanti L, Rivera JJ, Pampati V. et al. One day lumbar epidural adhesiolysis and hypertonic saline neurolysis in treatment of chronic low back pain: A randomized double-blind trial. *Pain Physician* 2004; 7: 177-186. See [Evidence Table](#). Manchikanti L, Boswell MV, Rivera JJ et al. A randomized, controlled trial of spinal endoscopic adhesiolysis in chronic refractory low back and lower extremity pain. *BMC Anesthesiology* 2005; 5:10. See [Evidence Table](#).

The use of Epidural Lysis of Adhesions in the evaluation of chronic low-back pain does not meet the *Group Health Medical Technology Assessment Criteria*.

#### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

The CDC estimates that there are about 200,000 people in the United States (US) living with a spinal cord injury (SCI) (CDC 2014). Depending on the vertebral level and the degree of completeness, SCI can result in a variety of degrees of neurological deficit. Individuals with traumatic, motor-complete SCI abruptly lose the ability to stand and walk, relying on wheelchairs as a means of locomotion. Eventually, extreme inactivity causes rapid and marked alteration in body composition and can lead to additional complications such as ulcers, weakened bones, digestive disorders, and urinary tract infections (UTI). To add to this, the loss of mobility can negatively impact a patient's quality of life (QoL) and places SCI patients at higher risk for secondary medical conditions such as, diabetes and cardiovascular disease, to name a few (Spungen, Asselin et al. 2013).

A variety of techniques have been attempted to restore walking abilities with limited success. The concept of exoskeletons was first introduced in Russia in 1890, however, the first true exoskeleton was developed in the US, for military use, and consisted of an outer framework for the lower extremities powered by motors and hydraulics to deliver at least part of the energy for movement. When applied, the device was intended to enable soldiers to carry heavy objects while running or climbing stairs. Several different prototypes have been developed for the military, however, none have been able to overcome a variety of technological limitations such as power source and joint flexibility. In more recent years, the concept of an exoskeleton has been applied in the medical field to aid in the rehabilitation of patients with loss of motor function due to stroke or SCI (Talat, Esquenazi et al. 2013). Currently, several devices have been developed for this indication, however, only one company, Argo Medical Technologies, Inc. (Marlborough, MA), has received clearance for marketing in the United States (US).

The ReWalk™ was designed to allow patients with paraplegia, due to SCI, to fully weight bear while standing and to ambulate over ground. In its entirety, the system includes two leg braces with motorized joints and motion sensors, a harness, and a backpack for holding the computer that controls the device as well as a battery that is estimated to last for three to four hours. The device can facilitate standing, walking, and sitting modes and operates by powering hip and knee motion allowing patients functional and independent walking with the use of lofstrand forearm crutches to maintain balance. Use of the ReWalk™ requires training in a rehabilitation setting (Zeilig, Weingarden et al. 2012).

### Medical Technology Assessment Committee (MTAC)

02//09/2015: MTAC REVIEW

## Exoskeleton

**Evidence Conclusion:** The literature search revealed only a small number of publications relating to the exoskeleton. No randomized controlled trials (RCT) comparing exoskeletons to wheelchairs were revealed. The FDA's approval relied on three observational studies that assessed the safety and tolerance of the ReWalk. In each of the studies, patients were trained to use the device in a clinical setting under the guidance of a physical therapist. Upon training completion (approximately 8 weeks), subjects underwent performance evaluations. None of the studies were carried out in a home-setting or assessed long-term performance. No studies were selected for critical appraisal due to methodological limitations such as study design and small sample size. An extensive list of ongoing studies relating to exoskeletons was revealed after searching in the National Institute of Health's clinical trials database. Conclusions: There is insufficient evidence to support the effectiveness of exoskeleton suits for ambulation compared to wheelchairs. There is insufficient evidence to support the safety of exoskeleton suits for ambulation compared to wheelchairs.

**Articles:** The literature search revealed only a small number of publications relating to the exoskeleton. No randomized controlled trials (RCT) comparing exoskeletons to wheelchairs were revealed. The FDA's approval relied on three observational studies that assessed the safety and tolerance of the ReWalk. In each of the studies, patients were trained to use the device in a clinical setting under the guidance of a physical therapist. Upon training completion (approximately 8 weeks), subjects underwent performance evaluations. None of the studies were carried out in a home-setting or assessed long-term performance. No studies were selected for critical appraisal due to methodological limitations such as study design and small sample size. An extensive list of ongoing studies relating to exoskeletons was revealed after searching in the National Institute of Health's clinical trials database.

The use of Exoskeleton does not meet the *Group Health Medical Technology Assessment Criteria*.

Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

###### Extracorporeal Photopheresis for Acute and Chronic Graft vs. Host

Medical necessity review no longer required for this service.

###### Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma (CTCL)

Must meet all of the following:

1. The extracorporeal device must be FDA approved;
2. The patient has cutaneous t-cell lymphoma that has not responded to other forms of treatment;
3. The use is for palliative treatment of associated skin manifestations.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Extracorporeal photopheresis (ECP) is a treatment modality for graft-versus-host disease (GVHD) and cutaneous t-cell lymphoma (CTCL). CTCL refers to several clonal t-cell malignancies that primarily manifest as skin conditions. GVHD is a complication of allogenic stem cell transplantation.

Extracorporeal photopheresis (ECP) is one of the treatment options for refractory acute and chronic GVHD. ECP involves removing the patient's peripheral blood and separating it into leukocyte-depleted blood and leukocyte-enriched plasma. The leukocyte-depleted blood is returned to the patient. The leukocyte-enriched plasma is exposed to ultraviolet light in the presence of an extracorporeally administered photosensitizing agent, 8-methoxypsoralen (8-MOP). The cells are then re-infused into the patient and die in one-week period. During that week, they are capable of stimulating an anti-idiotypic t suppressor response. The exact mechanism of action of ECP is not known. The Therakos Photopheresis System is FDA approved as a class III medical device specifically for photopheresis (Greinix et al., 2000; Woltz et al., 2006).

There are no agreed-upon standards for the optimal frequency and duration for ECP treatment in patients with chronic GVHD, and there is wide variability in practice. Patients may be treated two or three days a week every two to three weeks for 3 to 30 months (Woltz et al., 2006).

Extracorporeal photopheresis (ECP) is also a treatment option for CTCL. ECP involves removing a portion of the patient's blood and separating into red and white blood cells by centrifugation. The red cells are returned to the patient. The white cells are mixed with a photosensitizing agent, 8-methoxypsoralen or methoxsalen (Uvadex, Therakos), and irradiated with ultraviolet light (UVA light, 320-400 nm). When activated, the photosensitizing agent binds with the cellular DNA of the white cells and accelerates their death. The altered cells are then re-infused into the patient. The intention is that these cells will stimulate an immune response against the damaged pathogenic t cell clones. In the pivotal study upon which FDA approval was based, a case series with 37 patients by Edelson and colleagues, a greater treatment effect was seen in patients with erythrodermic CTCL (later-stage

disease) compared to those with plagues or tumors. This distinction has been difficult to confirm in later case series because studies generally include patients at different stages of clinical disease and do not report findings separately by disease stage. The effectiveness of ECP for treating CTCL, particularly Sezary Syndrome, continues to be debated in the literature. Some of the controversies are whether prior treatment with systemic corticosteroids and systemic chemotherapy reduces the effectiveness of ECP and which sub-groups of patients are most likely to benefit from ECP treatment. To date, there have not been any randomized controlled trials comparing ECP to other treatments for CTCL (Apisarnthanarax et al., 2002; Russell-Jones, 2000; FDA Web site; Therakos Web site).

The FDA has approved the photopheresis device UVAR and the photosensitizing Uvadex (both by Therakos) for the palliative treatment of skin manifestations of cutaneous t-cell lymphoma that has not responded to other forms of treatment. ECP is covered by Medicare for the same indication.

[Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma \(CTCL\)](#)

## Medical Technology Assessment Committee (MTAC)

### *Extracorporeal Photopheresis in the Treatment of Acute and Chronic Graft Versus Host Disease*

#### BACKGROUND

Graft-versus-host disease (GVHD) is a complication of allogenic stem cell transplantation (SCT). There are two forms of GVHD, acute and chronic. Acute GVHD occurs within the first 100 days of transplantation. In acute GVHD, the T-lymphocytes from the donor recognize tissues or cells in the recipient as foreign and produce a multi-organ (i.e. skin, liver, intestines) autoimmune-like syndrome. The T-lymphocytes use information from genetic markers known as human leukocyte antigens (HLA) to detect differences. Even when donors are matched for HLA markers, GVHD can occur because minor differences in these markers could still exist. Efforts to prevent acute GVHD include using closely matched donors, umbilical cord blood and/or post transplant immunosuppression with drugs including cyclosporine and methotrexate. Acute GVHD is commonly treated with corticosteroids which produce sustained responses in 50-80% of patients depending on the initial severity of disease. Second-line therapy includes different combinations of immunosuppressive agents. Newer treatments include infusion of mesenchymal stem cells (MSC), down-regulation of antigen-presenting cells (APC) and suicide gene transduced T cells (Bacigalupo, 2007). Chronic GVHD can occur after the first 100 days post-transplant, either in patients who experienced acute GVHD or a de novo onset. It is the main cause of late morbidity and mortality after allogenic SCT. Chronic GVHD generally involves donor T cells expanding and attacking the host's immunologic system; its pathophysiology is poorly understood compared to acute GVHD (Woltz et al., 2006; PerezSimon et al., 2006). Standard first-line treatment for chronic GVHD includes prednisone alone or in combination with a calcineurin inhibitor such as cyclosporin or tacrolimus. A recent review article (Perez-Simon et al., 2006) states that there is no generally accepted salvage treatment for patients with chronic GVHD who do not respond to prednisone. Treatments that have been used for refractory chronic GVHD include mycophenolate mofetil, anti-interleukin-2a receptor antagonists, sirolimus, pentostatin, CD20 antagonists, tumor necrosis factor- $\alpha$  antagonists and extracorporeal photopheresis. Other, newer treatments include anti-CD25 immunotoxin and inhibition of nuclear factor- $\kappa$ B. The authors of the review article recommend that chronic GVHD patients enter clinical trials for salvage treatment if at all possible. Extracorporeal photopheresis (ECP) is one of the treatment options for refractory acute and chronic GVHD. ECP involves removing the patient's peripheral blood and separating it into leukocyte-depleted blood and leukocyte-enriched plasma. The leukocyte-depleted blood is returned to the patient. The leukocyte-enriched plasma is exposed to ultraviolet light in the presence of an extracorporeally administered photosensitizing agent, 8-methoxypsoralen (8-MOP). The cells are then re-infused into the patient and die in one-week period. During that week, they are capable of stimulating an antiidiotypic T suppressor response. The exact mechanism of action of ECP is not known. The Therakos Photopheresis System is FDA approved as a class III medical device specifically for photopheresis (Greinix et al., 2000; Woltz et al., 2006). There is no generally agreed-upon standards for the optimal frequency and duration for ECP treatment in patients with chronic GVHD, and there is wide variability in practice. Patients may be treated two or three days a week every two to three weeks for 3 to 30 months (Woltz et al., 2006). ECP for acute and chronic graft versus host disease was first reviewed by MTAC in 2002. At that time, the empirical evidence consisted of small case series, with sample sizes varying from 3 to 23. The item failed MTAC evaluation criteria, and the Health Plan Medical Directors decision was to review requests on a case-by-case basis. A new review is being requested due to the length of time since the previous review,

and recent changes made to Medicare criteria. Medicare now covers ECP for patients with chronic GVHD whose disease is refractory to standard immunosuppressive drug treatment.

#### **06/12/2002: MTAC REVIEW**

##### **Extracorporeal Photopheresis in the Treatment of Acute and Chronic Graft Versus Host Disease**

**Evidence Conclusion:** There is not enough evidence to permit conclusions on the effectiveness of extracorporeal photopheresis for treating acute or chronic graft-versus-host disease.

**Articles:** The search yielded 16 articles. There were no randomized controlled trials. Seven of the articles were reviews or editorials, two were case reports and seven were small case series (varying in size from n=3 to n=23). Due to the low grade of evidence and the small size of the studies, no evidence tables were created.

The use of extracorporeal photopheresis in the treatment of acute and chronic graft versus host disease does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **08/20/2007: MTAC REVIEW**

##### **Extracorporeal Photopheresis in the Treatment of Acute and Chronic Graft Versus Host Disease**

**Evidence Conclusion:** The published studies that evaluated actigraphy for the assessment of insomnia were conducted on selected groups of patients and used different actigraph models, software, and scoring algorithms. Most studies were conducted in sleep laboratories where recording conditions are standardized and the artifacts controlled. These controls would be lost when the actigraphy devices are used in the home environment, where it is intended for use. Also the algorithms that were validated for a specific model, mode of operation, or in a selected population may by not be equally accurate when used with a different brand of device, different gender or age group. The studies reviewed compared actigraphy to PSG, but the authors did not indicate whether the investigators interpreting the results of one test were blinded to the results of the other. The overall results of the studies reviewed, indicate that compared to polysomnography, actigraphy had a high sensitivity (92-98%) but very low specificity (28-48%) in detecting insomnia. It was also found to overestimate the total sleep time and sleep efficiency. Actigraphy tends to overestimate sleep in people with insomnia when they are lying quietly as quiet wakefulness could be miscoded as sleep. Insomnia patients can remain inactive for a period of time attempting to fall asleep. On the other hand actigraphy may underestimate the amount of sleep and overestimate the duration awake among those who are asleep but are restless or have large amounts of movements during sleep. The use of actigraphy for the assessment of periodic leg movements in sleep was evaluated in only a few small studies with methodological limitations. It was compared with polysomnography with bilateral anterior tibialis electromyography (BATEMG). However, EMG and leg actigraphy are not interchangeable, and each measures a different event. One records electrical activity of a certain muscle and the other records leg acceleration. Leg activity may be due to movement artifacts produced by obstructive sleep apnea. Kemlink et al (2007) did not exclude patients with suspicious sleep apnea and did not adjust for it in the analysis. In conclusion there is insufficient evidence to determine that actigraphy would replace PSG or add to its value in the diagnosis and management of patients with sleep disorders.

**Articles:** No randomized or non-randomized controlled trials were identified. The empirical evidence continues to consist of case series. The largest case series on ECP for acute GVHD (n=59) and for chronic GVHD (n=71) identified in the search were critically appraised. In addition, a case series on ECP in pediatric patients with either acute or chronic GVHD (n=77) was critically appraised. There were additional smaller case series. The studies reviewed include: Greinix HT, Knobler RM, Worel N et al. The effect of intensified extracorporeal photochemotherapy on long-term survival in patients with severe acute graft versus host disease. *Stem Cell Transplant* 2006; 91: 405-408. See [Evidence Table](#). Couriel DR, Hosing C, Saliba R et al. Extracorporeal photochemotherapy for the treatment of steroid-resistant chronic GVHD. *Blood* 2006; 107: 3074-3080. See [Evidence Table](#). Messina C, Locatelli F, Lanino e et al. Extracorporeal photochemotherapy for pediatric patients with graft versus host disease after hematopoietic stem cell transplantation. *Br J Hematol* 2003; 122 118-127. See [Evidence Table](#).

The use of extracorporeal photopheresis in the treatment of acute and chronic graft versus host disease does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma (CTCL)**

##### **BACKGROUND**

Cutaneous T-cell lymphoma (CTCL) refers to several clonal T-cell malignancies that primarily manifest as skin conditions. The classical subsets of CTCL include mycosis fungoides (MF), the most common form, and Sezary Syndrome (SS). MF usually presents as chronic eczematous or psoriasiform patches or plaques whereas SS is characterized by erythroderma and leukemia. SS is sometimes viewed as an advanced form of MF. According to the CTCL disease staging system (stage IA-IVB), patients with Sezary Syndrome have stage IV disease. (Apisarnthanarax et al., 2002; Duvic et al., 2003; RussellJones et al., 2000). Therapeutic options differ according

to clinical disease stage. Early patch-plaque MF (Stage 1 and IIA) is generally a benign and chronic condition and can be treated with conservative therapies such as topical corticosteroids, retinoids and mechlorethamine (nitrogen mustard). Early stage disease can also be treated with ultraviolet B (UVB) phototherapy or psoralen plus ultraviolet A photochemotherapy (PUVA). Some of the treatments used in early stage disease, such as PUVA or oral bexarotene, are also used for later stage disease but may be less effective. Historically, the most common treatment for late-stage disease (Stage IIB-IVB) is chemotherapy. No single-agent or multi-agent regimen has been shown to be clearly superior to the others. Disadvantages of systemic chemotherapeutic agents are that they have immunosuppressive effects which can lead to opportunistic infections, sepsis or death (Apisarnthanarax et al., 2002). Extracorporeal photopheresis (ECP) is another treatment option for CTCL. ECP involves removing a portion of the patient's blood and separating into red and white blood cells by centrifugation. The red cells are returned to the patient. The white cells are mixed with a photosensitizing agent, 8-methoxypsoralen or methoxsalen (Uvadex, Therakos), and irradiated with ultraviolet light (UVA light, 320-400 nm). When activated, the photosensitizing agent binds with the cellular DNA of the white cells and accelerates their death. The altered cells are then reinfused into the patient. The intention is that these cells will stimulate an immune response against the damaged pathogenic T cell clones. In the pivotal study upon which FDA approval was based, a case series with 37 patients by Edelson and colleagues, a greater treatment effect was seen in patients with erythrodermic CTCL (later-stage disease) compared to those with plaques or tumors. This distinction has been difficult to confirm in later case series because studies generally include patients at different stages of clinical disease and do not report findings separately by disease stage. The effectiveness of ECP for treating CTCL, particularly The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations. © Group Health Cooperative. All Rights Reserved. Sezary Syndrome, continues to be debated in the literature. Some of the controversies are whether prior treatment with systemic corticosteroids and systemic chemotherapy reduces the effectiveness of ECP and which sub-groups of patients are most likely to benefit from ECP treatment. To date, there have not been any randomized controlled trials comparing ECP to other treatments for CTCL (Apisarnthanarax et al., 2002; Russell-Jones, 2000; FDA website; Therakos website). The FDA has approved the photopheresis device UVAR and the photosensitizing Uvadex (both by Therakos) for the palliative treatment of skin manifestations of cutaneous T-cell lymphoma that has not responded to other forms of treatment. ECP is covered by Medicare for the same indication. Extracorporeal photopheresis for CTCL has not been reviewed previously by MTAC. ECP for the treatment of graft versus host disease was reviewed by MTAC in June, 2002.

#### **06/05/2006: MTAC REVIEW**

##### **Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma (CTCL)**

**Evidence Conclusion:** There are no randomized controlled trials evaluating the efficacy of extracorporeal photopheresis for treating patients with CTCL. The published literature consists of small, predominantly retrospective case series. The ECP treatment protocol was similar in the case series that were reviewed, generally consisting of treatment every 4 weeks with a tapering off by lengthening treatment intervals in patients who achieved a response. Data from case series suggests that ECP might be helpful for treating skin manifestations of CTCL, the FDA approved indication. However, there are no data on the efficacy of ECP for skin conditions compared to an alternative treatment or no treatment. In the single prospective study, 27/37 patients had a positive response to treatment, defined as at least a 25% reduction in the skin score. 24/29 patients with erythroderma had a positive response after a mean follow-up of 42 weeks (Edelson et al., 1987). A study published 5 years later on the 29 patients with erythroderma (Heald et al., 1992) found that most of the patients had at least some improvement in skin manifestations of CTCL and 6 had a complete remission. It is not possible to draw conclusions about survival after ECP treatment due to the lack of comparative data from RCTs. Predicted median survival using life-table analysis in the Heald/Edelson study was 60 months from time of diagnosis of the erythrodermic state. One of the case series (Fraser-Andrews et al. 1998) included a non-randomized comparison group of patients who did not receive ECP treatment. They did not find a statistically significant difference in median length of survival from time of SS diagnosis in the two groups (39 months in ECP-treated patients vs. 26.5 months in non-ECP treated patients,  $p=0.12$ ). Other than a lack of randomization, limitations of the Fraser-Andrews study was the wide variety of other treatments patients received before, during and after ECP treatment, or instead of ECP treatment. It is difficult to attribute a response to the ECP treatment itself. The limited data on use of ECP for CTCL identified few adverse effects.

**Articles:** No randomized controlled trials were identified. The empirical studies were all case series, each with a sample size of less than 50. Desirable features of case series were prospective design, larger sample size, clear eligibility criteria, longer follow-up and survival included as an outcome. Three studies included survival as an outcome in addition to treatment response, had sample sizes  $n>25$  and had reasonably long-term follow-up; however, only one of them was prospective. These three studies were critically appraised. The prospective study reporting on patient survival was the original Edelson (1987) study, with follow-up data reported by Heald and colleagues in 1992. Excluded studies include a prospective study that included only 14 patients and a small

(n=20) study that included survival as an outcome, but was retrospective and did not specify eligibility criteria. *Studies reviewed include:* Heald P, Rook A, Perez M et al. Treatment of erythrodermic cutaneous T-cell lymphoma with extracorporeal photochemotherapy. J Am Acad Dermatol 1992; 27: 427-433. (Follow-up of Edelson R et al. NEJM 1987; 316: 297-303). ## Clinical Review Criteria

### Fecal GI infusion for the Treatment of C. Difficile infection

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare

##### The Centers for Medicare and Medicaid Services (CMS)

Medicare payment for the preparation of the donor specimen would only be made if the specimen is ultimately used for the treatment of a beneficiary. CMS made CPT code 44705 invalid for Medicare and created the HCSPCS code G0455 that includes both the preparation of the specimen and the instillation into the recipient patient. See the 2013 Medicare Physician Fee Schedule available online at <http://www.gpo.gov/fdsys/pkg/FR-2012-11-16/pdf/2012-26900.pdf> beginning on page 69052 (or page 162 of the pdf file).

##### For Non-Medicare

Fecal GI infusion is covered when **ALL of the following** are met:

- 1) Clostridium difficile infection confirmed by a positive stool test for C. difficile toxin
- 2) Has had at least two recurrences following adequate antibiotic therapy (10 or more days of vancomycin at a dose of greater than or equal to 125 mg four times per day or 10 or more days of metronidazole at a dose of 500 mg three times per day).

##### FMT capsule, G3 OpenBiome

If the above criteria are met, oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory clostridium difficile infection is covered.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Clostridium difficile (C difficile) is the leading cause of antibiotic associated diarrhea and its rates continue to rise. During the past several years, the incidence of C difficile infection (CDI) has increased to an epidemic level; it has become more severe, more refractory to standard treatment, and more likely to relapse. According to the CDC, the number of hospitalized patients with any CDI discharge diagnoses more than doubled from approximately 139,000 to 336,600, and the number with a primary CDI diagnosis more than tripled, from 33,000 to 111,000 from 2000 to 2009. This rise in incidence and severity of the disease is possibly associated with the emergence of the hypervirulent strain (NAPI/ribotype 027). CDI is responsible for a spectrum of infections including uncomplicated diarrhea, pseudomembranous colitis, and toxic megacolon, which may lead to sepsis and even death. It often occurs in patients in health-care settings where antibiotics are prescribed and symptomatic patients are concentrated. The most common risk factor for CDI is the use of broad spectrum antibiotics or the concomitant use of multiple and prolonged antimicrobials. Other risk factors include advanced age (65 years or older), recent organ transplantation, gastrointestinal surgery, inflammatory bowel disease, immunosuppressive drugs, presence of multiple co-morbidities, and others. Mature colonic bacterial microbiota (community of micro-organisms) in a healthy adult is generally resistant to C difficile colonization. Any factor altering the balance of intestinal microbiota leads to a selective advantage and colonization by C difficile colonization after exposure to the bacteria. The standard treatment for C difficile associated disease includes discontinuation of offending/inducing antibiotic and treatment with metronidazole or vancomycin. Most patients initially respond to this therapy, but 15-30% experience a symptomatic recurrence after discontinuation of the treatment. The risk of recurrence rises to 40% after a first recurrence and to more than 60% after two or more recurrences. The increased incidence and severity of CDI, and the high recurrence rate with conventional treatments have led researchers to explore alternative strategies and therapies with varying degrees of success. These include the use of additional courses of metronidazole and vancomycin, pulsed/tapered antibiotics, the use of new drugs as nitazoxanide and fidaxomicin, immune therapy such as IV immunoglobulin, active immunization, toxin binding, and alternative approaches as the

use of probiotics ( such as lactobacillus species, which is a low-virulent microorganism that could compete with *C difficile* for nutrients and sites of mucosal adherence), and fecal transplantation to recreate the colonic environment (Brandt 2012, Guo 2012, Kassam 2011, 2013).

Fecal transplantation (FT), also known as fecal microbiota transplantation (FMT), fecal bacteriotherapy, feco-therapy, fecal microbiota reconstitution, or human probiotics infusion, refers to the process of instilling a liquid suspension of stool from a healthy donor into the gastrointestinal (GI) tract of another person, theoretically to promote normalization of flora and restore the intestinal microbiota. It is of particular utility in recurrent or refractory *C difficile* infection. The exact mechanism of FMT in treating CDI is not clear, but may involve the re-colonization of microbiota with missing components to generate colonization resistance or direct antagonistic activity of the normal microbiota to *C difficile*. There is also the possibility that the transplantation of donated flora results in an immunological response facilitating the eradication of *C difficile*. The re-establishment of the normal composition of the intestinal flora by the use of human fecal microbiota was first used by Ben Eiseman in 1958 for the treatment of four patients with pseudomembranous colitis. Lately, FMT has received more attention with the publication of promising results of case series. It is however, not widely accepted as a therapeutic tool due to lack of published trials with long-term outcomes and concerns regarding its safety and acceptability (Guo 2012, Matilla 2012).

There is no clear definition of CDI, its recurrence, relapse or re-infection, and there is no standardized protocol for FMT as regards the choice of donor (family member or volunteer donor), screening of donors, quantity and preparation of stools collected, form of infusion, and measurement of outcomes. There is also no consensus on the most appropriate form of delivery for the fecal microbiota. Until 1989 retention enema was the most common route for FMT; subsequently it was infused via nasogastric tube, colonoscopy and more recently self-administered enemas. The colonoscopic approach seems to be the most common and favored approach as it allows the examination of the disease extent and inoculation of the entire colon and ileum. Regardless of the delivery method, the steps of the procedure are similar and include evaluating the patient eligibility, patient consent, identification and screening of donors, preparation of the sample, and infusion of the suspension prepared. Donor stool is most often used within 8 hours of passage, but frozen samples have been thawed and used 1-8 weeks after passage. Stool is commonly suspended in saline; however water, milk, and yogurt have also been used as diluents. The suspension is filtered through gauze pads or strainer, and then aspirated into syringes for use. The volume of stool suspension used for FMT varied between studies from less than 200 ml to 500 ml or more. Patients undergoing FMT typically remain on their CDI antimicrobials until 2-3 days prior to the procedure. Bowel preparation is performed regardless of the route. If infused via nasogastric tube, the suspension is applied after fitting the tube in place. After the infusion the tube is rinsed with saline solution and removed. If applied via colonoscopy, the colonoscope is inserted and advanced to the terminal ileum, and then working backwards the stool suspension is administered, most in the terminal ileum and ascending colon. The aftercare requires regular clinical checkups and testing the stools for *C difficile*. The risk of the procedure includes risks associated with application as perforation and hemorrhage, as well as the risk of microbial translocation and sepsis. FMT is relatively contraindicated in patients with severe comorbid conditions or those taking immunosuppressants, though such patients have been successfully treated with the fecal transplant (Brandt 2011, Gough 2011, Postigo 2012, Rohlke 2012, Kleger 2013, Aroniadis 2013).

Fecal transplantation is not regulated by FDA, to date, as fecal matter is organic. According to the FDA the complex nature of FMT products presents specific scientific and regulatory challenges. The Center for Biologics Evaluation and Research (CBER), together with the National Institute of Allergy and Infectious Disease (NIAID) are holding a public workshop in May 2013, to facilitate clinical development of FMT.

## Medical Technology Assessment Committee (MTAC)

### ***Fecal GI infusion for the Treatment of C. Difficile infection***

**04/15/2013: MTAC REVIEW**

**Evidence Conclusion:** There is some evidence from one small RCT that fecal transplantation has a significantly higher success rate than vancomycin in treating patients with recurrent *C difficile* infection. Meta-analyses of case series with no control groups also show a high cure rate of recurrent CDI with FMT. There is insufficient evidence to determine whether FMT is effective for the treatment of patients with the more virulent strain ribotype 027 *C difficile*. There is insufficient evidence to determine the most effective and safe modality for delivering the FMT. There is insufficient evidence to determine the long-term efficacy and safety of FMT.

**Articles:** The literature search for studies on fecal transplantation for the treatment of *C difficile* infection revealed one recent RCT (van Nood 2013), and four systematic reviews (Gough 2011, Guo 2012, Kassam 2013 and Sofi 2013). The latter two pooled the results of the published studies in meta-analyses. Sofi and colleagues analyses combined the results of case series and case reports, while Kassam and colleagues excluded the small case

series (<10 subjects) and case reports in an attempt to minimize bias. The search also identified a review comparing nasogastric versus colonoscopic FMT (Postigo 2012), and a protocol for a Cochrane review, which is still being prepared. van Nood 2013 RCT, and the Kassam and colleagues' meta-analysis that had a more valid methodology were selected for critical appraisal: van Nood E, Vrieze A, Nieuwdorp M, et al. Duodenal infusion of donor feces for recurrent *Clostridium difficile*, *N Engl J Med*. 2013; 368:407-415. [See Evidence Tables](#). Kassam Z, Lee CH, Yuan Y et al. Fecal Microbiota Transplantation for *Clostridium difficile* Infection: Systematic Review and Meta-Analysis. *Am J Gastroenterol* 2013; Mar 19. doi:10.1038/ajg.2013.59 [See Evidence Tables](#).

The use fecal GI infusion for the treatment of *C. difficile* infection meets the *Group Health Medical Technology Assessment Criteria*.

### **Oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory *Clostridium difficile* infection**

#### BACKGROUND

*Clostridium difficile* (*C difficile*) infection (CDI) is one of the most prevalent hospital acquired infections in the United States and is the leading cause of antibiotic associated diarrhea. The incidence of CDI has increased to an epidemic level; it has become more severe, more refractory to standard treatment, and more likely to relapse. According to the CDC, CDI was estimated to have caused almost half a million infections in the United States in 2011, and 29,000 deaths within 30 days of the initial diagnosis. It is believed that the rise in incidence and severity of the disease may be related to the emergence of the hypervirulent strain of the organism (NAP1/BI/027) that is particularly associated with higher rates of treatment failure and recurrence (Youngster 2014, Hirsch 2015, CDC webpage accessed November 2015). CDI is responsible for a spectrum of infections including uncomplicated diarrhea, pseudomembranous colitis, and toxic megacolon, which may lead to sepsis and even death. It often occurs in patients in health-care settings where antibiotics are prescribed and symptomatic patients are concentrated. The most common risk factor for CDI is the use of broad spectrum antibiotics or the concomitant use of multiple and prolonged antimicrobials. Other risk factors include advanced age (65 years or older), recent organ transplantation, gastrointestinal surgery, inflammatory bowel disease, immunosuppressive drugs, presence of multiple co-morbidities, and others. Mature colonic bacterial microbiota (community of micro-organisms) in a healthy adult is generally resistant to colonization and overgrowth of pathogenic bacteria. Any factor altering the balance of intestinal microbiota allows pathogens such as *C difficile* to proliferate and dominate the gut ecosystem (Matilla 2012, Rohlke 2012, Sofi 2012, Brandt 2012, Kassam 2013, Hirsch 2015). The standard management of CDI includes discontinuation of offending/inducing antibiotic and treatment with metronidazole or vancomycin. Most patients initially respond to this therapy, but 15-30% experience symptomatic recurrence after discontinuation of the treatment. It is reported that antibiotics targeting CDI may eradicate the active infection, but do not restore the long-lasting dysbiosis of the microbiota, which is the major risk factor for relapse. This risk rises to 40% after a first recurrence and to more than 60% after two or more recurrences. The increased incidence and severity of CDI, and the high recurrence rate with conventional treatments have led researchers to explore alternative strategies and therapies with varying degrees of success. These include the use of additional courses of metronidazole and vancomycin, pulsed/tapered antibiotics, the use of new drugs as nitazoxanide and fidaxomicin, immune therapy such as IV immunoglobulin, active immunization, toxin binding, and alternative approaches such as use of probiotics as lactobacillus species, which is a low-virulent microorganism that could compete with *C difficile* for nutrients and sites of mucosal adherence, and fecal microbiota transplantation (Brandt 2012, Guo 2012, Kassam 2013, Hirsch 2015). Fecal microbiota transplantation (FMT), also known as fecal transplantation (FT), fecal bacteriotherapy, fecotherapy, fecal microbiota reconstitution, or human probiotics infusion, refers to the process of transplantation of stools from a healthy individual into the gastrointestinal (GI) tract of the affected patient, theoretically to promote normalization of flora and restore the intestinal microbiota. It may be particularly useful in recurrent or refractory *C difficile* infection. The exact mechanism of FMT in treating CDI is not clear, but may involve the re-colonization of microbiota with missing components to generate colonization resistance or direct antagonistic activity of the normal microbiota to *C difficile*. There is also the possibility that the transplantation of donated flora results in an immunological response facilitating the eradication of *C difficile*. The re-establishment of the normal composition of the intestinal flora by the use of human fecal microbiota was first used by Ben Eiseman in 1958 for the treatment of four patients with pseudomembranous colitis. Lately, FMT has received more attention with the publication of promising results of a small RCT and a number of case series (Guo 2012, Matilla 2012, van Nood 2013). There is no standardized protocol for FMT as regards the choice of donor (family member or volunteer donor), screening of donors, quantity and preparation of stools collected, form of infusion, and measurement of outcomes. There is also no consensus on the most appropriate form of delivery for the fecal microbiota. Traditionally FMT has been performed by transplanting a liquid suspension of feces from a related healthy donor into the gastrointestinal tract of the affected patient through nasogastric tube, endoscopy, enema, or colonoscopy. The traditional methods are time-consuming, may be technically challenging, unaesthetic, and not accepted by many patients (Brandt 2011, Gough 2011, Postigo 2012, Rohlke 2012, Kleger 2013,

Aroniadis 2013). More recently, orally administered capsules containing cryopreserved fecal-material have been described. The capsules are generally prepared using fecal material harvested from unrelated healthy donors fulfilling strict criteria including screening negative for HIV, hepatitis A, B, and C as well as *Treponema pallidum*. Fecal matter is collected under sterile conditions, combined with saline, processed, sieved, centrifuged, and mixed again with saline along with glycerol, to protect the biological material from becoming damaged when frozen. The fecal material is then dispensed into double or triple capsules and stored at -80°C (-112°F). The capsules should be kept frozen until the time of administration and ingested as quickly as possible after extraction from the freezer. Capsules may be kept at room temperature for up to 90 minutes for patient comfort and ease of swallowing. Another described method is the immediate freezing and storing of the fecal suspension or slurry in 5 or 10 ml syringes at -80°C then thawing and triple encapsulating it prior to its use. Capsules should never be refrozen, and should be disposed of if not used within 90 minutes. OpenBiome (Boston, MA) a stool bank that created a fecal transplant pill (G3) recommends the intake 30 capsules, swallowed consecutively in a single session for the treatment of CDI (OpenBiome website, Youngster 2014, Hirsch 2015). FMT capsule G3 (OpenBiome) are size 00 (approximately the size of a large multivitamin) and are provided with two placebo test capsules. The patient is asked to ingest one test capsule prior to the start of treatment, under direct observation of the physician, to ensure the patient's ability to swallow. Any clinical concerns suggesting an aspiration risk is an absolute contraindication to capsule administration. Other contraindications include severe complicated CDI, dysphagia, history of gastroparesis, allergy to any of the ingredients, adverse events attributable to a previous FMT, and any condition that the treatment may pose a health risk (OpenBiome website). According to OpenBiome, FMT Capsule G3 may be used as a treatment for *C. difficile* infection not responsive to standard therapies in accordance with the FDA's guidance on the use of fecal microbiota for transplantation, and in clinical trials under an Investigational New Drug (IND) application.

#### 12/21/2015: MTAC REVIEW

#### **Oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory *clostridium difficile* infection**

**Evidence Conclusion:** There is a lack of published studies on the use of oral cryopreserved FMT capsules for patients with relapsing or refractory CDI. Currently the literature on oral FMT capsules for patients with relapsing *C. difficile* infection (CDI) consists of two small case series and one case report. Youngster and colleagues (2014) (evidence table 1), evaluated the safety and rate of resolution of diarrhea following the administration of cryopreserved FMT capsules in 20 patients (11-89 years of age) with refractory *C. difficile* infection. The oral capsulized FMT was prepared from stool samples gathered from healthy adult volunteers who had been comprehensively screened for infectious diseases and avoided eating common allergens for several days before donating. Each patient ingested 15 FMT capsules consecutively each day for two successive days. If their symptoms did not improve within 72 hours, they were offered a second course of treatment with fecal material from the same donor. They were followed-up for 6 months and the primary outcomes were safety and clinical resolution of diarrhea with no relapse at 8 weeks. The results of the study show that after the first 2 days of treatment, 14 of the 20 patients (70%) experienced clinical resolution of diarrhea, defined as less than 3 bowel movements /24 hours, and remained symptom free for 8 weeks. After a second course of treatment, four of the remaining patients became symptom free, resulting in an overall 90% rate of symptom resolution. No serious adverse events were reported. The study was a small observational study with no control or comparison group and relied on patient report on clinical outcomes. Patients with symptomatic improvement were not retested for *C. difficile*. The authors indicated that it was a pilot feasibility study that only provides preliminary data on the safety and effectiveness of this the oral capsulized FMT. Hirsch et al, 2015 (Evidence table 2), conducted a chart review of 19 patients treated with orally administered FMT capsules for recurrent CDI. FMT was prepared from stools donated by healthy volunteers unrelated to the recipients. Before receiving the FMT, the patients were required to discontinue any CDI antimicrobial treatment for 24 hours and were given a proton pump inhibitor on the evening and morning prior to the therapy. After a light breakfast, they received 6-22 capsules of FMT under supervision in an outpatient setting and were instructed to sit upright and not eat for an hour after ingesting the capsules. Patients were encouraged to drink 4 oz. of fermented milk product twice daily and to consume pro-biotic nutrients for at least 3 days after the FMT. They were followed-up by phone interviews within 2 days, 3 weeks, and after 90 days to assess the response to the therapy and adverse events. Those with recurrent CDI were retreated with antimicrobial therapy and subsequently offered repeat FMT (approximately 6 weeks after the initial FMT) and followed up for an additional 90 days. The primary outcome was resolution of CDI associated diarrhea without relapse assessed at 90 days after the last FMT. 13 of the 19 patients treated (68%) responded to a single course, and four responded to the second course of therapy with a total response rate of 89%. No serious adverse events were reported. The study was a small retrospective case series with no control or comparison group, and relied on patient and family report on clinical outcomes. In addition, the follow-up duration was insufficient to determine the long-term safety and effectiveness of the orally ingested FMT capsules. It is also worth noting that the authors have financial ties to Symbiotic Health Inc. Conclusion: There is insufficient evidence to determine that orally ingested FMT capsules prepared from stools provided by volunteer donors is safe and effective for the treatment

of patients with CDI. There is insufficient evidence to determine that orally ingested FMT capsules prepared from stools provided by volunteer donors is safe and effective for the treatment of patients with CDI with the more virulent strain *C difficile* (NAP1/B1/027). There is insufficient evidence to determine the long-term efficacy and safety of orally ingested FMT capsules. Case series may only generate hypothesis and large RCTs with long-term follow up are studies are needed to support the observed findings and determine the optimal donor, optimal dose of FMT, long-term safety, and long-term efficacy of cryopreserved oral capsulized FMT.

**Articles:** The literature search revealed two small cases series (one prospective and one retrospective) and a case report on the use of oral cryopreserved FMT capsules for patients with relapsing CDI. There are no published meta-analyses or randomized controlled trials, to date, that compared the use of the oral FMT capsules to standard therapy or to other traditional methods of delivering FMT for the treatment of refractory or relapsing CDI. The following two case series were critically appraised. Youngster I, Russell G, Pindar C, et al. Oral, capsulized, frozen fecal microbiota transplantation for relapsing Clostridium difficile infection. *JAMA*. 2014 Nov 5; 312(17):1772-1778. See [Evidence Table 1](#). Hirsch BE, Saraiya N, Poeth K, et al. Effectiveness of fecal-derived microbiota transfer using orally administered capsules for recurrent Clostridium difficile infection. *BMC Infect Dis*. 2015 Apr 17; 15:191 See [Evidence Table 2](#).

The use of Oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory clostridium difficile infection does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Fibrin Glue Injection for Treatment of Perianal Fistula

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

No criteria were developed at this time for Commercial Members as there is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies (and/or) provides better long term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

An anal fistula is a chronically infected, abnormal tunnel between the anal canal and the outer skin of the anus. Anal fistulae often drain watery pus which can irritate the surrounding outer tissues. Anal fistulae can occur as a result of an unhealed sore and they are also associated with Crohn's disease, tuberculosis, cancer of the large intestine and gonorrhoea.

The standard treatment for anal fistulae is fistulotomy, a surgical procedure in which the infected area is opened up and allowed to drain. Possible complications of surgery are fecal incontinence and permanent gas incontinence. Modifications to fistulotomy (e.g., island flap anoplasty) have been found to reduce the rates of incontinence; they may have lower rates of efficacy.

Fibrin glue is an alternative to fistulotomy. The FDA approved commercially made fibrin sealants in 1998 (although not specifically for repair of anal fistulae). The two products approved by the FDA are Tisseel and ViGuard. The main active ingredient in fibrin glue is fibrinogen, a protein from human blood. Fibrinogen forms a clot when combined with thrombin, another human blood protein. Before the availability of these products, fibrinogen was extracted from the patients' blood (autologous fibrin glue). The commercial fibrin sealants have a higher concentration of fibrinogen, the quantity is standardized and the sealants are quicker to prepare.

Fibrin glue is applied in the operating room. The basic procedure (Cintron) is to examine the patient and identify primary and secondary fistula tract openings that are then cleaned. Any abscess identified during the examination is drained. The two components of the fibrin glue are injected simultaneously into the secondary fistula tract opening until the glue is seen coming from the primary tract opening. Vaseline gauze is then placed over both the primary and secondary openings.

### Medical Technology Assessment Committee (MTAC)

#### *Fibrin Glue*

#### **08/12/2002: MTAC REVIEW**

**Evidence Conclusion:** In the articles reviewed, autologous fibrin glue as well as two commercial products, Tisseel and ViGuard, were used. The single RCT identified (Hwang) found that autologous fibrin glue healed anal fistulae faster than conservative treatment with total parenteral nutrition. The RCT is not strong evidence because only 13 patients were included in the study and fibrin glue was not compared to standard treatment (fistulotomy). The cohort study (Cintron) compared autologous fibrin glue to the two commercial products and did not find significant differences in treatment success (no drainage). Overall, 62% of patients with transsphincteric fistulae and 82% of patients with intersphincteric fistulae had no draining after treatment. The Partlj article was a case series with 69 patients who received treatment with Tisseel. Wounds healed in a median of 12 days. Both the Partlj and Cintron studies reported relatively high rates of recurrence. Recurrence was 54% in wounds under 3.5 cm and 11% in wounds  $\geq 3.5$  cm; comparative studies on recurrence and wound size are needed. Only the Partlj

study reported on incontinence; all patients in the case series remained continent. However, this case series is subject to selection bias. No studies compared fibrin sealants to the standard surgical procedure.

**Articles:** The search yielded 13 articles, most of which were case reports or case series. There was one small (n=13) randomized controlled trial and one prospective cohort study which were reviewed. A large case series, which had the longest follow-up, was also reviewed. Hwang TL, Chen MF. Randomized trial of fibrin tissue glue for low output enterocutaneous fistula. *Br J Surg* 1996; 83: 112. See [Evidence Table](#).

The use of fibrin glue in the treatment of perianal fistula does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Hip Surgery Procedures for Femeroacetabular Impingement Syndrome

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None

*CMS has no national or local coverage determinations or policies regarding the surgical treatment of FAI syndrome.*

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Femeroacetabular impingement (FAI) syndrome is a recently recognized diagnosis in primarily younger individuals where relatively minor abnormalities in the joint (orientation or morphology) are thought to cause friction/impingement and pain. It is theorized that FAI starts the breakdown of cartilage, leading to osteoarthritis. There are two types of FAI: cam impingement (non-spherical femoral head or abnormality at the head-neck junction) and pincer impingement (deep or retroverted acetabulum resulting in over coverage of the femoral head). Proponents believe that surgical correction of the impinging deformities will alleviate the symptoms and retard the progression of OA degeneration. Surgery to correct FAI includes arthroscopy, open dislocation of the hip, and arthroscopy combined with a mini-open approach. The purpose of the surgery is to remove abnormal outgrowths of bone and damaged cartilage, and to reshape the femoral neck to ensure that there is sufficient clearance between the rim of the acetabulum and the neck of the femur.

#### Medical Technology Assessment Committee (MTAC)

##### Femeroacetabular Impingement Syndrome

##### 06/17/2013: MTAC REVIEW

**Evidence Conclusion:** There is no new evidence that would change or add to the recommendations of the HTA review as regards the conservative or surgical treatment of femeroacetabular impingement. The results of these non-randomized observational studies as well as other published retrospective series with or without a comparison group should be interpreted with caution. Due to the nature of the study design, they are subject to selection bias, observation bias, confounding and other limitations, and only provide the lowest grade of evidence.

**Articles:** Larson CM, Givens R, Stone RM, et al. Arthroscopic debridement versus refixation of the acetabular labrum associated with femeroacetabular impingement. Mean 3.5 –year follow-up. *Am J Sports Med.* 2012;40:1015-1021. Larson and colleagues (2012) reported on outcomes of two cohorts of patients with femeroacetabular impingement who were treated with either arthroscopic debridement or refixation of the acetabular labrum in one center, but at different time periods. The mean follow-up ranged between 24 and 72 months with a mean of 42 months. The results indicate that the labral fixation was associated with better Harris Hip Scores (HHS), Short Form-12 (SF-12) and visual analog scale (VAS) for pain outcomes compared to arthroscopic focal debridement. Zingg PO, Ulbrich EJ, Buehler TC, et al. Surgical hip dislocation versus hi

arthroscopy for femeroacetabular impingement. Clinical and morphological short-term results. *Arch Orthop Trauma Surg.* 2013;133:69-79. Zingg and colleagues (2013) compared surgical hip dislocation versus hip arthroscopy in 38 patients presenting with clinically FAI that was morphologically verified with plain radiographs and MRI. In 28 of the 38 participants the selection of the procedure was based on the patient's decision, and only 10 agreed to be randomly allocated to either procedure. There were statistically significant differences in the morphological pathology (in terms of acetabular coverage angle, and head-neck offset ratio) between the two groups at baseline. The primary outcome of the study was the alpha angle on a cross-table view. The results of the study showed that patients in the hip arthroscopy group had faster recovery and better short-term outcomes compared to those treated with surgical hip dislocation. However the hip arthroscopy showed some overcorrection of the cam deformity and limited frequency of labrum refixations, which the authors indicate that they may lead to negative impact on long-term outcomes.

The use of FIS does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Foot Care

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Manuals

[Chapter 15 section 290 – Foot Care](#)

Local Coverage Determinations (LCD)

[Treatment of Ulcers & Symptomatic Hyperkeratoses \(L34199\)](#)

LCD for Routine Foot Care (L24356) has been retired - use medical necessity criteria

LCD for Symptomatic, Pathological Nail and its Treatment (L24366) has been retired - use medical necessity criteria

And for facility-based services billed using a UB form, see [LCD for Treatment of Ulcers & Symptomatic Hyperkeratoses \(L36107\)](#)

#### For Non-Medicare Members

- I. For the purpose of the Clinical Review Criteria foot care\* is defined as:
  - A. Cutting or removal of corns or calluses;
  - B. Trimming, cutting, clipping, or debriding of nails;
  - C. Other hygienic and preventative maintenance care, such as cleaning and soaking the feet, the use of skin creams to maintain skin tone of either ambulatory or bedfast patients, and any other service performed in the absence of localized illness, injury, or symptoms involving the foot.
  - D. Asymptomatic foot care is not a covered service. The criteria below identify when foot care is covered. They are divided into sections of foot care for the asymptomatic and symptomatic foot.
- II. Foot care services as medically necessary when EITHER of the following criteria is met:
  - A. The foot care services that are associated with systemic conditions that are significant enough to result in severe circulatory insufficiency and/or areas of desensitization in the lower extremities, including, but not limited to, ANY of the following:
    1. diabetes mellitus
    2. peripheral vascular disease
    3. peripheral neuropathy
    4. Non traumatic amputation of a foot or part thereof
      - See below 3B for documentation requirements
  - B. Evaluation/debridement of mycotic nails, in the absence of a systemic condition, when BOTH of the following conditions are met:
    1. There is pain or secondary infection resulting from the thickening and dystrophy of the infected toenail plate.
    2. If ambulatory, there is pain to a degree that there is difficulty walking and/or abnormality of gait.
- III. Exclusions
  - A. General diagnosis such as arteriosclerotic heart disease, circulatory problems, vascular disease, and venous insufficiency are not sufficient to permit coverage of routine foot care. Likewise, incapacitating injuries or illness such as rheumatoid arthritis, CVA, fractured hip and blindness are not diagnoses for which routine foot care is payable

\*Not provided more frequently than every 60 days

- B. For neuropathies chart must record the physical findings of severe loss of sensation to the degree that non-professional services might pose a danger to the patient. For peripheral vascular disease, must document peripheral pulses.
- C. For chronic thrombophlebitis the chart must document significant physical findings (edema, superficial varicosities, or skin discoloration)

**Foot care for the symptomatic foot is covered on a per visit basis. The member should contact their primary care physician when they are experiencing pain, ulcers or infection in the feet to obtain a referral for these services:**

Clinical Indication	Supporting Information	Exclusions
The foot care as a necessary and integral part of otherwise covered service such as diagnosis and treatment of ulcers, wounds, or infections	Provider office-visit note that indicates the clinical condition being treated. The pathological state that makes care no longer routine is when one or more of the following characteristics are described: Pain, Inflammation of the nail bed, Inflammation of the surrounding soft tissue, infection, and/or abscess (i.e ingrown toenail)	Treatment of flat foot Foot care to prevent ingrown toenails

### **Section I:**

#### *Conditions requiring further review:*

- Diabetes mellitus 250.00 - 250.93 E10-E13.9
- Arteriosclerosis obliterans (A.S.O. arteriosclerosis of the extremities, occlusive peripheral arteriosclerosis) 440.20 - 440.32, I70- I70.599
- Buerger's disease (thromboangitis obliterans 443.1 I73.1
- Peripheral vascular disease 443.9 I73.9

#### *Conditions approved without review:*

- Peripheral neuropathies involving the feet:
  - Mononeuritis of lower limb 355.0 -355.9 G57.00-G59
  - Hereditary and idiopathic peripheral neuropathies 356.0 - 356.9 G60.0 - G60.9
  - Acute infective polyneuritis polyneuropathy in collagen vascular diseases 357.0 - 357.1 G61.0-G63; M05.50-M05.59
  - Polyneuropathy in diabetes, malignancy, and other diseases 357.2 - 357.4 E08.40-E13.42, G13.10, G13.1, G63-G65.2, A52.12, M34.83
  - Polyneuropathy due to alcohol, drugs, and other toxic agents 357.5 - 357.7 G62.1-G62.82
  - \* Neuropathy, other and unspecified 357.8 - 357.9 G61.81-G62.9
    - Associated with malnutrition and vitamin deficiency:
      - malnutrition (general, pellagra)
      - alcoholism
      - malabsorption (celiac disease, tropical sprue)
      - pernicious anemia
    - \* Associated with carcinoma
    - \* Associated with diabetes mellitus
    - \* Associated with drug and toxins
    - \*Associated with multiple sclerosis 340.0 G35
    - Paraplegia 344.1 G04.1, G82.20-G82.22
    - Quadraplegia 344.0-344.09 G82.50-G82.54
    - Monoplegia 344.30-344.32 G83.10-G83.14
    - \* Associated with uremia (chronic renal disease) 585, 586 N19
    - Associated with traumatic injury 958.3, 958.4, 959.7 T79.8XXA, T79.4XXA, S-83.001A-S99.929A
    - Associated with leprosy 030-030.9 A30.5-A30.8 or neurosyphilis 094-094.1 A52.11-A52.17
    - Associated with hereditary disorder:
      - hereditary sensory radicular neuropathy 265.2 E52
      - angiokeratoma corporis diffusum (Fabry's) 272.7 E75.21-E77.9
      - amyloid neuropathy 277.3 E85.9
- Chronic thrombophlebitis if the lower extremities 451.0-451.2 I80.00-I80.03, I80.10-I80.13, I80.201 I80.299, I80.3

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Asymptomatic foot care or routine foot care is usually not covered for members in the absence of localized illness, injury or symptoms involving the foot. Most Group Health coverage contracts exclude routine foot care coverage. Group Health developed criteria consistent with the Medicare those published by Medicare.

### Foot care includes:

- Cutting or removal of corns or calluses
- Trimming, cutting, clipping, or debriding of nails
- Other hygienic and preventative maintenance care, such as cleaning and soaking the feet, the use of skin creams to maintain skin tone of either ambulatory or bedfast patients, and any other service performed in the absence of localized illness, injury, or symptoms involving the foot.
- Debridement of nails is a procedure that is needed to remove excessive material (reduce thickness and length) from a dystrophic nail but not a non-dystrophic nail. In contrast, trimming of nails is a procedure that may be directed at either type of nail.

## Clinical Review Criteria

### Galectin-3 Blood Assay Test

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

None

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies for congestive heart failure (CHF).

The use of Galactin-3 for all other indications does not meet medical necessity because its clinical utility has not been established.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Heart failure (HF) is one of the most frequent and challenging medical disorders. It is a complex progressive disease with high morbidity and mortality. The prognosis of patients with HF is poor despite the advances made in the diagnosis, medical management, and device therapies. It is thus important to diagnose HF early and to identify the patients at higher risk of poor outcomes (Lok 2013, Browners 2014).

Accurate risk stratification of HF patients may help in the decision making for managing the disease; including individualizing the therapeutic approach and the proper use of invasive and costly therapies. However, risk prediction in acute, chronic, and new onset HF remains a challenge. Clinical parameters, such as advanced age, higher New York Heart Association (NYHA) functional class, reduced left ventricular ejection fraction (LVEF), lower body mass index, renal dysfunction, and anemia, have all been associated with poor outcomes in HF, but are not significant predictors of mortality. In recent years efforts were made to find biomarkers that might help in the risk stratification, and prognostication of acute and chronic heart failure. Brain natriuretic peptide (BNP) and its N-terminal part (NT-proBNP) have become well-established markers used in the diagnosis and management of HF patients. Both are released in response to myocyte stretch and provide useful information for HF diagnosis, prognosis, and response to therapy. However, natriuretic peptides only indicate ventricular loading conditions and may not reveal other important mechanisms for HF. Other novel biomarkers from different physiopathological pathways such soluble ST2, growth differentiation factor-15, highly sensitive troponins, and Galectin-3, have recently emerged and are being evaluated for their potential use in adding value to the risk stratification of HF patients. For a biomarker to be useful to a clinician, it should be available, accurate, and reliable. It also should add incremental value to the clinical variables or other established markers, provide prognostic information, have an impact on patient management, and be responsive to interventions (Carrasco-Sanchez 2014, Coburn 2014, Filipe 2014, Gruson 2014, Pouleur 2014, Schmitter 4014, Srivatsan 2014).

Galectin-3 (Gal-3) is a member of a family of proteins comprising soluble  $\beta$ -galactoside-binding lectins that have regulatory roles in fibrogenesis, inflammation, tissue repair, and cell proliferation. It is mainly known for its role as a mediator of tumor growth, progression, and metastases. Gal-3 is also associated with increased age, diabetes, nephropathy, and fibrotic conditions such as liver fibrosis, renal fibrosis, idiopathic lung fibrosis, and chronic pancreatitis. Recently, it has been suggested that Gal-3 may play a role in the pathophysiology of HF through promotion of inflammation, myocardial fibrosis and myocardial remodeling, which are key processes for the development and progression of HF. It was thus suggested that an increased Gal-3 level in the circulation may reflect active and excessive myocardial fibrogenesis in patients with HF, and can thus be used as a marker for

poor prognosis related to excessive and potential irreversible myocardial fibrosis (Lok 2010, Gullestad 2013, Carrasco-Sanchez 2013, Suarez 2014).

GAL-3 is measured in the circulation by manual or automated assays. The enzyme linked immunosorbent assay manual assay (ELISA) is the most frequently used method in the published studies. Manual assays are however, laborious and take considerable time for sampling, handling, incubation, and washing steps. More recently, several automated assays with faster delivery of the results, have been developed and are commercially available. A number of manual and automated assays have received FDA approval for measuring circulating Gal-3. Others are still seeking approval. The ARCHITECT Galectin-3 assay, BGM Galectin -3™ are among those approved by the FDA to be used in conjunction with clinical evaluation as an aid in assessing the prognosis of patients diagnosed with chronic heart failure.

Galectin-3 testing in HF patients has not been previously reviewed by MTAC. It is being reviewed for its use as a prognostic marker in patients with heart failure based on requests from contracted providers for its coverage.

## Medical Technology Assessment Committee (MTAC)

### ***Galectin-3 Blood Assay Test***

#### **02/09/2015: MTAC REVIEW**

**Evidence Conclusion:** 1. Prognostic value of galectin-3 in patients with acute or chronic heart failure: The published studies on the prognostic value of Gal-3 in patients with HF are mainly secondary studies analyzing data from existing databases for RCTs examining the effect of drug therapy or other interventions on outcomes of patients with HF. In these studies blood samples were obtained once at baseline and the plasma was stored for years at temperatures below 70o-80oC. Baseline plasma Gal-3 levels were then correlated with the incidence of CVD, HF, rehospitalization, and mortality during follow-up. The results were not validated in external cohorts and could be related to specific characteristics of the patients studied, or other unmeasured cofounders. There are several other issues with these kinds of analyses that would limit generalization of their results. Retrospective analyses may only suggest correlation and not causality; blood samples were obtained only once in the majority of studies, with no serial measurements of Gal-3 and thus cannot determine whether it varies by time and the effects of this variation if any, the plasma samples were frozen and it is unknown if Gal-3 would degrade over the years. In addition, a number of these studies used arbitrary cutoff levels for Gal-3 to categorize patients into subgroups in order to test for interactions and associations. It was also questioned whether the detection of Gal-3 in the circulation accurately reflects activity in the tissues. The ideal study for evaluating the prognostic value of a novel biomarker would be a prospective study with long-term follow-up that examines the additive or incremental value of the new biomarker on top of existing established prognostic markers or clinical variables. The results should then be externally validated in other patient populations. In general, the analyses of the published studies suggest that the plasma concentration of Gal-3 is high in patients with HF. There is insufficient evidence however, to determine that the high plasma level of Gal-3 in these patients is an independent prognostic marker for poorer outcomes. The results of the published analyses are conflicting; some suggest that after adjusting for many clinical variables including NT-proBNP, elevated Gal-3 levels may be associated with higher rates of all-cause mortality, CV events and /or rehospitalization in patients with heart failure. Other analyses, on the other hand, show that after adjusting for similar or additional clinical variables including NT-proBNP, Gal-3 is not a significant independent prognostic marker for any of the outcomes studied (Table 3 shows the differences in the variables adjusted for). There were variations between the studies in their inclusion criteria, patient characteristics, cause, type, severity, duration, and therapies used for managing the heart failure. There were also differences in population sizes, duration of follow-up, number of covariables used in the multivariate analyses, and the cutoff for Gal-3, which was mainly arbitrarily selected. Studies that showed a significant association between Gal-3 and outcomes tended to be smaller studies that adjusted for less clinical variables in their analyses. The two largest studies HF-ACTION (Felker et al, 2012) and CORONA (Gullestad et al, 2014) showed that Gal-3 was significantly associated with the risk of primary outcomes studies in the univariate analyses performed, but the association observed was no longer significant when series of multivariable models including NT-proBNP were performed. Chen and colleagues (2015) performed a meta-analysis of 11 studies with 8,419 participants (Evidence table 1) to assess the association between Gal-3 and adverse outcomes in HF patients. The pooled results of the analysis suggest that increased serum Gal-3 was associated with higher all-cause mortality or CV mortality after adjusting for other established factors. These results however, have to be interpreted with caution due to several limitations. The meta-analysis pooled the results of studies including patients with acute or chronic, and with systolic or diastolic heart failure, and conducted among different patient populations. Two of the 11 studies included in the analysis were performed by the same principal authors among the same group of patients. There was significant heterogeneity between the studies as well as significant publication bias. The population sizes varied between the included studies from 240 to 1,440 patients, and the follow-up duration ranged between 1 and 8.7 years. There were also differences between the studies in the cutoff values for Gal-3 and the variables adjusted for in

calculating the hazard ratios (table 3). Meijers et al's (2014) pooled analysis (Evidence table 2) of three clinical trials showed that patients with elevated Gal-3 (>17.8 ng/mL) were more likely to be re-hospitalized for HR at 30, 60, 90, and 120 days after discharge. Gal-3 was found to be an independent predictor for re-hospitalization after adjusting for age, gender, NYHA class, renal function, LVEF, and BNP. Addition of Gal-3 to the clinical risk model comprising these variables significantly improved the net risk classification of patients for postdischarge rehospitalization and fatal events at each time point. The pooled analysis had its limitations and its results should be interpreted with caution.

2. Incremental value of galectin-3: The most commonly used way to evaluate the ability of a prognostic HF biomarker in predicting an event is to assess the area under the Receiver Operator Curve (AUC) which is a balance of sensitivity and specificity of the test or tool, and to compare it with a gold standard (C-statistics). However, a small but statically significant difference between the AUC for the gold standard and biomarker studied, may be clinically irrelevant, and there is no generally agreed upon clinically improvement in the C-statistics (Januzzi 2014). Area under Receiver Operator Curve (AUC) for Gal-3, NT-proBNP, and combinations

Author/ Study	N of patients	Outcome	AUC						
			Clinical model	Ref. † model	Gal-3	NT-proBNP Or BNP	Clinical or Reference model +Gal-3	Clinical model +BNP	Gal-3 +BNP
Zhang et al, 2015	1,440	All-cause death CV death		0.82	0.71	0.79	0.83		0.81
Ahmad et al 2014/ HF-ACTION	813	Pump failure SCD	0.82		0.76	0.83	0.83	0.87	
De Boer et al, 2010/C OACH	592	Death or HF hospitalization			0.67	0.65 (BNP)			0.69
Lok, et al, 2010/ DEAL-HF* 2013	232 209	All-cause mortality			0.61 2	0.611			
Van Kimmenda de 2006**	599	Mortality			0.68	0.63			0.69
					0.74	0.67			

†Reference model included sex, age, DM, ischemic HD, SBP, NYHA functional class, LVEF, ARB/ACE I, B-blocker, hemoglobin, sodium, and NT-proBNP.

\*Patients with high baseline levels of both markers were observed to have approximately 1.5-2-fold higher mortality rate compared to those in other categories.

\*\* The combination of an elevated galectin-3 with NT-proBNP was a better predictor of mortality than either of the 2 markers alone.

oCutoff values for Gal-3 were: 22.4 for in-hospital death in Zhang et al's study (sensitivity =0.69 and specificity =0.62), 13.9 ng/mL in HF-ACTION, and 18.05 ng/mL in DEAL-HF

oCutoff values for NT-proBNP were: 2,472 pg/mL in Zhang et al's study , and 852 pg/mL in HF-ACTION.

Accuracy of Gal-3 in the diagnosis of HF was studied in a small study with N= 35 patients with HF and 43 controls (Sheng et al, 2014) showing the following results:

	Sensitivity %	Specificity %	Accuracy %	PPV %	NPV %	AUC
Gal-3	94.3	65.1	78.2	68.8	93.3	0.891
NT-proBNP	77.1	90.7	84.6	87.1	83.0	0.896

At a cutoff of 17.8 ng/mL for Gal-3 and 100 pg/mL for NT-proBNP

90.7 84.6 87.1  
83.0 0.896

3. Clinical utility of Galectin-3: The literature search did not identify any randomized controlled trial that examined the use of Gal-3 as a target in HF therapy, or that evaluated its impact on selecting a management strategy for

patients with HF. Published studies on the disruption of galectin-3 gene to block myofibroblast activation are experimental, with the hypothesis that direct inhibition of Gal-3 may be possible by N-acetylcysteine-lysyl-proline (Ac-SDKP), a naturally occurring tetrapeptide that prevents and reverses inflammation and collagen deposition in heart after hypertension or myocardial infarction (Hrynchyshyn 2013). Studies on anti-galectin-3 therapy for heart failure are ongoing. The effect of measuring the concentration of circulating Gal-3 on patient management was indirectly examined in post hoc analyses of data obtained from RCTs evaluating different therapies for HF; rosuvastatin in the CORONA study and valsartan in the Val-HeFT.

The CORONA study (Kjekshus et al, 2007) aimed at examining the beneficial effects of rosuvastatin among patients with chronic, symptomatic, systolic, ischemic heart failure. The trial randomized 5,011 patients over the age of 60 years, with chronic ischemic heart failure to receive 10 mg of rosuvastatin or placebo per day. The primary composite outcome was death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke. Secondary outcomes included death from any cause, any coronary event, death from cardiovascular causes, and the number of hospitalizations. After a median follow-up of 32.8 months the results of the trial showed that rosuvastatin did not reduce the primary outcome or the number of deaths from any cause in these older patients with systolic heart failure, but reduced the number of cardiovascular hospitalizations. In a post hoc analysis of CORONA study, Gullestad and colleagues (2012) investigated whether plasma Gal-3 can identify patients with chronic HF for whom statins are effective. Of the 5,011 patients enrolled in the CORONA study, 1,462 (29%) patients had baseline plasma specimens available for measuring Gal-3. These were obtained from nonfasting blood samples obtained at baseline and stored at -80°C. There were significant baseline differences between this subset of patients and the entire CORONA participants. For this secondary analysis, the investigators categorized patients into two groups based on the median Gal-3 baseline level (19.0 ng/mL) and found that after a median follow-up of 32.8 months, patients with Gal-3 below the median level who were assigned to rosuvastatin had significantly lower primary event rate, lower total mortality, and lower rates for the composite outcome of all-cause mortality and HF hospitalization, compared to placebo. No benefits were observed for patients with Gal-3 above the median level. The authors noted that the combination of Gal-3 and NT-proBNP (at cutoff of 102.7 pmol/L) identified patients with a large benefit from rosuvastatin treatment. Val-HeFT trial (Cohn et al, 2001) was a randomized placebo-controlled trial that enrolled 5,010 patients >18 years of age with symptomatic HF to evaluate the efficacy of valsartan. Blood was sampled and the separated plasma was stored at -70°C. The primary outcomes of Val-HeFT were all-cause mortality and the first morbid event (defined as death, sudden death with resuscitation, hospitalization for HF, or the administration of intravenous inotropic drug or vasodilator for four or more hours without hospitalization). The results of the trial showed that after a median follow-up duration of 23 months, valsartan had no effect on mortality, but reduced the first morbid event by 13% and hospitalization for HF by 28%. These 3 endpoints were analyzed in the Galectin-3 substudy by Anand and colleagues (2013). This post hoc analysis of Val-HeFT trial examined whether circulating Gal-3 levels can predict the response to valsartan. Baseline samples for measuring Gal-3 were available for 1,650 patients (~30% of the participants). The overall results of this secondary analysis indicate that the use of valsartan was not associated with a beneficial effect on any outcome in this subgroup of patients with available baseline Gal-3 measurements. The authors then arbitrarily categorized patients into two groups based on the median level of Gal-3 (16.2 ng/mL) and found that valsartan treatment was associated with a significant decrease in hospitalization only among patients with Gal-3 below the median level and not for those with levels above the median. This is a posthoc analysis with several limitations, and does not directly examine the impact of measuring Gal-3 levels on patient management, and/or treatment outcomes. The results of these post hoc analyses should be interpreted with caution due to several limitations. The studies did not directly examine the impact of measuring Gal-3 levels on patient management, and/or treatment outcomes. They were secondary analyses that included less than one third of the population in each of the two trials, there were some significant baseline differences between the patients with Gal-3 measurements and the entire participants in each of the studies, Gal-3 was measured from specimens obtained at baseline and stored for years, and the results of the trials did not show any significant effect of either drug used (rosuvastatin or valsartan) on the primary outcomes studied. **Conclusions:** There is insufficient evidence from longitudinal studies with long-term follow-up and serial measurements of Gal-3 to determine that elevated circulating Gal-3 levels are independent prognostic markers for poor outcomes in patients with HF. There is insufficient evidence to determine that Gal-3 adds clinically significant incremental value to established markers and clinical variables. There is insufficient evidence to determine that circulating Gal-3 has an impact on management decisions made for patients with HF.

**Articles:** The literature search revealed over 200 articles on Galectin-3 and heart failure. The great majority were unrelated to the current review. There were several published studies on the prognostic value of Gal-3 in patients with heart failure. These were mainly secondary analyses of data or subsets of data collected for patients enrolled in large cohort studies or randomized controlled trials that investigated different other therapies or interventions. The search also identified a pooled analysis of the results of 3 trials (Meijers 2014), and a more recent meta-analysis (Chen et al, 2015) that pooled the results of 11 studies. The literature search did not identify any RCT that directly studied the impact of using the plasma levels Gal-3 on the management of patients with HF.

The two meta-analyses were selected for critical appraisal (Evidence tables 1 & 2). The characteristics of the studies included in the larger meta-analysis as well as selected studies published in the last 5 years and not included in the meta-analyses were reviewed and summarized in [Evidence Table 3](#). Chen A, Hou W, Zhang Y et al. Prognostic value of serum galectin-3 in patients with heart failure: a meta-analysis. *Int J Cardiol* 2015;182:168-170. See [Evidence Table 1](#). Meijers WC, Januzzi JL, de Filippi C, et al. Elevated plasma galectin-3 is associated with near-term rehospitalization in heart failure: a pooled analysis of 3 clinical trials. *Am Heart J*. 2014 Jun;167(6):853-60.e4. See [Evidence Table 2](#).

The use of Galectin-3 Blood Assay Test does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Gender Reassignment Surgery

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

**For Microsoft employees:** use the Microsoft contact

**For PEBB -** [Uniform Medical Plan Transgender Services Clinical Criteria and Policy](#)

**For Sound Health and Wellness** see the [Sound Health & Wellness Trust Gender Dysphoria Coverage Policy](#)

**For Providence Health & Services** – Policy will be effective 1/1/2017

**For FEHB plans:** see the Benefits and Coverage Transgender Services Policy

**For Medicare and Non-Medicare Members:** Members must be enrolled in the GHC transgender services program

- I. Requirements for Mastectomy (i.e., initial mastectomy, with nipple sparing or tattooing) for female-to-male patients:
  - A. 18 years and older
    1. Single letter of referral from a qualified mental health professional\*; *and*
    2. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; *and*
    3. Capacity to make a fully informed decision and to consent for treatment; *and*
    4. 18 years of age or older *and*
    5. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question
  - B. For member 16 years- 18 years, members must meet all of the following:
    1. Ample time of living in the desired gender role
    2. After one year of testosterone treatment
    3. Meet criteria above, except number 4
    4. Must have parental consent or be legally emancipated
- ❖ Note that a trial of hormone therapy is not a pre-requisite to qualifying for a mastectomy for members 18 years age or older
- ❖ Male-Female (M-F) breast augmentation surgery is not a covered service as it is considered cosmetic.
- II. Requirements for gonadectomy (hysterectomy and oophorectomy in female-to-male and orchiectomy in male to-female):
  - A. Two referral letters from qualified mental health professionals\*, one in a purely evaluative role. At least one letter should be an extensive report. Two separate letters or one letter with two signatures is acceptable. One letter from a master's degree mental health professional is acceptable if the second letter is from a psychiatrist or PhD clinical psychologist; *and*
  - B. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; *and*
  - C. Capacity to make a fully informed decision and to consent for treatment; *and*
  - D. Age of majority (18 years or older); *and*
  - E. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; *and*
  - F. Twelve months of continuous hormone therapy as appropriate to the member's gender goals (unless the member has a medical contraindication or is otherwise unable or unwilling to take hormones – chart notes must describe the contraindications in detail )

- III. Requirements for genital reconstructive surgery (Vaginectomy, colpectomy, metoidioplasty, vaginoplasty, colovaginoplasty, penectomy, clitoroplasty, labioplasty, phalloplasty, scrotoplasty, urethroplasty, testicular prosthesis (expanders and implants), penile prosthesis. M–F hair removal in the pubic surgical area.)
- A. Two referral letters from qualified mental health professionals\*, one in a purely evaluative role (At least one letter should be an extensive report. Two separate letters or one letter with two signatures is acceptable. One letter from a master's degree mental health professional is acceptable if the second letter is from a psychiatrist or PhD clinical psychologist); and
  - B. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; and
  - C. Capacity to make a fully informed decision and to consent for treatment; and
  - D. Age 18 years and older; and
  - E. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; and
  - F. Twelve months of continuous hormone therapy as appropriate to the member's gender goals (unless the member has a medical contraindication or is otherwise unable or unwilling to take hormones); and
  - G. Twelve months of living in a gender role that is congruent with their gender identity (real life experience)

The following procedures are **not covered** as a part of this benefit:

- Breast augmentations/silicone injections of the breast
- Blepharoplasty
- Facial feminization surgery including but not limited to: facial bone reduction, facial hair removal, and certain facial plastic reconstruction
- Rhinoplasty
- Lip reduction/enhancement
- Face/forehead lift
- Chin/nose implants
- Trachea shave/reduction thyroid chondroplasty
- Laryngoplasty
- Liposuction
- Mons Resection (15839)
- Hair implant
- Jaw shortening/sculpting/facial bone reduction
- Collagen injections
- Removal of redundant skin
- Voice modification surgery
- Drugs for hair loss or growth
- Mastopexy
- Calf implants
- Cheek/malar implants
- Abdominoplasty
- Neck tightening
- Pectoral implants
- Travel expenses
- Reversal of genital surgery or reversal of surgery to revise secondary sex characteristics
- Sperm preservation in advance of hormone treatment or gender surgery
- Cryopreservation of fertilized embryos
- All other cosmetic procedures that do not meet medical necessity

\* Characteristics of a Qualified Mental Health Professional:

1. Master's degree or equivalent in a clinical behavioral science field granted by an institution accredited by the appropriate national accrediting board. The professional should also have documented credentials from the relevant licensing board or equivalent; and
2. Competence in using the Diagnostic Statistical Manual of Mental Disorders and/or the International Classification of Disease for diagnostic purposes; and
3. Ability to recognize and diagnose co-existing mental health concerns and to distinguish these from gender dysphoria;
4. Knowledgeable about gender nonconforming identities and expressions, and the assessment and treatment of gender dysphoria; and
5. Continuing education in the assessment and treatment of gender dysphoria. This may include attending relevant professional meetings, workshops, or seminars; obtaining supervision from a mental health professional with relevant experience; or participating in research related to gender nonconformity and gender dysphoria.

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Gender identity disorder (GID) more commonly known as transsexualism manifests, with constant and persistent conviction, the desire to live as a member of the opposite sex and progressively take steps to live in the opposite sex role full-time.

Transsexuals usually present to the medical profession with a diagnosis of transsexualism, a sophisticated understanding of their condition, and a desired course of treatment, that is, hormone therapy and sex-reassignment surgery. The therapeutic approach to gender identity disorder consists of three elements: hormones followed by real life experience and, finally, surgery.

Due to the far-reaching and irreversible results of hormonal and/or surgical transformational measures, a careful diagnosis and differential diagnosis is absolutely vital to the patient's best interest. In and of themselves, a patient's self-diagnosis and the intensity of his desire for sex reassignment cannot be viewed as reliable indicators of transsexuality. A vital part of the long-term diagnostic therapy is the so-called real-life experience, in which the patient lives as a member of the desired sex continually and in all social spheres in order to accumulate necessary experience.

Hormone therapy and sex-reassignment surgery are superficial changes in comparison to the major psychological adjustments necessary in changing sex. Treatment should concentrate on the psychological adjustment, with hormone therapy and sex-reassignment surgery being viewed as confirmatory procedures dependent on adequate psychological adjustment. Psychiatric care may need to be continued for many years after sex-reassignment surgery. The overall success of treatment depends partly on the technical success of the surgery, but more crucially on the psychological adjustment of the transsexual, and the support from family, friends, employers and the medical profession.

## Evidence and Source Documents

There was no evidence review conducted for these criteria. They were developed in response to a request to develop a rider for these services that may be purchased by employer groups.

### For Non-Medicare Members

Members must meet all of the following criteria:

1. The member is at clinical risk for a genetic condition because of current documented symptoms being displayed or a strong family history of the condition.
2. The test is scientifically valid and can be adequately interpreted.
3. The results will directly affect a member's clinical management or reproductive decisions.
4. After appropriate clinical work-up, and informed consent by the appropriate practitioner, the genetic test is indicated.

Genetic testing is not covered for the medical management of a family member who does not have Group Health coverage.

For **specific tests listed** below the member must meet the criteria above **AND** the specific test criteria below:

Cardiology	Criteria
Arrhythmogenic Right Ventricular Cardiomyopathy-ARVC Genes	MCG* (GHC-0627)
Brugada Syndrome - CACNA1C, CACNB2, GPD1L, KCNE3, SCN1B, SCN3B, and SCN5A Genes	MCG*(GHC-0594)
Catecholaminergic Polymorphic Ventricular Tachycardia - RYR2 and CASQ2 Genes	MCG* (GHC-0636)
Coronary Artery Disease - 9p21 Allele	MCG* (A-0657)
Coronary Artery Disease - KIF6 Gene	MCG*(A-0656)
Coronary Artery Disease Gene Expression Testing	MCG* (A-0652)
Coronary Artery Disease Genetic Panel	MCG* (A-0658)
Dilated Cardiomyopathy-ANKRD1, DMD, LDB3, LMNA, MYBPC3, MYH7, RBM20, TNN13, TNNT2 Genes	MCG* (GHC-0648)
Hypertrophic Cardiomyopathy-Sarcomere Genes	MCG* (GHC-0633)
Long QT Interval Syndromes-Cardiac Ion Channel Genes	No additional criteria need to be met beyond numbers 1 - 4 on page one.

Endocrinology	Criteria
Diabetes Mellitus - ABCC8, CEL, FTO, GCK, HNF1A, HNF1B, HNF4A, INS, KCNJ11, KLF11, NEUROD1, and PDX1 Genes	There is insufficient evidence in the published medical literature to show clinical utility.
Diabetes Mellitus, Type 2 - KCNJ11, KCNQ1, PPARG, and TCF7L2 Genes	A-0826: This service is not covered per MCG 20th Edition guidelines.

Gastroenterology	Criteria
HLA Testing for Celiac Disease:	<ol style="list-style-type: none"> <li>1. Is medically appropriate for symptomatic patients <ol style="list-style-type: none"> <li>a. Despite being on a gluten free diet <b>OR</b></li> <li>b. With indeterminate serology/biopsy results</li> </ol> </li> <li>2. It is not covered for <ol style="list-style-type: none"> <li>a. Asymptomatic people <b>OR</b></li> <li>b. Screening</li> </ol> </li> </ol>
Hemochromatosis - HFE Gene	MCG* (GHC-0599)
Intrahepatic Cholestasis - JaundiceChip Resequencing Array	A-0784: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines.
Pancreatitis, Hereditary - PRSS1 Gene	MCG* (GHC-0646)

Genomic Testing Methods and Technologies	Criteria
Cytochrome P450 - 3A4/3A5 Genotyping	A-0775: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines.
Micro Array for Evaluation of Intellectual Disability	<ol style="list-style-type: none"> <li>1) Chromosomal microarray testing may be considered medically necessary for genetic evaluation of an individual when all of the following criteria are met: <ol style="list-style-type: none"> <li>a) There is documentation in the medical record of significant dysmorphic physical features or congenital anomalies</li> <li>b) Results are expected to affect clinical management of the patient for whom the test is ordered</li> <li>c) Testing has been requested following evaluation and genetic counseling by a healthcare professional who has appropriate genetic training and experience.</li> </ol> </li> <li>2) Chromosomal microarray testing may be considered medically necessary for prenatal diagnosis using genetic material obtained by chorionic villus sampling (CVS) or amniocentesis when: <ol style="list-style-type: none"> <li>a) There is a known chromosomal deletion or duplication identified in at least one biologic parent or a biologic sibling, or</li> <li>b) A fetal malformation known to be potentially associated with a chromosomal abnormality has been identified by fetal ultrasound and diagnosis by fluorescence in situ hybridization (FISH) testing alone is not possible, and</li> <li>c) Results are expected to directly affect reproductive decisions for the parent(s) or clinical management of the fetus or newborn.</li> </ol> </li> <li>3) Chromosomal microarray testing may be considered medically necessary for testing of one or both parents when a chromosomal deletion or duplication has been identified in one or more of their offspring and: <ol style="list-style-type: none"> <li>a) Parental testing is necessary to guide a reproductive decision, or</li> </ol> </li> </ol>

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

Genomic Testing Methods and Technologies	Criteria
	<p>b) Parental testing is necessary to determine the clinical significance of the chromosome abnormality found in the child, and</p> <p>c) The result is expected to directly affect clinical management of the child</p> <p>The following are not covered:</p> <ul style="list-style-type: none"> <li>• CMA testing for the evaluation of developmental disability, intellectual disability, or autism spectrum disorders in the absence of significant physical dysmorphism.</li> <li>• CMA to confirm the diagnosis of a disorder or syndrome that is routinely diagnosed based on clinical evaluation alone.</li> </ul>
Genome-Wide Association Studies	MCG* (A-0531) This is not covered per MCG guidelines
MicroRNA Detection	MCG* (A-0705) This is not covered per MCG guidelines
MicroRNA Detection - Heart Failure	A-0838: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
MicroRNA Detection - Inflammatory Bowel Disease	A-0839: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
MicroRNA Detection - Ischemic Heart Disease	A-0840: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
MicroRNA Detection - Kidney Disease	A-0841: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Molecular Profiling	A-0789: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines.
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Fetal Rhesus D (RhD) Genotyping	A-0847: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Microdeletion Syndromes	A-0848: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Monogenic Disorders	A-0849: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Sex Chromosome Disorders	A-0850: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines.
Septin 9 (SEPT9) DNA Methylation Testion	MCG* (A-0706) This is not covered per MCG guidelines
Telomere Analysis	MCG* (A-0672) This is not covered per MCG guidelines
Topographic Genotypic- PathFinder TG	MCG* A-0632 This is not covered per MCG guidelines
Whole Genome/Exome Sequencing - Immunodeficiency Disorders	A-0866: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines.
Whole Genome/Exome Sequencing - Intellectual Disability	A-0867: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Whole Genome/Exome Sequencing - Metabolic Disorders	A-0868: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Whole Genome/Exome Sequencing - Mitochondrial DNA Disorders	A-0869: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Whole Genome/Exome Sequencing - Neurodevelopmental Disorders	A-0870: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Whole Genome/Exome Sequencing - Neurologic Disorders	A-0871: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Whole Genome/Exome Sequencing - Undiagnosed Genetic Disorders	A-0872: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Whole Genome/Exome Sequencing	No additional criteria need to be met beyond numbers 1 - 4 on page one.

Hematology	Criteria
Alpha Thalassemia - HBA1 and HBA2 Genes	MCG* (A-0808)
Beta Thalassemia - HBB Gene	MCG* (A-0815)

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

Fetal and Neonatal Alloimmune Thrombocytopenia - Human Platelet Antigen (HPA) Genotyping	MCG* (A-0793)
Factor V Leiden Thrombophilia-F5 gene	No longer require medical review
Fanconi Anemia-FANC Gene	MCG* (GHC-0683)
Hemoglobinopathies, Thalassemias and Sickle Cell Disease - HBA1, HBA2, and HBB Genes	MCG* (GHC-0604)
Hyperhomocysteinemia - MTHFR Gene	MCG*(A-0629)
Post-Transfusion Purpura - Human Platelet Antigen (HPA) Genotyping	A-0800: This service is not covered per MCG 20th Edition guidelines
Prothrombin Thrombophilia - F2 Gene	MCG* (GHC-0613)
Sickle Cell Disease - HBB Gene	MCG* (A-0864)
Von Willebrand Disease-VWF Gene	MCG* (GHC-0688)

Metabolic and Developmental Disorders	Criteria
Angelman Syndrome DNA Methylation Testing - UBE3A Gene	MCG* (GHC-0708)
Ashkenazi Jewish Genetic Panel	MCG*(GHC-0592)
Beckwith-Wiedemann Syndrome - CDKN1C Gene	MCG* (A-0765)
Bloom Syndrome-BLM Gene	MCG*(GHC-0682)
Canavan Disease - ASPA Gene	MCG* (GHC-0595)
Deafness, Hereditary - GJB2 and GJB6 Genes	MCG* (GHC-0596)
Fragile X-Related Disorders-FMR1 Gene	MCG* (A-0602)
Fragile X-Associated Primary Ovarian Insufficiency - FMR1 Gene	MCG* (A-0829)
Fragile X-Associated Tremor/Ataxia Syndrome - FMR1 Gene	MCG* (A-0830)
Gaucher Disease - GBA Gene	MCG* (GHC-0603)
Glycogen Storage Disease, Type 1 G6PC Gene	MCG* (GHC-0684)
Joubert Syndrome - AHI1, ARL13B, CC2D2A, CEP41, CEP290, C5orf42, INPP5E, KIF7, NPHP1, OFD1, RPGRIP1L, TCTN1, TCTN2, TCTN3, TMEM67 (MKS3), TMEM138, TMEM216, TMEM231, and TMEM237 Genes	MCG* (A-0785)
Lesch-Nyhan Syndrome - HPRT1 Gene	MCG* (GHC-0606)
Maple Syrup Urine Disease-BCKDHA	MCG* (GHC-0681)
Maple Syrup Urine Disease, Type 3 - DLD Gene	MCG* (A-0776)
Mucopolipidosis IV-MCOLN1 Gene	MCG* (GHC-0686)
Niemann-Pick Disease (Acid Sphingomyelinase Deficiency) - SMPD1, NPC1, and NPC2 Genes	MCG* (GHC-0611)
Prader-Willi Syndrome DNA Methylation Testing	MCG* (GHC-0707)
Rett Syndrome-FOXP1 and MECP2 Genes	MCG* (GHC-0687)
Tay-Sachs Disease and Variants - HEXA Gene	MCG* (GHC-0614)
Usher Syndrome - ADGRV1 (GPR98), CDH23, CIB2, CLRN1, DFNB31, HARS, MYO7A, PCDH15, USH1C, USH1G, and USH2A Genes	MCG* (A-0802)

Miscellaneous	Criteria
Autosomal and X-Linked Recessive Disease Carrier Screening - Expanded Gene Panels	A-0768: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Familial Mediterranean Fever-MEFV Gene	MCG* (GHC-0689)
Hereditary Hemorrhagic Telangiectasia - ACVRL1, ENG, and SMAD4 Genes	MCG* (GHC-0704)
Male Infertility - Y Chromosome Microdeletion Analysis	MCG* (A-0803)
Malignant Hyperthermia Susceptibility-RYR1 Gene	MCG* (GHC-0690)

Nephrology	Criteria
Polycystic Kidney Disease (Autosomal Recessive) - PKHD1 Gene	MCG* (A-0852)

Neurology	Criteria
Alzheimer Disease - APOE, APP, CLU, CR1, PICALM, PSEN1, and PSEN2 Genes	MCG* (GHC-0590)

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

<b>Neurology</b>	<b>Criteria</b>
Alzheimer Disease (Late Onset) - APOE Genotyping	A-0809: This service is not covered per MCG 20th Edition guidelines.
Amyotrophic Lateral Sclerosis (ALS) - SOD1 Gene	No additional criteria need to be met beyond numbers 1 - 4 on page one.
Ataxia-Telangiectasia - ATM Gene	MCG* (GHC-0593)
CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) - NOTCH3 Gene	MCG* (GHC-0668)
Charcot-Marie-Tooth Hereditary Neuropathy, Type 1 - EGR2, LITAF, MPZ, NEFL, and PMP22 Genes	MCG* (A-0691)
Charcot-Marie-Tooth Hereditary Neuropathy, Type 2 - MFN2 Gene	MCG* (A-0816)
Charcot-Marie-Tooth Hereditary Neuropathy, Type 4 - GDAP1 and PRX Genes	MCG* (A-0818)
Charcot-Marie-Tooth Hereditary Neuropathy, Type X - GJB1 and PRPS1 Genes	MCG* (A-0819)
Familial Dysautonomia-IKKBAP Gene	MCG* (GHC-0685)
Huntington Disease - HTT Gene	MCG* (GHC-0605)
Muscular Dystrophies (Duchenne, Becker) - DMD Gene	MCG* (GHC-0608)
Myotonic Dystrophy-DMPK Gene	MCG* (GHC-0609)
Myotonic Dystrophy, Type 2 - CNBP Gene	MCG* (A-0844)
Nemaline Myopathy - ACTA1, CFL2, KBTBD13, KLHL40, KLHL41, NEB, TNNT1, TPM2, and TPM3 Genes	MCG* (A-0792)
Parkinson Disease - ATP13A2, LRRK2, PARK2, PARK7, PINK1, and SNCA Genes	MCG* (A-0671)
Spinal Muscular Atrophy - SMN1 and SMN2 Genes	MCG* (GHC-0659)

<b>Oncology</b>	<b>Criteria</b>
Acute Lymphoblastic Leukemia - BCR-ABL1 Fusion Gene Testing	MCG* (A-0759)
Acute Promyelocytic Leukemia - PML-RARA Fusion Gene Testing	MCG* (A-0760)
BRACAnalysis Large Rearrangement Test (BART)	MCG* (GHC-0638)
Breast Cancer Gene Expression Assays	See <a href="#">Oncotype Dx</a>
Breast Cancer - HER2 Testing	MCG* (A-0766)
Breast or Ovarian Cancer, Hereditary - BRCA1 and BRCA2 Genes (see genetic testing and screening policy)	MCG* (GHC-0499)
Cancer of Unknown Primary: Gene Expression Profiling	MCG* (A-0673)
Chronic Eosinophilic Leukemia/Hypereosinophilic Syndrome - FIP1L1-PDGFRα Fusion Gene Testing	MCG* (A-0770)
Chronic Myelogenous Leukemia - BCR-ABL1 Fusion Gene Testing	MCG* (A-0771)
Cologuard	See <a href="#">Fecal DNA Testing</a>
Colon Cancer Gene Expression Assay - ColoPrint	A-0822: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines
Colon Cancer Gene Expression Assay - GeneFx Colon	A-0821: This service is not covered per MCG 20 <sup>th</sup> Edition guidelines.
Colorectal Cancer - KRAS and NRAS Genes	MCG* (A-0773)
Colorectal Cancer - BRAF V600E Testing	MCG* (GHC-0772)
Cowden Syndrome - PTEN Gene	MCG* (GHC-0585)
DecisionDx- Melanoma	There is insufficient evidence in the published medical literature to show

Date Sent: February 28, 2017

**\*The MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting this service, please send the following documentation to support medical necessity:**

- Any genetic counseling notes if applicable
- Results of prior genetic testing

- Last 6 months of specialist notes of that is being reviewed (i.e., neurological notes, medical oncology notes, cardiology notes)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Evidence and Source Documents

[Array Comparative Genomic Hybridization \(aCGH\) for the Genetic Evaluation of Patients with Intellectual Disability DecisionDx- Melanoma](#)

[HLA Testing for Celiac Disease](#)

[Micro Array for Evaluation of Intellectual Disability](#)

[OVA1 for Assessment of Ovarian Cancer](#)

[Risk Prognosticator Tests](#)

[Thyroid Nodule Gene Expression Testing \(Afirma\)](#)

## Background

Genetic screening is used to identify the genetic disorders or the potential for transmission of genetic disorders in populations at risk for a particular genetic disorder. Genetic screening is only appropriate when the natural history of the disease is understood; the screening tests are valid and reliable; sensitivity, specificity, false-negative, and false-positive rates are acceptable; and effective therapy is available. A sufficient benefit must be derived from a screening program to justify its cost.

## Medical Technology Assessment Committee (MTAC)

### ***Array Comparative Genomic Hybridization (aCGH) for the Genetic Evaluation of Patients with Intellectual Disability***

#### BACKGROUND

Intellectual disability, also termed mental retardation or cognitive disability, affects approximately 1-3% of the general population and is defined as a significant impairment in cognitive and adaptive functions, with the age of onset before 18 years. It is a serious and lifelong condition that presents significant challenges to families and to public health. Determining the specific etiology of intellectual disability may help to provide answers related to prognosis, recurrence risk, and treatment. Intellectual disability can be caused by anything that damages or interferes with the growth or maturation of the brain; however, genetic (chromosomal) abnormalities are one of the main causes of intellectual disability (Galasso 2010, Sagoo 2009). Chromosomal abnormalities are deletions and duplications of genomic material and are commonly referred to as copy number variations. Conventional methods for detecting these abnormalities include karyotyping and florescent in situ hybridization (FISH). Karyotyping involves visualizing the chromosome for large gains or losses in chromosomal material and is generally the first step in cytogenetic analysis. Karyotyping can detect chromosomal abnormalities such as deletions, duplications, inversions, and translocations across the entire genome; however, it lacks the resolution necessary to detect abnormalities smaller than 3-5 megabases (Mb; 3-5 million base pairs). FISH uses florescent-labeled chromosome-specific probes to detect chromosomal abnormalities. FISH can detect submicroscopic abnormalities and is often used in situations where the karyotype is normal, but there is a high clinical suspicion of a deletion syndrome. However, FISH is a targeted method and requires prior knowledge of the chromosome region(s) of interest to request the appropriate FISH test. Additionally, FISH can only screen a limited number of genomic regions at a time (Breman 2009, Fruhman 2010, Galasso 2010, Gropman 2010). Array comparative genomic hybridization (aCGH) is a more recent technology used to identify copy number variations by comparing patient DNA with reference DNA. It is currently used as an adjunct to conventional methods. There are two types of aCGH: targeted and whole-genome. Targeted arrays are designed to interrogate areas of the genome with known clinically significant abnormalities. Whole genome arrays provide high resolution coverage of the entire genome. This can lead to the discovery of new copy number variations. Compared to conventional methods, aCGH has a higher resolution and is able to simultaneously detect copy number variations in multiple regions of the genome. Additionally, unlike FISH, knowledge of the chromosome region(s) of interest does not need to be determined in advance because a single array assay detects all genomic variants represented on the array. Array CGH is not without limitations. It cannot detect totally balanced translocations or inversions; it performs suboptimally for polyploidy; and has not been optimized for prenatal diagnosis of point mutations. Because aCGH cannot identify the exact location of a duplicated chromosome, further testing with karyotype or FISH may be necessary. Another limitation is the potential to identify novel copy number variants with unknown clinical significance (Fruhman 2010, Moeschler 2008). Array CGH is a laboratory-developed test and is commercially available from several different laboratories. Laboratory-developed tests are licensed under the Clinical Laboratory Improvement Amendments (CLIA) and do not require clearance from the FDA.

#### 4/18/2011: MTAC REVIEW

### Array Comparative Genomic Hybridization (aCGH) for the Genetic Evaluation of Patients with Intellectual Disability

**Evidence Conclusion:** Analytic validity The BCBS review identified several studies that evaluated the sensitivity of aCGH. The sensitivity of aCGH testing compared to conventional methods (karyotype and/or FISH) ranged from 73% to 100%. As false-positive rates were inconsistently reported, specificity could not be determined (BCBS 2009). Clinical validity

**Articles:** No studies were identified that evaluated the impact of conventional methods or aCGH on patient outcomes other than diagnostic yield. Results from the BCBS review suggest that diagnostic yield in patients with intellectual disability ranged from 5 to 16.7%, which represents a significant improvement compared to conventional methods. The number needed to test by aCGH to detect one clinically relevant abnormality ranged from 25 to 6 depending on the diagnostic yield. Limitations of these studies include: different aCGH resolution, patient selection criteria ranged from none to stringent criteria, and three different types of arrays were used (targeted, whole-genome, and those that combined targeted and whole-genome arrays) (BCBS 2009).

Diagnostic yield <sup>1</sup> of aCGH, karyotype, and FISH			
	aCGH	FISH	karyotype
	4-7%	5-6%	
Diagnostic yield	(In those negative by karyotype and FISH)	(In those negative by karyotype)	3-5%

<sup>1</sup>Estimates from Stankiewicz 2007.

Clinical utility The BCBS review included two small studies with a high risk of bias and found that there was insufficient evidence to determine the clinical utility of aCGH testing (BCBS 2009). Conclusion: Analytic validity: There is fair evidence that aCGH testing had good sensitivity compared to conventional methods; however, there is insufficient evidence to determine the specificity or reproducibility of this test. Clinical validity: There is fair evidence that aCGH increases diagnostic yield over conventional methods; however, this is an intermediate outcome. Clinical utility: There is insufficient evidence that patients managed with the genetic test had better outcomes than patients managed without the genetic test.

In 2009, Blue Cross and Blue Shield (BCBS) evaluated the use of aCGH for the genetic evaluation of patients with developmental delay/ mental retardation. Studies were selected for review if they were published after the 2009 review and did not support the BCBS recommendations. No studies were identified that would change the BCBS recommendations. The following review was critically appraised: Blue Cross and Blue Shield Association. Special report: aCGH for the genetic evaluation of patients with developmental delay/mental retardation or autism spectrum disorder. Assessment Program. Volume 23, No. 10. April 2009.

The use of Array Comparative Genomic Hybridization (aCGH) for the genetic evaluation of patients with intellectual disability does not meet the *Group Health Medical Technology Assessment Criteria*.

### HLA Testing for Celiac Disease

#### BACKGROUND

Celiac disease is a chronic, autoimmune disorder that affects approximately 1% of children and adults in the United States. In individuals with celiac disease, the ingestion of gluten proteins found in wheat, rye, and barley lead to an autoimmune reaction that causes small intestine mucosal injury. Damages in the small intestine can cause gastrointestinal symptoms and interfere with the absorption of nutrients from food. This may lead to malnutrition-related problems such as anemia, vitamin deficiencies, osteoporosis, and neurological disorders. A gluten-free diet typically resolves symptoms and can prevent long-term consequences (Tack 2010). There are a variety of tests available to diagnose celiac disease. The gold-standard for diagnosing celiac disease is a small intestine biopsy. However, this test is not a perfect gold-standard as false positive and false-negative results may occur due to interobserver variability, patchy mucosal damage, low-grade histological abnormalities, and technical limitations. Additionally, histological features are not unique to celiac disease. Serum antibody tests are used as an initial screening tool to detect and support the presence of celiac disease and to select which patients should undergo a biopsy. Two of the most sensitive and specific serological tests for diagnosing celiac disease are tests that assess the presence of IgA autoantibodies against the endomysium of connective tissue (EMA) (sensitivity 62-81%, specificity 80-99%) and against tissue transglutaminase (tTGA) (sensitivity 81-88%, specificity 84-99%). While these test are accurate, they are not without limitations. For example, the EMA test correlates with the degree of mucosal damage. As such, the sensitivity of this test is lower in patients with milder cases (higher chance of false negative results). Additionally, false negative results may occur in patients with an IgA deficiency and in patients who are already on a gluten-free diet. In patients with an IgA deficiency, serum IgA testing can be replaced by using IgG assays, which are less sensitive than IgA assays. Another test that can be used to rule out the diagnosis of celiac disease is human leukocyte antigen (HLA) genotyping. It has been reported that

approximately 90-95% of patients with celiac disease are carriers of the HLA-DQ2 heterodimer and most of the remaining patients carry the HLA-DQ8 heterodimer. Since virtually all patients with celiac disease carry one of these heterodimers, celiac disease is highly unlikely when both are absent. It has been proposed that using HLA genotyping as an initial screening tool may avoid future concerns about the condition and eliminate further diagnostic testing. However, HLA typing is not a perfect solution since around 25-40% of the general population carries either HLA-DQ2 or DQ8, of which the majority never develop the disease. Other situations where HLA genotyping may be useful is when the diagnosis of celiac disease is unclear based on serological and/or histological findings. Additionally, HLA genotyping can be performed in patients who are already on a gluten free diet (Tack 2010, Hadithi 2010).

#### 4/18/2011: MTAC REVIEW

##### HLA Testing for Celiac Disease

**Evidence Conclusion:** Analytic validity There are a variety of methods used for HLA genotyping. Each of these assays has its advantages and limitations (Monsuur 2008, Lavant 2009). Clinical validity A recent prospective cohort study evaluated the accuracy of serologic tests and HLA-DQ genotyping used alone and in combination for diagnosing celiac disease compared to small intestine biopsy. Results from this study suggest that both tTGA and EMA are sensitive and specific tests for diagnosing celiac disease. HLA-DQ testing was also highly sensitive, but was not as specific as serologic testing. The addition of HLA-DQ genotyping to serum antibody tests did not increase test performance compared to serologic testing alone. Results should be interpreted with caution as only 16 patients were diagnosed with celiac disease (Hadithi 2007). Sensitivity and specificity of serologic testing and HLA-DQ typing for diagnosing celiac disease

	Sensitivity (95% CI)	Specificity (95% CI)
HLA-DQ testing		
HLA-DQ2 or DQ8	100 (79-100)	57 (52-62)
Serologic testing using IgA		
tTGA	81 (54-95.9)	99.1 (97.7-99.7)
EMA	81 (54-95.9)	99.1 (97.7-99.7)
tTGA & EMA	81 (54-95.9)	99.3 (98-99.9)
Both serologic testing & HLA-DQ testing		
tTGA & HLA-DQ	81 (54-95.9)	99.3 (98-99.3)
EMA & HLA-DQ	81 (54-95.9)	99.1(97.7-99.8)
tTGA, EMA, & HLA-DQ	100 (79-100)	99.3 (98-99.9)

Abbreviations: EMA= antiendomysium antibody; tTGA= antitransglutaminase antibody.

Another observational study investigated whether HLA genotyping would be useful to identify first-degree relatives of patients with celiac disease who do not need further screening for celiac disease. Fifty-four families with at least two siblings with celiac disease were selected to participate in the study. In total, 245 (52.5%) first-degree relatives agreed to participate. The diagnosis of celiac disease was based on duodenal biopsy and medical records. Of all of the first-degree relatives, 17.6% (N=43) did not carry any of the celiac disease risk alleles. Of these relatives, only one was diagnosed with celiac disease (Karinen 2010). Clinical utility

Because of its low specificity HLA genotyping may not be an ideal initial screening test for diagnosing celiac disease. However, HLA genotyping may be useful in certain situations, such as when the diagnosis of celiac disease is unclear based on serologic and histologic findings and when patients are already on a gluten free diet, to rule out celiac disease. Additionally, as negative serologic or histologic test results do not exclude the development of celiac disease later in life, the use of HLA genotyping in patients who are at increased risk for celiac disease may prevent unnecessary serologic and histologic testing. Conclusion: Analytic validity: There are a variety of methods used for HLA genotyping. Each of these assays has its advantages and limitations. Clinical validity: There is fair evidence that HLA genotyping may be a useful adjunct in the diagnosis of celiac disease as it has a high negative predictive value. Clinical utility: No studies were identified that addressed the clinical utility of HLA genotyping for celiac disease; however, early identification and treatment of the disease can prevent short- and long-term complications.

**Articles:** Articles were selected for review if they included at least 25 subjects and assessed the accuracy of HLA genotyping compared to the small intestine biopsy. A prospective cohort study was selected for review.

The following study was critically appraised: Hadithi M, von Blomberg ME, Crusius BA, et al. Accuracy of serologic tests and HLA-DQ typing for diagnosing celiac disease. *Ann Intern Med* 2007; 147:294-302. See [Evidence Table](#)

The use of HLA testing for celiac disease does meet the *Group Health Medical Technology Assessment Criteria*.

##### Micro Array for Evaluation of Intellectual Disability

###### BACKGROUND

Intellectual disability, also termed mental retardation or cognitive disability, affects approximately 1-3% of the general population and is defined as a significant impairment in cognitive and adaptive functions, with the age of

onset before 18 years. It is a serious and lifelong condition that presents significant challenges to families and to public health. Determining the specific etiology of intellectual disability may help to provide answers related to prognosis, recurrence risk, and treatment.

Intellectual disability can be caused by anything that damages or interferes with the growth or maturation of the brain; however, genetic (chromosomal) abnormalities are one of the main causes of intellectual disability (Galasso 2010, Sagoo 2009).

Chromosomal abnormalities are deletions and duplications of genomic material and are commonly referred to as copy number variations. Conventional methods for detecting these abnormalities include karyotyping and fluorescent in situ hybridization (FISH). Karyotyping involves visualizing the chromosome for large gains or losses in chromosomal material and is generally the first step in cytogenetic analysis. Karyotyping can detect chromosomal abnormalities such as deletions, duplications, inversions, and translocations across the entire genome; however, it lacks the resolution necessary to detect abnormalities smaller than 3-5 megabases (Mb; 3-5 million base pairs).

FISH uses florescent-labeled chromosome-specific probes to detect chromosomal abnormalities. FISH can detect submicroscopic abnormalities and is often used in situations where the karyotype is normal, but there is a high clinical suspicion of a deletion syndrome. However, FISH is a targeted method and requires prior knowledge of the chromosome region(s) of interest to request the appropriate FISH test. Additionally, FISH can only screen a limited number of genomic regions at a time (Breman 2009, Fruhman 2010, Galasso 2010, Gropman 2010).

Array comparative genomic hybridization (aCGH) is a more recent technology used to identify copy number variations by comparing patient DNA with reference DNA. It is currently used as an adjunct to conventional methods. There are two types of aCGH: targeted and whole-genome. Targeted arrays are designed to interrogate areas of the genome with known clinically significant abnormalities. Whole genome arrays provide high resolution coverage of the entire genome. This can lead to the discovery of new copy number variations. Compared to conventional methods, aCGH has a higher resolution and is able to simultaneously detect copy number variations in multiple regions of the genome. Additionally, unlike FISH, knowledge of the chromosome region(s) of interest does not need to be determined in advance because a single array assay detects all genomic variants represented on the array. Array CGH is not without limitations. It cannot detect totally balanced translocations or inversions; it performs suboptimally for polyploidy; and has not been optimized for prenatal diagnosis of point mutations. Because aCGH cannot identify the exact location of a duplicated chromosome, further testing with karyotype or FISH may be necessary. Another limitation is the potential to identify novel copy number variants with unknown clinical significance (Fruhman 2010, Moeschler 2008).

Array CGH is a laboratory-developed test and is commercially available from several different laboratories. Laboratory-developed tests are licensed under the Clinical Laboratory Improvement Amendments (CLIA) and do not require clearance from the FDA.

#### 04/18/2011: MTAC REVIEW

##### Array Comparative Genomic Hybridization (aCGH)

**Evidence Conclusion:** Analytic validity - The BCBS review identified several studies that evaluated the sensitivity of aCGH. The sensitivity of aCGH testing compared to conventional methods (karyotype and/or FISH) ranged from 73% to 100%. As false-positive rates were inconsistently reported, specificity could not be determined (BCBS 2009). Clinical validity - No studies were identified that evaluated the impact of conventional methods or aCGH on patient outcomes other than diagnostic yield. Results from the BCBS review suggest that diagnostic yield in patients with intellectual disability ranged from 5 to 16.7%, which represents a significant improvement compared to conventional methods. The use of Array Comparative Genomic Hybridization (aCGH) for the genetic evaluation of patients with intellectual disabilities does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Risk Prognosticator Test**

#### **BREVAGen**

##### **BACKGROUND**

According to the American Cancer Society, breast cancer is the second leading cause of death in women in the United States after lung cancer. Current methods of assessing breast cancer risk include the Breast Cancer Risk Assessment Tool (BCRAT) otherwise known as the Gail model. This model incorporates individual risk factors such as basic demographic information, reproductive history and medical history. Recent genome wide association studies have identified several single nucleotide polymorphisms (SNPs) associated with an increased risk of breast cancer leading to an additional dimension and understanding of risk (Easton, Pooley et al. 2007; Stacey, Manolescu et al. 2007; Stacey, Manolescu et al. 2008). The BREVAGen™ (Phenogen Sciences, Inc., Charlotte, NC) is a risk stratification test for sporadic breast cancer. Intended for use as an adjunct to the Gail model, the test consists of two parts, the first, a series of questions to determine clinical risk and the second, a buccal swab to analyze specific genetic markers. The latter part of the test, includes a panel of seven SNPs associated with breast cancer risk and does not include either of the BRCA mutations. Ultimately, a patient's risk is calculated by multiplying the product of the individual SNP risks by the Gail model risk. According to the BREVAGen™ website, the test is only suitable for women of European descent aged 35 years or older. No test combining the results of SNP analysis with clinical factors to predict breast cancer risk has been approved or cleared by the U.S. Food and Drug Administration (FDA). BREVAGen™ is offered as a laboratory developed tests and only requires oversight under the Clinical Laboratory Improvement Amendments of 1988 (CLIA). The development and use of this laboratory developed test is restricted to laboratories certified as high complexity under CLIA. Under the current regulatory program, CLIA requires that laboratories demonstrate quality systems which includes validation and proficiency testing.

### **12/16/2013: MTAC REVIEW**

#### **BREVAGen**

**Evidence Conclusion:** *Analytic Validity* Although the seven breast cancer associated SNPs were identified in genome wide association studies (Easton, Pooley et al. 2007; Stacey, Manolescu et al. 2007; Stacey, Manolescu et al. 2008), there are no publications that specifically report on the analytic validity of the BREVAGen™ panel. *Clinical Validity* The BREVAGen™ test was clinically validated in a nested case-control cohort study. The study included 1,664 women from the US Women's Health Initiative (WHI) who developed breast cancer between randomization and study completion and 1,636 age-matched breast cancer-free controls (Mealiffe, Stokowski et al. 2010). Overall, the study suggests that the BREVAGen may add predictive accuracy to the Gail Model, however, the degree of improved risk prediction is modest and the clinical implications are not well established. The study is not generalizable as the included population was limited to postmenopausal white non-Hispanic women. In addition, four of the authors were employees of the developer of the BREVAGen™ during the time of publication and the analyses were relevant to the development of the product. Ideally, additional studies should be completed to further assess the clinical validity of the combined Gail and SNP risk model. *Clinical Utility* Theoretically, the BREVAGen™ test can provide information that can help guide physicians in making individualized patient management decisions, such as appropriate counseling, screening regimens and risk reduction strategies, however, there is no published literature to support the clinical utility.

Conclusion: There is no evidence to determine the analytic validity of the BREVAGen™. There is some evidence to suggest that the addition of the BREVAGen™ panel is superior in determining breast cancer risk compared to Gail score alone. There is no evidence to determine the clinical utility of the BREVAGen™.

**Articles:** A search of PubMed was completed for the period through November 2013 for studies on the accuracy of BREVAGen™ for detecting the absence or presence of certain common genetic variations associated with an increased risk for developing breast cancer. The search strategy used the terms BREVAGen, Breast Cancer Risk Tool, Gail Model, genetic risk, single nucleotide polymorphism, breast cancer, and sporadic with variations. To identify ongoing clinical trials, a search of the National Institute of Health Clinical Trials website was also conducted using the same methodology. Articles were limited to those published in the English language with human subject enrollment. The search was supplemented by an examination of article reference lists in addition to the PubMed related articles function. The literature search for BREVAGen™ revealed one publication that clinically validates the Breast Cancer Risk Model in combination with the genetic and clinical information. The following study was selected for review: Mealiffe ME, Stokowski RP, Rhees BK, et al. Assessment of clinical validity of a breast cancer risk model combining genetic and clinical information. *Journal of the National Cancer Institute*. 2010;102(21):1618-1627. [See Evidence Table](#).

The use of BREVAGen does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Fibroblast Growth Factor Receptor 3 (FGFR3) for Urothelial Carcinoma**

#### **BACKGROUND**

It is estimated that approximately 70,530 new cases of bladder cancer will be diagnosed in the United States in 2010, and 14,680 will die of the disease (Jemal 2010). The most commonly occurring form of bladder cancer in the United States is urothelial carcinoma (also known as transitional cell carcinoma). The clinical spectrum of urothelial carcinoma can be divided into 3 categories: non-muscle-invasive, muscle-invasive, and metastatic disease. This review will focus on non-muscle-invasive urothelial cancer (NMIUC), which makes up approximately 75-80% of urothelial carcinoma. NMIUC includes stage Ta (noninvasive papillary carcinoma), Tis (carcinoma in situ), and T1 (tumor invades subepithelial connective tissue) tumors. The standard treatment for stage Ta, Tis, and T1 tumors is transurethral resection of bladder tumor (TURBT). Depending on prognosis adjuvant intravesical chemotherapy or immunotherapy may also be considered. However, despite treatment a significant number of patients will develop recurrence within 1 to 2 years of the initial treatment. Because of the high risk of recurrence careful surveillance is required for patients with NMIUC (Chou 2010, Cheng 2011, NCCN 2011, Pollard 2010). Assessing the risk of progression and recurrence is important for planning therapy. The risk for tumor progression and recurrence is estimated using factors such as histological grade, stage, depth of invasion, and extent of disease; however, the ability of these factors to predict clinical outcome is limited (Burger 2008, Cheng 2011, NCCN 2011). Recently, it has been suggested that molecular biomarkers such as fibroblast growth factor receptor 3 (FGFR3) may be useful for predicting clinical outcome and planning therapy. FGFR3 regulates cell growth, differentiation, and angiogenesis. More than 70% of low-grade noninvasive papillary urothelial carcinomas harbor FGFR3 mutations. Studies suggest that urothelial carcinomas that harbor FGFR3 mutations may be associated with improved prognosis (Cheng 2011). The CertNDx molecular grading assay (Predictive Biosciences, Inc.) was designed as a tool to be used in conjunction with clinical and histological parameters to aid in the clinical management of NMIUC. This test uses two biomarkers to determine molecular grade. The first biomarker is FGFR3 and the second is Ki-67, which is a marker of cell proliferation (Cheng 2011). Patients with molecular grade 1 (mG1) have FGFR3 mutations and low Ki-67 levels. Patients with molecular grade 2 (mG2) have FGFR3 mutations with high Ki-67 levels or wild-type FGFR3 and low Ki-67 levels. Patients with molecular grade 3 (mG3) are FGFR3 wild-type and have high Ki-67 levels. Patients with molecular grade 1 have favorable prognosis, patients with molecular grade 2 have intermediate prognosis, and patients with molecular grade 3 have poor prognosis.

#### **10/17/2011: MTAC REVIEW**

### **Fibroblast Growth Factor Receptor 3 (FGFR3) for Urothelial Carcinoma**

**Evidence Conclusion:** Analytic validity- No studies were identified that addressed the analytic validity of the CertNDx molecular grading assay. Clinical validity - A recent prospective observational study evaluated the prognostic value of both WHO 1973 and 2004 grading systems, markers CK20, FGFR3, and Ki-67, and molecular grade (combination of FGFR3 and Ki-67) in 221 patients with urothelial carcinoma. In univariate analysis, WHO grade 1973, WHO grade 2004, pathological stage, FGFR3, Ki-67 status, and molecular grade were significantly associated with progression in stage; however, in a multivariate model, only WHO grade 1973 and 2004 remained significantly associated with progression in stage. None of the variables measured were significantly associated with recurrence-free survival (Burger 2008). Another study that included 255 patients with primary urothelial carcinoma also found that the combination of FGFR3 and Ki-67 status was not an independent predictor of recurrence-free or disease-specific survival (van Oers 2007). However, an observational study that included 286

patients with urothelial carcinoma found that in a multivariate analysis, the combination of FGFR3 and Ki-67 status predicted progression, recurrence rate, and disease-specific survival (van Rhijn 2003). Clinical utility - No studies were identified that addressed the clinical utility of the CertNDx molecular grading assay.

Conclusion: Analytic validity: No studies were identified that addressed the analytic validity of the CertNDx molecular grading assay. Clinical validity: Results from observational studies regarding the prognostic value of molecular grade (FGFR3/Ki-67) are mixed. Clinical utility: No studies were identified that addressed the clinical utility of the CertNDx molecular grading assay.

**Articles:** No studies were identified that addressed the analytic validity or clinical utility of the CertNDx molecular grading assay. Several studies were identified that evaluated the clinical validity of the CertNDx molecular grading assay. The most recent study was selected for review. The following study was critically appraised: Burger M, van der Aa MN, van Oers JM, et al. Prediction of progression of non-muscle-invasive bladder cancer by WHO 1973 and 2004 grading and by FGFR3 mutation status: a prospective study. *Eur Urol.* 2008;54:835-843. See [Evidence Table](#).

The use of FGFR3 for urothelial carcinoma does not meet the *Group Health Medical Technology Assessment Criteria*.

### **MammaPrint Test**

#### **BACKGROUND**

Breast cancer affects almost 10% of women in western countries and is a major cause of morbidity and mortality. Most patients with lymph node negative disease may be successfully treated with surgery and local irradiation. Those with more aggressive disease may benefit from adjuvant chemotherapy and hormone therapy which could significantly improve their overall and disease-free survival. It is generally accepted that breast cancer patients with the poorer prognosis would gain the most benefits from systemic adjuvant therapy. The use of this adjuvant therapy is thus one of the most critical treatment decisions during the clinical management of breast cancer patients. Currently those with aggressive breast cancer are identified according to a combination of criteria including age, clinical stage and size of the tumor, histological type and grade of cancer, axillary node status, and hormone-receptor status. The ability of these criteria to predict outcome and disease progression is imperfect. Within a given patient population at a specific predicted risk of recurrence, there are some patients whose actual clinical outcome does not match that predicted by the indicators. As a result some of those who need adjuvant therapy do not receive it, while others may receive unnecessary toxic therapy (Kallioniemi 2002, DeVigier 2002). To overcome these issues, scientists are attempting to identify more accurate prognostic indicators. Microarray technology is revolutionizing researchers' understanding of cancer biology through the simultaneous study of the expression of tens of thousands of genes. Molecular profiling is the classification of tissue or other specimens for diagnostic, prognostic, and predictive purposes based on multiple gene expression. The potential value of gene expression profiling in assessing the risk of post-surgical breast cancer recurrence has been extensively investigated over the last few years. This has led to important insights in the molecular heterogeneity of cancers by revealing biologically and clinically relevant subtypes of tumors previously indistinguishable by the conventional approaches (Bertucci 2005). Due to the biological heterogeneity of breast cancers, women with the same stage of the disease may vary widely in their response to treatment and prognosis. Several gene expression-based predictors for breast cancer have been developed, but have not been used in routine clinical practice. According to researchers, this is mainly due to the limited validation and the limited clinical description of the molecular subtypes. Validation is a major challenge for microarray studies especially those with clinical implications as it requires a large sample size and because the results are influenced by the patient selection and by choice of the methods used to analyze gene expression data (Calza 2006, Hu 2006, Ioannidis 2007). The Amsterdam 70-gene profile (MammaPrint®) was first developed using supervised gene expression profiling analysis of frozen tumor samples from two distinct patient populations. All were <55 years of age, and had lymph node negative disease. 44% had distant metastases within 5 years of completing treatment and 56% did not. By comparing the gene expression profile of patients with or without metastases, a signature 70-gene set that correlated with the outcome was identified and internally validated with the same group (van't Veer 2002), and externally validated in two retrospective groups (Van De Vijver 2002 and Buyse 2006, see evidence tables). MammaPrint® from Agendia is a qualitative in vitro diagnostic test service performed in a single laboratory using the gene expression profile of breast cancer tissue samples to assess a patient's risk for distant metastases. The MammaPrint assay uses a panel of the Amsterdam 70-gene profile described above. It is a microarray based gene expression analysis of RNA extracted from breast tumor tissue. The MammaPrint® analysis is designed to determine the activity of specific genes in a tissue sample compared to a reference standard. Its index ranges from -1.0 to +1.0. Tumor samples with an index above the threshold of +0.4 are classified as low risk, and those with an index equal to or less than the threshold are classified as high risk. The test requires fresh frozen samples which are shipped to the Agendia reference laboratory in the Netherlands. It is performed for breast cancer patients <61 years old, with Stage I invasive breast cancer or Stage II node negative invasive breast cancer, with tumor size <5 cm. It is indicated for use by physicians as a prognostic marker only, along with other clinicopathological factors. It is not

intended for diagnosis, or for predicting or detecting response to therapy, or to help select the optimal therapy for patients (FDA).

## 08/06/2007: MTAC REVIEW

### MammaPrint Test

**Evidence Conclusion:** The identification and validation of gene expression panels to improve risk prediction or treatment outcomes is a multistep process that starts by 1. Identifying the candidate genes (analytic validity), followed by 2. Evaluating the genetic panel associations with risk prediction or treatment outcomes in preliminary performance studies in relevant population (clinical validity), and 3. Determining whether the use of the multigenetic assay would direct the management of patients and improve outcomes (clinical utility). The most reliable method for validation is to derive a prognostic/predictive gene set from a training set and then apply it to a completely independent set, the test set, (Simon 2003, Ionnidis 2006, and Hu 2006). The MammaPrint test was developed based on research performed in the Netherlands Cancer Institute. The training set was derived from a study by van't Veer and colleagues that included 98 women < 55 years of age at diagnosis, with primary breast cancer (34 developed distant metastases within 5 years, 44 were disease free after at least 5 years). All patients were lymph node negative. 5 µg total RNA was isolated from frozen tumor material for each patient. The authors used inkjet-synthesized oligonucleotide microarrays that included 25,000 genes. Following several techniques 5000 genes were selected from the microarray, and then optimized to 70 genes with which a prognosis profile was established. The authors conducted a cross validation and concluded that a classification system based on these 70 genes outperformed all clinical variables in predicting the likelihood of distant metastases within five years. They noted however, that a selection of the patients based on the outcome (distant metastases or disease free in 5 years) was a limitation to the study. The same research team followed the initial study with a validation study (Van De Vijver, 2002) that included 295 women with either lymph node negative or lymph node positive breast cancer. The authors calculated the correlation coefficient of the level of expression of the 70- predictor genes identified in their initial study. They then classified the women with a correlation coefficient > 0.4 as having a good prognosis gene expression signature, and all the others as having a poor prognosis gene expression signature. In this validation set however the authors included 61 patients from the original training group used to derive the RNA expression signature, which could overestimate the relative risk and inflate the discriminating power of the test. The validation study included women < 55 years of age, with small tumors and at stage I or II of the disease which may not represent the entire spectrum of patients with breast cancer. Adjuvant hormone therapy or chemotherapy or both were given to most of the patients with lymph node positive disease. The Translational Research Network of the Breast International Group (TRANSBIG) also conducted an independent validation study of the prognostic signatures in a retrospective series of 302 untreated patients in five European countries. The study included only women node negative early stage breast cancer who had not received systemic adjuvant therapy, and thus may not represent the all patients with breast cancer. Its overall results showed that the 70-gene signature provided prognostic information on time to distant metastases and overall survival independent of the other clinical predictors. In conclusion, the selection of the 70- predictor genes was based on analyses of tumors from patients < 55 years of age with lymph node negative cancer who do not represent all women with breast cancer. The test proved to perform well as an independent prediction tool among the selected women studied. This however, does not necessarily indicate that it would predict treatment response. To date there are no published studies that show if modification of adjuvant therapy based on this test would improve disease free or overall survival. A large randomized controlled trial (Microarray for Node negative Disease may Avoid Chemotherapy [MINDACT]) that will evaluate the clinical utility of MammaPrint is underway. The trial will directly compare the use of prognostic information provided by the standard clinicopathological criteria vs. the MammaPrint test to decide whether to offer adjuvant chemotherapy to node-negative breast cancer patients. The MINDACT plans to prospectively include 6000 women, and follow-them up for a long duration in order to determine 5-year disease free-survival rate.

**Articles:** The literature search revealed multiple articles on molecular and gene-expression profiling in general. For the MammaPrint test in particular, there was a published study on the training set (to develop or derive the predictive classifier or model) by Van't Veer and colleagues, and three validation studies to evaluate the predictive accuracy of the model (Van De Vijver 2002, Buyse 2006, and Glas 2006). All studies were reviewed but only the first two validation studies were critically appraised, Glas, et al's study was not selected for critical appraisal due to patient overlap with the van De Vijver study. It is to be noted that Van De Vijver, van't Veer, and several other principal authors are named inventors on a patent application for the 70-gene signature used in the studies. All studies also had financial ties to the manufacturer. *The following studies were critically appraised:*  
Van De Vijver MJ, He YD, van't Veer LJ, et al. A gene expression signature as a predictor of survival in breast cancer. *N Engl J Med* 2002;347:1999-2009. See [Evidence Table](#). Buyse M, van't Veer, L, Viale G et al on behalf of the TRANSBIG Consortium. Validation and clinical utility of a 70-gene prognostic signature for women with node negative breast cancer. *J Natl Cancer Inst* 2006;98:1183-1192. See [Evidence Table](#).

The use of the MammaPrint test in the treatment of recurring cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## **OVA1™ Test for the Assessment of Suspected Ovarian Cancer**

### **BACKGROUND**

In the United States, ovarian cancer is the fifth leading cause of all cancer-related death among women. It is estimated that in 2010, there were 21,880 new cases of ovarian cancer and 13,850 deaths from ovarian cancer (Jemal 2010). The incidence of ovarian cancer increases with age with approximately two thirds of cases being diagnosed in women over the age of 55. Women with a family history of ovarian or breast cancer or who are carriers of the BRCA gene mutations are also at increased risk for ovarian cancer (Clarke-Pearson 2009). For patients with early stage disease, survival rates are greater than 90%; however, they are less than 30% for patients with advanced disease. Because of the lack of specific symptoms during the early stage approximately 70% of cases are diagnosed with advanced disease (Carter 2011). The most commonly used tests for the detection of ovarian cancer are transvaginal ultrasound (TVS) and serum CA-125. Recently, the FDA approved the OVA1™ test (Quest Diagnostics, Inc.) to be used as an adjunct to clinical/radiological evaluations for women planning surgery for an adnexal mass. This test measures the serum levels of 5 potential biochemical markers for ovarian cancer (transthyretin, apolipoprotein A1, transferrin, CA-125, and  $\beta$ 2-microglobulin). The results of the test are then interpreted using a proprietary algorithm to yield a single score ranging from 0 to 10 to indicate the likelihood that the adnexal mass is benign or malignant. A high probability for malignancy is defined as a score of at least 5.0 in premenopausal women or 4.4 in postmenopausal women. The goal of the OVA1™ test is to provide additional information to aid in identifying patients who should be referred to a gynecologic oncologist for surgery (Carter 2011, Muller 2010). Studies suggest that women who receive their initial surgical care from an experienced gynecologic oncologist have improved outcomes and greater overall survival. Because of this the National Comprehensive Cancer Network (NCCN) recommends that all patients should undergo surgery by an experienced gynecologic oncologist (NCCN 2011). It is important to emphasize that this test is not approved for ovarian cancer screening and is not intended for use as a stand alone test. Another limitation of this test is that assay interference may occur in patients with rheumatoid factor levels of at least 250 IU/mL and triglyceride levels greater than 4.5 g/L (Muller 2010). In 2009, the FDA approved the use of this test for women over the age of 18 with an ovarian adnexal mass for which surgery is planned and have not yet been referred to an oncologist.

### **10/17/2011: MTAC REVIEW**

#### **OVA1™ Test for the Assessment of Suspected Ovarian Cancer**

**Evidence Conclusion:** *Analytic validity* - No studies were identified that evaluated the analytic validity of the OVA1™ test. *Clinical validity* - A recent observational study that included 524 women with ovarian tumors who were planning to undergo surgery compared the sensitivity and specificity of physician assessment alone (which included the use of CA 125) or combined with the OVA1™ test for identifying ovarian tumors at high risk for malignancy. Results from this study suggest that the addition of the OVA1™ test to physician assessment increased the sensitivity and the negative predictive value, but decreased the specificity and the positive predictive value (Ueland 2011). The performance of the American College of Obstetricians and Gynecologists (ACOG) referral guideline for women with a pelvic mass and the effect of replacing CA 125 with the OVA1™ test was also evaluated in this study population. The substitution of CA 125 for the OVA1™ test increased the sensitivity and the negative predictive value of the ACOG guidelines, but decreased the specificity and the positive predictive value (Miller 2011). *Clinical utility* - No studies were identified that evaluated the clinical utility of the OVA1™ test. **Conclusion:** Analytic validity: No studies were identified that evaluated analytic validity of the OVA1™ test. Clinical validity: Results from a recent observational study suggest that when added to physician assessment or substituted for CA 125, the OVA1™ test increased the sensitivity and negative predictive value of these assessments, but decrease the specificity and positive predictive value. Clinical utility: No studies were identified that evaluated the clinical utility of the OVA1™ test.

**Articles:** No studies were identified that assessed the analytic validity or clinical utility of the OVA1™ test. Two studies were identified that addressed the clinical validity of the OVA1™ test. Both of these studies were selected for review. The following studies were selected for critical appraisal: Ueland FR, Desimone CP, Seamon LG, et al. Effectiveness of a multivariate index assay in the preoperative assessment of ovarian tumors. *Obstet Gynecol* 2011; 117:1289-1297. See [Evidence Table](#). Ware Miller R, Smith A, DeSimone CP, et al. Performance of the American College of Obstetricians and Gynecologists' ovarian tumor referral guidelines with a multivariate index assay. *Obstet Gynecol*. 2011;117:1298-1306. See [Evidence Table](#).

The use of OVA1 for ovarian tumors does not meet the *Group Health Medical Technology Assessment Criteria*.

## **Thyroid Nodule Gene Expression Testing (Afirma)**

### **BACKGROUND**

Thyroid nodules are very common; they are clinically identified in 5-7% of the population, and incidentally on ultrasonography in up to 50% of women and 20% of men over the age of 50. The thyroid nodules are typically benign, but 5-15% prove to be malignant. It is thus recommended that any identified nodule measuring one

centimeter or more in diameter be diagnostically evaluated. Thyroid fine needle aspiration (FNA) biopsy is the most widely used method for clinical evaluation of a suspicious thyroid nodule. FNA is a safe and simple outpatient procedure that yields cellular material suitable for cytological analysis. However 15-30% of the biopsied nodules has indeterminate cytology and cannot be conclusively diagnosed by FNA biopsy alone. Most patients with indeterminate lesions (defined in the Bethesda System as Atypia of Undetermined Significance or Follicular Lesion of Undetermined Significance, suspicious for Follicular or Hurthle Cell neoplasm and suspicious for malignancy) are referred to surgery. Currently, surgery is performed for both diagnostic and therapeutic purposes in these patients with indeterminate aspirates. Surgery has high operative efficacy in removal of thyroid cancer, however approximately three-quarters of the nodules with indeterminate FNA cytology are ultimately found to be benign on final surgical pathology. Thus, a large proportion of patients with indeterminate nodules may undergo unnecessary partial or complete thyroidectomy with its potential surgical complications and risk of long-term morbidity (Alexander 2012, Duick 2012, Walsh 2012, Ali 2013). In an attempt to preoperatively classify the indeterminate thyroid nodules different novel diagnostic tests and molecular markers have been investigated. These include immunohistochemistry, mutation and gene rearrangement testing, and gene expression and microarray analysis. Each has its performance characteristics and diagnostic values. Ideally a molecular marker or panel of markers would be accurate in differentiating benign from malignant in any lesion that is considered suspicious or indeterminate. It should be simple to use, reproducible by all institutions, and cost-effective. Genetic markers associated with malignancy such as mutation markers (e.g. BRAF, RAS) and gene rearrangements (e.g. RET/PTC and PAX8-PPAry) have high specificity and positive predictive values; and when detected they can "rule in" the diagnosis of thyroid cancer, However, they have limited sensitivity and negative predictive values as they fail to detect a large proportion of malignant samples that do not contain one of the mutations or rearrangements being tested, i.e. mutation or rearrangement markers cannot 'rule out' malignancy when not detected ( Alexander 2012, Kouniavsky 2012, Ward 2013). Microarray techniques seek to identify patterns of expressed RNA in the human genome that are predictive of benign or malignant thyroid disease. Unlike single gene mutations or rearrangements, microarray diagnostic tests involve tens to hundreds of expressed genes. The currently available diagnostic microarray for use in thyroid nodule analysis is the Afirma Gene Expression Classifier (GEC) recently developed by Veracyte, Inc. It is a genomic test designed with the intention of preoperative identification of benign thyroid nodules in patients with indeterminate FNA cytopathological results. The test assesses gene expression from mRNA isolated from thyroid FNA samples by comparing the mRNA expression detected in a thyroid FNA against a panel of 167 molecular genes. It uses a multidimensional algorithm to identify the thyroid FNA samples with a benign gene expression pattern (Alexander 2012, Kim 2012, Ward 2013). Afirma GEC is commercially owned by Veracyte Corporation; South San Francisco, California and is offered through a sole source, Clinical Laboratory Improvement Amendments (CLIA), a certified reference laboratory. Afirma CEC analysis is indicated only for nodules with indeterminate cytology, and is not performed on cytologically benign, malignant, or nondiagnostic (insufficient FNA samples) nodules. The assay classifies nodule as either benign or suspicious for malignancy. With a preoperative identification of a nodule that is benign rather than malignant, observation or ultrasound follow-up could be recommended instead of thyroid surgery, i.e. potentially avoids unnecessary surgery (Alexander 2012, Duick 2012, Ward 2013).

## **10/21/2013: MTAC REVIEW**

### **Thyroid Nodule Gene Expression Testing (Afirma)**

**Evidence Conclusion:** Analytic validity Evaluating the analytic performance of Afirma GEC includes studying the stability of RNA in FNAs during collection, storage, and shipment; reproducibility of the test; and its analytic sensitivity and specificity under various conditions e.g. interference of the assay with bloody FNA and genomic DNA. The literature search revealed one study (Walsh and colleagues, 2012) that evaluated the analytic performance of Afirma GEC in a number of substudies. The investigators obtained prospective FNA samples aspirated in vivo from 43 patients from outpatient clinics, preoperatively, or immediately after surgical excision. The samples were placed in FNAProtect preservative solution and shipped chilled or frozen, then stored at -80°C upon receipt. The RNA was extracted and its yield examined for quantity and quality using positive (tissue lysate) and negative (water) as controls. Three different lots of controls were tested over several weeks of independent runs by 3 different operators to determine reliability of the test. Multiple lots of benign and malignant total RNA were manufactured and used as process controls to determine the analytic sensitivity of the test using different RNA input quantity and under different dilution of malignant FNA content. These studies indicated tolerance to variation in RNA input across a range of 5-25 ng. as well as dilution of malignant FNA material down to 20%. Analytic specificity of the test using malignant samples mixed with blood (up to 83%) and genomic DNA (up to 30%) showed minimal assay interference. However benign FNA samples mixed with relatively high proportions of blood had a potential for yielding false positive results. The authors also examined the stability of RNA in FNAs during collection and shipment and found that RNA content within FNAs preserved in FNAProtect was stable for up to 6 hours at room temperature with no change in RNA yield, and that the FNA storage and shipping temperatures had no significant effect on GEC scores. They also examined the reproducibility of the test and indicated that it was reproducible from extraction through GEC results, including variation across operators, runs,

reagent lots, and laboratories. The authors concluded that the analytical performance and reproducibility of the Afirma Gene Expression Classifier was successfully verified. The research was supported by Veracyte Corporation, (the maker of Afirma GEC), and the authors of the study were either employed by, or were consultants to the corporation. Clinical validity A perfect test would have high sensitivity and high specificity in correctly detecting or excluding a condition. A molecular diagnostic test with high sensitivity offers a high negative predictive value when the risk of malignancy (ROM) is low, and can “rule out” malignancy. Conversely, a test with high specificity offers high positive predictive value and can “rule in” cancer. To be of use in avoiding surgery, a test that better distinguishes benign from malignant nodules needs to have high sensitivity and high negative predictive value. The literature search identified two published studies on the validation of Afirma GEC (Chudova et al, 2010, and Alexander et al. 2012); both funded by Veracyte Corporation the maker of Afirma GEC. The more recent and larger validation study by Alexander and colleagues (evidence table 1), was a double-blind prospective multicenter validation study. 4,812 thyroid FNAs were obtained from 3,789 patients. 577 (12%) samples were classified as indeterminate, and less than half (46%) were ultimately selected for GEC analysis. Molecular results were compared to the gold standard of post-surgical histopathology interpreted by a panel of blinded endocrine histopathologists for clinical validation. The overall sensitivity of the Afirma test was 92% with a negative predictive value (NPV) of 93% (95% for atypical or follicular lesions of undetermined significance (AUS/FLUS), 94% for a follicular neoplasm, and 85% for a lesion suspicious for malignancy). It is to be noted that the predictive values of a test vary with the prevalence of the disease in the population studied and may not be generalized to other groups. A better analysis would be the likelihood ratios which are not affected by prevalence. Seven of the 85 (8.2%) overall cancers were diagnosed incorrectly by the GEC as benign (false negative). The authors attributed the false negative results to insufficient RNA in the FNA sample used for GEC. The test had an overall low specificity and positive predictive values (52% and 47% respectively). Atypical or follicular lesions of undetermined significance (AUS/FLUS) accounted for almost 50% of the indeterminate thyroid FNAs samples. 43% of these FNA were reclassified with the GEC as benign and 57% remained in their suspicious category. Other investigators showed that repeat FNAs without a molecular test can also accurately reclassify >50% of the nodules in the AUS/FLUS category as benign (Faquin 2013). The study was conducted to validate the GEC accuracy by comparing it to surgical histopathology, and the authors did not compare its performance to repeat FNA or other immunochemical testing. Clinical utility The clinical utility of Afirma GEC was evaluated in a retrospective study by Duick and colleagues, 2012, (Evidence table 2). They obtained their data from 21 endocrinology practices in 11 states. The authors conducted a chart review of 368 patients with 395 cytologically indeterminate thyroid nodules that were GEC benign. 7.6% of these patients with Afirma GEC benign nodules underwent surgery and 94.4% were managed nonoperatively. The study did not have a comparison group, but the authors compared the 7.6% surgical rate to a 74% historical rate of diagnostic surgery (P<0.001). The indications for surgery for those with GEC benign results included a large size or rapid growth of the nodules, local pressure symptoms, or the presence of a second suspicious nodule or malignant nodule. The authors explained that these were similar to indications for surgery on nodules with benign FNA cytologically. The study was retrospective, used a historical comparison, and investigated the decision-making of endocrinologists experienced in managing patients with thyroid nodules, which may differ from that made by primary care providers or other specialists. In addition the authors of the study did not provide data on long-term follow-up of those who were managed by watchful waiting rather than surgery. In conclusion, there is insufficient evidence to determine whether Afirma GEC is more accurate than repeat FNA or immunochemical testing in reclassifying cytologically indeterminate thyroid nodules. There is also insufficient evidence to determine the impact of Afirma GEC on clinical management and net health outcomes in patients with indeterminate thyroid nodules.

**Articles:** The literature search for gene expression classifier for preoperative identification of benign thyroid nodules with indeterminate fine needle aspiration cytopathology revealed a number of articles on molecular diagnostic tests. Many were reviews, editorials, letters, or were unrelated to the current review. The search identified a study on the analytic validity of the test, two on its clinical validity, and retrospective study on its clinical utility. The following studies were selected for critical appraisal. Alexander EK, Kennedy GC, Baloch ZW, et al. Preoperative diagnosis of benign thyroid nodules with indeterminate cytology. *N Engl J Med.* 2012;367:705-715. [See Evidence Table](#) Duick DS, Klopper JP, Diggans JC, et al. The impact of benign gene expression classifier test results on the endocrinologist-patient decision to operate on patients with thyroid nodules with indeterminate fine-needle aspiration cytopathology. *Thyroid.* 2012 22:996-1001. [See Evidence Table](#)

The use of does Afirma® Thyroid FNA Analysis (Gene Expression Classifier) for Thyroid Nodules with Indeterminate Fine Needle Aspiration Cytopathology not meet the *Group Health Medical Technology Assessment Criteria*.

## **DecisionDx - Melanoma**

### **BACKGROUND**

Skin cancer is extremely common accounting for nearly half of all cancers in the United States. Melanoma, the most aggressive type of skin cancer, occurs as a result of abnormal melanocytes, most often caused by over-

exposure to ultraviolet radiation from the sun. When detected early, cutaneous melanoma can be surgically excised resulting in a 5-year overall survival rate of 91%-97%. Despite these odds, however, the clinical behavior of cutaneous melanoma is highly variable and some melanomas, that appear less risky, will develop into advanced disease and require extensive treatments such as additional surgery, immunotherapy, targeted therapy, chemotherapy and radiation therapy (ACS 2015). As with all cancers, a primary challenge is predicting prognosis. Conventional methods of melanoma staging are characterized by the American Joint Committee on Cancer (AJCC) TNM System. The TNM system specifically refers to Tumor thickness, spread to nearby lymph Nodes, and Metastasis. Based on history and physical exam, as well as, biopsy, imaging and pathology, the TNM system groups patients with melanoma into stages, 0-IV based on the advanced nature of the disease (Balch, Gershenwald et al. 2009). The stage of the melanoma is an estimate of prognosis and will ultimately guide treatment options. Recently, gene expression profiling (GEP) has been proposed for use in cancer management. The technique specifically analyzes the patterns of genetic material contained in tumor cells and has the potential ability to predict clinical outcomes associated with cancer. One such test, the DecisionDx-Melanoma™, developed by Castle Biosciences Inc. (Friendswood, TX), is described to more accurately classify stage I and II melanoma. Proposed as an adjunct to conventional staging systems, the DecisionDX-Melanoma test includes 31 genes, 28 of which have previously been associated with melanoma and the remaining three, controls (Winnepenninckx, Lazar et al. 2006). The results of the DecisionDx-Melanoma test is further claimed to stratify stage I and II melanomas into one of two classes; class one identifying patients as low risk of metastasis, or class two indicating high risk. The developer claims that the information provided by the DecisionDx-Melanoma test enables physicians to tailor, patient specific, surveillance and treatment plans informing, for example, the intensity of surveillance, need for referral to specialists, evaluation of adjuvant treatments and clinical trial eligibility (CastleBiosciencesInc. 2015).

#### **04/20/2015: MTAC REVIEW**

##### **DecisionDx - Melanoma**

**Evidence Conclusion:** The study aimed to develop a prognostic genetic signature based on previous analyses of cutaneous melanoma tumors. To do this, the investigators included 268 archived tissue samples and divided the sample into two cohorts, development (n=164) or validation (n=104). The investigators compared the patient clinical outcomes at five years with the GEP test prediction. Overall, Kaplan-Meier analysis indicated that the five year disease free survival (DFS) rates in the validation cohort were 97% and 31% for predicted class 1 and 2, respectively (p<0.0001). These results were comparable to the DFS rated in the development cohort, 100% and 38% for class 1 and class 2, respectively (p<0.0001). The investigators ultimately concluded that in patients with primary cutaneous melanoma, the GEP signature accurately predicts metastasis risk (Gerami, Cook et al. 2015). [Evidence Table 1] The investigators had the clear intent to develop and validate a GEP for predicting metastatic risk in stage I and II cutaneous melanoma. The patient sample was well defined and the study design, cohort, appeared to be appropriate for the development of the genetic signature. To validate the test, however, the study relied on archived tumor samples with at least five years of follow-up. While this is a sufficiently long time to detect the outcome of interest, and the investigators used an independent sample, a prospective study would be a more appropriate design for validation. With that said, the investigators report that samples were collected at a similar point in the course of the disease, diagnosis, however the diseases progression at diagnosis may have varied between patients and it is not clear if the investigators were blinded to prognostic factors. On a final note, the study was funded by the test manufacturer and at least two of the investigators have financial ties with Castle Biosciences, Inc. Conclusions: There is limited evidence to conclude that the DecisionDx-Melanoma test is valid. There is insufficient evidence to conclude that the DecisionDx-Melanoma test has prognostic accuracy in predicting metastatic risk. There is insufficient evidence to conclude that the DecisionDx-Melanoma test is not harmful to patients. There is insufficient evidence to establish the clinical utility and therapeutic impact of the DecisionDx-Melanoma test.

**Articles:** The literature search was carried out to identify studies relating to the prognostic value of the DecisionDx-Melanoma test. The search revealed a variety of publications discussing the use of GEP and one publication identifying the genes associated with melanoma progression and prognosis (Winnepenninckx, Lazar et al. 2006). No studies were identified in which the DecisionDX-Melanoma was prospectively analyzed and followed-up in populations with Stage I and II melanoma. A search of the NIH Clinical Trials database identified two manufacturer sponsored prospective studies currently in the enrollment stage. The best, currently available, evidence was a development and validation study published by Castle Biosciences, Inc. The following articles were selected for critical appraisal: Gerami P, Cook RW, Wilkinson J, et al. Development of a prognostic genetic signature to predict the metastatic risk associated with cutaneous melanoma. *Clinical Cancer Research*. 2015;21(1);175-183. See [Evidence Table](#).

The use of DecisionDx-Melanoma does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **OVA1 Assessment for Ovarian Cancer**

##### **BACKGROUND**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

Ovarian cancer is the most lethal gynecological malignant worldwide. The five-year overall survival is over 90% in patients with stage I disease and only 20-40% for stages III and IV. Unfortunately, because of the lack of specific symptoms during the early stage approximately 70% of cases present with an advanced stage disease. Detection of ovarian cancer at an early stage would have a significant impact on reducing mortality, however to date; there is no screening or biomarker test that meets the criteria for a beneficial screening test in asymptomatic women with early ovarian cancer (Carter 2011, Cohen 2014, Leung 2014). Serum CA-125, a high molecular weight glycoprotein, remains the most widely used biomarker for the confirmation of diagnosis and management of ovarian cancer. Serum CA-125 however, is more prominently expressed in patients with late stage serous tumors; it is elevated in 50-60% of women with stage I epithelial ovarian cancer, and in 75-90% of patients with advanced stage disease. Elevated circulating CA-125 has also been documented in uterine fibroids, endometriosis, pregnancy, menstruation, benign ovarian neoplasms, liver cirrhosis, and other malignancies making it a less useful marker for the detection of ovarian cancer (Autelitano 2012, Cohen 2014). Improvements have been made in the preoperative diagnosis of ovarian cancer by combining serum CA-125 concentration with ultrasound score and menopausal status, into a Risk of Malignancy Index (RMI) which was found to outperform CA-125 alone in discriminating between a benign and malignant pelvic mass. Over the past two decades diagnostic triage methods incorporating clinical algorithms, serum biomarkers, imaging, or a combination of these techniques have been investigated to improve its diagnostic efficiency in predicting ovarian malignancy in women with adnexal masses. The Risk of malignancy Algorithm (ROMA) and OVA1 test are two algorithms recently developed for the assessment of malignancy risk in these women. These are not screening tests, but are potential tools to further triage women to the appropriate provider once the decision for surgical intervention has been made (Autelitano 2012, Bristow 2013, Cohen 2014). Combining multiple variables or markers in a single biomarker assay (in vitro diagnostic multivariate assay [IVDMIA, or MIA]) has the potential advantage of complementing the information provided by a single-valued index. The inclusion of biomarkers in an IVDMIA requires that they are complementary and collectively outperform a single marker with respect to its intended uses. CA-125 remains the best tumor marker, and the selection of additional biomarkers is based mainly on their ability to detect malignancy in cancer patients with low CA-125 level or to reduce false positive results among non-cancer patients with elevated serum CA-125 levels (Zhang 2012). Ova1™ test (developed by Vermillion and licensed to Quest Diagnostics, Inc.) is the first IVDMIA of protein biomarkers cleared by the FDA to be used as an adjunct to clinical and radiological evaluations for women over the age of 18 who have planned to undergo surgery for an adnexal mass and have not been referred to a gynecologic oncologist. Studies suggest that women who receive their initial surgical care from an experienced gynecologic oncologist are more likely to have better outcomes including surgical staging, optimal debulking, and improved median and overall-5-year survival. Ova1™ test is a qualitative test that measures the serum levels of 5 potential biochemical markers for ovarian cancer (CA-125, prealbumin, apolipoprotein A-1,  $\beta$ 2-microglobulin, and transferrin). The results of the test are then interpreted using a proprietary algorithm to yield a single score ranging from 0 to 10 to indicate the likelihood that the adnexal mass is benign or malignant. A high probability for malignancy is defined as a score of  $\geq 5.0$  in premenopausal women or  $\geq 4.4$  in postmenopausal women. The decision for selecting these cutoff values was made to emphasize the need for high sensitivity to minimize the risk of false negative results for patients who actually have a malignant lesion. A limitation to OVA1™ is that all the included markers with the exception of CA-125 are acute phase reactants that may be nonspecific for ovarian cancer. Another limitation is interference of triglyceride levels greater than 4.5g/L or rheumatoid factor levels more than 250IU/mL with the biomarkers assay (Muller 2010, Carter 2011, Zheng 2012, Leung 2014).

#### **04/20/2015: MTAC REVIEW**

##### **OVA1 Assessment for Ovarian Cancer**

**Evidence Conclusion:** The main purpose of adding biomarkers to an established tumors biomarker as CA-125, in a multivariate index assay (MIA), is to achieve a very high sensitivity without sacrificing the specificity. However, the published studies evaluating OVA1™ showed the test improved the sensitivity of the physicians' assessment in predicting ovarian malignancy in women with adnexal masses, but at the cost of reducing the specificity and positive predictive value. The FDA cleared the OVA1™ test based on the results of Ueland and colleagues' study that was reviewed earlier by MTAC in 2011. The study compared the sensitivity, specificity, and predictive values of physician assessment with or without adding the multivariate index assay (MIA) in identifying high-risk ovarian tumors. The study enrolled 590 women (524 evaluable with both MIA and CA-125-II) with a documented ovarian mass on imaging and planned surgery within 3 months of imaging. 53% of the women were enrolled by non-gynecologic oncologists and the rest by gynecological oncologist. The MIA index assay test was performed on preoperative serum samples, and the results were correlated with preoperative physician assessment. There was no specific protocol for the clinical assessment. Using surgical pathology as the gold standard, 161 women were diagnosed with a malignant and 363 with a benign ovarian tumor. The results of the analysis showed that the sensitivity of non-gynecologic oncologists' assessment increased from 72% to 92% with the addition of the MIA

test (78% and 99% respectively for gynecologic oncologists). The negative predictive value increased slightly with the addition of the MIA test. On the other hand, the specificity and positive predictive values dropped significantly with the addition of the assay ( the specificity was reduced from 83% to 42% for non-gynecologic oncologists and from 75% to 26% for gynecologic oncologists and the positive predictive value dropped from 60% to 36% and from 63% to 43% in the two groups of respectively). The studies published after that pivotal study were conducted mainly by the same group of investigators who either analyzed the results of women enrolled in some or all 44 sites participating in the study. The studies were sponsored by Vermillion Inc., and the investigators had financial ties to the company. The largest and most recent of these studies (Longoria et al 2014) (Evidence table 1) compared the accuracy and predictive values of the multivariate index assay, OVA1™ to clinical assessment, CA-125-II, and the modified American Congress of Obstetricians and Gynecologists (ACOG) guidelines, for the detection of early-stage ovarian cancer in 1,016 women undergoing surgery for an adnexal mass. The authors did not indicate whether the assessors were blinded to the other tests and/or clinical evaluation results. The study did not include women without adnexal masses or with other disorders that may lead to elevated levels of CA-125 or any of the other biomarkers included in the assay. Overall, similar to the Ueland and colleagues' study, as well as the other published studies using MIA test, Longoria, et al's study showed that the addition of OVA1™ to clinical assessment may significantly improve the sensitivity of detecting early-stage ovarian cancer, but at the expense of reducing the specificity, which would result in referral of more patients with benign conditions to gynecologic oncologists for surgery. The overall results of the study show the following: **Comparative performance for evaluable women in all cancer cases (from evidence table 1)**

	Sensitivity %	Specificity %	PPV %	NPV %
OVA1	92.2%	49.4%	37.9%	94.9%
Clinical assessment*	74.5%	86.3%	64.6%	91.0%
OVA1 + clinical assessment	95.3%	44.2%	36.4%	96.6%
CA 125-II	70.6%	89.6%	69.5%	90.1%
Modified ACOG guidelines**	80.0%	76.5%	53.3%	91.9%

\*The authors did not clearly explain that clinical assessment included CA125-II for all women

\*\* Included: very elevated CA125 (>67U/mL), ascites, and evidence of abdominal or distant metastasis for premenopausal women.

For postmenopausal women the ACOG criteria were Elevated CA125 (>35 u/mL, nodular or fixed pelvic mass, ascites, and evidence of abdominal or distant metastasis.

The studies had enrolled selected groups of women with adnexal masses who were referred to surgery in multiple centers with no standardized process for data collection or referral practice. The referral pattern was retrospectively analyzed, and the impact of the test on health outcomes was not evaluated. In addition, the studies were funded by Vermillion Inc, the developer of the test, and the principal investigators had financial ties to the company. The performance of OVA1™ was not compared to other risk assessment algorithms as ROMA, ultrasound-based risk assessment models, or other diagnostic tools that may lead to similar sensitivity and superior specificity to OVA1™. Conclusion: The published studies do not provide sufficient evidence to determine the clinical utility and impact of using OVA1™ assay on health outcomes of women with ovarian tumors.

The use of OVA 1 does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

GHC considers genetic testing panels medically necessary when the results are expected to directly affect treatment, management, surveillance or reproductive decisions and when all genes or genetic variants included in

the panel have high quality, evidence-based guidelines established to direct clinical management based on results.

**Testing for individual components of a panel may be medically necessary in some clinical situations. Separate clinical criteria for these components may apply.**

Cancer susceptibility genetic panels may be covered for an individual who meets the genetic testing panel criteria above and **ONE of the following**:

- 1) Exhibits a personal and/or family history indicating elevated risk for breast or ovarian cancer and **ALL of the following**:
  - a) Meets GHC criteria for [BRCA genetic](#) testing
  - b) Has documentation in the medical record of findings in personal and/or family history consistent with **ONE or more of the following**:
    - i) Li-Fraumeni syndrome (TP53 gene)
    - ii) Cowden syndrome (PTEN gene)
    - iii) Peutz-Jehger syndrome (STK11 gene)
    - iv) Hereditary diffuse gastric cancer syndrome (CDH1 gene)
  - c) The genetic panel requested is limited to the following genes:
    - BRCA1
    - BRCA2
    - PTEN
    - STK11
    - CDH1
    - TP53
  - d) Has had consultation with a medical geneticist or certified genetic counselor who is recommending the test and who has documented the indication for testing and its expected impact on clinical management or surveillance.
- 2) Exhibits a personal and/or family history indicating an elevated risk for colorectal cancer and the following:
  - a) Has documentation in the medical record of findings in personal and/or family history consistent with both Lynch syndrome and a familial polyposis syndrome (FAP, MAP or JPS)

**OR**

  - b) Meets GHC criteria for **either** [Lynch syndrome or FAP](#) and has documented findings consistent with **ONE of the following**:
    - Familial adenomatous polyposis (APC and/or MUTYH genes)
    - Li-Fraumeni syndrome (TP53 gene)
    - Cowden syndrome (PTEN gene)
    - Juvenile Polyposis syndrome (SMAD4 and BMPR1A genes)

**And**

  - c) Has had consultation with a medical geneticist or certified genetic counselor who is recommending the test and who has documented the indication for testing and its expected impact on clinical management or surveillance.
  - d) The genetic panel requested is limited to the following genes:

**MLH1, MSH2, MSH6, PMS2, EPCAM, APC, MUTYH, PTEN, STK11, CDH1, TP53, SMAD4, BMPR1A, CHEK2**

The following genetic panels are **not considered medically necessary** because the current scientific evidence is not yet sufficient to establish how test results from all components of these panels should be used to direct treatment decisions. There is also insufficient evidence to establish that use of these genetic panels to guide treatment decisions results in improved patient health outcomes.

This list is not all-inclusive as new genetic panel tests are frequently being developed.

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

The emergence of new genetic testing technology, including next generation sequencing and chromosomal microarray, has made possible the ability to examine many genes simultaneously. This in turn has resulted in a proliferation of new genetic testing panels. The intended use for these panels varies.

For example, for hereditary disorders, a clinical diagnosis may already be established, in which case genetic testing is performed to determine the specific causative mutation and a diagnostic genotype. In other cases, the clinical findings may suggest a number of possible etiologies, in which case genetic testing is performed in the hope of making a specific diagnosis.

For cancer panels, intended uses also differ. Some panels may be intended to identify the presence of a hereditary syndrome predisposing to the development of certain cancers. Other panels look for somatic mutations in a tumor biopsy specimen with the intent of identifying a cancer's primary site of origin and/or identifying a molecular target to help in selecting treatment.

Panels using next generation sequencing technology are currently available in the areas of cancer, cardiovascular disease, neurologic disease, and for prenatal testing and screening. These panels are intuitively attractive to use in clinical care because they can analyze multiple genes quickly and may lead to greater efficiency in the work-up of genetic disorders. It is also possible that in some cases these "bundled" gene tests can be performed more cost efficiently than individual sequencing, although this may not be true in all cases.

On the other hand, the use of newer sequencing techniques is associated with a higher rate of results which may be of uncertain clinical significance and/or for which there are no reliable evidence-based guidelines regarding management or surveillance. This can potentially lead to unnecessary follow-up testing and procedures, which have their own inherent risks and cost.

The design and composition of genetic panel tests are not standardized. The make-up of each panel is determined by the specific laboratory that has developed the test. In addition, the composition of any individual panel is likely to change over time, as new genetic variations are discovered and added to the existing panels.

[Ambry Genetic's Next-Generation Panels \(BreastNext, OvaNext, CancerNext\)](#)  
[Coloseq™ Colon Cancer Panel](#)

## Medical Technology Assessment Committee (MTAC)

### ***Ambry Genetic's Next-Generation Panels (BreastNext, OvaNext, CancerNext)***

#### BACKGROUND

Understanding the underlying genetic contribution to cancer can give insight to individual and familial risk. This is especially important with hereditary cancer since risk-reducing strategies for additional primary cancers can vary based on molecular diagnosis. Identifying an underlying genetic cause can also aid in the diagnostic process since relying on family history alone can be challenging. Numerous genetic mutations are associated with certain types of hereditary cancer. Traditionally, Sanger sequencing has been considered the gold standard in mutation detection and is still the method of choice for most diagnostic labs. However, since multiple genes are implicated in each type of cancer, testing by traditional sequencing can be burdensome and expensive. Advancements in sequencing technologies have made it possible to generate a large amount of data quickly and cost effectively ([Choi, Scholl et al. 2009](#)). Next generation sequencing (NGS) provides investigators with the required capacity to analyze large panels of genes or whole genomes in a single run (panel testing) ([Previati, Manfrini et al. 2013](#)). As a result, these technologies are enabling new tailor-made approaches to diagnostic testing with an increasing number of commercially available genetic panels ([Walsh, Lee et al. 2010](#); [Michils, Hollants et al. 2012](#)). Ambry Genetics offers four different genetic testing panels for hereditary cancers ([Keiles 2013](#)). These panels address three specific types of cancer that may be inherited including breast, ovarian and colorectal. The mutations included in these panels are associated with varying levels of risk of developing cancer, and only some of the mutations are associated with well-defined cancer syndromes which have established clinical management guidelines ([Burke, Petersen et al. 1997](#)).

TABLE 1: PANEL NAME AND DESCRIPTION	
PANEL NAME	DESCRIPTION
<i>BreastNext™</i>	Next-generation sequencing panel that simultaneously analyzes 16 genes that contribute to increased risk for breast cancer including BRCA1 and BRCA2.
<i>OvaNext™</i>	Next-generation sequencing panel that simultaneously analyzes 21 genes that contribute to increased risk for breast ovarian and/or uterine cancers.
<i>Colonext™</i>	Next-generation sequencing panel that simultaneously analyzes 14 genes that contribute to increased risk for colon cancer.
<i>CancerNext™</i>	Next-generation sequencing panel that simultaneously analyzes 24 genes that contribute to increased risk for breast colon, ovarian, uterine and other cancers.

There is no standardization to the make-up of genetic panels. Composition of the panels is variable, and different commercial products for the same condition may test a different set of genes. The make-up of the specific panels is determined by the specific lab that has developed the test. In addition, the composition of any individual panel is likely to change over time, as new mutations are discovered. The majority of cancer panel tests are laboratory derived tests that are not subject to U.S. Food and Drug Administration (FDA) approval. Labs are subject to Clinical Laboratory Amendment (CLIA) regulations that monitor high-complexity testing.

### 10/21/2013: MTAC REVIEW

#### **Ambry Genetic's Next-Generation Panels (BreastNext, OvaNext, CancerNext)**

**Evidence Conclusion:** Analytic Validity According to Ambry Genetics, the analytic sensitivity for the 22 genes analyzed on their cancer susceptibility panels by next generation sequencing is 96-99% ([Keiles 2013](#)), however, no publications were found to support these claims. No published literature addressed the analytic validity of the Ambry Genetics' Next-Gen Cancer Panels. Clinical Validity While it may be possible to evaluate the clinical validity of sequencing of individual genes found on these panels, the clinical validity of Ambry Genetics' Next-Gen Cancer Panels, which include mutations associated with unknown or variable cancer risk, is uncertain. No published literature addressed the clinical validity of panel testing for cancer susceptibility with NGS. Clinical Utility Theoretically, identifying an individual with a genetic mutation that indicates a high risk of developing cancer could lead to changes in clinical management and improved health outcomes including modifications in cancer surveillance and treatment guidance. However, identifying mutations that have intermediate or low risk of developing cancer is of limited clinical utility. With potential harms, such as psychological stress and unnecessary prophylactic intervention, the management for patients found to have one of these mutations is not well defined. No published literature addressed the clinical utility of the Ambry Genetics' Next-Gen Cancer Panels. Conclusion There is insufficient evidence to determine the analytic validity, clinical validity or clinical utility of the Ambry's Next-Gen Cancer Panels.

**Articles:** A search of PubMed was completed for the period through August 2013 for studies on the accuracy of NGS for predicting risk of hereditary breast ovarian and colon cancer. The search strategy used the terms *next generation, cancer panel, BreastNext, breast cancer, ColoNext, colon cancer, OvaNext, ovarian cancer and CancerNext* with variations. To identify ongoing clinical trials, a search of the National Institute of Health Clinical Trials website was also conducted using the same methodology. Articles were limited to those published in the English language with human subject enrollment. The search was supplemented by an examination of article bibliographies in addition to the PubMed *related* articles function.

The use of Ambry next generation does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **Coloseq™ Colon Cancer Panel**

##### BACKGROUND

Approximately 2% to 5% of colorectal cancer (CRC) can be attributed to inherited syndromes such as Lynch syndrome (also known as hereditary non-polyposis colon cancer), familial adenomatous polyposis (FAP), and MUTYH-associated polyposis. Patients with these syndromes are at higher risk for CRC and, therefore, require more intensive surveillance programs. Lifetime CRC risk is 50-80% for patients with Lynch syndrome, 100% for patients with FAP, and 80% for patients with MUTYH-associated polyposis compared to 5-6% for patients without these syndromes ([Kaz and Brentnall 2006](#); [Jasperson, Tuohy et al. 2010](#)). There are several different strategies used to identify families at high-risk for developing these syndromes, however, genetic testing is the gold standard for diagnosing Lynch syndrome and FAP. To date, clinical diagnostic criteria for MUTYH-associated polyposis have not been fully established; however, genetic testing may be warranted in individuals with more than 10 colorectal adenomas who are negative for APC mutations ([Jasperson, Tuohy et al. 2010](#)). Genetic testing of high-risk families allows for a more accurate diagnosis and more specific targeting of clinical screening and surveillance

protocols to gene carriers in the family. Additionally, genetic testing allows for the identification of family members who did not inherit the mutation and therefore do not warrant intensive surveillance programs. ColoSeq™ is a comprehensive genetic test for the prediction and diagnosis of hereditary colon cancer that uses next generation sequencing to detect mutations in multiple genes associated with Lynch syndrome, FAP, and MUTYH-associated polyposis. Initially, the panel was developed to include seven genes that have a well-established role in clinical decision making for patients with Lynch or polyposis syndromes. Since then, however, the panel has undergone several evolutions to include four additional genes in June of 2012, two more genes in January of 2013 and, most recently, the addition of six genes in October of 2013. With a total of 19 genes now included, the panels utility has now expanded into the realms of endometrial, breast, and thyroid cancer, to name a few. ColoSeq is not approved by the Food and Drug Administration (FDA) but clinical laboratories that develop and validate tests for in-house use are regulated under the Clinical Laboratory Improvement Amendments (CLIA) of 1988.

**10/16/2013: MTAC REVIEW**

**ColoSeq™ Colon Cancer Panel**

**Evidence Conclusion:** *Analytic Validity* One publication from the Journal of Molecular Diagnostics was identified that addressed the analytic validity of ColoSeq™ (Pritchard, Smith et al. 2012). The study presents 99.4%-100% sensitivity and 99.4%-100% specificity. The paper was limited to the seven genes that were included on the original panel and thus does not provide sufficient evidence for the 19 gene panel that is currently used. No publications were identified that validated the entire 19 gene panel that has since evolved. *Clinical Validity* Pritchard and colleagues present that the clinical validity is achieved by targeting and validating only genes that, when mutated, are well-established causes of hereditary colon cancer leading to the conclusion that incorporating the results of the ColoSeq™ testing into clinical-decision making was now straightforward. The addition of new genes and inclusion of additional cancers compromise this claim. No publications were identified that addressed the clinical validity of the ColoSeq™ cancer panel. *Clinical Utility* Originally, the ColoSeq panel was designed to focus only on genes that have a well-established role in clinical decision making and patient management. The recent expansion of the ColoSeq panel compromises the overall clinical utility. No published literature addressed the clinical utility of the ColoSeq™ cancer panel.

Conclusion: There is insufficient evidence to determine the analytic validity, clinical utility and clinical validity of ColoSeq™ for the identification of hereditary colon cancer.

**Articles:** A search of PubMed was completed for the period from April 2012 to November 5<sup>th</sup>, 2013 for studies on the accuracy of ColoSeq™ for detecting hereditary colon cancer. The search strategy used the terms *ColoSeq™, genetic testing, Lynch syndrome, familial adenomatous polyposis (FAP), MUTYH-associated polyposis, and colon cancer* with variations. To identify ongoing clinical trials, a search of the National Institute of Health Clinical Trials website was also conducted using the same methodology. Selected articles were limited to those published in the English language enrolling human subjects. The search was supplemented by an examination of article reference lists in addition to the PubMed *related articles* function. **Screening of articles:** The literature search for ColoSeq™ revealed one July 2012 publication on the development and validity of the assay (Pritchard, Smith et al. 2012). Due to recent additions (October 2013) to the ColoSeq™ cancer panel, this publication is no longer applicable and was not reviewed.

The use of ColoSeq™ does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Treatment of Gastroesophageal Reflux Disease - GERD

- Stretta Procedure
- CR BARD's Endoscopic Suturing System
- Endoscopic Placement of a Bulking Material at the Lower Esophageal Sphincter
- LINX Reflux Management System

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare members

Procedure(s):	CPT Code(s)	CMS Coverage Guidelines – NCD, LCD, LCA	GHC Medical Policy
Transesophageal radiofrequency energy <b>Examples:</b> CSM Stretta™ System, or the Stretta procedure	43257	Non-Covered Services (L35008)	N/A
Transoral incisionless fundoplication (TIF) <b>Examples:</b> EsophyX	43210	Non-Covered Services (L35008) (See also LCA for Non-coverage of Transoral Incisionless Fundoplication (A52885) regarding non-coverage of TIF).	N/A
Linx Reflux Management System	C9737, 0392T, 0393T	Non-Covered Services (L35008)	N/A
Endoscopic injection of a bulking agent <b>Examples:</b> pyrolytic carbon-coated zirconium oxide spheres (Durasphere®)	43192, 43201, 43499	None	GHC Medical Policy - Treatment of Gastroesophageal Reflux Disease - GERD
Endoscopic submucosal implantation or injection of a biocompatible polymer <b>Examples:</b> • Enteryx, • polymethylmethacrylate [PMMA] beads(1) the Gatekeeper Reflux Repair system	43192, 43201, 43499	None	GHC Medical Policy - Treatment of Gastroesophageal Reflux Disease - GERD
Transesophageal endoscopic gastroplasty <b>Examples:</b> • EndoCinch • Plicator • StomaphyX	43499	None	GHC Medical Policy - Treatment of Gastroesophageal Reflux Disease - GERD

##### For Non-Medicare members

Group Health has elected to use the Radiofrequency Energy Delivery to Gastroesophageal Junction (Stretta) (A-0209) MCG\* for medical necessity determinations. This service is not covered per MCG guidelines.

**\*The MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting this service, please send the following documentation to support medical necessity:**

- Last 6 months of clinical notes from requesting provider &/or specialist (GI, general surgeon)

**Background**

Gastroesophageal reflux disease (GERD) is a one of the most common medical disorders in the United States. It is a chronic disorder that is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett’s esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture.

Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up (Lafullarde, 2001).

More recently endoscopic or endoluminal approaches for treating GERD have either been approved or are still under trial. These various methods can be divided in three broad categories:

1. Methods that create a controlled stricture (radiofrequency),
2. Methods that attempt to create a fundoplication,
3. Methods that bulk the gastroesophageal junction (injecting bulking agents).

The ideal procedure should be safe, effective, with long-term effects, and do not affect future surgical options.

According to the Montreal Consensus, gastroesophageal reflux disease (GERD) is defined as a condition which develops when the reflux of stomach contents cause troublesome symptoms and/or complications. GERD is a mechanical disorder that is caused by a defective lower esophageal sphincter, a gastric emptying disorder, or failed esophageal peristalsis. Typical symptoms of GERD include heartburn and regurgitation; however, overtime reflux can cause ulceration, Barrett’s esophageous, airway disease, and esophageal cancer. It is estimated that 40% of individuals in the United States suffer from GERD on a monthly basis. Current treatment options for GERD include long-term use of acid suppression medications or surgical intervention. While treatment with acid suppressing medications such as proton pump inhibitors and histamine 2-receptor blockers are effective, they do not treat the underlying mechanical disorder. Additionally, not all patients respond to these therapies (Zagol 2011, Stefanidid 2010).

Surgery is another treatment option for patients with GERD. According to the Society of American Gastrointestinal and Endoscopic Surgeons (SAGES), surgical therapy should be considered in patients with a diagnosis of reflux who (Stefanidid 2010):

- Have failed medical management (due to inadequate symptom control, severe regurgitation not controlled with acid suppression, or medication side-effects)
- Opt for surgery despite medical management (due to quality-of-life considerations, lifelong need for medication intake, expense of the medication, etc.)

- Have complications of GERD (e.g., Barrett's esophagus, peptic stricture)
- Have extra-esophageal manifestations (asthma, hoarseness, cough, chest pains, aspiration)

There are a variety of surgical procedures used for the treatment of GERD. Currently, there is no consensus on the best procedure for all patients. The choice of procedure is often based on anatomic considerations and expertise; however, the laparoscopic Nissen fundoplication has emerged as one of the most widely used techniques. With fundoplication, the gastric fundus is wrapped around the lower end of the esophagus to reduce gastric reflux. The fundal wrap can be either total (360°) or partial (less than 360°). Studies suggest that approximately 90% of patients who undergo Nissen fundoplication achieve symptom relief. Side effects of this procedure include dysphagia, hyperflatulence, inability to belch, bloating, and postsurgery bowel symptoms (AGA 2008, Stefanidid 2010).

Transoral incisionless fundoplication using the EsophyX device (EndoGastric Solutions, Inc., Redmond, WA) has been proposed as a less invasive alternative to traditional surgical procedures. This procedure attempts to decrease the reflux of stomach acid into the esophagus through the reconstruction of an anti-reflux barrier. The EsophyX device is inserted transorally, under direct endoscopic visualization, into the stomach and is positioned at the junction of the stomach and the esophagus. Once positioned, the device uses suction and transmural fasteners to facilitate the recreation of the esophageal gastric valve. The result is an omega shaped valve 3-5 cm in length and 200-300° in circumference. This procedure may also reduce hiatal hernias that are less than 2 cm in size through the use of a built in vacuum invaginator. As this procedure is incisionless and can often be performed on an outpatient basis it is an attractive alternative to conventional surgical procedures (Jafri 2009, Louis 2010).

The EsophyX system had been cleared by the FDA for use in transoral tissue approximation, full-thickness plication and ligation in the gastrointestinal tract for the treatment of GERD in patients with symptomatic chronic GERD who require and respond to pharmacological therapy. This device may also be used to narrow the gastroesophageal junction and reduce hiatal hernia  $\leq 2$  cm in size in patients with symptomatic chronic GERD. The EsophyX system has not been previously reviewed by the Medical Technology Assessment Committee and is being review based on request from bariatric surgery and a member appeal.

### ***CR BARD's Endoscopic Suturing System (Endocinch Therapy, Endoluminal Plication) for the Treatment of GERD***

#### BACKGROUND

Gastroesophageal reflux disease (GERD) is a chronic disorder that affects as many as 14 million Americans. It is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett's esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture. Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up (Lafullarde, 2001). More recently endoscopic or endoluminal approaches for treating GERD have either been FDA approved or are still under investigation. These various methods can be divided in three broad categories: 1. Methods that attempt to create a fundoplication (plicating techniques), 2. Methods that create a controlled stricture (radio frequency), and 3. Methods that bulk the gastroesophageal junction (injecting bulking agents). The ideal procedure should be safe, effective over a long term, and would not affect future surgical options. Currently, there are three plicating devices: The endoCinch (C.R. Bard's endoscopic suturing system, the ESD, and the Full-Thickness Plicator. The first two have been approved by the FDA, and the last was not approved to date. Endoluminal plication uses mechanical techniques to hinder reflux by approximation of tissue at or below the gastroesophageal junction. The EndoCinch (CR BARD Endoscopic technologies, Massachusetts, USA) system was the first FDA approved

endoscopic sewing machine method for treating GERD. It was developed by Swain CP et al in London UK, in the mid-1980s. In the Bard method, an oroesophageal tube (19.7 mm in diameter and 30 cm long) is placed to facilitate passage of the suturing device. The suture capsule, which is similar to a sewing machine, is attached to an endoscope and loaded with a suture. After placing the suture capsule, under vision, over the selected site at the gastroesophageal junction, suction through the external vacuum line is applied. This pulls a fold of tissue into the capsule cavity, and the needle driver places the suture. Suction is released and the tissue is withdrawn from the capsule. The procedure is repeated on an adjoining site. Drawing two sutured sites together creates a plication. It is reported that the procedure is technically difficult, has a steep learning curve, and that the results are likely to be operator-dependent. Conscious sedation might not be sufficient and a general anesthesia may be needed. Adverse effects associated with the procedure include pharyngitis, vomiting, abdominal pain, chest pain, mucosal tear, hypoxia, and bleeding. The Bard's Endoscopic Suturing system was FDA approved in March 2000, for the treatment of GERD. The ESD (Wilson-Cook Medical, Winston-Salem, N.C.) another endoscopically assisted endoluminal suturing device was also approved by the FDA for soft-tissue apposition. The Full-Thickness Plicator (Ndo Surgical, Inc, Mansfield, Mass) is another plication device that had not been approved by the FDA at time the search was made.

## **02/13/2003: MTAC REVIEW**

### **Endocinch Therapy in the Treatment of GERD**

**Evidence Conclusion:** The studies reviewed show that the procedure is associated with a reduction in the frequency and severity of heartburn and regurgitation symptoms. Patients had an improved quality of life, and there was a significant reduction in the use of antisecretory medications in two of the studies. However, the procedure was performed on a highly selected group of patients (those with hiatal hernia >3 cm, esophageal stricture and Barrett's esophagus were excluded). Moreover, the follow-up duration of all studies was short, and insufficient to determine the recurrence rate and long term-efficacy of the procedure. Filipi's study was an RCT, yet the patients were randomized to two different suture configurations of the same procedure and not to an alternative treatment. Randomized controlled studies with long-term follow-up are needed to compare the procedure with other medical and surgical antireflux therapies, and assess the sustained effect of the procedure and the long-term relief from symptoms without using antisecretory medications.

**Articles:** The search yielded 12 articles, all on the Bard technique. There was one randomized controlled trial, one case-control study and one case series. The rest were reviews, tutorials, letters or dealt with the technical aspect of the procedure. There were no published studies on the Wilson-Cook ESD, or the Ndo Full-Thickness Plicator. Evidence tables were created for the three studies identified in the search:

Filipi CJ, Lehman GA, Rothstein RI, et al. Transoral flexible endoscopic suturing for treatment of GERD. A multicenter trial. *Gastrintest Endosc* 2001; 53:416-422. See [Evidence Table](#). Mahmoud Z, McMahon BP, Arfin Q, et al. Endocinch therapy for gastro-esophageal reflux disease: a one year prospective study. *Gut* 2003, 52:34-39. See [Evidence Table](#). Velanovich V, Ben-Menachem T, and Goel S. Case-control comparison of endoscopic gastroplication, with laparoscopic fundoplication in the management of gastroesophageal reflux disease. Early symptomatic outcomes. *Surg laparosc Endosc Percutan Tech* 2002, 12:219-223. See [Evidence Table](#).

The use of Endocinch therapy in the treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Endoscopic Placement of a Bulking Material at the Lower Esophageal Sphincter for the Treatment of GERD**

#### **BACKGROUND**

Gastro-esophageal reflux disease (GERD) is a chronic disorder that affects as many as fourteen million Americans. It is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett's esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture. Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up ((Lafullarde, 2001). More recently endoscopic or endoluminal approaches for treating GERD have either been approved or are still under trial. These various methods can be divided in three broad categories: 1. Methods that create a controlled stricture (radiofrequency), 2. Methods that attempt to create a fundoplication, and 3. Methods that bulk the gastroesophageal junction (injecting bulking agents). The ideal procedure should be safe, effective, with long-term effects, and do not affect future surgical options. Endoscopic injection of an inert material into the submucosa of

the distal esophagus has been tried with the intention to impede the reflux. The bulking effect results from both the material injected and the tissue response. Examples of the bulking agents used are bovine collagen, ethylene vinyl alcohol, polytetrafluoroethylene and others. These are injected through long catheters and small gauge needles under endoscopic guidance. In the experiments conducted the resulting improvement in reducing the LES pressure and GERD symptoms were temporary, and did not last long, either due to the biodegradation or migration of the injected material. Other nonbiodegradable substances, injected into the submucosa or muscle, and with the use of different application techniques are still under trial. These methods are still in the investigational stage and are not approved by the FDA.

#### **02/13/2003: MTAC REVIEW**

##### **Bulking Material in the Treatment of GERD**

**Evidence Conclusion:** There is insufficient evidence to determine the efficacy and safety of endoscopic injection of bulking material for the treatment of GERD.

**Articles:** The search did not yield any study. Two studies were revealed from review articles. Both were pilot studies with no comparison groups. One included only a series of 15 patients (10 in Brussels and 5 in Rome), and the other was a case series with only ten participants.

The use of bulking material in the treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **Magnetic Sphincter Augmentation – (LINX® Reflux Management System)**

##### **BACKGROUND**

Gastroesophageal Reflux Disease (GERD) is an extremely common clinical manifestation of excessive reflux of acidic gastric components. Also referred to as chronic acid reflux, GERD is characterized by a chronic, often progressive dysfunction of the lower esophageal sphincter (LES) allowing acids and biles from the stomach to flow back into the esophagus. Common symptoms include heartburn, regurgitation and dysphagia and can adversely impact the quality of life by interfering with daily activities, disturbing sleep, and reducing productivity. Left untreated GERD can lead to more serious complications such as esophageal stricture, Barrett's esophagus and esophageal cancer (Gorecki 2001). Simple diet and lifestyle modifications can ease some of the symptoms associated with GERD, however, more severe or frequent cases may require pharmaceutical treatment with antacids, H2-receptor antagonists or proton pump inhibitors (PPIs). Some cases of GERD, however, will not respond to medications and may require surgical intervention. Laparoscopic fundoplication (LF), has long been considered the gold standard of antireflux surgery. The technique involves wrapping the upper part of the stomach (gastric fundus) around the lower end of the esophagus in an effort to reinforce the LES. Although LF has a high success rate, the procedure is non-reversible and has been associated with a variety of potential side-effects such as dysphagia, loss of belching and vomiting and increased flatulence and bloating. The LINX® Reflux Management System, developed by Torax® Medical (St. Paul, MN), was designed to prevent back flow into the esophagus and is suggested as an alternative to anti-reflux surgery. More specifically, the magnetic sphincter augmentation (MSA) device is a series of interlinked magnetic beads implanted laparoscopically at the junction between the esophagus and stomach that acts as a reinforcement of the LES. The device relies on small wires that allow the magnetic beads to expand and allow the flow of foods and liquids into the stomach while preventing reflux at the same time. According to the manufacturer, the LINX Reflux Management System requires less recovery time, provides immediate relief and faster return to solid foods compared with other surgical interventions. To add to this, the device can be removed if side-effects, such as dysphagia, pain and bloating, become unbearable. The LINX® Reflux Management System received US Food and Drug Administration (FDA) approval on March 22, 2012. The device is intended for use in patients with GERD who continue to have symptoms despite the use of a maximum medical therapy for the treatment of reflux. More specifically, it is intended for use in patients who would be considered candidates for anti-reflux surgery. This topic has not previously been reviewed by the Medical Technology Assessment Committee (MTAC) and is currently under consideration due to coverage decision support.

#### **12/15/2014: MTAC REVIEW**

##### **LINX Reflux Management System**

**Evidence Conclusion:** A feasibility trial by Lipham and colleagues, included 44 patients and aimed to assess the long-term safety and effectiveness of the LINX Reflux Management System (up to 3.7 years). In this study, patient's baseline measurements were used as the control for comparison with post-implant measurements. In all outcome measures improvements were seen with reduced esophageal acid exposure, improved GERD-HRQL scores and decreases in use of PPIs. As a result, the investigators concluded that sphincter augmentation with LINX provides long-term clinical benefits with no safety issues (Lipham, DeMeester et al. 2012). [Evidence Table 1](#) In the second study, a pivotal trial by Ganz and colleagues, the investigators sought to evaluate the safety and

effectiveness of the LINX Reflux Management System. The study included 100 patients with GERD and assessed esophageal pH as well as manometry and barium esophagography. The investigators report that 64% (95% CI, 54%-73%) of patients achieved success with normalization of esophageal acid exposure, or a  $\geq 50\%$  reduction in exposure at one year. Additional endpoints were also promising with 50% or more improvements seen in 92% of patients on the GERD-Health Related Quality of Life (HRQL) questionnaire. Although the authors concluded that the LINX device resulted in a decreased exposure to esophageal acid, improved reflux symptoms and allowed cessation of PPIs in the majority of patients, they also noted that additional prospective RCTs with appropriate controls are necessary for confirmation. (Ganz, Peters et al. 2013). [Evidence Table 2](#) Finally, the third study, by Riegler and colleagues, evaluated 249 patients who had undergone MSA and LF and completed one-year follow-up. With the overall goal to compare the clinical experience of each procedure, the investigators evaluated patients reflux symptoms, PPI use, side effects and complications. At one year, both groups showed improvement in total GERD-HRQL score (20 vs. 3 in the MSA group and 23 vs. 3.5 in the LF group) and discontinuation of PPIs was higher in the MSA group with 81.8% of patients abstaining and only 63% in the LF group ( $P=0.009$ ). The investigators concluded that both MSA and LF were comparable but that MSA should be considered as the first-line surgical option [Evidence Table 3](#). Adverse events and complications were documented in all three of the critically appraised publications. In addition, a recent publication from Lipham and colleagues provides a safety analysis of the first 1,000 patients treated with the MSA device. The analysis included safety related events collected from the published literature, FDA databases for device related complications and information provided by the manufacturer for over 1,000 patients treated worldwide between February 2007 and July 2013. This paper was not critically appraised, however, the safety data is generally summarized in table one, below. (Lipham, Taiganides et al. 2014).

Table 1. Summary of events by source		
Source of data	# of events included in analysis	Breakout
Clinical literature	32	<ul style="list-style-type: none"> <li>• 9 device removal</li> <li>• 20 esophageal dilation</li> <li>• 3 hospital readmissions</li> </ul>
MAUDE database	20	<ul style="list-style-type: none"> <li>• 19 device removal (includes US and OUS)</li> <li>• 1 device erosion</li> </ul>
Manufacturer's database	59	<ul style="list-style-type: none"> <li>• 8 device removal</li> <li>• 1 intra/perioperative complication</li> <li>• 11 hospital readmission</li> <li>• 39 esophageal dilation</li> </ul>

Generally speaking, the body of evidence is limited by small sample sizes, short-term follow-up, as well as a lack of randomization and adequate comparators. Selection bias may be an issue in the third study as the selection of intervention was ultimately made by the surgeon at the time of surgery. It should also be noted that the majority of studies assessing the LINX Reflux Management System are either funded by the device manufacturer or authored by consultants to the manufacturer. Ultimately the body of evidence provides insufficient evidence to support the safety and effectiveness of the LINX Reflux Management System. Conclusions: There is insufficient evidence to support the effectiveness of the LINX Reflux Management System in patients with refractory GERD. There is insufficient evidence to support the safety of the LINX Reflux Management System in patients with refractory GERD.

**Articles:** The literature search revealed just over 100 publications relating to treatment of GERD using sphincter augmentation many of which were not directly applicable to the objective at hand. No randomized controlled trials (RCTs) were revealed comparing the LINX Reflux Management System with alternative surgical interventions such as LF. The FDA's 2012 approval relied on two publications, a pivotal clinical trial and a feasibility study, which were selected for critical appraisal. Post-approval studies of the LINX Reflux Management System, required by the FDA, are currently ongoing. In addition to the pivotal and feasibility trial, two additional studies were considered. The first was a recent observational study comparing MSA to laparoscopic fundoplication (LF) and the latter, a safety analysis of the first 1,000 patients treated with MSA (this study was not critically appraised but discussed in the evidence summary). The following articles were selected for critical appraisal: Lipham JC, DeMeester TR, Ganz RA, et al. The LINX® reflux management system: confirmed safety and efficacy now at 4 years. *Surgical Endoscopy*. 2012;26:2944-2949. [See Evidence Table 1](#). Ganz RA, Peters JH, Horgan S, et al. Esophageal Sphincter Device for Gastroesophageal reflux disease. *NEJM*. 2013;368(8):719-727. [See Evidence Table 2](#). Reigler M, Schoppman, Bonavina L, et al. Magnetic sphincter augmentation and fundoplication for GERD in clinical practice: one-year results of a multicenter, prospective observational study. *Surgical Endoscopy*. 2014. [See Evidence Table 3](#).

The use of LINX Reflux Management System does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Stretta Procedure (Electro-Surgical Coagulation-Radio-Frequency [RF] Application- Curon Medical Inc's CSM Stretta System) for the Treatment of GERD**

#### **BACKGROUND**

Gastroesophageal reflux disease (GERD) is a one of the most common medical disorders in the United States. It is a chronic disorder that is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett's esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture. Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up (Lafullarde, 2001). More recently options include injection therapy to the lower esophageal sphincter, endoscopic sewing procedures, and radiofrequency ablation therapy. The ideal procedure should be safe, effective for a long time, and would not affect future surgical options. This review evaluates the radiofrequency techniques. Radiofrequency (RF) energy has been used for the general surgical application of tissue coagulation for more than 70 years. RF energy leads to collagen shrinkage, and in turn tissue contraction and tightening. Recently RF is being used for different clinical purposes, including its application to the gastroesophageal junction. The Stretta System (Curon Medical, Sunnyvale, CA) consists of a RF control module and a flexible Stretta catheter. The catheter has a 20F soft bougie tip and a balloon, which opens in a surrounding basket. On its widest area after balloon inflation, the catheter has four nickel-titanium needle electrodes (5.5 mm long), which can be extended in the LES muscle. The catheter is introduced transorally and positioned at the Z-line (squamocolumnar junction). It aspirates and irrigates the esophageal lumen with water to prevent surface injury. The four electrodes provide 60 to 300 J of RF energy to each needle, heating the surrounding muscle tissue to the target temperature between 65° and 85° C while cooling the mucosal with its irrigation system. 15 to 25 lesion sets are created in the region from 2 cm proximal to 1 cm distal to the Z-line by rotating the catheter 45 degrees and varying its linear position. The RF-induced burns eventually scar down and create a reflux barrier. The mechanism of action of RF is reported to be a reduction in the frequency of LES relaxations, as well as physical alteration in tissue compliance and wall thickness of the gastroesophageal junction. The Curon Medical Inc.'s CSM Stretta System was approved by the FDA on April 18, 2000. Curon recommends the device for mild or moderate cases of GERD only. The Stretta procedure is reported to be easy to learn and apply. However, there is a concern that if the scars continue to contract, at least some patients will develop a stricture that could be difficult to manage. Other adverse events that may be associated with the procedure include chest pains, fever, mucosal tear, and dysphagia.

#### **12/10/2003: MTAC REVIEW**

#### **Electro-Surgical Coagulation (radio-frequency application) in the treatment of GERD**

**Evidence Conclusion:** Of the studies reviewed, a RCT compared Stretta procedure to sham treatment, and a non-randomized longitudinal study compared it to laparoscopic fundoplication. The third was just a survey from a registry with no control or comparison group. Corley et al's trial was randomized and controlled however, it was a small study, with a high dropout rate, and some baseline differences between the two groups, that were not adjusted for in the analysis. Moreover, the procedure was compared to a sham treatment and not to another intervention e.g. laparoscopic fundoplication. The follow-up duration might have been insufficient to determine the long-term sustained effects, or potential late harms that could be associated with the procedure. In addition, the patients included in the study were highly selected for the trial and may not represent typical GERD patients. Richard et al's study was not randomized and patients were highly selected for each procedure. It was not blinded, not powered, and the follow-up duration was as short as 2 months for some patients, which is insufficient to determine the long-term durability of benefits or harms of the procedure. Both Corley's and Richard's studies were financially supported by Curon Medical, the manufacturer of the Stretta system. The third study reviewed was a retrospective survey of patients who underwent the Stretta procedure in several centers, with no reference to the inclusion/exclusion criteria, or techniques used for performing the procedure. Overall, the results of the studies show that radiofrequency application to the gastroesophageal junction to selected GERD patients is associated with improvement in symptoms and quality of life compared to sham treatment or laparoscopic

fundoplication. The heartburn improvement associated with GERD vs. sham treatment was significant in the per protocol analysis but not with the ITT analysis in Corley's trial.

**Articles:** The search yielded 9 articles. There were no meta-analyses or randomized controlled trials. There were only three empirical studies all of which were case series. One had a very small sample, and only three months follow-up. The other two with relatively larger sample sizes, and longer follow-up duration were selected for critical appraisal. In December 2001, Curon Medical announced the completion of two major clinical trials, one of which is a RCT of the Stretta vs. sham treatment. To date these studies have not been published. *Evidence tables were created for the following studies:* Triadafilapoulos G, DiBaise JK, Nostrant T, et al. The Stretta procedure for the treatment of GERD: 6 and 12-month follow-up of the U.S. open label trial. *Gastrointest Endosc* 2002, 55:149-156. See [Evidence Table](#). Houston H, Khaitan L, and Richards WO. First year experience of patients undergoing the Stretta procedure. *Surg Endosc* 2002, Nov 20. See [Evidence Table](#).

The use of electro-surgical coagulation (radio-frequency application) in the treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

## 02/13/2003: MTAC REVIEW

### **Electro-Surgical Coagulation (radio-frequency application) in the treatment of GERD**

**Evidence Conclusion:** The two case series reviewed show that the Stretta procedure may be a promising treatment for GERD. Patients had significant reduction in the esophageal acid exposure and use of antisecretory medication, as well as significant improvement in their quality of life scores, compared to those before the intervention. However, the studies were case series that provide the lowest grade of evidence. In the studies reviewed, participants were highly selected for the procedure. Only patients with small or no hiatal hernias, no dysphagia, stricture, or Barrett's disease as well as those whose symptoms are controlled by pharmacological treatment were included in the studies. Moreover, the interpreters of the results were not blinded to the treatment, the follow-up duration was insufficient, dropout rate was high, and there were no comparison or control groups. In conclusion, there is insufficient evidence to determine the efficacy of the Stretta procedure in the treatment of GERD. Prospective randomized studies with larger sample sizes, comparison to another intervention or treatment, and a long follow-up duration will be needed.

**Articles:** The search yielded seven review articles and two empirical studies: (1) A RCT comparing radiofrequency ablation to sham treatment, and (2) A longitudinal non-randomized study comparing the procedure to fundoplication. *Evidence tables were created for these two studies as well as a patient registry published prior to 2003 that was not included in the earlier review:* Corley DA, Katz P, Wo JM, et al. Improvement of gastroesophageal reflux symptoms after radiofrequency energy: A randomized, sham-controlled trial. *Gastroenterol* 2002;125:668-672. See [Evidence Table](#). Richards WO, Houston HL, Torquati A, et al. Paradigm shift in the management of gastroesophageal reflux disease. *Ann Surg* 2003; 237:638-649. See [Evidence Table](#). Wolfson HC, and Richards WO. The Stretta procedure for the treatment of GERD: A registry of 558 patients. *J Laparoendosc Adv Surg Tech* 2002;6:395-402. See [Evidence Table](#).

The use of electro-surgical coagulation (radio-frequency application) in the treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

### **EndoGastric Solutions Stomaphy X™ Endoluminal Fastener, InScope™ Tissue Apposition System, Transoral Incisionless Fundoplication**

#### BACKGROUND

Obesity surgery: The EndoGastric Solutions StomaphyX™ endoluminal fastener and delivery system is a sterile, single-use device for use in transoral tissue approximation and ligation in the GI tract. The system consists of an ergonomic, flexible fastener delivery device and sterile polypropylene fastener implants. The device is introduced into the body through the mouth under endoscopic visualization. Once inside the stomach, the stomach wall is suctioned into the tissue port on the StomaphyX™ creating a large plication. Non-resorbable polypropylene fasteners are then deployed across the fold to hold the tissue in place. Typically 10 to 20 folds are required depending on the patient's anatomy. The pleats created in the stomach will reduce its size, which would potentially lead to early satiety and weight loss. According to the manufacturer, the StomaphyX™ procedure is incisionless, adjustable, and revisable. It is usually performed as an outpatient procedure, and is intended for individuals who want an alternative to invasive weight loss surgery, or those who have had previous gastric bypass surgery and are regaining weight. The EndoGastric Solutions StomaphyX™ endoluminal fastener and delivery system was cleared for marketing by the FDA in February 2007 for use in endoluminal trans-oral tissue approximation and ligation in the GI tract. The InScope™ Tissue Apposition System is a sterile, single patient used disposable suture system for approximating and securing soft tissue within the gastrointestinal tract. It is intended to perform suturing in conjunction with endoscopes having a working channel of 2.8 mm or larger. The system can be used to treat variety of defects endoscopically including ulcers and perforations (FDA Web site).

The InScope™ Tissue Apposition System was cleared by the FDA for marketing in January 2007 to be used for the placement of sutures and approximation of soft tissue. GERD: According to the Montreal Consensus, gastroesophageal reflux disease (GERD) is defined as a condition which develops when the reflux of stomach contents cause troublesome symptoms and/or complications. GERD is a mechanical disorder that is caused by a defective lower esophageal sphincter, a gastric emptying disorder, or failed esophageal peristalsis. Typical symptoms of GERD include heartburn and regurgitation; however, overtime reflux can cause ulceration, Barrett's esophageous, airway disease, and esophageal cancer. It is estimated that 40% of individuals in the United States suffer from GERD on a monthly basis. Current treatment options for GERD include long-term use of acid suppression medications or surgical intervention. While treatment with acid suppressing medications such as proton pump inhibitors and histamine 2-receptor blockers are effective, they do not treat the underlying mechanical disorder. Additionally, not all patients respond to these therapies (Zagol 2011, Stefanidid 2010). Surgery is another treatment option for patients with GERD. According to the Society of American Gastrointestinal and Endoscopic Surgeons (SAGES), surgical therapy should be considered in patients with a diagnosis of reflux who (Stefanidid 2010): Have failed medical management (due to inadequate symptom control, severe regurgitation not controlled with acid suppression, or medication side-effects). Opt for surgery despite medical management (due to quality-of-life considerations, lifelong need for medication intake, expense of the medication, etc.). Have complications of GERD (e.g., Barrett's esophagus, peptic stricture). Have extra-esophageal manifestations (asthma, hoarseness, cough, chest pains, aspiration). There are a variety of surgical procedures used for the treatment of GERD. Currently, there is no consensus on the best procedure for all patients. The choice of procedure is often based on anatomic considerations and expertise; however, the laparoscopic Nissen fundoplication has emerged as one of the most widely used techniques. With fundoplication, the gastric fundus is wrapped around the lower end of the esophagus to reduce gastric reflux. The fundal wrap can be either total (360°) or partial (less than 360°). Studies suggest that approximately 90% of patients who undergo Nissen fundoplication achieve symptom relief. Side effects of this procedure include dysphagia, hyperflatulence, inability to belch, bloating, and postsurgery bowel symptoms (AGA 2008, Stefanidid 2010). Transoral incisionless fundoplication using the EsoPHYX device (EndoGastric Solutions, Inc., Redmond, WA) has been proposed as a less invasive alternative to traditional surgical procedures. This procedure attempts to decrease the reflux of stomach acid into the esophagus through the reconstruction of an anti-reflux barrier. The EsoPHYX device is inserted transorally, under direct endoscopic visualization, into the stomach and is positioned at the junction of the stomach and the esophagus. Once positioned, the device uses suction and transmural fasteners to facilitate the recreation of the esophageal gastric valve. The result is an omega shaped valve 3-5 cm in length and 200-300° in circumference. This procedure may also reduce hiatal hernias that are less than 2 cm in size through the use of a built in vacuum invaginator. As this procedure is incisionless and can often be performed on an outpatient basis it is an attractive alternative to conventional surgical procedures (Jafri 2009, Louis 2010). The EsoPHYX system had been cleared by the FDA for use in transoral tissue approximation, full-thickness plication and ligation in the gastrointestinal tract for the treatment of GERD in patients with symptomatic chronic GERD who require and respond to pharmacological therapy. This device may also be used to narrow the gastroesophageal junction and reduce hiatal hernia ≤2 cm in size in patients with symptomatic chronic GERD. The EsoPHYX system has not been previously reviewed by the Medical Technology Assessment Committee and is being review based on request from bariatric surgery and a member appeal.

#### **04/09/2008: MTAC REVIEW**

##### **Endoluminar Fasteners**

**Evidence Conclusion:** There is insufficient published evidence to determine the efficacy and safety of the EndoGastric Solutions StomaphyX™ endoluminar fastener for weight loss. There is insufficient published evidence to determine the efficacy and safety of the InScope™ Tissue Apposition System for endoscopic gastric sutures.

**Articles:** The literature search did not reveal any published studies, on the EndoGastric Solutions StomaphyX™ endoluminar fastener and delivery system, or on the InScope™ Tissue Apposition System. Information about the systems was obtained from the FDA and the manufacturer's Web sites.

The use of endoluminar fasteners in the treatment of obesity does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **08/15/2011: MTAC REVIEW**

##### **Endoluminar Fasteners**

**Evidence Conclusion:** Two case-series were selected for review that evaluated the safety and effectiveness of transoral incisionless fundoplication (TIF) for the treatment of GERD. The first study followed 110 subjects for a median of 7 months and the second study followed 86 subjects for 12 months. The primary outcome in both of these studies was GERD Health-Related Quality of Life (GERD-HRQL). Both studies found significant reductions

in GERD-HRQL compared to baseline. However, results from these studies should be interpreted with caution as both studies were case-series (lowest-quality evidence). Serious adverse events included two perforations and a post-TIF intraluminal bleeding that required a blood transfusion. Other adverse events included: left shoulder pain, abdominal pain, sore throat, nausea, and epigastric pain (Barnes 2011; Cadière 2008). **Conclusion:** There is insufficient evidence to determine the safety and efficacy of transoral incisionless fundoplication for the treatment of GERD.

**Articles:** To determine the safety and efficacy of transoral incisionless fundoplication using the ExophyX system for the treatment of GERD. Screening of articles: No randomized controlled trials were identified that addressed the safety or efficacy of transoral incisionless fundoplication using the ExophyX system for the treatment of GERD. Studies were not selected for review if they included less than 25 subjects. The largest studies with the longest duration of follow-up were selected for review. The following studies were critically appraised: Barnes WE, Hoddinott KM, Mundy S, Williams M. Transoral incisionless fundoplication offers high patient satisfaction and relief of therapy-resistant typical and atypical symptoms of GERD in community practice. *Surg Innov* 2011; 18:119-129. See [Evidence Table](#). Cadière GB, Buset M, Muls V, et al. Antireflux transoral incisionless fundoplication using EsophyX: 12-month results of a prospective multicenter study. *World J Surg* 2008; 32:1676-1688. See [Evidence Table](#).

The use of endoluminal fasteners in the treatment of GERD does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Gynecomastia

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

See [Local Coverage Article: Cosmetic vs. Reconstructive Surgery \(A52729\)](#)

##### For Non-Medicare Members

Group Health has elected to use the Mastectomy for Gynecomastia (GHC-0273) MCG\* for medical necessity determinations.

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Gynecomastia is a unilateral or bilateral enlargement of the male breast due to benign proliferation of glandular elements. Pubertal gynecomastia resolves without intervention in the majority of cases. Gynecomastia in postpubertal males may be due to persistent pubertal gynecomastia, medications, liver disease, kidney disease, testicular tumors, or endocrine disorders. The cause remains undetermined in about 25% of cases. Male breast cancer is uncommon and usually presents as a discrete breast mass.

##### For Non-Medicare Members

###### A. The member must have **ONE of the following**:

1. A diagnosis of cystic fibrosis.
2. A diagnosis of bronchiectasis:
  - Characterized by daily productive cough for at least 6 continuous, months or, frequent (i.e. more than 2/year) exacerbations requiring antibiotic therapy, and
  - Confirmed by high resolution, spiral, or standard CT scan
3. Neuromuscular Disorder
  - Acid maltase deficiency
  - Anterior horn cell diseases, including amyotrophic lateral sclerosis
  - Hereditary muscular dystrophy
  - Multiple sclerosis
  - Myotonic disorders
  - Other myopathies
  - Paralysis of the diaphragm
  - Post-polio
  - Quadriplegia regardless of underlying etiology.

###### B. And meet **ALL of the following** criteria:

1. Well-documented failure of standard treatments to adequately mobilize retained secretions with all of the following:
  - Chest physical therapy and flutter device at least twice daily (when age appropriate)
  - A pattern of hospitalizations at least annually or more
  - Significantly deteriorating clinical condition
2. Be under the care of a pulmonologist
3. Had a rental trial to confirm compliance before purchase

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Conventional chest physical therapy (CPT), also known as percussion and postural drainage (P/PD) has traditionally been the standard of care of secretion clearance methods for patients with excessive or retained lung secretions. Depending on the severity of the disease or the presence of infection, CPT is performed in 1-3

sessions per day, each lasting between 23-30 minutes. These are administered by a physical therapist or a trained caregiver. CPT is labor intensive and time consuming, which could lead to poor compliance.

A number of airway clearing devices have thus been developed for independent use with little or no assistance by others. These include the high-frequency chest wall oscillation (HFCWO), which is an external non-invasive respiratory modality that mobilizes airway secretions from the small peripheral airways. The technique typically produces compression of the chest wall via an inflatable vest linked to an air pulse generator. The generator delivers an intermittent flow to the vest which rapidly compresses and releases the chest wall at a variety of frequencies. Consequently, an oscillation of airflow within the airways is achieved. The researchers believe that the underlying mechanisms include increased airflow-mucous interaction causing a reduction in viscoelasticity, production of airflow bias that promotes a cephalad movement of the mucous, as well as the enhancement and stimulation of ciliary activity (Osman 2010).

HFCWO is most commonly used for assisting mucous secretion in patients with disorders associated with abnormally thick mucous hypersecretion but preserved muscle function such as cystic fibrosis. It has also been advocated as an adjunctive therapy to assist cough clearance in patients with neuromuscular disorders who have relatively normal mucus but weak respiratory muscles (Chaisson 2006, Osman 2010, Finder 2010).

The FDA has cleared several airway clearing systems for delivering high-frequency chest wall oscillation to promote airway clearance and improve bronchial drainage in situations where physicians recommend external manipulation of the thorax. These systems include the Vest™ Airway Clearance System (also known as the ABI Vest or the ThAIRapy Vest, or the ThAIRapy Bronchial Drainage System), Medpulse Respiratory Vest System, and the FREQUENCER which produces sound wave stimulation to oscillate and loosen mucous secretion in the chest.

HFCWO is most commonly used with cystic fibrosis patients who have abnormally thick secretions. It has also been used for other conditions such as bronchiectasis. Another proposed application is treating patients with neuromuscular disorders, who may have impaired cough and may not be able to clear their airways. An inadequate cough in these patients can lead to atelectasis or pneumonia. Other possible treatments for airway clearance in patients with neuromuscular disorders include percussion and postural drainage (P&PD), the traditional procedure, autogenic drainage, positive expiratory pressure therapy, flutter valve and intrapulmonary percussive ventilation (IPV) (Panitch et al., 2006; Langenderfer, 1998).

Neuromuscular diseases are a heterogeneous group of inherited or acquired disorders characterized by progressive irreversible weakness of functional groups of skeletal muscles including the respiratory muscles necessary for ventilation and cough. Depending on the severity of the disorder, ineffective cough and clearing of respiratory secretions can present as frequent respiratory infections, pneumonias, and atelectasis. As the disorder progresses, the patients may develop spinal deformities, gas exchange abnormalities, sleep disorders, and cardiac dysfunction. These and any concomitant pulmonary disorder can severely compromise the existent muscle weakness and precipitate respiratory failure (Chaisson 2006, Yuan 2010).

The Vest™ Airway Clearance System (Hill-Rom, ST Paul, Minnesota), consists of a 1. Non-stretching inflatable cloth-like vest that covers the entire thorax and provides high frequency chest wall oscillation; 2. Large-bore tubing connects the vest to the air-pulse generator; and 3. An air pulse generator that creates pressure to inflate and deflate the vest against the thorax. The vest is inflated to a constant pressure to maximize the surface area over which high frequency (5-20 Hertz), small volume pressure impulses are transmitted externally to the entire chest area. Pressure pulses are controlled by the patient and applied during expiration. A typical treatment may last for 20-30 minutes, and consists of periods of compression separated by huff coughs (Chatburn 2007).

## Medical Technology Assessment Committee (MTAC)

### ThAIRapy/ABI Vest

#### 12/13/2000: MTAC REVIEW

**Evidence Conclusion:** The scientific evidence does not permit conclusions about the effect of the ThAIRapy/ABI Vest® on health outcomes. The two randomized trials had small sample sizes and threats to validity that make their findings inconclusive. The Arens study did not find differences between patients (n=50) randomized to the ABI Vest® compared to chest physical therapy, but this may have been due to low statistical power (the authors did not discuss statistical power issues). The Kluff study included only 29 individuals, had a brief intervention (4 days total), no “wash-out” period between the ABI vest and chest physical therapy interventions (patients had a different intervention each day), gave nebulized saline to the ABI vest but not the physical therapy group, and examined sputum weight, an intermediate outcome measure. The Warwick and Hansen study, an interrupted time

series design had the smallest sample size (n=16) and the validity was seriously threatened by possible selection bias. None of the available studies examined clinical outcomes such as pulmonary exacerbations or hospitalizations and no information was provided on short-term or long-term adverse health outcomes associated with the use of the ABI Vest®.

**Articles:** The search yielded 20 articles. 11 articles were not directly relevant or were review articles. Of the remaining 9 articles, 5 were randomized controlled trials (RCTs). The two RCTs with the largest sample sizes were selected for critical appraisal (the remaining three RCTs all had sample sizes of less than 20 patients). In addition, an interrupted time-series analysis with longer-term follow-up of patients was reviewed. Arens R, Gozal D, Omlin KJ, Vega J, Boyd KP, Keens TG, Woo MS. Comparison of high frequency chest compression and conventional chest physiotherapy in hospitalized patients with cystic fibrosis. *Am J Respir Crit Care Med* 1994; 150: 1154-7. See [Evidence Table](#). Kluft J, Beker L, Castagininio M, Gaiser J, Chaney H, Fink RJ. A comparison of bronchial drainage treatments in cystic fibrosis. *Pediatr Pulmonol* 1996; 22: 271-74. See [Evidence Table](#). Warwick WJ, Hansen LG. The long-term effect of high-frequency chest compression therapy on pulmonary complications of cystic fibrosis. *Pediatr Pulmonol* 1991; 11: 265-71. See [Evidence Table](#).

The use of ThAIRapy/ABI Vest® for treatment of cystic fibrosis does not meet the *Group Health Medical Technology Assessment Criteria*.

### **ThAIRapy/ABV Vestâ**

#### **10/08/2003: MTAC REVIEW**

**Evidence Conclusion:** There is no published empirical evidence on the use of the Vest™ Airway Clearance System for bronchiectasis. There is no new published evidence on the use of the Vest™ Airway Clearance System for cystic fibrosis. The summary of the evidence on the ABI vest from December, 2000 is: "The scientific evidence does not permit conclusions about the effect of the ThAIRapy/ABI vest on health outcomes. The two randomized trials had small sample sizes and threats to validity that make their findings inconclusive. The Arens study did not find differences between patients (n=50) randomized to the ABI vest compared to chest physical therapy, but this may have been due to low statistical power (the authors did not discuss statistical power issues). The Kluft study included only 29 individuals, had a brief intervention (4 days total), no "wash-out" period between the ABI vest and chest physical therapy interventions (patients had a different intervention each day), gave nebulized saline to the ABI vest but not the physical therapy group, and examined sputum weight, an intermediate outcome measure. The Warwick and Hansen study, an interrupted time series design had the smallest sample size (n=16) and the validity was seriously threatened by possible selection bias. None of the available studies examined clinical outcomes such as pulmonary exacerbations or hospitalizations and no information was provided on short-term or long-term adverse health outcomes associated with the use of the ABI vest."

**Articles:** The search yielded 6 articles. There were no new empirical studies on the Vest™ Airway Clearance System for cystic fibrosis. There were no empirical studies on the Vest™ Airway Clearance System for bronchiectasis.

The use of ThAIRapy/ABI Vestâ for treatment of cystic fibrosis does not meet the *Group Health Medical Technology Assessment Criteria*.

### **High Frequency Chest Wall Oscillation**

#### **02/04/2008: MTAC REVIEW**

**Evidence Conclusion:** There is no empirical evidence on the safety and effectiveness of the Vest™ Airway Clearance System for improving health outcomes in patients with neuromuscular disease.

**Articles:** The search yielded 11 articles. When limited to English language publications and human populations, there were 7 articles. Only 2 of the 7 articles, both of them reviews/opinion pieces, specifically addressed the topic of interest, airway clearance for patients with neuromuscular weakness. The remaining articles were on different, related topics. No empirical studies were identified. One of the review articles (Panitch, 2006) stated that HFCWO has not been studied in patients with neuromuscular disease.

The use of High-frequency chest wall oscillation (HFCWO) for treatment of neuromuscular deficiency does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **10/18/2010: MTAC REVIEW**

##### **High Frequency Chest Wall Oscillation**

**Evidence Conclusion:** The evidence on the use of high-frequency chest wall oscillation (HFCWO) therapy in patients with neuromuscular disorders is very limited and insufficient to determine the safety and effectiveness of the Vest™ Airway Clearance System for improving health outcomes in these patients. The published studies to date have very small sample sizes and short follow-up durations. Those with a control group have several threats

to their internal validity. Among these are unblinding, including heterogeneous groups of population, potential selection bias, insufficient power to detect significant differences between therapies, relatively high dropout rates, and/or analyses were not based on intention to treat. Additionally the studies were funded by the manufacturer of the airway clearance systems used.

**Articles:** The majority of published literature on high-frequency chest wall oscillation (HFCWO) was on its use for patients with cystic fibrosis and other obstructive airway diseases. The literature search for studies published after the last MTAC review of the technology for patients with neuromuscular disorders revealed only one small RCT that compared the use of HFCWO to the standard chest physiotherapy among a small group of pediatric population with cerebral palsy or neuromuscular disease. Yuan N, Kane P, Shelton K, et al. Safety, tolerability, and efficacy of high-frequency chest wall oscillation in pediatric patients with cerebral palsy and neuromuscular diseases: an exploratory randomized controlled trial. *J Child Neurol.* 2010;25:815-821. See [Evidence Table](#)

The use of High-frequency chest wall oscillation (HFCWO) for treatment of neuromuscular deficiency does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### High Intensity Focused Ultrasound (HIFU) for the treatment of localized Prostate Cancer

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Prostate cancer is the second most frequently diagnosed cancer across the globe (Wolff et al., 2015). A 2008-2010 data estimated that 15% of men in the United States will be diagnosed with prostate cancer at some point in their lives (Wolff et al., 2015). However, the mortality rate is low because it is a slow growing cancer.

Treatment is based on a number of factors including tumor stage, prostate specific antigen (PSA) value, Gleason score (GS), patient's age, concomitant diseases, life expectancy and patient's preference (Warmuth, Johansson, & Mad, 2010). A wide range of options are available for prostate cancer and these include active surveillance, watchful waiting, radical prostatectomy, hormone therapy, radiotherapy, external beam radiotherapy (EBRT), brachytherapy and chemotherapy (Wolff et al., 2015). High Intensity Focused Ultrasound (HIFU) and cryotherapy are being considered as treatment options.

HIFU is a procedure in which beams target localized tissue without destroying the surrounding tissue and the high energy produced by HIFU leads to coagulative necrosis (Dogra, Zhang, & Bhatt, 2009). Two mechanisms including hyperthermia and acoustic cavitation cause the destruction of the tissue (Kennedy, Ter Haar, & Cranston, 2014). First, high energy is produced and converted to heat as the ultrasound wave disseminates through the tissue. This high energy leads to extreme temperatures surpassing the threshold level of protein denaturation (>43 degree C) resulting in coagulative necrosis. In the surrounding areas of the target zone, temperatures decrease suddenly keeping the outside tissues unaffected. Second, the interaction between ultrasound and micro-bubbles of water in the sonicated tissue result in cavitation. Cavitation may lead to diffusion of energy reinforcing tissue destruction (Stride & Coussios, 2010).

For this procedure, a transducer, covered by a condom through which cooled water is circulated to cool the rectal wall, is inserted into the rectum and several images are taken. The transducers generate very precise small lesions destroying the prostate partially or completely (Cordeiro et al., 2012).

HIFU is non-invasive and non-ionizing technique that is believed to have some advantages over other thermal therapy such as cryotherapy, laser ablation, and photothermal therapy and radiofrequency interstitial tumor ablation (Cordeiro et al., 2012). Two types of systems have been approved by the Food and Drug Administration (FDA). These include the Sonablate 450 (developed by SonaCare Medical) and the Ablatherm HIFU (EDAP TMS SA) both of which received FDA approval in October and November 2015 respectively. HIFU is indicated for primary treatment and salvage treatment for localized prostate cancer.

#### Medical Technology Assessment Committee (MTAC)

##### *High Intensity Focused Ultrasound (HIFU) for the treatment of localized Prostate Cancer*

**MTAC REVIEW: 06/21/2016**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

**Evidence Conclusion:** INTC reviewed the technology in 2008 and concludes that there is insufficient evidence to determine whether the technology is medically appropriate for any patient and that the existing evidence regarding how HIFU treats prostate cancer is of insufficient quantity and quality. In April 2016, INTC conducted another review of the technology and concludes that: “the body of evidence that is available from which to assess the efficacy and safety of HIFU for localized prostate cancer (as primary and salvage therapy) is very low quality. The risk of bias in existing studies is high. Across studies, there is variation and/or lack of information regarding patient selection criteria, how HIFU was delivered, how outcomes were measured, and how long patients were followed”

INTC review can be adopted.

### **HIFU for Primary and Salvage therapy**

**Systematic Review of the Efficacy and Safety of High-Intensity Focused Ultrasound for the Primary and Salvage Treatment (Warmuth, Johansson, & Mad, 2010)** (evidence table 1) The aim of this study was to assess the efficacy and safety of HIFU in the primary and salvage treatment for prostate cancer. The primary outcomes were the biochemical disease-free survival rate, the negative biopsy rate, overall survival rates, prostate cancer-specific survival rates, adverse events, and QOL. The literature search was performed from 200 to 2010 and included 20 case series (with more than 50 participants) in which 93% of patients were treated with primary therapy and 7% for salvage HIFU. For all HIFU procedures, the biochemical disease-free survival rate was between 78% and 84%, 45%- 84%, and 69% at 1, 5, and 7 years, respectively. The negative biopsy rate was 86% at 3 months and 80% at 15 months. Overall survival rate and prostate-cancer specific survival rate were reported in 1 study and were 90% and 100% at 5 year and 83% and 98% at 8 year, respectively. Adverse events were mainly related to the urinary tract (1-58%), potency (1-77%) and rectum (0-15%).

The study has several limitations including the study design lacking control group, long term follow-up was not available and the quality of evidence of included studies was low, surrogate outcomes were used and the central question is whether surrogate outcomes corroborate with overall survival, QOL, and prostate cancer specific survival, and the possibility for publication bias. The evidence is of low quality; therefore results should be interpreted with caution.

**Ablative therapy for people with localized prostate cancer: a systematic review and economic evaluation (Ramsay et al., 2015)** (evidence table 2) This systematic review indicates that the biochemical failure rate of HIFU was higher (statistically significant) than that of EBRT at 1 year but no statistically significant difference was observed at 5 years. The results also indicate statistically significant lower rate of disease free survival for HIFU compared to EBRT at 1 year. At 4 years, overall survival was better for HIFU compared to EBRT. Compared to RP, there was an increased risk of biochemical failure for HIFU at 1 and 5 years. But this difference was not significant. Also, in term of disease free survival, no statistical significant difference was noted when HIFU was compared to RP at 1 year. At 3 years, the difference was not statistically significant. For urinary incontinence, erectile dysfunction, or bowel problems (not in the table), data were insufficient to reach a conclusion. Results were not statistically significant for dysuria or urinary retention. Nonetheless, high proportion of urethral stricture was observed for HIFU. When comparing HIFU to active surveillance (AS) (not on the table), there was no difference in overall survival or erectile dysfunction. The results are mixed and due to the poor quality of case series included in the review, with the lack of long term findings, the result should be interpreted with caution.

### **HIFU for Salvage therapy**

#### **High intensity focused ultrasound (HIFU) for definitive treatment of prostate cancer (Cordeiro et al., 2012)**

The purpose of this review was to update the available literature on HFU as definitive treatment of prostate cancer and to describe the techniques extensively and give an overview of historical background. Searched was conducted from 200 to December 2011. The search included case series with more than 50 participants assessing efficacy and safety of HIFU. No RCTs were identified and only 33 uncontrolled studies were identified. HIFU as salvage therapy after EBRT was assessed in two case series. The mean age was 68 years with mean preoperative PSA ranged from 6.89 to 7.73 ng/mL and Gleason score (GS) was  $\geq 8$ . Prostate volume preoperatively ranged from 18-21.4 mL; 34-56% received neoadjuvant androgen-deprivation therapy (NADT). Patients were followed for 15-18 months. The negative biopsy rate ranged from 73-80%; patients achieving PSA  $\leq 5$  ng/ml was 61% in one study; the mean PSA Nadir ranged from 1.97-2.38 ng/ml and disease free survival ranged from 38-53% (30 mos-36mos). In terms of complications, urinary retention represented 7.8%, urinary tract infections (1.4- 3.5%), urinary incontinence (7-31.5%), bladder stenosis (17%), rectal urethral fistula 3 weeks after HIFU (3-6%) and erectile dysfunction was not assessed. The authors concluded that HIFU seems to control cancer on the short to medium term with less adverse events compared to established therapies.

There was heterogeneity among the studies; individual studies are case series resulting in low quality evidence. In addition, long term data was not available. Therefore, results should be interpreted with caution.

### Additional studies

Subsequent studies (assessing HIFU as primary or salvage therapy) to the systematic reviews aforementioned were non-randomized controlled trial and did not compare HIFU to other treatment options. Accurate conclusions cannot be made from these studies. Summary of additional studies for HIFU as primary therapy: Nine non-RCTs (Aoun et al., 2015; Sebastien Crouzet et al., 2014; Dickinson et al., 2016; Feijoo et al., 2016; Ganzer et al., 2013; Liu & Chiang, 2016; Mearini et al., 2015; Uchida et al., 2015; van Velthoven et al., 2015) were examined and were for the most part observational studies. The sample size ranged from 50 to 1002; follow-up varied from 12 to 108 months. Of the nine studies, only two were comparative (Aoun et al., 2015; Liu & Chiang, 2016) and the findings from these two studies indicate: for Liu, 2016 (HIFU vs. cryoablation), no differences between biochemical recurrence rates were found; for Aoun, 2015 (HIFU vs. brachytherapy), similar survival outcomes were observed with greater biochemical recurrence free survival in the brachytherapy group. Summary of additional studies for HIFU as salvage therapy: Five observational studies (Baco et al., 2014; Sébastien Crouzet et al., 2012; Song et al., 2014; Uddin Ahmed et al., 2012; Yutkin et al., 2014) were examined; the sample size varied from 19 to 290; follow-up ranged from 19.8 months to 51.6 months and there was heterogeneity in the measures of outcomes. The survival rates varied as well.

### Conclusion:

- No RCTs comparing HIFU to other treatment options were identified.
- The available evidence is of low quality since it is represented by non-comparative, case series/observational studies.
- The overall concerns are the lack of control group and long term follow-up, the use of surrogate outcomes raising the question of consistency with overall survival and QOL, and the variations in patient populations and biochemical progression-free survival.
- Conclusion on efficacy and safety of HIFU for the treatment of localized prostate cancer or recurrent localized prostate cancer cannot be drawn at this time.

**Articles:** No RCTs were identified. The following articles are selected for critical appraisal: Systematic Review of the Efficacy and Safety of High-Intensity Focused Ultrasound for the Primary and Salvage Treatment (Warmuth et al., 2010) (evidence table 1) Ablative therapy for people with localized prostate cancer: a systematic review and economic evaluation (Ramsay et al., 2015) (evidence table 2) High intensity focused ultrasound (HIFU) for definitive treatment of prostate cancer (Cordeiro et al., 2012)

The use of High Intensity Focused Ultrasound (HIFU) for the treatment of localized Prostate Cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Homogenous Mobility Shift Assay (HMSA) (Anser™ IFX test) for Infliximab (Remicade) Antibodies

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

No review is necessary for Medicare members at this time

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Many chronic inflammatory diseases are mediated by up-regulation of the pro-inflammatory cytokine tumor necrosis factor-alpha ((TNF)- $\alpha$ ). Protein-based drugs that block TNF- $\alpha$  such as Infliximab (IFX), are effective in reducing the disease activity of these inflammatory disorders. IFX is a chimeric mouse-human monoclonal antibody approved by the FDA for the treatment of patients with Crohn's disease, ulcerative colitis, rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, and chronic severe plaque psoriasis. IFX is highly effective in inducing and maintaining remission in a large proportion of these patients. However, more than 30% of cases fail to respond to anti-TNF- $\alpha$  therapy, and 20-60% of those who initially respond, lose their clinical response over time despite maintenance treatment. This loss of response (LOR) usually requires escalation of the dose, shortening the interval between doses, change in the anti-TNF agent to regain the clinical remission, or switching to a non-anti-TNF therapy (Wang 2012, Nanda 2013, Wang 2013, FDA web page accessed August 26, 2013).

The reason for loss of response to IFX is still debatable, but the anti-drug antibody formation is believed to play an important role. IFX is a chimeric mouse/human IgG1 molecule and thus the antibodies are primarily directed against the murine fragment. Antibodies to IFX (ATI), also frequently called human antichimeric antibodies (HACAs), are reported to develop in up to approximately 60% of patients depending on the dosing schedule, administration of concurrent steroids or immunomodulators, and the method of measuring the antibodies in the blood. The antibodies can appear as soon as after the first IFX dose and can persist in the blood for up to 4.5 years even after discontinuation of the therapy. ATI may increase the drug clearance in treated patients and/or neutralize its effect. Researchers found that a lower serum IFX levels is associated with a significantly higher risk of loss of clinical response to the drug. This loss of clinical response and remission due to immunogenicity is a potential major limitation to IFX leading to clinical relapse, impaired quality of life, and increased cost of care. Anti-drug antibodies may also cause serum sickness and hypersensitivity reactions. Despite these observed associations, some researchers dispute the clinical relevance of anti-infliximab antibodies and question whether the presence of antibodies to TNF agents is directly correlated to the decreased efficacy. To date, there is insufficient knowledge about the factors influencing the formation of the antibodies, and on whether the immune reaction to IFX can be transient. It is assumed however, that once the antibody is initiated, it cannot be overcome (Afif 2010, Kopylov 2012, Vande Casteele 2013, Nanda 2013, Wang 2013).

It is suggested that accurate monitoring of the serum drug and anti-drug antibody levels should be an important part of therapy in patients receiving anti TNF- $\alpha$  drugs. However, there is no gold standard technique or test for the detection and quantitative measurement of anti-infliximab antibodies (ATI). Anti-drug antibodies and drug levels in the serum are assessed by the bridging ELISA method, or less commonly by the radioimmunoassay (RIA) method. Each of these two methods has its limitations; the main limitation of the bridge ELISA method is its inability to accurately detect the antibodies in the presence of the drug in the circulation due to cross interference

between the drug and the assay. This lowers the sensitivity of the test in detecting antibodies in the presence of IFX. Thus, ELISA can accurately measure the anti-drug antibodies only when there is no drug in the circulation, which limits its clinical utility. RIA method is limited by its complexity, safety concerns of handling radioactive material, and prolonged time needed to reach equilibrium for proper management (Wang 2012).

A novel Homogenous Mobility Shift Assay (HMSA) was recently developed and validated by group of researchers In San Diego (Wang and colleagues 2012) to quantitatively measure the induced ATI and IFX levels in serum samples of patients treated with infliximab. The Anser™IFX test is not ELISA-based and is believed to be able to measure both the serum concentrations of infliximab and infliximab antibodies in the presence of serum infliximab. In the HMSA, serum samples are acidified during sample preparation to dissociate drug-anti-drug-antibody (IFX-ATI) complexes, thereby allowing the detection of ATI in the presence of IFX and overcoming the limitation of bridge ELISA (Castele 2013).

## Medical Technology Assessment Committee (MTAC)

### Homogenous Mobility Shift Assay (HMSA)

#### 10/21/2013: MTAC REVIEW

**Evidence Conclusion: Analytic validity** There is insufficient evidence to determine the analytic validity of the existing tests for measuring the antibodies to IFX. There is no gold standard technique for anti-infliximab antibodies (ATI) measurement, and comparing the technical performance and accuracy of ATI assays in detecting ATI in the presence of IFX may be problematic. As indicated in the introduction the ELISA and RIA have their limitations, and there are no standards available for comparison. Several confounding factors can influence the measurement of these antibodies, and in turn the accuracy and reproducibility of the test. **Clinical validity** The results of studies that examined the association between ATI and clinical efficacy of IFX are inconsistent. While some studies showed that detectable levels of ATI using different ELISA methods or RIA were correlated with low concentrations or undetectable trough levels of IFX and higher rates of loss of response to IFX treatment, others showed no significant effect of ATI on loss of response. Two published meta-analyses (Lee et al, 2012 and Nanda et al, 2013) had conflicting results. Both had their limitations and pooled the results of randomized trials together with observational studies. In these studies, ATI was measured at one time point which may not capture its possible fluctuating, transient, or latent occurrence; different methods and assays, mainly ELISA, were used to measure ATI with no standardization; patients were on different IFX regimes (episodic or maintenance); and immunosuppressants were used among some, but not all patients. Lee et al' (2012), meta-analysis pooled the results of 18 studies to determine the prevalence of ATI, its effect on perfusion reactions and on disease remission rates among IBD patients treated with infliximab. The analysis included 9 RCTs, 5 cohort studies, and 4 retrospective studies with a total of 3,326 patients. The pooled results showed that patients who tested positive for ATI (using ELISA) were at increased risk of infusion reactions (RR= 2.07 [95% CI, 1.61-2.67]), but with no significant difference in the rates of remission compared to those who tested negative for ATI (RR=0.90, 95% CI 0.79-1.02). On the other hand the pooled results of the more recent meta-analysis (Nanda et al, 2013) of 13 studies involving 1,378 patients with IBD showed that the presence of ATI was associated with lower IFX serum levels and significantly higher risk of loss of clinical response (LOR) to IFX with a pooled risk ratio for LOR = 3.2 (2.0-4.9). The ATI was measured by different methods including double antigen ELISA, antihuman chain ELISA, immunochromatography-based ELISA, fluid-phase RIA, and western blot. The results of the meta-analysis however, have to be interpreted with caution due to the high risk of bias in the studies included, significant heterogeneity between studies, publication bias, and combining the results of randomized studies together with of observational studies. In addition, there were differences between studies in the method of assessing ATI, IFX dosing regimens, immunosuppressants use, and assessment of clinical response. The Anser IFX (HMSA) Wang and colleagues (2012) developed and validated a homogenous mobility shift assay (HMSA) to measure the serum levels of infliximab (IFX) and antibodies to IFX (ATI). They compared the performance of the newly developed IFX-HMSA to bridge ELISA, and measured the ATI levels with the new test in 100 patients with ELISA positive ATI and found a high correlation between the two methods. HMSA identified five false-positive samples from the bridging ELISA method. Intra-and inter-assay precision rates for ATI were <4% and <15% respectively which, are considered high. The cutoff point of the assay was determined using sera of 100 healthy subjects who were naïve to IFX. The mean values of ATI in patient serum samples were significantly higher than those in the drug naïve health controls (mean  $\pm$ SD=9.57 $\pm$ 11.43, vs. 0.73  $\pm$  0.29, p<0.0001). The area under the curve (AUC) was 0.986, the sensitivity was 95% (95% CI, 88.72-98.36%) The authors concluded that the HMSA-IFX method showed a high assay sensitivity, precision and accuracy. However, validation was performed by using bridging ELISA methodology which can only accurately measure the anti-drug antibodies when there is no drug in the circulation.

**Clinical utility** In a retrospective study, Afif and colleagues (2010) evaluated the clinical utility of measuring Human Anti-chimeric Antibody (HACA) concentration in patients with IBD treated with infliximab. They used recorded data for 155 patients treated in one center (from 2003-2008) who had ATI and IFX concentrations measured. Testing

for IFX and ATI levels was performed by ELISA at the discretion of the treating physician with no systematic strategy, and was not done for all patients receiving IFX. 72% of the initial tests were ordered by a single physician, and the assay(s) used were not defined. Indications for testing were mainly due to loss of response (49%), partial response (22%) and autoimmune or delayed hypersensitivity reaction (10%). There was no control or comparison group and according to the authors, the study population represented only a subset of the total population receiving IFX at the clinic, and the clinical response was abstracted through review of patients' charts using predefined clinical criteria. The use of validated instruments as Crohn's disease Activity Index, Harvey-Bradshaw Index and endoscopic improvement could not be obtained retrospectively. 47% of the patients were on immunosuppressives, and 43 patients (29%) had the dose or frequency of IFX increased before testing. 35 patients had positive ATI based on which, the dose was increased in 6 patients, and 12 were put on a different anti-TNF. The overall results suggest that change to another anti-TNF in these ATI positive patients was associated with a significantly higher complete or partial response than those who received a dose escalation (92% vs. 17%). The authors concluded that measurement of ATI and IFX concentrations had an impact on management and was clinically useful. These results have to be interpreted with caution due to the study design and its imitations. In addition, there was no control group to determine whether any change in management in the absence of ATI measurement would have a similar or different clinical outcome. It also to be noted that 29% of the patients had the dose or frequency of IFX increased before testing. A more recent study (Vande Casteele and colleagues, 2013), used the new HMSA to retrospectively measure 1,232 consecutive frozen serum samples of 90 patients with IBD treated in one center from 1999-2011. The HMSA confirmed ATI in 59% of the patients, this was transient (disappeared by time) in 28% and was sustained in 72% of the patients. All treatment decisions to optimize and to stop therapy were based on clinical grounds and C-reactive protein level without knowledge of infliximab trough levels (TLI) or ATI status. The results of the analysis show that 68% of the patients with sustained ATI needed to discontinue IFX treatment vs. 13% with transient ATI (RR 5.1, 95% CI, 1.4-19.0). The overall results suggest, but do not provide good evidence that ATI may be transient, and that optimizing the IFX dose in patients with low-level ATI may be useful. It also indicates that sustained ATI increases the risk of loss of response to IFX. Based on these results, the authors recommended measuring IFX trough levels at week 14 and at time of loss of treatment response, and only measure ATI at consecutive time points when the trough levels of IFX are undetectable or low. These results have to be interpreted with caution due to the nature of the study and its limitations. In conclusion there is insufficient evidence to determine analytic and clinical validity of HMSA in detecting ATI to IFX. There is also inconclusive evidence to determine that ATI measurement has a significant impact on management of patients treated with infliximab or significant effect on clinical outcomes.

**Articles:** The published literature on the validity and clinical utility of measuring the antibodies to infliximab (ATI) levels among patients treated with IFX agent is limited. The therapeutic effect of IFX and measuring of the drug and antibody levels were mainly studied for patients with inflammatory bowel disease (IBD). The search revealed one study on the development and validation of a HMSA test, two meta-analyses on the impact of anti-IFX among IBD patients, two observational retrospective studies on clinical utility of measuring the anti-chimeric antibody concentration (ACAC), as well two studies that compared different ELISA methods in their ability to detect ATI. The meta-analysis with more valid methodology, the validation study on the new Anser IFX (HMSA) test, and the larger observational study on the clinical utility of detecting ATI were selected for critical appraisal, Afif W, Loftus EV, Faubion WA, et al. Clinical utility of measuring infliximab and human anti-chimeric antibody concentrations in patients with inflammatory bowel disease. *Am J Gastroenterol.* 2010; 105: 1133-1139. ## Clinical Review Criteria

### Home INR Monitoring

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Home Prothrombin Time/International Normalized Ratio (PT/INR) Monitoring for Anticoagulation Management (190.11).</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

Group Health has elected to use the Prothrombin Time (INR) Home Monitoring Device (A-0650) MCG\* for medical necessity determinations.

**\*The MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting this service, please send the following documentation to support medical necessity:**

- Documentation of initial start date for warfarin
- Last 6 months of clinical notes from requesting provider &/or specialist (orthopedics, cardiology)

Home testing is usually not recommended for a frequency of more than once a week.

Additional software or hardware required for downloading data from home prothrombin time testing systems to computers for the management of anticoagulation will not be covered because each is considered a convenience item and not medically necessary.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Oral anticoagulation (OAC) therapy is used for the prophylaxis and /or treatment of thromboembolic complications of deep vein thrombosis, embolic stroke, pulmonary embolism, cardiac valve replacement, and atrial fibrillation, as well as postmyocardial infarction. The aim of the therapy is to maintain a level of anticoagulation that will prevent thromboembolic events without increasing the risk of hemorrhagic complications. Warfarin is an oral anticoagulant that interferes with the cyclic interconversion of vitamin K which in turn leads to depletion its dependant coagulation factors including prothrombin. It is estimated that more than a million patients are treated annually with warfarin in the USA (Koerner 1998).

In the USA, almost 40,000 mechanical heart valves are implanted annually. Mechanical valves are associated with a risk of thrombus formation and emboli. This risk is reduced by lifetime treatment with oral anticoagulants. Biologic implants on the other hand, have a lower thrombogenicity and do not require long-term anticoagulation. Thromboembolism, together with anticoagulant-induced hemorrhage, account for three fourths of all complications after mechanical heart valve replacement. These events were found to be associated with the intensity of oral anticoagulation therapy and fluctuation of international normalized ratio (INR) values. (Edmunds 1987).

Atrial fibrillation (AF), a common arrhythmia, is a leading cause of thromboembolism. It is common among the elderly, and its prevalence increases with age (1% among 60 year old population, 5% among those aged 70-75 and >10% for 80+ years patients. (Ezekowitz 1999). The incidence of ischemic stroke among these patients may be as much as six times higher than among others with no AF. Studies show that oral anticoagulants significantly reduce the rate of stroke among AF patients (Eldor 2002). However, older patients treated with OAC have a higher rate of bleeding mainly due to the slower metabolism of the drug, and its interaction with other underlying chronic health problems. These patients should thus have better monitoring, and more rigorous regulation of the OAC to optimize their therapy, and prevent intracerebral hemorrhages, and other bleeding complications.

The intensity of anticoagulation treatment also needs to be controlled closely due to the narrow therapeutic range of warfarin, the potentially life threatening effects of both over, and under-dosing, and its interaction with other drugs or foods like leafy green vegetables. Several other factors may affect the patients' response to warfarin control including compliance to therapy, underlying liver or kidney diseases, infections, diet, and others.

Oral anticoagulation therapy has been monitored for almost 50 years with the prothrombin time (PT) test. The test is easy to perform but its results may widely vary between institutions, and even within the same institution. In 1983 the WHO proposed the international normalized ratio (INR) in attempt to standardize PT measurements. The proposal was supported by the International Committee for Standardization in Hematology in 1985, and INR is the current standard for monitoring anticoagulation therapy. It is calculated as:  $INR = \frac{\text{patient PT}}{\text{mean normal PT}}$ . The recommended therapeutic INR range for oral anticoagulant therapy is 2.0-3.0 for the majority of indications. A higher range of 2.5-3.5 is recommended for patients with mechanical heart valves, and when therapy is recommended to prevent recurrent MI (Koerner 1998). Monitoring patients on OAC requires frequent testing, which in turn requires frequent venous punctures, and regular visits to a physicians' office or lab, as well as lab standardization. Patients on a stable OAC are seen every 4-6 weeks. It was found that at this rate of testing, 40-60% of the PT measurements fall in the desired therapeutic range (Hortskotte, 1998).

Patients using long-term OAC usually worry about complications, regular visits to the physician or lab, frequent venous punctures that may be difficult at times, dietary limitations, freedom at traveling, and other concerns that may affect their quality of life. There has always been an interest in developing an accurate faster and easier way to measure PT. Currently several monitors for finger stick testing of PT are available. These include CoaguChek, CoaguChek plus, ProTime Microcoagulation System, and Harmony INR Monitoring System. These monitors require only a finger stick whole blood rather than the citrated venous blood, and the patients can perform it at home. Among the other advantages of these systems is the immediate INR results, and convenience. In theory patient self-testing at home increases the duration when the patient is within the therapeutic INR range, increases compliance, and patient interaction with his physician, and allows better control of OAC, which in turn reduces morbidity and mortality.

Self-management or personal-self testing however is not suitable for everyone. Patients need to operate the machine, and self-sample blood, they have to be free from any major visual problems, tactile dysfunction, or severe tremors to be able to mechanically handle self-testing, they also have to be reliable and complying with the dosage algorithm.

After Joint Replacement Patients undergoing major orthopedic surgery; hip or knee arthroplasty, or hip fracture repair are in the highest risk category for venous thromboembolism (VTE) solely on the basis of the orthopedic procedure itself. Without prophylaxis, the rate of deep vein thrombosis or pulmonary embolism in these patients range from 40% to 84%, and is the most common cause of death. It is thus recommended to use some type of prophylaxis for total knee replacement (TKR), total hip replacement (THR), and hip fracture surgery. The currently available methods of thromboprophylaxis include intermittent pneumatic calf compression, elastic compression stockings, or the use of pharmacological agents.

Warfarin is the most commonly used pharmacological agent followed by low molecular weight heparin (LMWH). The American College of Chest Physicians (ACCP) recommends either adjusted-dose warfarin (INR range 2.0 to 3.0); started preoperatively or immediately after the hip or knee replacement, or SC LMWH therapy. The duration of thromboprophylaxis is controversial and varies widely between practices, ranging from 1-12 weeks postoperatively. Studies have shown a peak incidence of postoperative DVT two to three weeks after total hip arthroplasty. This, together with the shorter durations of hospitalization, extending the use of antithrombotic prophylaxis for up to 5 weeks is becoming more common ( Schuringa 1999, Geerts 2001, Frederick 2003, He Xing 2008).

The intensity of anticoagulation treatment needs to be controlled closely due to the narrow therapeutic range of warfarin, its interaction with several other drugs and foods, and the potentially life threatening effects of both over-

and under-dosing of the drug. Monitoring patients on oral anticoagulation (OAC) therapy requires frequent testing, which in turn requires frequent venous punctures, laboratory standardization, and regular clinical visits.

There is an ongoing interest in developing a faster and easier way to accurately measure prothrombin time (PT). Currently several home testing systems have received FDA approval for use. These include CoaguChek, CoaguChek plus, ProTime Microcoagulation System, INRatio Prothrombin Time Monitoring System, Harmony INR Monitoring System, AcuSure, and Rubicon. These monitors may be used at home and only require a fingerstick whole blood rather than the citrated venous blood. They also give immediate INR results. In theory, patient self-testing at home increases the duration within the therapeutic INR range, increases compliance, patient interaction with his physician, and allows better control of OAC which reduces morbidity and mortality. Personal self-testing with or without self-management is however is not suitable for everyone. Patients have to be reliable and free from any major visual problems, tactile dysfunction, or severe tremors to be able to mechanically handle self-testing. They also have to comply with the dosage algorithm.

## Medical Technology Assessment Committee (MTAC)

### Home INR Monitoring

#### 08/13/2003: MTAC REVIEW

**Evidence Conclusion:** Ideally the outcomes of randomized controlled studies for the effectiveness of a test should demonstrate its effect in altering treatment, and improving the health outcomes. Two important health outcomes, bleeding and thromboembolism, were only studied in ESCAT (Kortke 2001), and time in the therapeutic range, an intermediate outcome, was used in all other studies. Kortke et al, in the ESCAT randomized controlled trial, followed 600 patients with mechanical heart valves for at least 2 years (25-51 months). They evaluated the event rates, as well as time in the therapeutic range. Less than 10% of the randomized sample took part in the 25-30 month follow-up. Patients in the self-management group had significantly less overall grade III complications (severe hemorrhage or thromboembolism) compared to those in the standard care group. The trial also showed that significantly more measurements were in the therapeutic range among patients in the self-management group. Sawicki's RCT in which 84% of the participants had heart valve replacement, also showed that a higher proportion of patients in the self-management group were within the INR target range compared to those in the routine care group. This difference was only statistically significant at three months of follow-up but not after six months. In Watzke's trial, 57% of the patients had mechanical heart replacement, and 24.5 % had atrial fibrillation. It also showed that a higher proportion of measurements among patients in the self-management group were in the therapeutic range vs. those in the standard care group, however the P value was not provided. Eldor's study on elderly patients with atrial fibrillation was too small, non randomized and had insufficient power to detect any difference between the groups. In conclusion there is some evidence that selected patients with mechanical heart valve replacement, who self-monitor their PT, and self manage their OAC therapy, have better control of their INR values, than those receiving a standard care. Only one trial with several limitations, showed some benefit in reducing the severe complications associated with OAC treatment. The other studies had insufficient sample sizes, and follow-up durations to study that outcome. It is worth noting that the studies were conducted among selected groups of patients and cannot be generalized to all patients with mechanical heart replacement. There is insufficient evidence to determine the effect of home INR monitoring on patients with atrial fibrillation.

**Articles:** The search yielded 28 articles. Many were reviews and tutorials. Abstracts, and studies conducted to evaluate the accuracy of the portable PT monitoring systems were not reviewed. The purpose of this review is assessing the home use of the monitors for patients with mechanical heart valves, or atrial fibrillation, and not for evaluating the portable systems that have been in use since 1987 (known as point of service). There were three randomized controlled trials, and three non-randomized controlled studies on self-testing/home INR monitoring. Trials conducted among patients with mechanical heart valves, or atrial fibrillation were selected. *The following articles was critically appraised:* Kortke H, and Korfer R. International Normalized Ratio self-management after mechanical heart valve replacement: is an early start advantageous? *Ann Thorac Surg* 2001; 72:44-48. See [Evidence Table](#) Sawicki PT. A structured teaching and self-management program for patients receiving oral anticoagulation. A randomized controlled trial. *JAMA* 1999; 281:145-150. See [Evidence Table](#) Watzke H.H, Forberg E, Svolba G, et al. A Prospective Controlled Trial Comparing Weekly Self-Testing and Self-dosing with the Standard Management of Patients on Stable Oral Anticoagulation. *Thromb Haemost* 2000; 83: 661-665. See [Evidence Table](#) Eldor A, and Schwartz J. The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does not meet the *Group Health Medical Technology Assessment Criteria*.

#### 08/01/2005: MTAC REVIEW

## Home INR Monitoring

**Evidence Conclusion:** Ideally the outcomes of randomized controlled studies for the effectiveness of a test should demonstrate its effect in altering treatment, and improving the health outcomes. Clinical endpoints for studies on self-management of anticoagulation therapy would be bleeding and thromboembolic complications. However, time within therapeutic INR range was used by some studies as a surrogate outcome to assess the quality of treatment based on self-management. In ESCAT I study (Koertke 2001) previously reviewed, 1,200 patients 6-11 days after a mechanical heart replacement were randomly divided into two groups: one monitored by family physicians, and the other controlling INR values at home. Patients were followed for at least 2 years (25-51 months) and the primary outcome was the rate of thromboembolic events and hemorrhage, and stability of INR values. Six hundred patients (50% of the randomized sample) were included in the analysis, dropouts and deaths were not included, and analysis was not based on intention to treat. The results of the trial showed that patients in the self-management group had significantly less overall grade III complications (severe hemorrhage or thromboembolism) compared to those in the standard care group. It also showed that significantly more measurements were in the therapeutic range among patients in the self-management group. ESCAT II study (Koertke 2003) was a large (N=3,300), multicenter RCT that randomized patients to two INR targets for self-management. The primary outcomes were the rate of thromboembolic events and hemorrhage, and the stability of INR values. It is an ongoing trial and the published articles only present the interim analysis with data on 55% of the total sample size. The investigators compared the results of the two INR targets for self-management in this trial, and included data on thromboembolism and bleeding for the group controlled by general practitioner from ESCAT I study, which is not a valid comparison. ESCAT I was conducted years earlier, in a single center, and on a different group of patients. In this latter study, patients in the self-managed group had a higher mean INR value (3.0) compared ESCAT II study (2.8 for the conventional-dose INR, and 2.4 in the low-dose INR patients with aortic valve replacement). Overall, the interim results of ESCAT II study show that 72% to 74% of the patients in the low and conventional INR range, respectively, were within target range. The bleeding and thromboembolic rates were <1% in each of the two groups. There was no difference between them in thromboembolic rates, and the difference in the bleeding rates did not reach statistical difference. There is no new evidence to determine the effect of home INR monitoring on patients with atrial fibrillation.

**Articles:** The search yielded 20 newer articles many of which were reviews and editorials. Studies conducted to evaluate the accuracy of the portable PT monitoring systems were excluded. The purpose of this review is to assess the home use of the monitors for patients with mechanical heart valves or atrial fibrillation, and not for evaluating the portable systems that have been in use since 1987 (known as point of service). There were two publications on one large randomized controlled trial (ESCAT II) that compared two INR targets for self-management of anticoagulants after mechanical valve replacement, a small RCT that included patients with different indications for anticoagulation, and small case series with intermediate outcomes. SMART, a large ongoing trial on self-management of anticoagulation was also identified but no results were published to date. The ESCAT II trial was critically appraised: Kortke H, Minami K, Boethig, et al. INR self-management permits lower anticoagulation levels after mechanical heart valve replacement. *Circulation* 2003;108 II:75-78. Kortke H, Zittermann A, Minami K, et al. Low-dose International normalized ratio self-management: A promising tool to achieve low complication rates after mechanical heart valve replacement. *Ann Thorac Surg* 2005;79:1909-1914.

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does not meet the *Group Health Medical Technology Assessment Criteria*.

## 08/07/2006: MTAC REVIEW

### Home INR Monitoring

**Evidence Conclusion:** The previous MTAC reviews of home INR monitoring showed some evidence that selected patients with mechanical heart valve replacement who self-monitor and manage their OAC therapy, may have better control of their INR values, than those receiving standard care. All studies were conducted among selected groups of patients and the results might not be generalized to all patients with mechanical heart replacement. There was insufficient evidence to determine the safety and efficacy of home INR monitoring on clinically important outcomes as thromboembolic events, major hemorrhage, and death. There was also insufficient evidence to determine the benefit of home INR monitoring in patients with atrial fibrillation. Heneghan et al's recent meta-analysis (2006) assessed the effects of self-monitoring with/ or without or self-management of anticoagulation compared with standard monitoring. The meta-analysis had valid methodology, was well-conducted, and 10 out of the 14 studies it included were judged to be of good quality. The authors also performed a sensitivity analysis by excluding the studies with the lowest quality. However, the control groups in the trials received their routine care in different settings. The results of a recent meta-analysis (van Walraven, 2006) showed that the study setting has a major influence on anticoagulation control. Moreover, the majority of the trials included in Heneghan's meta-analysis, provided education and training sessions only to the patients randomized to self-testing, not to the entire study population. Education increases awareness, motivation, and may modify the patient's attitude and behavior. The education and training were given after randomization, and those who could

not complete the training sessions or were incapable of self testing and/or self-management either left the study or were transferred to the routine care group. This resulted in a high dropout rate (20% to > 30%) in the intervention groups, and intention to treat analysis was not conducted in all the trials, which could overestimate the observed results. Ideally, training would be performed prior to randomization to eliminate those who are unable to complete it, and/or are incapable of self testing or self-management, from participating in the trial. The results of this meta-analysis indicate that the thromboembolic events, major bleeds, and death rates were significantly lower in the self-monitoring groups versus the controls who were managed by their personal physicians, anticoagulation management clinics, or managed service. Those who both self-tested and self-adjusted their therapy dose had significantly lower thromboembolic events and mortality rates but a non-significant reduction in the rate of hemorrhage. The difference in thromboembolic event rates was not significant between the intervention and control groups in the pooled results of the 3 trials conducted among patients with mechanical heart valves. The authors did not report on the difference in major hemorrhage or death rate among these patients, and no subgroup analysis was provided for patients with atrial fibrillation. Kaiser Permanente INTC recalculated some of the results of Heneghan's meta-analysis using ITT analysis, and found no significant differences between the intervention and routine care group in the percent of subjects with a mean INR in the therapeutic range, and in the major hemorrhagic events in the self-management vs. those receiving care in AMS (anticoagulation management services). Fitzmaurice, et al's (2005) study was a relatively large, multicenter, randomized, and controlled trial. However, it had several limitations and potential biases. Less than 25% of the eligible patient agreed to participate in the trial, and were actually randomized to the study groups. Training on self-testing was given after randomization and only to the intervention group not to the entire population, which resulted in a higher dropout rate (43%) in the self-management group compared to 11% of those in the routine care group. Those who were considered incapable of self managing withdrew from the trial or were returned to the routine care group. The study population who self-selected to enroll was younger and included more men than the eligible population. Moreover, participants in the intervention group tested their INR more frequently than those in the routine care group (mean every 12 days vs. 38 days) group, and apparently received more care, which is another potential source of bias. Patients in the routine care group were managed in a variety of models including anticoagulation clinics, hospital outpatient clinics, and primary care clinics which may have an influence on their anticoagulation control, and outcomes. Overall the results of this RCT show no significant differences between the intervention and routine care groups in the percent of time spent within therapeutic INR range (primary outcome) or in the rates of serious bleeding, or serious thrombosis. Patients in a target INR of 3.5 had poorer control before and during the study compared to those with target INR of 2.5. However patients in the intervention group with a 3.5 target INR showed a significant improvement between the pre-study and study periods. No such improvement was observed for those with a 2.5 INR target in either group, or those with a 3.5, target in the routine care group. These results of the Heneghan's meta-analysis and Fitzmaurice's RCT may not be generalizable to all patients treated with long-term oral anticoagulants. The study participants were highly motivated, mainly younger, willing to take and complete a structured training course on self-management, and capable of performing self-testing correctly and reliably.

**Articles:** The search revealed 7 newer randomized trials that were published after the last review, as well as a meta-analysis of RCTs that assessed the effects of self-monitoring or self-management of anticoagulation compared with standard monitoring. Only three of the recent RCTs were relevant (Fitzmaurice 2005, Voler 2005, and Menedez-Jandula 2005). The latter two were included in the meta-analysis. Studies conducted to compare two home INR monitors, or to evaluate the accuracy of the portable PT monitoring systems were excluded. The purpose of this review is to assess the home use of the monitors for patients receiving long-term anticoagulation treatment, and not for evaluating the portable systems that have been in use since 1987 (known as point of service). Two ongoing trials were also identified: 1. Self-Management of Anticoagulation, a Randomized Trial (SMART) which is a large multicenter trial on self-management of anticoagulation and, 2. The Home INR Study (THINRS) with more than 400 patients from VA Medical Centers with atrial fibrillation and/or mechanical heart valve who are expected to be anticoagulated indefinitely. The trial compares anticoagulation (AC) management using home monitoring devices to high quality management implemented by an AC service. It will have a minimum of 2 years of follow-up, and the primary outcome is event rates (stroke, bleeding or death). Heneghan's (2006) meta-analysis and the RCT that was not included in the meta-analysis were critically appraised. Heneghan C, Alanzo-Coello P, Garcia-Alamino JM et al. Self-monitoring of oral anticoagulation: a systematic review and meta-analysis. *Lancet* 2006; 367:404-11. See [Evidence Table](#) Fitzmaurice DA, Murray ET, McCahon D, et al. Self-management of oral anticoagulation: randomized trial. *BMJ* 2005;331:1057- See [Evidence Table](#)

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does meet the *Group Health Medical Technology Assessment Criteria*.

## **12/01/2008: MTAC REVIEW**

### **Home INR Monitoring**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

**Evidence Conclusion:** There is insufficient published evidence to determine the safety and efficacy of home INR monitoring for thromboprophylaxis warfarin therapy post knee or hip replacement surgery. An ideal study would be a randomized controlled trial that compares health outcomes of home INR monitoring of the warfarin dose to routine monitoring in hospital or anticoagulation management services. The trial should address the effect of INR home monitoring on altering treatment, and preventing thromboembolism without increasing bleeding risks. The only published study on home thromboprophylaxis with warfarin anticoagulation therapy after hip and knee replacement surgery was a case series that studied the efficacy of a program designed to maintain the prophylactic anticoagulant oral therapy within the target range. The patients did not monitor their own INR or adjust their own therapy. Instead it was coordinated between Home Care and community laboratory, and dose adjustments were made by the patient's family physician. Yet the program failed to achieve the target INR in almost 60% of cases during the six weeks postoperatively. Conclusion There is insufficient evidence to determine that: Home INR monitoring after joint replacement surgery increases the percentage of time spent within the therapeutic INR range, compared to routine care. Home INR monitoring, vs. routine care, after joint replacement surgery is effective in reducing the deep vein thrombosis and pulmonary embolic events rates, without increasing hemorrhagic events.

**Articles:** The search did not reveal any RCT that compared outcomes of monitoring of INR post joint replacement at home vs. in the hospital or anticoagulation management centers. There was only one published empirical study on the home prophylaxis with warfarin after hip and knee arthroplasty. Schuringa P, Yen D. Home prophylactic warfarin anticoagulation program after hip and knee arthroplasty. Can J Surg. 1999;42:360-362. See [Evidence Table](#)

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does meet the *Group Health Medical Technology Assessment Criteria*.

# Clinical Review Criteria

## Phlebotomy Service in the Home Setting

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

Phlebotomy services in the home setting for medically indicated laboratory tests are covered when the patient meets the following criteria:

- 1) The patient is under the care of a physician – the order for the laboratory test must be signed by a licensed ARNP, MD or DO.
- 2) It is not possible to coordinate the phlebotomy service with a clinic visit.
- 3) Patient must be **confined to the home**.

**Note:** Homebound comprises **three** criteria:

- a) Patient must be essentially homebound, i.e., there exists a normal inability to leave home and, consequently, leaving home would require a considerable and taxing effort and the assistance of another person or use of an assistive device.
- b) Confinement must be related to a medical or physical condition.
- c) Any absence of an individual from the home attributable to the need to receive health care treatment, including regular absences for the purpose of participating in therapeutic, psychosocial, or medical treatment in an adult day-care program shall not disqualify an individual from being considered to be confined to their home. Any other absence of an individual from the home shall not so disqualify an individual if the absence is of infrequent or of relatively short duration. An absence for the purpose of attending a religious service shall be deemed to be an absence of infrequent or short duration.

#### Examples of homebound are as follows:

- A patient who is blind or senile and requires the assistance of another person to leave his/her residence.
- A patient who has just returned from a hospital stay, involving surgery and suffering from resultant weakness and pain.

#### Examples which don't meet the definition of homebound:

- Patient doesn't drive or have a car available.
- An aged person who does not often travel from their home because of feebleness/insecurity brought on by advanced age would not be considered confined to their home for purposes of receiving home health services unless they meet one of the above conditions.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Phlebotomy services are a covered benefit in Group Health benefit plans. In most circumstances this service is available at the local medical center. There are a few patients for which travel to the medical center is not possible because of physical impairments. The home health benefit does not cover in home phlebotomies in the absence of receipt of other qualifying skilled services. The criteria are developed for those patients who are not eligible for home health services and yet are unable to come to the clinic for laboratory tests. (NOTE: the home health benefit does not cover in home phlebotomies in the absence of other qualifying skilled services – see the [home health admission criteria document](#).)

### Home Pulse Oximetry – Rental for Home Use

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

##### Local Coverage Article

##### [Oxygen and Oxygen Equipment – Policy Article – A33677](#)

“Oximeters (E0445) and replacement probes (A4606) will be denied as non-covered because they are monitoring devices that provide information to physicians to assist in managing the beneficiary's treatment.”

##### For Non-Medicare Members

Covered for all Commercial Groups (with DME benefit) in the home when the following criteria are met:

- 1) The patient has a clinical condition that is characterized by sudden or frequent fluctuating oxygen levels that are clinically significant.
- 2) The device will be used to measure oxygen level in order to determine treatment.
- 3) The caregiver has been trained in the use of the equipment and how to address changes in oxygen level.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

The pulse oximeter is a completely noninvasive device that provides a means of continuous and quick real-time estimates of arterial oxygen saturation (SaO<sub>2</sub>). It has been validated relative to transcutaneous oxygen tension, and arterial blood gas measurement. (Fanconi, 1985). The device estimates arterial hemoglobin saturation by measuring the light absorbance of pulsating vascular tissue at two wavelengths. It is easy to use and interpret, and does not need any special training or new skills on the part of the user. It also requires a little setup time, and adds no risk to the patient.

Pulse oximetry is becoming a standard of practice during general anesthesia in the United States (Eichhorn, 1986). It is also used as an independent monitor in emergency rooms and intensive care units. Other clinical applications of the device include monitoring patients during transport, respiratory monitoring during narcotic administration, and the evaluation of home-oxygen therapy.

The pulse oximeter however, has some limitations; it does not provide an early warning of decreasing arterial oxygen tension (PaO<sub>2</sub>), and may fail to detect an inadvertent endobronchial intubation in the operating room. It also cannot distinguish more than two hemoglobin species in the blood, thus methemoglobin, and carboxyhemoglobin will cause errors in the pulse oximeter saturation (SpO<sub>2</sub>) if present in large amounts. Artifacts signals created by patient motion or external light may also create a technical problem and interfere with the device in estimating the oxygen saturation. It was also reported that circumstances that reduce the amplitude of finger pulsation e.g. hypothermia, hypotension, or the administration of a vasoconstrictive drug would adversely affect the accuracy of the device (Yelderman, 1983).

The home pulse oximeter is being reviewed due to several requests received by Clinical Review for coverage for adult patients with progressive pulmonary disease, pediatric patients with RVS, or patients being discharged home but requiring continued monitoring to ensure stability in the home.

#### Medical Technology Assessment Committee (MTAC)

##### Home Pulse Oximetry

##### 10/08/2003: MTAC REVIEW

**Evidence Conclusion:** There are insufficient published studies to provide evidence on the home use of pulse oximeters among adults or children with respiratory failure or chronic pulmonary disease.

**Articles:** The search yielded 46 articles. A large number was not related to home monitoring of oxygen saturation, and a few addressed the home use of pulse oximetry for the diagnosis of sleep apnea. The search did not reveal any empirical study conducted among adults with chronic obstructive lung disease using home pulse oximeter to monitor their oxygen saturation. The search revealed three small case series conducted among either healthy infants to assess their oxygen saturation during the first six months or among infants with bronchopulmonary dysplasia receiving home oxygen therapy. None of the studies was critically appraised.

The use of home pulse oximetry in the management of oxygen levels for adults or children with respiratory failure or chronic pulmonary disease does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

Group Health has elected to use the Home Oxygen (GHC-0343) MCG\* for medical necessity determinations.

\*MCG are proprietary and cannot be published and/or distributed. However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

**If requesting this service, please send the following documentation to support medical necessity:**

- Last 6 months of clinical notes from requesting provider and/or specialist (palliative care, primary care, pulmonary care)
- Most recent Pulse Oximetry documentation and/or most recent at rest &/or activity log

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

In 1986, Group Health Cooperative experienced an increased use of home oxygen and could find no clinical evidence in patient charts that would support the use of oxygen. In addition, once a patient was placed on home oxygen they were never re-tested to verify continued need of the treatment. In 1989, a task force was initiated to review use and develop clinical indications for use at Group Health. The task force reviewed the current literature and adopted the Medicare home oxygen criteria. In addition, they defined several situations where exceptions would be appropriate. The program was initiated for review of all home oxygen requests, and to set up testing and re-testing programs. The program was submitted to Medicare for approval. Medicare not only approved it, but also adopted several of its most critical features such as the re-testing program.

## Clinical Review Criteria

### Hyperbaric Oxygen Therapy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Hyperbaric Oxygen Therapy (20.29)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

Hyperbaric oxygen may be indicated with a confirmed diagnosis of **ONE or more of the following**:

1. Chronic severe diabetic ulcer, and need for initial treatment, as indicated by **ALL of the following**:
  - a. Must have complete evaluation and treatment for any underlying peripheral vascular or neuropathic disease. To assess vascular status there must be a documented exam of femoral, popliteal, dorsalis pedis and posterior tibial pulses. If absent or reduced, must have documented ABI Scores. If questionable accuracy of ABI score, due to diabetes, a vascular surgeon consult is needed.
  - b. Minimal to no healing present despite conventional wound treatment for minimum of 30 days, including **ALL of the following**:
    - Documentation of adequate diabetic control and most recent HbA1C
    - Pressure reduction or offloading for at least 8 weeks. (Must have documentation at each visit of the use (or of noncompliance) of walker boot, knee, scooter, or wheelchair)
    - Topical wound treatment. Need documentation regarding what specific products have been used, duration, and effectiveness (ie apligraf, dermagraph, saline, hydrogels, hydrocolloids, alginates, or wound vac)
    - Appropriate wound debridement (practitioner must have appropriate training to perform) and
    - Wound is not infected and if the wound was previously infected, the wound has been treated with appropriate antibiotics (may need infectious disease consult)
  - c. Severe wound documented by (Medicare) Wagner grading, as indicated by **one or more of the following**:
    - Grade 3 ulcers are deep and involve abscess(es), osteomyelitis (bone infection) and/or joint sepsis.
    - Grade 4 ulcers include gangrene (decay of body tissues) in the forefoot (anterior third of the foot) or heel region(s).
    - Grade 5 ulcers involve extensive gangrene.
  - d. Transcutaneous tissue oxygenation (PtcO<sub>2</sub>) levels of **one or more of the following**:
    - PtcO<sub>2</sub> of 25 mm Hg (3.3 kPa) or greater on room air
    - PtcO<sub>2</sub> value less than 25 mm Hg (3.3 kPa) on room air that meets **one or more of the following**:
      - i. PtcO<sub>2</sub> increase of more than 20 mm Hg (2.7 kPa) while breathing 100% oxygen via face mask at normal atmospheric pressure or
      - ii. PtcO<sub>2</sub> increase of greater than 200 mm Hg (26.6 kPa) in chamber during hyperbaric oxygen therapy
2. Chronic severe diabetic ulcer, and need for continued treatment, as indicated by **ALL of the following**:
  - a. Adherent to hyperbaric oxygen therapy
  - b. Documented evidence of improvement after 24 visits and need for continuing improvement after that point
  - c. Fewer than 40 total treatments
3. Decompression illness or suspected intravascular gas embolism
4. Carbon monoxide (CO) poisoning is unconscious and has a carboxyhemoglobin level over 40%.

5. Central retinal artery occlusion
6. Gas gangrene (inpatient only)
7. Idiopathic sudden sensorineural hearing loss (will need 20 visits maximum).
8. Clostridial and non-clostridial myonecrosis: Plan of care indicates use will be in conjunction with other medical/surgical therapies and will not interfere with or delay surgical debridement. (provided for hospital inpatient only)
9. Necrotizing soft tissue infections (provided for hospital inpatient only)
10. Osteoradionecrosis as indicated by **ONE or more of the following**:
  - a. Mandibular/maxillary osteoradionecrosis (diagnosis is typically made by a clinical exam with exposed bone, and/or by imaging). History of previous radiation therapy to the mandible or maxilla of at least 5,000-7,000 rads.
  - b. Osteoradionecrosis in other sites, as an adjunct to conventional treatment. Osteoradionecrosis presents some months/years after radiation (sternum, long bones).
  - c. 30 pre/10 post treatments
11. Soft tissue radionecrosis as an adjunct to conventional treatment: Typically bowel, bladder, larynx or wounds in area of prior radiation therapy. Must wait 6 months post completion of radiation therapy. Requires visualization of the damaged area with serial exams to monitor progress (e.g. cystoscopy, laryngoscopy, sigmoidoscopy). Additional health plan review if 30 treatments are exceeded. (40 max). Total radiation dose and field must be documented. Must have **ONE of the following**:
  - a. Radiation-induced proctitis diagnosed by sigmoidoscopy
  - b. Radiation-induced hemorrhagic cystitis diagnosed by cystoscopy
  - c. Radiation-induced head and neck soft tissue injury – soft tissue radionecrosis, typically of the larynx, or in a radiated field.
12. Dental extractions must meet **ALL of the following**:
  - a. Clinical plan on file from the dentist/oral surgeon detailing planned extractions timeline
  - b. History of at least 5,000-7,000 rads received to the teeth planned for the extraction
  - c. 20 pre/10 post treatments
13. Chronic refractory osteomyelitis, unresponsive to both conventional medical and surgical treatment. Must have a prior infectious disease consultation and surgical consultation regarding debridement. Any hardware should be removed if feasible. Not indicated for acute osteomyelitis. If involves a distal toe, requires physician consultation prior to auth. Any treatments beyond 30 should have physician consultation. Pelvic bone osteomyelitis from decubiti requires debridement and flap surgery and does not respond well to hyperbaric.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Hyperbaric oxygen therapy consists of placing a patient inside a pressurized chamber in which the patient breathes 100% oxygen under a pressure of greater than one atmosphere. Generally, there is a gradual increase to approximately two-and-a-half times the normal atmospheric pressure. Patients receive up to 40 treatment sessions lasting between 45 and 300 minutes. There are monoplace chambers for one person and multi-place chambers that can accommodate two or more patients. (Leach et al, 1998; Porter & Brian, 1999).

Hyperbaric oxygen therapy has both a mechanical (pressure) and physiological (oxygen) component. The increased pressure causes compression of gas bubbles in the body and is useful for conditions such as decompression illness. Breathing 100% oxygen at increased pressure allows more oxygen to reach non-healing tissue, and helps to prevent tissue from dying to a lack of oxygen and blood (Porter & Brian, 1999).

Potential adverse events of hyperbaric oxygen therapy include myopia lasting for weeks or months, ruptured middle ear, seizures, lung damage and oxygen toxicity. The most common complication is a lack of pressure equalization on both sides of the eardrum which can cause pain and bleeding into the middle ear. The high concentration of oxygen also presents a fire hazard (Porter & Brian, 1999; oral cancer foundation).

## Medical Technology Assessment Committee (MTAC)

### **Hyperbaric Oxygen for Treatment of Radiation Induced Cerebral Necrosis**

#### BACKGROUND

Many types of cerebral cancer are treated with external beam, stereotactically focused or implanted radiation. One of the most common and debilitating sequelae of high dose radiation is tissue destruction and necrosis. Radiation-induced necrosis (RIN) manifests itself as headache, ataxia, cranial nerve palsy, seizures, and visual loss. Necrotic tissue had historically been surgically re-sected when anatomically feasible or left untreated. One proposed method of treatment is the use of hyperbaric oxygen therapy (HBOT) which increases tissue oxygen concentration and may stimulate angiogenesis and establish a new blood supply to healthy cerebral tissue. Typically hyperbaric oxygen is administered by placing patients into a whole-body hyperbaric chamber and exposing them to oxygen concentrations of 2 times normal atmospheric pressure for a period of 2-4 hours, once a day. Treatments are usually repeated usually 20-40 times with symptomatic improvement used as the measure of treatment success.

#### **08/11/1999: MTAC REVIEW**

### **Hyperbaric Oxygen for Treatment of Radiation Induced Cerebral Necrosis**

**Evidence Conclusion:** Evidence identification was conducted by searching MEDLINE from 1996-1999 using terms radiation necrosis, radiation injuries, cerebral necrosis and hyperbaric oxygenation. Dr. Kindwall, the author of a recent review, identified 2 case series (n=10, n=2) as the only published data on hyperbaric oxygen for treating cerebral radiation-induced necrosis. The Kaiser Permanente New Technology hotline staff was also unable to identify any additional literature reporting original data. Data from the case series of 10 patients, 8 of whom had biopsy-proven RIN, demonstrated that, with a median follow up of 7 months post HBOT, symptoms completely resolved in 1 patient, improved in 4 patients, did not get worse in 1 patient, and ended up worse in 4 patients. One patient developed ear pain from HBOT and had ear tubes placed and one developed sinusitis and discontinued treatment. Because this study was a case series rather than a randomized trial, it is not possible to determine whether hyperbaric oxygen therapy improves the clinical outcome of patients with radiation-induced cerebral necrosis beyond what would be expected with corticosteroid therapy alone. The best published scientific evidence on treating radiation induced cerebral necrosis with hyperbaric consists of a case series of 10 patients, 8 of whom had biopsy-proven RIN, demonstrated that, with a median follow up of 7 months post HBOT, symptoms completely resolved in 1 patient, improved in 4 patients, did not get worse in 1 patient, and ended up worse in 4 patients. One patient developed ear pain from HBOT and had ear tubes placed and one developed sinusitis and discontinued treatment. Because this study was a case series rather than a randomized trial, it is not possible to determine whether hyperbaric oxygen therapy improves the clinical outcome of patients with radiation-induced cerebral necrosis beyond what would be expected with corticosteroid therapy alone.

**Articles:** Chuba, PJ, et al, Cancer 1997;80:2005-2012

The use of hyperbaric oxygen does not meet *Group Health Medical Technology Assessment Criteria*.

### **Hyperbaric Oxygen Therapy for Prophylactic Treatment after Head and Neck Radiation to Prevent Osteoradionecrosis (ORN) of the Mandible**

#### BACKGROUND

Hyperbaric oxygen therapy consists of placing a patient inside a pressurized chamber in which the patient breathes 100% oxygen under a pressure of greater than one atmosphere. Generally, there is a gradual increase to approximately two-and-a-half times the normal atmospheric pressure. Patients receive up to 40 treatment sessions lasting between 45 and 300 minutes. There are monoplace chambers for one person and multiplace chambers that can accommodate two or more patients. (Leach et al, 1998; Porter & Brian, 1999). Hyperbaric oxygen therapy has both a mechanical (pressure) and physiological (oxygen) component. The increased pressure causes compression of gas bubbles in the body and is useful for conditions such as decompression illness. Breathing 100% oxygen at increased pressure allows more oxygen to reach non-healing tissue, and helps to prevent tissue from dying to a lack of oxygen and blood (Porter & Brian, 1999). Potential adverse events of hyperbaric oxygen therapy include myopia lasting for weeks or months, ruptured middle ear, seizures, lung damage and oxygen toxicity. The most common complication is a lack of pressure equalization on both sides of the eardrum that can cause pain and bleeding into the middle ear. The high concentration of oxygen also presents a fire hazard (Porter & Brian, 1999; oral cancer foundation). Osteoradionecrosis (ORN) of the mandible is a potential complication of head and neck irradiation. It is defined as a nonhealing, nonseptic lesion of bone (Clayman, 1997). The underlying cause of ORN is believed to be progressive vascular occlusion and tissue hypoxia after radiation treatment (Porter & Brian, 1999). Three types of ORN have been described. Type 1 occurs when a patient receives radiation therapy within 21 days of tooth extraction or mandibulotomy. Type 2 is induced by trauma. It generally occurs 3-6 years after radiation therapy, usually following a tooth extraction. Type 3 occurs spontaneously 6 months to 2 years after radiation therapy and is associated with higher radiation doses, neutron

beam therapy and brachytherapy (Cronje, 1998). Hyperbaric oxygen therapy is generally accepted as a treatment for patients who have ORN. The use of hyperbaric oxygen therapy is also proposed as a prophylactic treatment before dental work to prevent ORN in patients who have had irradiation of the head and neck.

#### **04/09/2003: MTAC REVIEW**

### **Hyperbaric Oxygen Therapy for Prophylactic Treatment after Head and Neck Radiation to Prevent Osteoradionecrosis (ORN) of the Mandible**

**Evidence Conclusion:** There is weak evidence from one randomized controlled trial (Marx), published in 1985, that prophylactic hyperbaric oxygen treatment of patients with previous head and neck irradiation before tooth removal lowers the incidence of osteoradionecrosis of the mandible compared to patients treated prophylactically with penicillin. The Marx study had a small sample size (n=74) and the methodology was not well described, leaving open the possibility of threats to validity such as selection bias, inadequate randomization and biased assessment of outcomes. The results of the Marx study have not been replicated. Many factors may have changed since 1985 making the findings less relevant including different radiation protocols that alter the likelihood of developing ORN, better alternative prophylactic treatments and better treatments for patients with ORN. Recent authors have questioned the need for prophylactic hyperbaric oxygen treatment before dental surgery for all patients who have received head and neck radiation before dental surgery because the incidence of post-extraction ORN is relatively low and over half of the patients who do develop ORN heal after conservative treatment. The Marx study has also been criticized as including a particularly high-risk group of patients. The incidence of ORN in the Marx study was 30% in the penicillin-treated group compared to a 5.8% incidence in the general population of post-radiation tooth extraction patients and a lower incidence, 2.1% in studies conducted in the 1990s (Clayman, 1997).

**Articles:** The search yielded 35 articles. Many of the articles were reviews or opinion pieces, dealt with technical aspects of the intervention or addressed the treatment of osteoradionecrosis with hyperbaric oxygen rather than prophylaxis. No randomized controlled trials on prophylactic use of hyperbaric oxygen to prevent osteoradionecrosis were included in the search findings. However, an RCT published in 1985 was identified from the reference list of a review article. In addition to the RCT, there were several case reports and small case series (n<30 patients). The RCT was critically appraised: Marx RE, Johnson RP, Kline SN. Prevention of osteoradionecrosis: a randomized prospective clinical trial of hyperbaric oxygen versus penicillin. JADA 1985; 111: 49-54. See [Evidence Table](#).

The use of hyperbaric oxygen in the prevention of osteoradionecrosis of the mandible does not meet the *Group Health Medical Technology Assessment Criteria*.

### **Hyperbaric Oxygen Therapy for Prophylaxis Before Breast Surgery**

#### **BACKGROUND**

Breast cancer is the most common cancer in women, other than skin cancer, and the second leading cause of cancer death among them. According to the American cancer society, a woman has a 1 in 7 chance of having invasive breast cancer some time during her life. As of the 2004, there are slightly over 2 million women living in the USA who have been treated for breast cancer. Conservative therapy with lumpectomy, axillary dissection, and irradiation, is a frequently used option for treating early breast cancer. This allows the patient to keep her breast and reduce the physical and psychological trauma associated with the modified radical mastectomy. Radiation therapy is also indicated with mastectomy under certain conditions. In both cases, radiotherapy is given in a moderate to high dose and may be associated with mild to severe complications that might have negative influence on the health and quality of life. Among these complications are arm lymphedema, subcutaneous fibrosis, painful hardening of the breast, shoulder pain rib fracture, damage to the lungs and heart and others (Gothard 2003, Feldmeier 1995). These complications may be due to early reactions to radiation, or late effects that occur after at least 90 days after the start of treatment (Pasquier, 2004). Late injuries are irreversible and progressive in the majority of cases. These may cause cellular depletion, reduction in vascular density, fibrosis and atrophy all of which may result in hypoxia, and in turn delayed healing of the wounds. Conservative measures may be adequate for managing moderate cases with minimal necrosis, but cases of extensive necrosis are more challenging. Hyperbaric oxygen (HBO) was first used for the treatment of radiotherapy patients in the 1950s (Pasquier, 2004). It is defined as the breathing of pure oxygen at pressure exceeding the normal atmospheric pressure of 100 kPa that increases the solubility of oxygen in the blood. HBO treatment is administered within hyperbaric chambers, which are compressed by air (Plafki 1998) Researchers indicate that hyperbaric oxygen therapy stimulates angiogenesis, osteogenesis, fibroblast activity, and collagen formation in irradiated tissues, which would increase the cellular level of oxygen. It has been reported that HBO therapy is associated with a low complication rate, but that there is uncertainty about the best time to start the treatment, and the number of sessions needed (Plafki 1998). There is also uncertainty on the efficacy of the treatment for the different complications, what are its side effects, who would respond to treatment, and for which symptoms.

**12/08/2004: MTAC REVIEW**

**Hyperbaric Oxygen Therapy for Prophylaxis Before Breast Surgery**

**Evidence Conclusion:** There is no evidence to date on the prophylactic use of hyperbaric oxygen therapy before breast surgery in patients with prior radiation therapy. There is also insufficient evidence on the efficacy of HBO therapy in the treatment of late sequelae in women receiving radiation after breast-conserving surgery. The study reviewed was a case series that provide the least grade of evidence. It was small nonrandomized, and with potential selection and observation bias. The results of the study show that patients who received a hyperbaric oxygen therapy had a significant reduction of pain, edema, and erythema compared to those who refused the therapy. There was no significant difference between the groups in the improvement of fibrosis or telangiectasia.

**Articles:** The search yielded 35 articles. Many were review articles, dealt with technical aspects of the therapy, or the use of hyperbaric oxygen for the treatment of radio-induced lesions in different tissues and organs other than the breast. The search did not reveal any study on the use of Hyperbaric Oxygen Therapy for prophylaxis in breast surgery in patients with prior radiation therapy. There was one prospective case series with a control group on the use of hyperbaric oxygen for the treatment of late sequelae of radiation therapy after breast surgery, a smaller series of 21 patients and control group, and a retrospective review of 23 cases.

The case series with a control group was selected for critical appraisal. Carl UM, Feldmeier JJ, Schmitt, et al. Hyperbaric oxygen therapy for late sequelae in women receiving radiation after breast-conserving surgery. *Int J Radiat Oncol Biol Phys.* 2001; 49:1029-31. See [Evidence Table](#).

The use of hyperbaric oxygen for prophylaxis before breast surgery does not meet the *Group Health Medical Technology Assessment Criteria*.

**Hyperbaric Oxygen Therapy for Treatment of Gastrointestinal Bleeding Related to Radiation Enteritis**

**BACKGROUND**

Hyperbaric oxygen therapy consists of placing a patient inside a pressurized chamber in which the patient breathes 100% oxygen under a pressure of greater than one atmosphere. Generally, there is a gradual increase to approximately two-and-a-half times the normal atmospheric pressure. Patients receive up to 40 treatment sessions lasting between 45 and 300 minutes. There are monoplace chambers for one person and multiplace chambers that can accommodate two or more patients. (Leach et al, 1998; Porter & Brian, 1999). Hyperbaric oxygen therapy has both a mechanical (pressure) and physiological (oxygen) component. The increased pressure causes compression of gas bubbles in the body and is useful for conditions such as decompression illness. Breathing 100% oxygen at increased pressure allows more oxygen to reach non-healing tissue, and helps to prevent tissue from dying to a lack of oxygen and blood (Porter & Brian, 1999). Potential adverse events of hyperbaric oxygen therapy include myopia lasting for weeks or months, ruptured middle ear, seizures, lung damage and oxygen toxicity. The most common complication is a lack of pressure equalization on both sides of the eardrum which can cause pain and bleeding into the middle ear. The high concentration of oxygen also presents a fire hazard (Porter & Brian, 1999; oral cancer foundation). The treatment of gastrointestinal bleeding related to radiation enteritis is one possible application of hyperbaric oxygen therapy.

**04/09/2003: MTAC REVIEW**

**Hyperbaric Oxygen Therapy for Treatment of Gastrointestinal Bleeding Related to Radiation Enteritis**

**Evidence Conclusion:** There is no published evidence on the effectiveness of hyperbaric oxygen therapy for the treatment of gastrointestinal bleeding related to radiation enteritis.

**Articles:** There were no published empirical studies. An abstract of a small case series (n=19) was identified in a review article. The abstract was presented at a professional meeting in 1998 and the study was not subsequently published.

The use of hyperbaric oxygen in the treatment of gastrointestinal bleeding related to radiation enteritis does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Intradiscal Electrothermal Therapy (IDET)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Thermal Intradiscal Procedures (150.11)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

Group Health has elected to use the Thermal Intradiscal Procedures (A-0217) MCG\* for medical necessity determinations.

**\*MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (Neurosurgeon, neurologist, physiatrist, pain specialists, orthopedic spine surgeon)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Intradiscal Electrothermal Therapy (IDET) is a minimally invasive procedure that was developed as a treatment for lumbar discogenic pain. It aims to reduce the symptoms of the disrupted disc by thermocoagulating annular tissue and contracting collagen fibrils. The SpineCATH™ Intradiscal Catheter delivers thermal energy to the posterior annulus via a resistive heater coil. The annulus is comprised of Type I and II collagen fibers, which are held together by hydrogen bonds in a triple helix formation. It has been shown that these bonds break when heated to 60°C to 75°C is applied to the tissue. After being heated to the optimum temperature the collagen fibers contract and thicken. Following thermal contraction, collagen tissue undergoes a remodeling or regeneration process. Remodeling includes fibroblast in-growth and proliferation as well as new collagen formation in the treatment areas. The treatment is performed on an outpatient basis, under fluoroscopy.

IDET (SpineCath, Smith and Nephew) received FDA approval for the “coagulation and decompression of disc material to treat symptomatic patients with annular disruption of contained herniated discs” (DHHS, letter 8/17/2001). It does not appear to be approved for other types of low back pain.

#### Medical Technology Assessment Committee (MTAC)

##### *Intradiscal Electrothermal Therapy (IDET)*

##### 10/11/2000: MTAC REVIEW

**Evidence Conclusion:** The study reviewed has a number of limitations including a small sample size, lack of a control group, potential selection bias, potential placebo effects, and the absence of significant improvements in outcomes after 6 months. Given the lack of peer-review studies and the limitation of this case series, the effectiveness of IDET for chronic back pain cannot be determined at this time.

Articles: Articles were selected based on study type. The only article found was a case series. A review article was reviewed, but no evidence table was created. *The articles selected for critical appraisal include:* Saal et al. Management of chronic discogenic low back pain with a thermal intradiscal catheter: A Preliminary Report. Spine 2000;25:382-388. See [Evidence Table](#)  
 The use of Intradiscal Electrothermal Therapy (IDET) in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria* (fails criteria 2 for effectiveness).

**07/14/2004: MTAC REVIEW**

**Intradiscal Electrothermal Therapy (IDET)**

**Evidence Conclusion:** The only published RCT on the effectiveness of IDET for discogenic low back pain (Pauza) does not provide strong evidence that IDET provides a clear clinical benefit to patients. In the *per protocol* analysis of 6 month follow-up data, the difference in the pain scores between the IDET and sham treatment groups just reached statistical significance (p=.045). Physical functioning measured by the SF-36 did not differ significantly between groups and the difference in the Oswestry disability scale did not attain statistical significance (p=.050). In the intention to treat analysis, there was a significant difference between groups in the proportion of patients who experienced >75% pain relief. The NNT=7 with a wide confidence interval, 95% CI=3 to 138 and there was no significant difference in the proportion of patients experiencing >50% pain relief. The sample size and length of follow-up were insufficient for quantifying any adverse effects of the treatment.

**Articles:** The search yielded 29 articles. There was one randomized controlled trial (Pauza) and this was critically appraised. There were also three case series with longer follow-up than the RCT and a cohort study. The other studies were not critically appraised because higher-grade evidence was available. The RCT reference was: Pauza KJ, Howell S, Dreyfuss P et al. A randomized placebo-controlled trial of intradiscal electrothermal therapy for the treatment of discogenic low back pain. *The Spine Journal* 2004; 4: 27-35. See [Evidence Table](#).

The use of Intradiscal Electrothermal Therapy (IDET) in the treatment of back pain does not meet the *Group Health Medical Technology Assessment Criteria* (fails criteria 2 for effectiveness).

## Clinical Review Criteria

### In Lieu of Hospital Admission to Skilled Nursing Facility (ILOH)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

Meets all the following clinical criteria for ILOH admission:

- 1) Meets **(MCG)\***, current edition Inpatient and Surgical Care Guidelines Clinical Indications for Admission to Inpatient Care for condition and treatment in an acute hospital setting.
  - a) On admission to a hospital or
  - b) At the end of the stay but requiring continued skilled nursing care that can be safely delivered in a skilled nursing facility
  - c) During evaluation in any of the following settings: emergency department, urgent care or clinic.
- 2) In lieu of hospital admission transfers to skilled nursing facilities are not appropriate when the care needs are limited to physical, occupational or speech therapy because these services alone do not require inpatient hospital care, except in an inpatient hospital rehabilitation admission. Inpatient hospital rehabilitation service intensity is not available in a skilled nursing facility.
- 3) Stable enough for management by the skilled nursing facility staff
  - a) does not require critical care services support or support available only in the hospital setting
  - b) does not require a high use of lab
- 4) Diagnosis established
- 5) Physician on-site rounding daily if needed, and access to physician 24 hours a day
- 6) Medically stable with clear plan of care and expected course
- 7) Patient agrees with ILOH plan of care

**\*MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health may share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

When a skilled nursing facility has the staff and services available to deliver a higher level of care, it is possible to transfer a patient earlier in the course of care to a skilled nursing facility rather than continuing care in the hospital. The most common use of this service is at the end of a hospital stay when acute care service needs have decreased but are still expected to persist for more than 2-3 days or on admission when acute care services are limited to intravenous administration of antibiotics or dressing changes that cannot be safely managed in the home through a home health provider. While use of the service is rare, it is appropriate for some plans of care.

##### RETIRED

Hybrid PET/CT or PET/MR: Covered when criteria for [PET Scans](#) are met.

CT/MR: There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Modern imaging technologies visualize different aspects of disease in non-invasive ways. Computed tomography (CT) and magnetic resonance (MR) are primarily used for imaging anatomical changes associated with an underlying pathology, whereas the molecular imaging techniques of positron emission tomography (PET) and single photon emission computed tomography (SPECT) capture functional or metabolic changes associated with the pathology. To identify a change in function without knowing accurately where it is localized, or to know there is an anatomical change without understanding the nature of the underlying cause, may compromise the clinical efficacy of both the anatomical and functional imaging techniques.

In an attempt to diagnose and stage disease processes, patients often undergo a number of different image studies and the images are usually viewed separately on different computer stations. Image data sets, however can be aligned retrospectively and presented as fused images thus allowing the interpretation of the two modalities to be correlated. In recent years there has been considerable progress in the development of fusion software to co-register different image modalities particularly for imaging the brain. One goal of fusion software is to align anatomical and functional images and allow improved spatial localization of abnormalities. The resulting correlation of the anatomical and functional images may clarify the nature of the abnormality and help diagnose or stage the underlying disease. Whereas successful image fusion software has been developed for the brain, the success achieved for imaging other parts of the body is still limited.

With the increasing importance of PET for diagnosis and staging in oncology, the combination of PET with an anatomical modality as CT or MR could actually improve the accuracy of each technique used separately.

Combining PET with CT is a technologically less challenging than combining it with MR in view of the extensive restrictions placed on the imaging environment by the strong magnetic field. It is challenging to develop PET detectors that can operate inside a MR scanner without causing significant artifacts in the MR images, and which can operate in a high and fluctuating magnetic field and radiofrequency. Commercial PET/CT scanners are now available, while the combined PET/MR scanners for human studies are not yet available.

The prototype combined PET/CT scanner was designed and built in collaboration between the University of Pittsburgh and CTI PET Systems, Inc. (Knoxville, TN). The system was operational from May 1998 until August 2001, and was used to scan more than 300 oncology patients. The first combined PET/CT tomograph approved by the FDA in August 2000 was manufactured by CTI PET Systems (Knoxville, USA) and was first presented at the 2000 Society of Nuclear Medicine Meeting in St. Louis. This is now distributed through Siemens and CTI. Later in 2000 GE Medical Systems (GEMS) also introduced a combined CT/PET system named the Discovery LS. Both dual modalities represent extension of the prototype design aiming at higher performance of both the CT and PET components without seeking necessarily a closer integration of the hardware scanner components. The level of physical integration of these commercial scanners is actually less than that of the original prototype.

There are several issues and challenges related to the hybrid devices including the risk of exposing the patients to additional radiation, longer examination time, and the cost of the device. Moreover, the transverse field of view of the CT tomograph is smaller than that of the PET component, which may result in lack of complete anatomical framework in very large patients. Another challenge for the hybrid device is to compensate for the effect of respiratory motion during both the CT and the PET. While standard CT exams are performed in breath-hold with full inspiration, the combined CT/PET exam should be performed with the patient breathing shallowly. This may lead to misalignment of the two images and a bias in the reconstructed emission activity distribution (Beyer 2002). The performance level of the device and its value in staging and follow-up of specific neoplasms and in specific anatomic regions also need to be evaluated.

## Medical Technology Assessment Committee (MTAC)

### Image Fusion

#### 10/09/2002: MTAC REVIEW

**Evidence Conclusion:** There is insufficient published evidence on which to base a conclusion about the effect of using the hybrid CT/PET on health outcomes.

**Articles:** The literature search yielded and 5 for CT and MR hybrid. The majority were opinion pieces, reviews, or dealing with technical aspects of the hybrid devices. There were three empirical articles on hybrid CT and PET, and one on hybrid MR and PET. Three of these four studies had very small sample sizes, and the fourth did not have clinically important outcomes. None of the articles revealed was suitable for critical appraisal.

The use of image fusion in the evaluation of illness and identification of pathology does not meet the *Group Health Medical Technology Assessment Criteria*.

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Heart failure (HF) is a complex clinical syndrome responsible for high morbidity and mortality in the world. The prognosis of HF remains poor and its burden on mortality, reduced quality of life, and healthcare cost is increasing across the world. The goals of HF treatment are to improve symptoms, slow the progression of the disease, and prolong survival (Martins da Silva 2013, Perrone-Filardi 2011, Nakou 2013, Jain 2014).

Treatment options for HF include medications, devices, and nonpharmacological interventions. Drug therapy for chronic heart failure including B-adrenergic blockade, vasodilators, angiotensin converting enzyme (ACE), inhibitors, mineralocorticoid receptor antagonists, and diuretics can relieve symptoms and/or improve survival. Devices as cardiac resynchronization therapy may improve outcomes in some patients with NYHA class II-IV heart failure, and implantable cardioverter defibrillators (ICDs) can reduce the risk of sudden cardiac death in patients with HF and reduced left ventricular ejection fraction (LVEF). However, these devices are not beneficial to all patients, are costly, and have potential significant complications. It is thus essential to identify the patients who are more likely to benefit from intensive therapies, and those among whom devices such as ICD are not indicated (Nakou 2013, Gupta 2014, Nakajima 2014).

Heart failure is characterized by sympathetic nerve hyperactivity (up to 50 times more active than normal), which serves as a compensatory mechanism for the cardiac dysfunction associated with HF. The increased sympathetic response is initially favorable to maintain the systemic hemodynamics and peripheral circulation. However, long-lasting and excess stimulation of sympathetic nerve function leads to deleterious consequences including myocardial remodeling, reduced LVEF, and electrical instability which increase the likelihood of arrhythmia and sudden cardiac death (SCD) (Martins da Silva 2013, Jacobson 2010, Nakata 2013, Treglia 2013).

Researchers found that persistent stimulation of sympathetic nerve function in failing hearts impairs the efficiency of reuptake, turnover, and storage of norepinephrine (NE) at presynaptic nerve endings, resulting in spill-over and deficiency in NE stores leading to a decline in the myocardial sympathetic innervation. On this pathophysiological basis, it was suggested that the assessment of the degree of sympathetic activation of the heart can potentially be an indicator of the severity of the disease process and provide an insight to the prognosis of a patient with HF. This has led to the development of radiotracers for single-photon computed tomography (SPECT) and positron emission tomography (PET) (Martins da Silva 2013, Nakata 2013, Gupta 2014).

Guanethidine is a false neurotransmitter that is taken up by the uptake pathway for NE into presynaptic terminal. Chemical modification and labeling with radioactive iodine produce metaiodobenzylguanidine (<sup>123</sup>I-MIBG), an analog of NE that permits the visualization of adrenergic innervation in vivo. After depolarization MIBG is released into the synaptic cleft similar to NE, but unlike NE it is not metabolized by monoamine oxidase (MAO) or catechol-

o-methyl-transferase (COMT), leading to higher cytoplasmic concentration that permits scintigraphic imaging in early and delayed phases (Treglia 2013, Gupta 2014).

The conventional protocol for scintigraphic myocardial imaging involves the injection of 123I-MIBG intravenously at rest after which early (from 10-30 minutes after administration), and delayed (3-4 hours after administration) images are obtained. The planar images with anterior view are adequate for evaluating cardiac sympathetic function. Tomographic images (SPECT) are often acquired to evaluate the regional myocardial uptake pattern. The most common semi-quantitative indices used for interpreting the images are the heart to mediastinum ratio (H/M) and washout rate (WR) obtained from the anterior planar images. Regions of interest are set in the heart (H: target region) and the mediastinum (M: background region) to obtain a mean count at each region. H/M ratio is calculated and the degree of accumulation evaluated based on the resulting ratio. The WR is an index that indicates the rate at which MIBG is washed out between the early and delayed images through comparison with the cardiac count in the early image. This may reflect turnover of catecholamines attributable to the sympathetic drives and measures the ability of the myocardium to retain. MIBG normal values for these are derived from control patients and may differ between institutions (Treglia 2013).

## Medical Technology Assessment Committee (MTAC)

### I MIBG Imaging for Heart Failure

#### 10/20/2014: MTAC REVIEW

**Evidence Conclusion:** AdreView Myocardial imaging for Risk Evaluation in Heart Failure (ADMIRE-HF., Evidence table 1), was the pivotal study that led to the recent FDA approval of 123I-MIBG use in HF patients) was a large, observational, multicenter study that evaluated the prognostic value of 123I-MIBG in HF patients. 961 participants with NYHA class II/III HF and LVEF <35% underwent 123I-MIBG myocardial perfusion imaging and were followed for a maximum of 2 years to assess the primary composite endpoint of HF progression necessitating hospital admission, life-threatening arrhythmic event, and cardiac death. During a median of 17 months of follow-up (range 2 days-30.4 months), 237 first cardiac events were observed. The analysis of the results suggests that H/M ratio <1.6 was most discriminative for identifying patients at higher risk of the composite endpoint and each of its components. Patients with H/M >1.60 had a significantly lower risk of cardiac events (HR 0.40; 95% CI, 0.25-0.64), lower rate of HF progression, lower rate of arrhythmic events, and higher 2-year survival rates. The incidence of cardiac death was <1% per year in patients with H/M >1.6 and 9.6% per year among those with H/M <1.6. The results also showed that late H/M ratio provided additional information to that of plasma BNP and LVEF for identifying patients at greater risk of cardiac events. The other parameters of the 123I-MIBG imaging (early H/M and washout rate (WR) were also associated with risk for cardiac events, but late H/M ratio was the only one with independent prognostic value. A subsequent retrospective analysis of the ADMIRE-HF (Shah 2012) suggests that 123I MIBG has prognostic value across the spectrum of LVEFs. Verschure D et al, 2014 (Evidence table 2) conducted a meta-analysis of individual patient data from 6 studies incorporating 636 chronic HF patients (599 from Europe and 37 from the USA) to determine the most appropriate prognostic endpoint for 123I-MIBG scintigraphy in patients with chronic heart failure. The primary outcomes were all-cause mortality, cardiac mortality, arrhythmic events, heart transplantation, and a composite outcome of all listed events. Overall, the results of the pooled analysis indicate that late H/M was an independent predictor for all outcomes studies except for arrhythmias. The lower late H/M is associated with higher risk. LVEF was also found to be an independent predictor for these events. The analysis did not examine whether MIBG has an incremental prognostic value over other independent variables. The etiology of HF i.e. ischemic vs. non-ischemic was not an independent predictor in the multivariate analysis for any of the outcome events. The meta-analysis had the advantage of including patient data from longitudinal studies, however, the authors did not evaluate the quality of the studies included, did not test for homogeneity or publication bias, or do a sensitivity analysis. The analysis did not include the Japanese studies or the ADMIRE-HF study. In addition, there were variations between the studies included in the technical aspects of the procedure as regards the collimator selection, and method used to measure the myocardial uptake. Nakata T, Nakajima K. and colleagues (2013, Evidence table 3) pooled data from six prospective cohort studies conducted in Japan from 1990 to 2009. The studies enrolled a total 1,322 patients with chronic HF, the mean follow-up duration was 78 months, and the five year outcomes were available for 933 patients. The five-year cardiac deaths were determined by the original study investigators. Multivariate analysis was performed using the variables age, gender, early H/M, late H/M, MIBG washout rate, NYHA functional class, LVEF, history of diabetes, hypertension, dyslipidemia, atrial fibrillation, sustained ventricular tachycardia, and medications used. BNP data was available for only 512 patients. The results of the analysis indicate that survival rates decreased with decreasing H/M independent of other markers as NYHA class, BNP, and LVEF. All-cause mortality progressively decreased with increasing H/M ratio. Based on the ROC curve, a late H/M ratio threshold of 1.68 identified patients at a significantly higher mortality. This analysis only included data from studies conducted in Japan, and the H/M values as well as the results may not be generalized to other geographic areas using other methodologies or in populations with different characteristics. Pooled results of two earlier meta-analyses (Verberne H et al, 2008 et al

and Kuwabara Y et al, 2011) also suggest that HF patients with reduced late H/M ratio or increased 123I-MIBG washout rate (WR) have a higher incidence of cardiac events compared to those with normal or relatively preserved uptake and washout rates. Incremental value of myocardial sympathetic innervation imaging with 123I-MIBG in heart failure patients Jain K and colleagues (2014) used data from ADMIRE-HF to assess the performance of four HF risk models (EFFECT, CARE-HF, MADIT-II and PACE) for predicting the composite clinical endpoint of cardiac death, progressive HF, or life-threatening arrhythmia. They then quantified the incremental prognostic utility of H/M ratio 123I-MBG imaging when added to each of the individual models. The results of the analysis suggest that H/M ratio >1.6 was consistent with the other models in identifying patient at lower risk of cardiac events, and that the addition of H/M to EFFECT, CARE-HF, MADIT-II and PACE models improved their discrimination by 33%, 59%, 49% and 37% respectively. These results however, have to be interpreted with caution as it was derived from post-hoc evaluation of risk factors in ADMIRE-HF study. It may be limited to the characteristics of the participants included as well as the limitations in the observational study design. Ketchum E, et al (2012) also used survival data from 961 NYHA II-III subjects in the ADMIRE-HF trial to investigate the incremental value of MIBG cardiac imaging when added to the Seattle Heart Failure Model (SHFM) for prediction of all-cause mortality. The results of the analysis showed that the addition of H/M to the SHFM in a Cox model significantly improved risk prediction ( $P < 0.0001$ ), with a greater utility in higher risk SHFM patients. The net reclassification improvement (NRI) was 22.7% ( $P < 0.001$ ), with 14.9% of subjects who died reclassified into a higher risk category than suggested by SHFM score alone ( $P = 0.01$ ) and 7.9% of subjects who survived reclassified into a lower risk category ( $P < 0.0001$ ). The 1-year area under the receiver-operator curve showed significant improvement for the combined model with H/M compared to the SHFM alone. Nakajima K, Nakata T, and colleagues (2014) used the same database (created By Nakata et al, 2013) to create a model for predicting fatal cardiac events by adding information from MIBG imaging. Nakata et al-'s pooled analysis included data for 1,322 chronic HF patients enrolled in cohort studies performed in Japan from 1990 to 2009. Prediction models were created with single and multiple variables to calculate cardiac mortality. Net reclassification improvement (NRI) analysis was based on prediction models with and without H/M ratio. The five-year risk levels were defined as low (<5%, corresponding to 1% mortality /year), intermediate (5-25%) and high (>25% corresponding to 5% mortality /year). During 5 years 205/933 patients (22%) died of a cardiac event. A multivariate analysis showed that age, gender, NYHA functional class (highest OR and X2 values), LVEF, and late MIBG H/M were significant predictors for 5-year cardiac mortality. The calculated ROC AUC (area under receiver operator curve) was 0.749 with the first 4 variables, and 0.780 after the addition of H/M ( $p = 0.0015$  for difference). The authors performed NRI analysis by the combination of age, gender, NYHA functional class and LVEF (model 1) and with the addition of late H/M (model 2). Patients who died with cardiac events were classified into the 3 risk levels according to the 2 models. The results indicate that classification was improved in 23 patients and made worse among 13 in model 2 vs. model 1. The net gain in classification was 4.9% ( $p = 0.096$ ). Of those who did not die of a cardiac event 38 were classified upwards and 103 downward with a net gain in classification of -9.0% ( $p < 0.0001$ ). This indicates that the addition of H/M is significantly improved the identification of patients at lower risk of cardiac death, i.e. it is more useful for reclassifying patients downwards to lower risk groups. This latter finding is contradictory to that observed in ADMIRE-HF study and the Ketchum and colleagues' analysis where MIBG was more effective in reclassifying patients upwards. The authors explained that this might be due to the differences between the Japanese trials and the ADMIRE-HF (USA and Europe) study. Participants in the Japanese trials were overall healthier as regards their NYHA functional class, LVEF level, higher prevalence of non-ischemic HF, and lower overall mortality. The mean H/M values were 1.71 in ADMIRE-HF, and 1.44 in the Japanese trials, which as the authors explained may be related to the technical differences between the imaging equipment in Japan vs. gamma cameras in the US and Europe. The study had its limitations as data were compiled from a number of studies conducted as early as 1990, with some variations in the population included, medication used, and MIBG imaging techniques. Its results need to be validated in prospective large studies.

Clinical Utility of myocardial sympathetic innervation imaging with 123I-MIBG in heart failure patients. There are no published randomized controlled trials to date that directly evaluated the benefit of 123I-MIBG imaging as an aid to clinical management of HF patients. A number of published studies evaluated the use of MIBG scintigraphy in monitoring improvement in sympathetic activity in HF patients treated with vasodilators and beta-blockers. Treatment decisions and selection therapy were not based on the results of MIBG imaging and thus may not be the right study design to evaluate the effect of the test on the management decisions and/or patient outcomes.

Conclusion: There is fair evidence from a number of observational studies and pooled analyses that 123I imaging of patients with heart failure and low LVEF may have an independent predictive value for estimating their risk of fatal cardiac events. There is some evidence from three analyses that H/M may have an additive (incremental) value to other risk models used for predicting cardiac mortality in patients with HF and low LVEF. There is insufficient evidence, to date, to determine that 123I-MIBG imaging of patients with heart failure and low LVEF impacts the management plan and/or improves patient outcomes. The review of the technology conducted Blue Cross Blue Shield Association, Kaiser Permanente. TEC program in April 2014 came to similar conclusions that there is evidence that myocardial MIBG innervation imaging provides prognostic information for cardiac events, and that there is a lack of evidence that the prognostic information will lead to improved health outcomes.

**Articles:** The literature search revealed over 200 articles on 123I-MIBG sympathetic imaging, many of which were unrelated to the current review. There were a number of published studies that examined the prognostic value of 123I-MIBG imaging of patients with HF. The studies include the pivotal ADMIRE-HF study that led to the FDA approval of using 123I-MIBG sympathetic imaging for patients with HF. The results of many of these published studies were pooled in four systematic reviews (Verberne et al, 2008, Kuwabara et al, 2011 [Japanese studies only], Nakata et al. 2013, and Verschure et al 2014 [European and USA studies]). Two subanalyses from the ADMIRE-HF study examined the ability of 123I MIBG in predicting the arrhythmic events and hospitalization in subpopulations were recently published (Sood et al 2013, and Parker et al, 2014). The search also identified the recent assessment of 123I-MIBG sympathetic imaging by Blue Cross Blue Shield Association, Kaiser Permanente. Technology Evaluation Center (TEC) Assessment Program. The literature search did not identify any trial that evaluated the clinical utility of the 123I-MIBG sympathetic imaging in heart failure patients, i.e. the impact of the test results on the management of patients. Treglia and colleagues 2013, reviewed studies that used the 123I MIBG to evaluate the effectiveness of different pharmaceutical agents in patients with HF. These studies did not actually examine the clinical utility of the test as the title of the review implies, as the management of the patients or selection of pharmaceutical agents were not based on the test results. The most recent pooled analyses (published after the TEC review) as well as the ADMIRE-HF study were selected for critical appraisal. Jacobson AF, Senior R, Cerqueira MD, et al. Myocardial iodine-123 meta-iodobenzylguanidine imaging and cardiac events in heart failure. Results of the prospective ADMIRE-HF (AdreView Myocardial Imaging for Risk Evaluation in Heart Failure) study. J Am Coll Cardiol. 2010;55 (20): 2212-2221. See [Evidence Table 1](#). Verschure DO, Veltman CE, Manrique A, et al. For what endpoint does myocardial 123 I-MIBG scintigraphy have the greatest prognostic value in patients with chronic heart failure? Results of a pooled individual patient data meta-analysis. Eur Heart J Cardiovasc Imaging. 2014 Sep;15 (9): 996-1003. See [Evidence Table 2](#). Nakata T, Nakajima K, Yamashina S, et al. A pooled analysis of multicenter cohort studies of (123) I-MIBG imaging of sympathetic innervation for assessment of long-term prognosis in heart failure. JACC Cardiovasc Imaging. 2013;6 (7):772-784. ## Clinical Review Criteria

### Implantable Loop Recorder (ILR)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Medicare does not have an NCD for implantable loop recorders. Noridian does not have a LCD for implantable loop recorders. Refer to GHC criteria below for coverage guidelines. (see below)

##### For Non-Medicare Members

Group Health has elected to use the Loop Recorder, Implantable (A-0122) MCG\* for medical necessity determinations.

- Implantable loop recorder (cardiac event monitor) may be indicated for **1 or more** of the following:
  - Atrial fibrillation, known or suspected, as indicated by **ALL** of the following
    - Cryptogenic stroke
    - Holter monitor or other noninvasive cardiac monitor contraindicated, or results unrevealing or indeterminate
    - Recurrent paroxysmal atrial fibrillation suspected, and test results may impact patient management
  - Syncope, as indicated by **ALL** of the following
    - Cardiac etiology of syncope, suspected, as indicated by **1 or more** of the following:
      - ECG results abnormal (eg, cardiac rhythm other than normal sinus, significant conduction abnormalities, Brugada ECG pattern, long QT syndrome)
      - Family history of sudden death
      - History of chronic heart failure
      - History of structural heart disease (eg, valvular aortic stenosis or hypertrophic cardiomyopathy) or severe coronary heart disease
      - Recent history of palpitations, abnormal heart rate, or symptomatic arrhythmia
      - Use of medication known to cause malignant arrhythmias (eg, antiarrhythmics, antidepressants, antihistamines)
    - Recurrent syncope, suspected
    - Test results negative or inconclusive, as indicated by **1 or more** of the following :
      - Electrophysiologic study
      - Non-implantable (external) loop recorder
      - Tilt table testing
      -

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Syncope has a complex differential diagnosis. Syncope that remains unexplained after standard evaluation does not appear to be associated with excess mortality (Savage et al., 1985) or serious adverse cardiovascular events (Kapoor, 1990). However, syncope recurrences are associated with fractures, automobile accidents and other complications (Kapoor, 1987).

Standard techniques for diagnosing syncope include history and physical examination, laboratory testing, exercise stress testing, Holter monitoring, tilt table testing and external loop recording. External loop recorders (“King of Hearts” model) store ECG data up to 4 minutes prior to and 1 minute after activation by a patient. They are worn on the wrist or around the waist, generally for up to 1 month.

The implantable loop recorder (ILR) is a new diagnostic tool for unexplained infrequent syncope. The ILR is a 61x19x8mm, recording device produced by Medtronic Reveal. It stores an ECG signal in a circular buffer capable of retaining 21 minutes of uncompressed signal or 42 minutes of compressed signal (can be divided into 1-3 parts). The ILR requires the patient or family member to use a hand-held pager-sized activator to “freeze” the memory buffer during or immediately following an episode of syncope. The device is implanted into the left infraclavicular region. Using local anesthesia, a 2 cm incision is made, a pocket the size and shape of the device is made and the ILR is placed in the pocket. The ILR can monitor patients for up to 14 months. The device is removed after a diagnosis of syncope is made or at the end of battery life.

Medicare approved coverage for this implantable device effective 10/1/1999. Group Health added it to the medical criteria subject area at that time.

MTAC reviewed this device at the February 2000 meeting and found the technology appears to be promising and safe for patients whose syncope is undiagnosed but there is not enough evidence to draw conclusions regarding reproducibility, safety and accuracy. The Health Plan Medical Director Group at their February 2000 meeting reviewed the MTAC findings and determined that there was good reason to recommend coverage for patients who had infrequent, undiagnosed episodes of syncope.

## Medical Technology Assessment Committee (MTAC)

### Implantable Loop Recorder

#### 02/10/1999: MTAC REVIEW

**Evidence Conclusion:** The one study evaluating the potential of the ILR to diagnose unexplained syncope obtained a diagnostic yield of 59% during a mean of 10.5 months of recording. Possible selection bias, conflict of interest on the part of the investigators and a lack of comparison with external loop recorders limit the ability of this study to determine efficacy of the ILR. Two studies evaluating the external loop recorders found point estimates for diagnostic findings of 25% and 36% after approximately one month of recording.

CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">NCD for Infusion Pumps (280.14)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

#### For Non-Medicare Members

The following criteria must be met for each specific type of treatment:

1. Chemotherapy for Liver Cancer:
  - a. Is receiving intra-arterial infusion of 5-FuR for the treatment of liver cancer.
  - b. One of the following:
    - Liver cancer for patients with primary hepatocellular carcinoma.
    - Duke's Class D colorectal cancer, in whom the metastases are limited to the liver, and where (1) the disease is unresectable or (2) the patient refuses surgical excision of the tumor.
2. Anti-Spasmotic Drugs for Severe Spasticity:
  - a. Use to administer anti-spasmotic drugs intrathecally (e.g., baclofen).
  - b. The patient has chronic intractable spasticity.
  - c. The spasticity is unresponsive to less invasive medical therapy as determined by the following criteria:
    - A 6-week trial, the patient cannot be maintained on noninvasive methods of spasm control, such as oral anti-spasmotic drugs, either because these methods fail to control adequately the spasticity or produce intolerable side effects.
    - The patient has responded favorably to a trial intrathecal dose of the anti-spasmotic drug.
3. Opioid Drugs for Treatment of Chronic Intractable Pain:
  - a. Used to administer opioid drugs intrathecally or epidurally.
  - b. Patient has severe chronic intractable pain of malignant or nonmalignant origin with a life expectancy of at least 3 months.
  - c. Are proven unresponsive to less invasive medical therapy as determined by:
    - The patient's history indicating that he/she would not respond adequately to non-invasive methods of pain control, such as systemic opioids (including attempts to eliminate physical and behavioral abnormalities which may cause an exaggerated reaction to pain); and
    - A preliminary trial of intraspinal opioid drug administration has been undertaken with a temporary intrathecal/epidural catheter to substantiate adequately acceptable pain relief and degree of side effects (including effects on the activities of daily living) and patient acceptance.

In addition to meeting the appropriate above criteria the patient does not have one of the following contraindications:

1. A known allergy or hypersensitivity to the drug being used (e.g., oral baclofen, morphine, etc.);
2. An infection;
3. Body size at the implant site is insufficient to support the weight and bulk of the device;

4. Other implanted programmable devices since cross-talk between devices may inadvertently change the prescription.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Implantable pumps are designed to provide a continuous infusion of medication to a specific body site. The pumps are used with morphine for malignant pain management, and the drug 5-FUdR for liver cancer chemotherapy and Baclofen for intractable spasticity.

About two-thirds of metastatic cancer patients experience moderate-to-severe pain (Smith et al., 2002). Chronic non-malignant pain is also common. One type of non-malignant pain, chronic low back pain, is the second most frequent cause of hospital admissions in the United States (Deer et al., 2004).

Options for initial treatment of chronic pain include exercise, physical therapy, individual counseling, pain education classes, medications such as NSAIDs and complementary/alternative treatments such as massage or acupuncture. Opioids are an option as part of a comprehensive treatment plan if patients fail other therapies (GHC chronic non-malignant pain guideline). A meta-analysis of studies on oral morphine by the Cochrane Collaboration found it to be an effective analgesic for cancer pain (Wiffen et al., 2003). Another Cochrane review on chronic low-back pain found a lack of high-quality evidence and concluded that the benefits of opioids for this type of pain remain uncertain (Deshpande et al., 2007). Disadvantages of opioid analgesics include potential side effects such as nausea and vomiting, constipation, itching and respiratory depression. Moreover, during long-term opioid therapy patients may develop a tolerance leading to a need for higher doses, and patients may become physically dependent on opioids, and experience withdrawal symptoms if the medication is suddenly stopped (Wiffen et al., 2003).

The delivery of pain medication in directly into the fluid that surrounds the spinal cord (intrathecal analgesia) began in the 1970s following the discovery of opioid receptors in the central nervous system. Potential advantages of intrathecal analgesia include the ability to relieve pain in patients with previously intractable pain; the need for a lower milligram dose of opioids compared to systemic administration which may result in fewer side effects; and the ability to easily adjust the dose of opioids. Spinal analgesia was first used to treat chronic cancer-related pain. The use of intrathecal pain pumps for non-malignant pain is more controversial due to the limited evidence on the ability of opioids to relieve non-malignant pain over the long-term. As with oral opioids, there are concerns about tolerance, dependence and addiction (Williams et al., 2000; Cohen & Dragovich, 2007). Side effects that have been associated with long-term intrathecal morphine therapy include nausea, vomiting, itching urinary retention, constipation, sexual dysfunction and edema (Ruan, 2007).

Chronic pain is a major public health problem in the United States and across the world. It has significant negative effects on patients' functional capacity and quality of life, as well as high direct and indirect costs for the health care system. In a Gallup Survey of "Pain in America" more than 4 out of 10 adults indicated that they experience pain on a daily basis. Chronic pain is a complex phenomenon that is difficult to define. The American Society of Interventional Pain Physicians (ASIPP) defined it as:

1. Pain that persists beyond the usual course of an acute disease or a reasonable time for any injury to heal that is associated with chronic pathologic processes that cause continuous pain or pain at intervals for months or years.
2. Persistent pain that is not amenable to routine pain control methods, and
3. Pain where healing may never occur (Boswell 2007).

Chronic non-cancer pain (CNCP) has also been defined as ongoing pain that lasts over six months, that is due to non-life threatening causes, and does not respond to available treatment methods (Ghafoor 2007).

A key to successful management of chronic pain is a multidisciplinary approach that optimizes medication use in conjunction with other nonpharmacological therapies including exercise, physical therapy, individual counseling, pain education classes, and complementary/alternative treatments such as massage or acupuncture. When conservative treatments fail, surgery to correct underlying causes is considered. These conservative and surgical therapies provide adequate pain relief for most but not all CNCP patients (Ghafoor 2007).

Intrathecal (IT) analgesia was introduced in the 1970s following the discovery of opioid receptors in the central nervous system, and was initially used for malignant pain in patients who have failed to obtain adequate pain relief,

or those with adequate analgesia but with intolerable side effects to drug therapy. Currently, it is being used for other indications such as chronic back pain, neuropathy, mixed neuropathic-nociceptive pain, and radicular pain from failed back syndrome. IT analgesia involves the delivery of pain medication directly into the fluid that surrounds the spinal cord to target the pre- and post-synaptic receptors in the dorsal horn of the cord (Koulousakis 2007, Smith 2008, Patel 2009).

There are two types of implantable intrathecal drug delivery systems (IDDS) available in the US. The fixed rate pump allows continuous infusion and bolus dose administration but does not have the option of changing the flow rate. The other, and most common implantable pump, is a programmable infusion system which is available in different reservoir sizes. The infusion pumps are typically implanted in the lower abdomen, just beneath the skin. A catheter is inserted into the intrathecal space of the spine, tunneled under the skin and connected to the implanted pump for medication delivery, and to an external programmer that controls infusion rate and records medication concentration, volume, and dosage. A drug is infused over an extended period of time and may be delivered at a constant or variable rate by calibrating the infusion pump according to the physicians' specification. The pump requires refilling regularly via subcutaneous port injections. A variety of analgesic/co-analgesic agents have been utilized to provide spinal analgesia however, morphine remains the gold standard and is the only opioid approved by the FDA for intrathecal delivery to treat chronic pain. The FDA approved the use of ziconotide, for patients unresponsive to intrathecally delivered morphine. It also approved the use baclofen with the use of implantable infusion pumps for patients with severe spasticity of spinal origin. However, off-label use of other drugs in IT pumps is common (Ghafoor 2007, Koulousakis 2007, Turner 2007).

The implantable infusion pump is an invasive alternative for medication delivery and requires ongoing maintenance and surgeries to periodically replace the pump. It has the potential benefit of providing more effective pain control by administering the analgesic drug directly to the target area, using lower doses of opioids compared to systemic administration, and the ability to adjust the dose of opioids. However, there are many risks and potential harms associated with IT drug therapy. These involve the problems related to the intrathecal drug delivery systems (IDDS), and the adverse events of the medications used. Serious complications that may occur after the intrathecal catheter placement include postoperative subarachnoid hemorrhage, meningitis, catheter tip inflammatory masses, infection, root irritation, reactive arachnoiditis, catheter dislocation, and pump failure. Drug-related side effects consist of dose-independent side effects as urinary retention, pruritis, pain due to bolus injection, perspiration, and sedation; and dose-dependent side effects as nausea, constipation, dysphoria, euphoria, sedation, respiratory depression, hypotension, central depression, and tachyphylaxias. As with oral opioids, there are concerns about tolerance, dependence, and addiction. Drug overdose could take place if the pump is inappropriately used or monitored; and drug withdrawal symptoms may occur with mechanical problems as pump failure or catheter blockage and kinking. There are also reports that patients with CNCP treated with intrathecal opioid therapy experience increased mortality compared to others with similar conditions treated with other therapies. It is thus recommended that pumps for chronic IT opioid application should only be implanted in specialized center. Before implantation the therapeutic effect of IT application should be assessed by a bolus trial or continuous injection via an external pump, connected to the intrathecal catheter through an implanted port (Cohen 2007, Koulousakis 2007, Smith 2008, Pasutharnchat 2009, Rathmell 2009, Coffey 2009).

In 1991, the Medtronic SynchroMed infusion system was approved by the FDA for the intrathecal delivery of morphine to treat malignant and non-malignant pain. The system consists of a pump that is generally implanted subcutaneously in the lower abdominal wall, a spinal catheter implanted into the lumbar intrathecal space between L1 and L4 and a programmer. The pump can be programmed via telemetry to control infusion modes and flow rates. SynchroMed is the only commercially available pump system that can be programmed outside the body. There are various models that differ in the size of the reservoir and the presence of a side catheter access port. Other implantable infusion pumps that have received FDA premarket approval include the Codman 3000 (Codman), Model 300 Constant Flow Implantable infusion Pump (Arrow international) and the infusaid implantable Infusion Pump (Strato/infusaid).

#### Assessment objectives:

- To determine whether implanted infusion pumps for delivering intrathecal opioids are effective for the control of chronic noncancer pain (CNCP).
- To determine whether the use of implanted infusion pumps for delivering intrathecal opioids improves the quality of life and functioning in patients with CNCP.
- To determine whether the use of implanted infusion pumps for delivering intrathecal opioids are more effective than other non-invasive alternative therapies for pain control in patients with CNCP.
- To determine whether the technology is safe for use in patients with CNCP.

## Medical Technology Assessment Committee (MTAC)

### *Implanted Pain Pumps for the Intrathecal Delivery of Opioids*

08/06/2007: MTAC REVIEW

**Evidence Conclusion:** Cancer pain: The best evidence on the safety and effectiveness of implanted intrathecal pain pumps is an RCT with 200 patients. Of the 74% of patients with follow-up data at 4 weeks, there was a significantly greater reduction in toxicity, marginally significant reduction in pain and marginally significant increase in clinical success in the group assigned to receive a SynchroMed implantable pain pump in addition to comprehensive medical management (CMM) compared to CMM alone. Estimated survival at 6 months was higher in the group assigned to pain pumps, but the difference did not reach statistical significance. Limitations of the study include lack of blinding which could lead to biased estimates of self-report pain outcomes, funding by the device manufacturer and substantial cross-over (only 70% of the patients evaluated at 4 weeks in the pain pump group actually received implants and 5% of patients in the non-implant group received implants). **Non-malignant pain:** The evidence on safety and effectiveness is insufficient. There were case series and a cohort study that only compared pre- to post-implant changes, not between-group differences. The studies tended to find a reduction in self-reported pain after pump implantation and a reduction in oral morphine use (1 or 2 year follow-up). There were no comparison interventions and sample sizes were small. Device-related complications were relatively common. **Articles:** The Medline search yielded one systematic review. This was published by the British Health Technology Assessment (HTA) group in 2000 and they did not identify any high-grade evidence. One randomized controlled trial was identified on malignant pain. Several articles were published based on this trial, the first on study outcomes in 2002. The article presenting the primary study outcomes (Smith et al., 2002) was critically appraised. No randomized controlled trials on non-malignant were identified. There was one non-randomized comparative trial which was critically appraised. (Thimineur et al., 2004). Two uncontrolled studies were also reviewed. Deer et al. (2004) reported data from the National Outcomes Registry for Low Back Pain. This registry was set up to prospectively collect data on patients with chronic low-back pain who underwent screening or a trial or an implanted pain pump. The other study was a prospective series using the Medtronic SynchroMed device (Anderson and Burchiel, 1999). There were other case series that had small sample sizes and/or did not mention whether a commercially available device was used. *Studies selected for critical appraisal were:* Smith TJ, Staats PS, Deer T et al. for the Implantable Drug Delivery Systems (IDDS) study. Randomized clinical trial of an implantable drug delivery system compared with comprehensive medical management for refractory cancer pain. *J Clin Oncol* 2002; 20: 4040-4049. See [Evidence Table](#). Thimineur MA, Kravitz E, Vodapally MS. Intrathecal opioid treatment for chronic non-malignant pain: a 3-year prospective study. *Pain* 2004; 109: 242-249. See [Evidence Table](#). Deer T, Chapple I, Classen A et al. Intrathecal drug delivery for treatment of chronic low back pain. *Am Acad Pain Med* 2004; 5: 6-13. See [Evidence Table](#). Anderson VC, Burchiel KJ. A prospective study of long-term intrathecal morphine in the management of chronic nonmalignant pain. *Neurosurg* 1999; 44: 289-300. See [Evidence Table](#).

The use of implanted pain pumps for the intrathecal delivery of opioids in the treatment of malignant pain meets the *Group Health Medical Technology Assessment Criteria*.

The use of implanted pain pumps for the intrathecal delivery of opioids in the treatment of non-malignant pain does not meet the *Group Health Medical Technology Assessment Criteria*.

10/18/2010: MTAC REVIEW

### *Implanted Pain Pumps for the Intrathecal Delivery of Opioids*

**Evidence Conclusion:** This re-review of the implantable infusion pumps for delivering intrathecal opioids did not identify any studies that would change the conclusion from the 2007 MTAC review of the technology for the control of chronic noncancer pain (CNCP). There is still insufficient published evidence on the safety and effectiveness of the infusion pump for the control of CNCP and/or improving the QoL of the patients. The published studies for this indication were small case series and observational studies with no control groups. Comparisons were made between pre- and post-implant changes, not between differences among groups receiving different therapies or interventions. The studies had multiple threats to validity and may only provide low quality evidence; they are subject to selection and observation bias, and did not take into account the placebo effect of the treatment, or assess outcome for patients who had not received the therapy. Moreover, the studies did not compare characteristics of patients who completed the study to those who dropped out, did not adjust for the use of additional therapies or other confounding factors, and were funded by the manufacturer. Overall, the results of the published studies indicate a reduction in self-reported pain, reduction in oral morphine use, and /or improvement in quality of life and psychological function. However, there was a significant proportion of side effects associated with the implanted pump, the catheter, and the IT opioid use.

The Washington State Health Technology Assessment (HTA) program reviewed the implantable infusion pump for drug administration to treat chronic non-cancer pain, in August 2008. After reviewing the evidence the Health Technology Clinical Committee (HTCC) concluded, "The evidence on infusion pumps did not demonstrate net health benefit because weak or unproven evidence of some effectiveness for certain patients was undermined by significant evidence of serious harms and adverse events associated with the implantation of infusion pumps. The committee found that infusion pumps were not proven to be equally or more safe or effective, and the cost, while not a significant factor for this decision was likely equivalent. Based on these evidentiary findings, the committee voted 8 to 2 for non-coverage." Conclusion: There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids is effective for the control of chronic non-cancer pain (CNCP). There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids improves quality of life and functioning in patients with CNCP. There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids is more effective than other non-invasive alternative therapies for pain control in patients with CNCP. There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids is safe for use in patients with CNCP.

**Articles:** The available published literature on intrathecal (IT) opioid therapy delivered through implanted pumps for chronic noncancer pain is limited and consists of systematic reviews that did not pool the results in meta-analyses, small case series, and observational cohort studies with no control or comparison groups. The literature search did not identify any meta-analyses or randomized controlled trials that compared IT opioid therapy with other non-invasive therapies published since the 2007 MTAC review. There was one retrospective cohort study (Atli 2010) reporting on 3-years outcome of chronic pain patients receiving IT treatment through implanted pumps, one case series (Shaladi 2007) of 24 patients with osteoporotic vertebral fractures treated with intrathecal morphine infusion, and another series (Duse 2009) reporting on psychological functionality of 30 patients with CNCP. The larger cohort study with a long-term follow-up was selected for critical appraisal: Atli A, Theodore BR, Turk DC, et al. Intrathecal opioid therapy for chronic nonmalignant pain: a retrospective cohort study with 3-year follow-up. *Pain Medicine* 2010; 11:1010-1016. See [Evidence Table](#).

The use of implanted pain pumps for the intrathecal delivery of opioids in the treatment of non-malignant pain does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Intensity Modulated Radiation Therapy (IMRT)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

See [LCD for Intensity Modulated Radiation Therapy \(IMRT\) \(L34080\)](#)

##### For Non-Medicare Members

Group Health has elected to use the Intensity Modulated Radiation Therapy (IMRT) (GHC-0455) MCG\* for medical necessity determinations

#### If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from oncologist and radiation oncologist

**\*MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Group Health can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Group Health Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Evidence and Source Documents

[Intensity-Modulated Radiation Therapy \(IMRT\) for Head and Neck Cancer](#)

[Intensity Modulated Radiation Therapy \(IMRT\) for Prostate Cancer](#)

#### Background

The aim of radical radiotherapy is to deliver a homogenous radiation dose to a tumor target with a minimal dose to surrounding normal tissue. Conventional external beam irradiation (EBRT) has been used to treat prostate cancer for more than thirty years. It partly achieves its goal, but leads to irradiation of unnecessarily large volumes of normal tissue. The proximity to the rectum and the bladder has limited the ability to deliver doses > 70 Gy to the prostate. This dose may be sufficient for many, but not all prostate cancer cases. The frequent persistence of local residual tumor after EBRT has been a matter of concern. The inability to eradicate some prostate cancers may be related to the lack of tumoricidal doses of radiotherapy on certain resistant clones of tumor cells.

Conformal radiotherapy (CRT) aims at minimizing the volume of normal tissue irradiated by shaping the dose distribution to conform tightly to the shape of the tumor, thus reducing the dose to the normal tissue surrounding it. The three dimension conformal radiotherapy (3D-CRT) is a further advancement to the 2D dose planning system. It entails direction of multiple beams conformed to the shape of the target from each beam's eye view (BEV). It thus enables a higher degree of certainty of target localization and permits the use of narrow margins around it. Its ultimate goal is to escalate the radiation dose to the target, while maximally excluding the adjacent normal tissue. However, there are situations in which 3D-CRT cannot produce a satisfactory treatment plan because of complex target volume shapes, or close proximity of sensitive normal tissue.

Most recently, an advanced form of 3D-CRT, called intensity modulated radiation therapy (IMRT) was developed to overcome these limitations by adding modulation of beam intensity to beam shaping. In this method intensity modulators, such as multiple leaf collimators (MLC), or beam modifiers are used to divide the treatment beam into a set of small beamlets, the intensity of which vary from 0-100%, independent of all other beamlets. IMRT can achieve any dose distribution, notably an abrupt decrease in the dose at the limit between the tumor volume and the adjacent normal tissue.

The benefits of IMRT will be greatest for patients with tumor targets that are concave, and where normal tissues around it are clinically important. Examples of these are the larynx, pharynx, and thyroid. The main focus for IMRT in the United States has been the prostate, which forms the largest single tumor site treated with IMRT. It is hoped that it will reduce the rectal and bladder doses of irradiation, allow further dose escalation and increase the cure rates.

Special software and computer control systems are necessary to implement IMRT. The planner has to define the anatomical contour of the target volume, the desired dose and the degree of inhomogeneity in the tumor volume. Several target volumes can be distinguished e.g. primary tumor and lymph nodes. The total dose or the dose per session to each target volume can be modulated. IMRT could be used for the whole duration of a radiotherapy treatment, or simply as a boost after more conventional treatment.

## Medical Technology Assessment Committee (MTAC)

### ***Intensity-Modulated Radiation Therapy (IMRT) for Head and Neck Cancer***

#### BACKGROUND

Intensity-modulated radiation therapy (IMRT) is a type of external beam radiation therapy that permits complex three-dimensional shaping of the radiation beams to precisely target the tumor. This allows for a larger dose of radiation to be applied to the tumor site, while minimizing exposure of the surrounding healthy tissue. Instead of a single, uniform beam as in traditional external beam radiation, IMRT involves the delivery of many small beams of varying intensity. Computer algorithms are used to coordinate the beams and plan the delivery of the radiation dose. Compared to other types of external beam radiation, IMRT is best able to generate concave dose distributions. Head and neck cancers may be particularly suited to treatment with IMRT because these tumors often have concave volumes and because head and neck tumors generally require relatively high doses (i.e. 60-70 Gy) of radiation and are in close proximity to critical tissues and organs that are radiation-sensitive (such as the salivary glands, inner and middle ears, temporomandibular joints, temporal brain and optic nerve). Head and neck cancers may also be good candidates for IMRT because of the relative lack of organ motion compared to other areas of the body. Due to the highly focused radiation dose, lack of motion is important. The most prevalent long-term adverse effect with radiation therapy for head and neck cancers is xerostomia (dry mouth) caused by damage to the salivary glands. This adverse effect may be reduced with IMRT. To date, several thousand patients worldwide have received IMRT treatment; so far, most of this has been for the treatment of prostate cancer. Several centers in the U.S. have been providing IMRT for head and neck cancer, most notably Washington University in St. Louis, the University of California, San Francisco (UCSF) and the University of Michigan (Cozzi & Fogliata, 2002). IMRT is a rapidly evolving technology that experienced clinicians believe will continue to evolve in the near future (Eisbruch, 2002).

#### 04/09/2003: MTAC REVIEW

### ***Intensity-Modulated Radiation Therapy (IMRT) for Head and Neck Cancer***

**Evidence Conclusion:** There is insufficient evidence to determine the effect of IMRT on health outcomes in patients with head and neck cancer compared to other types of radiation therapy. There is only one published comparative study with clinical outcomes, a retrospective cohort study. This study is limited because only 26 patients received IMRT (14 had post-operative IMRT and 12 had definitive IMRT). Although the findings suggest that there is a higher survival rate and lower rate toxicity rate with IMRT compared to other forms of radiation therapy, the statistics are unreliable due to the small number in the IMRT group. (Percentages are generally considered unstable when the sample size is less than 100). In the Lee case series, actuarial 4-year survival estimates were 98% for local-regional progression-free survival and 66% for distant metastasis-free survival. Two years after IMRT, 32% of patients had Grade I xerostomia and only 1 patient had Grade 2 xerostomia. In the Chao case series, the 2-year actuarial survival estimates was 85% for loco-regional control, (89% after salvage surgery). The case series were limited by lack of comparison groups, variable length of follow-up and inconsistent interventions (e.g. three different IMRT techniques were used over time in the Lee study, and in both case series, some patients had chemotherapy). In addition, each included a heterogeneous patient population in terms of cancer location and stage.

**Articles:** The search yielded 120 articles, many of which were reviews, opinion pieces, dealt with technical aspects of the procedure or addressed treatment planning only. There were no randomized controlled trials comparing clinical outcomes after IMRT versus other forms of radiation therapy. There was one non-randomized comparative clinical study, a retrospective cohort study. The other empirical studies were all case series. The most recent case series from the three major institutions performing IMRT for head and neck cancer (Washington University, UCSF and the University of Michigan) were identified. Two of these institutions had published series of over 50 patients with head and neck cancer who had received IMRT. The comparative study and the two largest case series were critically appraised: Chao KSC, Majhail N, Huang C et al. Intensity-modulated radiation therapy

reduces late salivary toxicity without compromising tumor control in patients with oropharyngeal carcinoma: A comparison with conventional techniques. *Radiother Oncol* 2001; 61: 275-280. See [Evidence Table](#)

The use of IMRT in the treatment of head and neck cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **06/01/2004: MTAC REVIEW**

##### **Intensity-Modulated Radiation Therapy (IMRT) for Head and Neck Cancer**

**Evidence Conclusion:** No new randomized or non-randomized comparative studies were identified. There were updates of earlier case series from two of the major institutions performing IMRT for head and neck cancer, UCSF and Washington University. There were also several new small case series. The new literature does not substantially change the conclusions of the April 2003 MTAC review.

**Articles:** Medline was searched from 2003 to May 2004 using the terms, "intensity-modulated radiation therapy", "IMRT", and "head and neck cancer", with variations. The search was limited to English language publication and human populations. No new randomized or non-randomized comparative studies were identified. There were updates of earlier case series from two of the major institutions performing IMRT for head and neck cancer, UCSF and Washington University. There were also several new small case series. Lee N, Xia P, Quivey JM. Intensity-modulated radiotherapy in the treatment of nasopharyngeal carcinoma: An update of the UCSF experience. *Int J Radiation Oncology Biol Phys* 2002; 53: 12-22. See [Evidence Table](#) Chao KSC, Ozyigit G, Tran BN et al. Patterns of failure in patients receiving definitive and postoperative IMRT for head-and-neck cancer. *Int J Radiation Oncology Biol Phys* 2003; 55: 312-321. See [Evidence Table](#)

The use of IMRT in the treatment of head and neck cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

##### **Intensity Modulated Radiation Therapy (IMRT) for Prostate Cancer**

###### **BACKGROUND**

The aim of radical radiotherapy is to deliver a homogenous radiation dose to a tumor target with a minimal dose to surrounding normal tissue. Conventional external beam irradiation (EBRT) has been used to treat prostate cancer for more than thirty years. It partly achieves this goal, but may lead to irradiation of unnecessarily large volumes of normal tissue. The proximity to the rectum and the bladder has limited the ability to deliver doses > 70 Gy to the prostate. This dose may be sufficient for many but not all prostate cancer cases. The frequent persistence of local residual tumor after EBRT has been a matter of concern. The inability to eradicate some prostate cancers may be related to the lack of tumoricidal doses of radiotherapy on certain resistant clones of tumor cells. Conformal radiotherapy (CRT) aims at minimizing the volume of normal tissue irradiated by shaping the dose distribution to conform tightly to the shape of the tumor, thus reducing the dose to the normal tissue surrounding it. The three dimension conformal radiotherapy (3D-CRT), is a further advancement to the 2D dose planning system. It entails direction of multiple beams conformed to the shape of the target from each beam's eye view (BEV). It thus enables a higher degree of certainty of target localization and permits the use of narrow margins around it. Its ultimate goal is to escalate the radiation dose to the target, while maximally excluding the adjacent normal tissue. However, there are situations in which 3D-CRT cannot produce a satisfactory treatment plan because of complex target volume shapes, or close proximity of sensitive normal tissue. Most recently, an advanced form of 3D-CRT, called intensity modulated radiation therapy (IMRT) was developed to overcome these limitations by adding modulation of beam intensity to beam shaping. In this method intensity modulators, such as multiple leaf collimators (MLC), or beam modifiers are used to divide the treatment beam into a set of small beamlets, the intensity of which vary from 0-100%, independent of all other beamlets. IMRT can achieve any dose distribution, notably an abrupt decrease in the dose at the limit between the tumor volume and the adjacent normal tissue. The benefits of IMRT will be greatest for patients with tumor targets that are concave, and where normal tissues around it are clinically important. Examples of these are the larynx, pharynx, and thyroid. The main focus for IMRT in the United States has been the prostate, which forms the largest single tumor site treated with IMRT. It is hoped that it will reduce the rectal and bladder doses of irradiation, allow further dose escalation and increase the cure rates. Special software and computer control systems are necessary to implement IMRT. The planner has to define the anatomical contour of the target volume, the desired dose and the degree of homogeneity in the tumor volume. Several target volumes can be distinguished e.g. primary tumor and lymph nodes. The total dose or the dose per session to each target volume can be modulated. IMRT could be used for the whole duration of a radiotherapy treatment, or simply as a boost after more conventional treatment. IMRT for prostate cancer was previously reviewed by MTAC in April, 2002. At that time, the evidence consisted of case series on the toxicity of IMRT and the item failed MTAC evaluation criteria.

#### **4/10/02: MTAC REVIEW**

##### **Intensity Modulated Radiation Therapy (IMRT) for Prostate Cancer**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

**Evidence Conclusion:** The studies reviewed aimed at determining the toxicity of the high-dose radiation delivered by IMRT. In both studies IMRT was not compared to a low dose conventional treatment, instead it was compared to 3D-CRT, which also uses a high dose irradiation, yet not modulated. Compared to 3D-CRT, IMRT was found to cause significantly lower acute, and late rectal toxicity in Zelefsky's study, and significantly higher acute rectal toxicity in the Shu study. In the two studies reviewed, there was no significant difference between the two treatments in the acute or late bladder toxicity. Both studies were not randomized and non-blinded, there were some variations in the base-line characteristics in the treatment groups, and no adjustments were made for confounding factors. Randomized controlled studies with long-term follow-up are needed to study the effect of IMRT on the outcome of the cancer, as well as the morbidity from the radiation.

**Articles:** The search yielded 55 articles most of which were reviews, case reports, editorials, and letters. The literature did not reveal any randomized controlled studies or meta-analyses. It also did not reveal any study on the effect of IMRT on the outcome of the prostate cancer. There were 2 articles on studies made to determine the toxicity of IMRT, and compare it to 3D-CRT. *The following articles were critically appraised:* Zelefsky MJ, et al. Clinical experience with intensity modulated radiation therapy (IMRT) in prostate cancer. *Radiotherapy and Oncology* 2000;55:241-9. See [Evidence Table](#) Shu H G, et al. Toxicity following high-dose three-dimensional conformal and intensity modulated radiation therapy for clinically localized prostate cancer. *Urology* 2001;57:102-7. See [Evidence Table](#)

The use of intensity modulated radiation in the treatment of prostate cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **2/11/04: MTAC REVIEW**

##### **Intensity Modulated Radiation Therapy (IMRT) for Prostate Cancer**

**Evidence Conclusion:** The evidence is limited by the lack of randomized controlled trials, comparison only to 3D-CRT rather than lower-dose standard radiotherapy, inconsistent length of follow-up, lack of actual survival data and potential confounding by androgen deprivation therapy in a substantial proportion of patients. Both studies reported on biochemical survival rates. Three-year actuarial PSA relapse-free survival varied from 81-92% in the Zelefsky study and thirty-month actuarial PSA relapse-free survival was 94% for IMRT and 88% for 3D-CRT (non-significant difference) in the Kuplian study. Change in PSA level is an intermediate outcome and may not be an accurate measure of prognosis. There appeared to be relatively low rates of serious late toxicity, but many patients were not followed up long enough to contribute to this analysis. In the Zelefsky study, 9 of the patients followed for a sufficiently long time (1%) developed grade 3 late toxicity. In the Kuplian study, actuarial grade 3 late rectal toxicity at 30 months was 2% in the IMRT group and 8% in the 3D-CRT group. The evidence is limited by the lack of randomized controlled trials, comparison only to 3D-CRT rather than lower-dose standard radiotherapy, inconsistent length of follow-up, lack of actual survival data and potential confounding by androgen deprivation therapy in a substantial proportion of patients. Both studies reported on biochemical survival rates. Three-year actuarial PSA relapse-free survival varied from 81-92% in the Zelefsky study and thirty-month actuarial PSA relapse-free survival was 94% for IMRT and 88% for 3D-CRT (non-significant difference) in the Kuplian study. Change in PSA level is an intermediate outcome and may not be an accurate measure of prognosis. There appeared to be relatively low rates of serious late toxicity, but many patients were not followed up long enough to contribute to this analysis. In the Zelefsky study, 9 of the patients followed for a sufficiently long time (1%) developed grade 3 late toxicity. In the Kuplian study, actuarial grade 3 late rectal toxicity at 30 months was 2% in the IMRT group and 8% in the 3D-CRT group.

**Articles:** The search yielded 102 articles, many of which were reviews, opinion pieces, dealt with technical aspects of the procedures or were on related procedures. There were no randomized controlled trials. There were three new case series publications by the Memorial Sloan-Kettering Cancer Center research group (led by Zelefsky). The patients included in the three publications overlapped. Two of the articles also included patients who were treated with 3D-CRT, but IMRT and 3D-CRT were not compared in analysis. The Zelefsky case series with the largest number of IMRT cases was critically appraised. In addition, there was a study conducted at the Cleveland Clinic which compared series of patients treated with short-course IMRT and 3D-CRT. There were no studies comparing IMRT to lower dose conventional radiotherapy. *The studies reviewed were:* Zelefsky MJ, Fuks Z, Hunt M et al. High-dose intensity modulated radiation therapy for prostate cancer: Early toxicity and biochemical outcome in 772 patients. *Int J Radiation Oncology Biol Phys* 2002; 53: 1111-1116. See [Evidence Table](#) Kuplian PA, Reddy CA, Carlson TP. et al. Preliminary observations on biochemical relapse-free survival rates after short-course intensity-modulated radiotherapy (70 Gy at 2.5 Gy/Fraction) for localized prostate cancer. *Int J Radiation Oncology Biol Phys* 2002; 53: 904-912. See [Evidence Table](#).

The use of intensity modulated radiation in the treatment of prostate cancer does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Infrared Thermography

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

National Coverage Determinations (NCD)

[Thermography \(220.11\)](#).

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Infrared thermography is a non-invasive imaging procedure. It produces representations of variation in temperature on the surface of the human skin. Distribution of skin temperature depends on complex relationships between the skin tissue, inner tissue, local vasculature and metabolic and hormonal activity. Use of thermography as a diagnostic tool is based on the premise that the abnormal issue, such as a tumor, would raise the temperature on the skin surface due to increased metabolic activity. In the 1950s and 60s, researchers found that local skin temperatures over a breast tumor were about 2-3 degrees higher than normal skin temperature.

Although, over the past several decades, there has been experimentation with protocols for obtaining and interpreting thermograms, to date there no established procedures for using thermography to enhance diagnosis of breast cancer or other abnormalities (Mital & Scott, 2007; Ohashi & Uchida, 2000). Among the conditions for which thermography has been proposed are Raynaud's phenomenon, gastric cancer, headaches, deep vein thrombosis, and impaired spermatogenesis in infertile men.

Several thermography devices have been approved by the FDA, including the Mark I Thermal Imager (IX-DR; Howell, MI) in 2002 and EMD Thermography System in 2006. The EMD Thermography system includes an infrared sensor that is placed in contact with the skin to measure temperature. In addition, special software is used to analyze and display the temperature measurements.

Both recently approved devices were considered to be substantially equivalent to predicate devices. Approval was based on the technology's ability to measure skin temperature, rather than their proven ability to improve diagnosis of any disease. According to FDA documents, thermography is indicated for use as an adjunctive medical imaging modality in situations where a physician chooses to use it.

#### Medical Technology Assessment Committee (MTAC)

##### *Infrared Thermography*

**06/04/2008: MTAC REVIEW**

**Evidence Conclusion:** There is no empirical evidence that adjunctive infrared thermography improves the diagnosis of any disease or abnormality.

**Articles:** No technology assessments conducted by other organizations were identified. The Medline search did not yield any empirical studies that evaluated the diagnostic accuracy of thermography as an adjunctive diagnostic modality for any indication. Several articles were identified that proposed methods for analyzing thermograms, or discussed technical aspects of using thermography.

The use of infrared thermography does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### InFUSE™ Bone Graft

- InFUSE™ Bone Graft/LT-CAGE™ Lumbar Tapered Fusion Device (Bone Morphogenetic Protein-2)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Medical necessity review is no longer required for Medicare members.

#### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies (and/or) provides better long-term outcomes than current standard services/therapies.

*\*Pending MTAC Review – See Medical Policy Coordinator for more details*

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

### Background

Anterior lumbar interbody fusion has been performed for decades to manage patients with symptomatic degenerative disc diseases. Initially, autologous bone, typically harvested from the iliac crest, was considered the gold standard for lumbar fusion. Spine surgeons however, have been seeking alternatives to the iliac crest harvest in order to avoid the pain, scarring and morbidity associated with the procedure, and yet maintain the high fusion rates. A variety of graft materials such as local bone, bones from bone banks, demineralized bone matrix, and platelet gels have been advocated but did not prove to be as effective as iliac crest grafts (Baskin 2003, Glassman 2005).

In the last decade, laboratory experiments showed that recombinant bone morphogenetic protein type 2 (rhBMP-2), a genetically engineered protein, was capable of initiating osteoconduction and achieving spinal arthrodesis in nonhuman primate models. Application of rhBMP-2 was then explored for lumbar fusion among humans, and demonstrated promising results. RhBMP-2 and its collagen sponge carrier manufactured from bovine Type I collagen, are placed inside a metallic tapered spinal fusion cage known as the LT-CAGE lumbar tapered fusion device. The device is implanted through an anterior opening or laparoscopic approach. The fusion cage maintains the spacing and temporarily stabilizes the diseased region of the spine, while the InFUSE Bone Graft induces new bone tissue at the site of implantation. The newly formed bone would permanently stabilize (fuse) this portion of the spine. The fusion process requires several months to complete (Baskin 2003, Glassman 2005).

In 2002, rhBMP-2 and the absorbable collagen sponge carrier ( InFUSE Bone Graft Medtronic Sofamor Danek, Memphis , TN ) was approved by the FDA as an iliac crest bone graft replacement for use in conjunction with lordotic tapered cages (LT-CAGE lumbar fusion device, Medtronic Sofamor Danek, Memphis , TN), in anterior lumbar single body fusion. According to the manufacturer, it is indicated for spinal fusion in skeletally mature patients (>18 years old, with radiographic evidence of epiphyseal closure) with degenerative disc disease at one level from (L4-S1).

InFUSE Bone Graft was reviewed by MTAC in 2003 and did not meet the Group Health Medical Technology Assessment criteria due to insufficient evidence on the safety and efficacy of the technology. It is being re-reviewed to update the evidence as many other health plans and Medicare are currently covering the technology.

## 10/08/2003: MTAC REVIEW

**Evidence Conclusion:** The trial reviewed does not provide sufficient evidence to conclude that InFUSE Bone Graft is equivalent or superior to the standard treatment. It was randomized and controlled; yet the authors compared improvements associated with the InFUSE Bone Graft with the preoperative condition, and not with the standard treatment. The trial shows that both treatments led to significant improvement in the back pain, leg pain, as well as pain associated with activity when compared to the preoperative scores. The two procedures were also associated with post-operative vs. baseline, high neurological success, patient satisfaction and bone fusion. The authors noted that the success rates and pain scores were similar between the two groups, based on the values observed and not on statistical tests of significance. It seems unlikely that there are any significant differences between the two groups, as the numbers, and scores are close. This may suggest that the effect of the two treatments may be similar, but the study isn't conclusive as it may have been underpowered to detect a difference, and was not designed as an equivalence trial that requires a larger sample size, and a different method of analysis than superiority trials.

**Articles:** The search revealed 4 randomized controlled studies and one case series. Three of the RCTs were conducted by the same principle investigator, and included patients from the same center: one large trial with 279 patients, and two smaller RCTs with 46, and 42 patients. The other trial revealed included only 14 patients. The search also revealed an article where the same principle investigator of the three RCTs pooled data from his trial as well as other 3 unpublished studies, two of which were non-randomized. It had a poor methodology, and cannot be categorized as a meta-analysis. The largest of the three RCTs conducted by the same investigator group was selected for critical appraisal. *The following study was critically appraised:*  
Burkus JK, Gornet MF, Dickman CA, et al. Anterior lumbar interbody fusion using rhBMP-2 with tapered interbody cages. *J Spinal Disord Tech.* 2002;15:337-49. See [Evidence Table](#).

The use of recombinant human bone morphogenetic protein (rhBMP-2) placed on an absorbable collagen sponge (ACS) in the treatment of degenerative disc disease does not meet the *Group Health Medical Technology Assessment Criteria*.

## 12/07/2009: MTAC REVIEW

### InFuse Bone Graft

**Evidence Conclusion:** There is a lack published material on the use of InFUSE Bone Graft for anterior lumbar interbody fusion, the indication for which the technology received the FDA approval. Glassman and colleagues' trial (2008) had the advantage of comparing rhBMP-2 to iliac crest bone graft in a randomized controlled trial with 2-year follow-up duration. However, the technology was used off-label for a posterolateral lumbar fusion among patients older than 60 years of age. Moreover, the trial was not blinded, and the authors did not discuss the method of randomization, or clearly describe the inclusion/ exclusion criteria. Non-blinding may be a source of observation bias, especially with the subjective primary outcomes of the trial. The investigators tried to partially overcome this limitation by blinding the orthopedic surgeons who evaluated the radiological outcomes. The authors also did not discuss any power analysis for determining the sample size, and analysis was not based on intention to treat. Overall, the results of the trial show significant improvements in health related quality of life, as well as the leg, and back pains at one and two years of follow-up among the patients in the two treatment groups, when compared to the preoperative status. There were no significant differences in the primary outcomes between the two interventions. The outcomes may appear similar, but the lack of significant statistical significance does not necessarily imply equivalence. The study was relatively small and might have been unpowered to detect significant differences between the study groups. It was not designed as an equivalence trial that requires a larger sample size and different method of analysis than a superiority trial. Radiographic evaluations at two years showed higher fusion rate with rhBMP-2 vs. ICBG (86.3% and 70.8%, respectively). In conclusion there is insufficient published evidence to conclude that InFUSE Bone Graft is equivalent, noninferior, or superior to the standard iliac crest bone graft in improving functional ability and quality of life of patients with symptomatic degenerative disc disease.

**Articles:** The search revealed over 30 articles on rhBMP-2 /InFUSE Bone Graft. Many were unrelated to the current reviews; others used rhBMP-2 in different formulations or in combination with other elements e.g. ceramic granules. Two articles (Glassman, et al 2005 and 2008) reporting on one and two years results of a randomized controlled study comparing the use of rhBMP-2 versus iliac crest bone graft (ICGB) for lumbar spine fusion, were identified as well as a small nonrandomized trial and two case series studies on the use of InFUSE Bone Graft. The RCT with the 2-year follow-up was selected for critical appraisal. Glassman SD, Carreon LY, Djurasovic M, et al. RhBMP-2 versus iliac crest bone graft for lumbar spine fusion: A randomized, controlled trial in patients over sixty years of age. *Spine.* 2008;33:2843-9. See [Evidence Table](#).

The use of recombinant human bone morphogenetic protein (rhBMP-2) placed on an absorbable collagen sponge (ACS) in the treatment of degenerative disc disease does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Inhaled Nitric Oxide (iNO) Therapy

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Non-Medicare Members

- A. Treatment of pulmonary hypertension (PHN) to reduce risk of chronic lung disease, and respiratory failure in infants born or at near term (>34 weeks)
1. Neonate does not have congenital diaphragmatic hernia, and
  2. Conventional therapies such as administration of high concentrations of oxygen, hyperventilation, high-frequency ventilation, the induction of alkalosis, neuromuscular blockade, and sedation have failed or are expected to fail.
  3. Treatment of Congenital Diaphragmatic Hernia (CDH)
    - a. iNO is required to stabilize a patient during transition to ECMO (Usually required for a few hours before)
    - b. iNO is required during transition off of ECMO when pulmonary arterial pressures are high ( this can be a period of time ranging from hours to several days)
- B. Treatment of pulmonary hypertension in pre-term newborns ( $\leq 34$  weeks)  
There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.
- C. Treatment of acute respiratory distress syndrome (ARDS) in adults and children  
There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.
- D. Treatment of Cyanotic Congenital Heart Disease with pulmonary hypertensive crisis (all pediatric patients)
1. The patient is being managed for acute pulmonary hypertension crisis and acute right heart failure with a predisposition to unrestricted over-circulation. OR
  2. The patient requires a surgical intervention with increased risk of pulmonary hypertension crisis and is receiving pulmonary vascular therapy AND
    - a. Typical course of treatment 3 days (this may be longer on a case by case basis) to transition to oral medications and wean-off iNO OR
    - b. The patient needs transplant for right heart failure and requires iNO for 1 week to several months.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

##### Treatment of persistent pulmonary hypertension (PPHN) and respiratory failure in infants born or at near term.

Persistent pulmonary hypertension of the newborn (PPHN) is an important cause of cardiorespiratory failure in the near-term neonate (>34 weeks). It occurs when normal cardiopulmonary transition fails to take place after birth; the newborn's arteries to the lungs remain constricted limiting the amount of blood flow to the lungs and therefore the amount of oxygen into the blood stream. PPHN can occur either as a primary condition of neonatal maladaptation or secondary to other conditions such as pneumonia, sepsis, hyaline membrane disease, meconium aspiration, congenital diaphragmatic hernia, or pulmonary hyperplasia. Causes of PPHN may be variable, but all lead to same physiologic changes; a persistently raised pulmonary vascular resistance that leads

to severe hypoxemia due to extra pulmonary shunting. Even with appropriate therapy, the mortality for PPHN remains between 5 and 10% (Gonzales 2009, Finer 2009, Steinhorn 2010).

The goal of therapy of PPHN is to maximize the amount of oxygen transported to the lungs and in turn to the systemic circulation. Conventional therapies include supplemental oxygen with often requires intubation and mechanical ventilation, induction of alkalosis, paralysis, sedation, as well as maintenance of temperature, electrolytes, glucose, and intravascular volume. Infants who fail conventional therapies may require treatment with extracorporeal membrane oxygenation (ECMO). During ECMO, the jugular vein and/or carotid artery is surgically bisected and connected to a heart-lung machine with a cannula to oxygenate the infant's blood. ECMO therapy can be life-saving, but is highly invasive, labor intensive, and has potential side-effects such as intracranial hemorrhage and ligation of the right common carotid artery (Steinhorn 2010).

Inhaled nitric oxide (iNO) has been investigated for the treatment of PPHN to improve oxidation, reduce the need for ECMO, and decrease mortality. Nitric oxide is a colorless, almost odorless gas that is naturally produced by various human tissues and is involved in several physiologic functions. It is a rapid and potent vasodilator, and because of its small gas molecule, it can be delivered as inhalation therapy to airspaces in close proximity to the pulmonary vascular bed. Once in the blood stream NO binds to hemoglobin and is rapidly inactivated with an estimated half-life of 3-5 seconds. The effect of iNO is limited to the lungs making it a selective pulmonary vasodilator without adverse systemic hemodynamic effect (DiBlasi 2010, Steinhorn 2010).

iNO therapy is not without harmful side effects. When oxygen and nitric oxide mix together, they chemically react to form nitrogen dioxide (NO<sub>2</sub>), which is toxic to the lungs. Nitrogen dioxide concentrations greater than 10 parts per million (ppm) have been known to induce pulmonary edema, alveolar hemorrhage, changes in the surface tension properties of surfactant, and death. NO<sub>2</sub> is dose- dependent and its concentrations should be maintained below 3 ppm by decreasing the iNO concentration if its level increases. Methemoglobinemia (MetHb), which impairs the ability of the hemoglobin molecule to bind with oxygen, is another harmful side effect of iNO therapy. MetHb is dose-dependent and its levels must be carefully monitored. Significant methemoglobinemia has been reported after accidental overdose of iNO, and a level >10% may cause cyanosis, headaches, muscle weakness, and tissue hypoxia. Laboratory and clinical studies have suggested that high doses of inhaled nitric oxide may increase the risk of bleeding, which is a serious concern because of the predisposition of premature newborns to intracranial hemorrhage (Kinsella 2006, Finer 2009, Henry 2012).

The recommended initial dose of iNO is 20 ppm, and the duration of its use is normally less than 5 days but may be maintained for up to 14 days, or until the underlying oxygen desaturation has been resolved. Abrupt discontinuation of the therapy can lead to worsening of PaO<sub>2</sub> and increasing pulmonary artery pressure. The use of iNO was approved by the Food and Drug Administration (FDA) in 1999 for the treatment of term and near-term neonates (>34 weeks) with hypoxic respiratory failure with clinical or echocardiographic evidence of pulmonary hypertension. Using iNO for other medical conditions is considered "off label" usage.

iNO therapy is provided through a delivery system used in conjunction with a ventilator or other breathing gas administration system. Nitric oxide delivery system consists of a nitric oxide administration apparatus, a nitric oxide gas analyzer, and a nitrogen dioxide gas analyzer. INOmax® (INO Therapeutics Inc., Clinton NJ) is a commercially available brand of iNO that received initial Food and Drug Administration approval in 1999 to be used as a vasodilator in conjunction with ventilatory support and other appropriate agents. In 2009, the FDA updated the INOmax safety labeling indicating that in patients with pre-existing left ventricular dysfunction, iNO may increase pulmonary capillary wedge pressure leading to pulmonary edema, even when used for a short time (FDA webpage accessed July 20, 2012).

### **Treatment of pulmonary hypertension in pre-term newborns**

Approximately 8-13% of all babies are born preterm (<37 weeks of gestation) across developed countries. Although survival rates have improved markedly in recent decades, preterm delivery still accounts for more than 75% of all perinatal complications and death. It is estimated that three fourths of preterm infants with birth weight <1000g develop respiratory distress syndrome (RDS), and 30- 40% are still oxygen dependent at a postmenstrual age (gestational age plus chronological age) of 36 weeks. Breathing failure in premature newborns may be complicated by raised pressure within the vessels that carry blood to the lungs (pulmonary hypertension). Those who require assisted ventilation are at high risk of developing long-term medical and neurocognitive impairment including bronchopulmonary dysplasia (BPD), which is characterized by arrested lung growth, reduced alveolarisation, and dysmorphic vasculature (i.e. the infants' lungs are not fully formed or are not able to make enough surfactant, which is a liquid that coats the inside of the lungs and helps keep them open so an infant can breathe in air once he or she is born). Without surfactant, the lungs collapse and the infant may not be able to

breathe in enough oxygen to support the body's organs. This may lead to neurodevelopmental impairment and damage to other organs (Barrington 2006, Askie 2010, 2011).

Conventional therapy of respiratory failure complicated by pulmonary hypertension in preterm newborn involves respiratory support, which includes assisted ventilation and continued distending pressure, the administration of surfactant, and sedation or muscle relaxation if needed.

iNO has been investigated as a treatment to prevent lung injury in preterm infants based on the findings from experimental studies performed on a variety of fetal animals and/ or premature animal models with hyaline membrane disease and elevated pulmonary artery pressure. These experiments showed that iNO therapy may enhance pulmonary angiogenesis and lung alveolarisation, reduce the pulmonary vascular resistance and improve oxygenation. Studies in full-term infants also showed that iNO may cause selective pulmonary vasodilatation reduce pulmonary artery pressure and improve ventilation /perfusion mismatch. However, the results of studies conducted among term or near-term infants cannot be extrapolated to the preterm babies because of the difference in pathophysiology of respiratory failure, and the difference in the potential risks of iNO in preterm infants. If iNO therapy leads to a decrease in required ventilation support, it may also lead to a reduction in lung injury and bronchopulmonary dysplasia. However, it is still uncertain which subpopulation of premature infants may profit most from iNO. There is also opposing data on whether exogenous NO is protective or destructive in the presence of hyperoxia. Inhaled nitric oxide has pro-oxidation and antioxidants activities and can potentially worsen lung injury. Preterm infants are also at higher risk of developing intracranial hemorrhage, and there is a concern about the effect of iNO in increasing the bleeding time (Barrington 2006, Love 2012).

Inhaled nitric oxide is provided through a delivery system used in conjunction with a ventilator or other breathing gas administration system. iNO delivery system consists of a nitric oxide administration apparatus, a nitric oxide gas analyzer, and a nitrogen dioxide gas analyzer. INOmax® (INO Therapeutics Inc., Clinton NJ) is a commercially available brand of iNO that received initial Food and Drug Administration approval in 1999 to be used as a vasodilator in conjunction with ventilatory support and other appropriate agents for the treatment of term and near-term (>34 weeks gestation) neonates with hypoxic respiratory failure associated with clinical or echocardiographic evidence of pulmonary hypertension. The use of iNO for other neonatal medical conditions is considered "off label" use.

### **Treatment of acute respiratory distress syndrome (ARDS) in adults and children**

Acute respiratory distress syndrome (ARDS) is a major source of morbidity and mortality, with a case fatality rate exceeding 30%. ARDS is defined by acute non-cardiogenic pulmonary edema, acute severe hypoxemia irrespective of positive end expiratory pressure, bilateral infiltrates on chest radiography, and a pulmonary artery occlusion pressure  $\leq 18$  in any adult or child more than one month old. Acute lung injury (ALI) is a milder form of the syndrome and both conditions are often referred to as acute hypoxemic respiratory failure (AHRF). They are characterized by an inflammatory process of the alveolar-capillary membrane that may result from a primary lung disease or is secondary to a number of systemic diseases. AHRF results in intrapulmonary shunting with hypoxemia and pulmonary hypertension. Hypoxemia in ARDS is mainly caused by ventilation perfusion mismatch leading to increased pulmonary shunting due to pulmonary vasodilatation in non-ventilated lung regions and vasoconstriction in ventilated areas (Milberg 1995, Afshari 2011, 2012).

Treatment of ARDS/ALI is mainly supportive and aims at improving gas exchange, control of infection, and preventing complications. The optimal therapy involves judicious fluid management, protective mechanical lung ventilation with low tidal volumes and moderate positive end expiratory pressure, multi-organ support, and treatment of the underlying cause, when possible. Pharmacotherapies have a very limited role in the management of ARDS, and to-date there is no effective medical treatment that improves survival for adult patients with the syndrome, although exogenous surfactant is beneficial in the pediatric population (Dushianthan 2011).

In 1991, inhaled nitric oxide (iNO) was shown to be a selective pulmonary vasodilator in patients with pulmonary hypertension, as well as in animals with pulmonary hypertension induced by drugs or hypoxia. Two years later, inhaled nitric oxide was introduced as a potential therapy for ARDS. Nitric oxide is a colorless, odorless gas that rapidly diffuses from alveoli through epithelial cells to gain direct access to the vasculature. Once in the blood stream it binds to hemoglobin and is rapidly inactivated with an estimated half-life of 3-5 seconds. The effect of iNO is limited to the lungs making it a selective pulmonary vasodilator without adverse systemic hemodynamic effects. iNO causes vasodilatation of ventilated lung units and redistribution of pulmonary blood flow away from non-ventilated lung areas. It decreases pulmonary vascular resistance, improves the ventilation perfusion mismatch, and subsequently reduces the elevated vascular resistance and pulmonary hypertension. It is also believed that iNO may also regulate both the immune and inflammatory responses (oxygenation by redistributing

pulmonary blood flow toward ventilated lung units in patients with this condition (Griffiths 2005, DiBlasi 2010, Dushianthan 2011, Pierrakos 2011).

iNO therapy is also associated with harmful side effects. Nitric oxide is unstable in air and when inhaled with high concentrations of oxygen, the gaseous NO slowly forms nitrogen dioxide which is potentially cytotoxic. A NO<sub>2</sub> concentrations higher than 10 parts per million (ppm) has been known to induce pulmonary edema, alveolar hemorrhage, changes in the surface tension properties of surfactant, and death. NO<sub>2</sub> is dose-dependent and its concentration should be maintained at a level below 3 ppm by decreasing the iNO concentration if it goes any higher. Methemoglobinemia (MetHb), which impairs the ability of the hemoglobin molecule to bind with oxygen, is another harmful side effect of iNO therapy. MetHb is dose-dependent and must be carefully monitored as significant methemoglobinemia has been reported after accidental overdose of iNO. A MetHb level >10% may cause cyanosis, headaches, muscle weakness, and tissue. Renal failure has also been reported with iNO use (Kinsella 2006, Finer 2009, Dushianthan 2011, Henry 2012).

Inhaled nitric oxide is provided through a delivery system used in conjunction with a ventilator or other breathing gas administration system. The delivery system consists of a nitric oxide administration apparatus, a nitric oxide gas analyzer, and a nitrogen dioxide gas analyzer. INOmax® (INO Therapeutics Inc., Clinton NJ) is a commercially available brand of iNO that received initial Food and Drug Administration approval in 1999. It was approved for use as a vasodilator, in conjunction with ventilatory support and other appropriate agents for the treatment of term and near-term (>34 weeks gestation) neonates with hypoxic respiratory failure associated with clinical or echocardiographic evidence of pulmonary hypertension. The use of iNO for other neonatal medical conditions and for treatment in the adult patient population is considered "off label" usage.

## Medical Technology Assessment Committee (MTAC)

### *iNO for Treatment of Persistent Pulmonary Hypertension*

#### **08/20/2012: MTAC REVIEW**

**Evidence Conclusion:** Treatment of persistent pulmonary hypertension (PPHN) and respiratory failure in infants born or at near term: There is fair evidence that inhaled nitric oxide therapy may improve oxygenation, and reduce the need for extracorporeal membrane oxygenation (ECMO), but does not significantly improve survival among term or near-term neonates with hypoxic respiratory failure and without congenital diaphragmatic hernia or other congenital heart disease. A Cochrane review conducted by Barrington and Finer (2006, updated 2009) pooled the results of 14 published trials on iNO for respiratory failure in term or near-term infants >34 weeks gestation. The studies included in the analysis had generally similar eligibility criteria, but with some variations in quality and size, as well as in the use of other therapies with some allowing high frequency ventilation with the jet or oscillator and surfactant treatment. The pooled results of the trials show that iNO given at an initial concentration of 20 ppm for term or near-term infants with hypoxic respiratory failure and who do not have a diaphragmatic hernia or congenital heart disease, is effective in reducing the need for ECMO therapy with NNT of 5. iNO did not have a survival benefit, and the two studies that reported long-term neurological and developmental outcomes showed that the therapy did not significantly increase or reduce neurodevelopmental disability or cerebral palsy among survivors. The limited evidence on the use of use of iNO in infants with diaphragmatic hernia, suggest that the outcomes were slightly worsened rather than improved with iNO therapy. A more recent RCT (Gonzalez 2010), not included in the Cochrane review, evaluated the efficacy of early vs. delayed use of iNO therapy in preventing newborns with moderate respiratory failure from developing severe hypoxemic respiratory failure. The study included infants born at ≥35 weeks of gestation, were less than 48 hours old, had moderate respiratory failure with an oxygenation index (OI) between 10 and 30, and with evidence of pulmonary hypertension. The study participants were randomized to receive early iNO with conventional mechanical ventilation at an initial concentration of 20 ppm, or to a control group that received conventional mechanical ventilation. The controls received iNO therapy and high frequency oscillatory ventilation (HFOV) if they reached an OI>40 (treatment failure). The trial was a RCT with valid analysis, but was not blinded and as the authors indicated it took over 5 years to be completed due to difficulty in early recruitment and interrupted supply of iNO. The availability of HFOV was also limited during the study and was thus only used for infants with treatment failure. In addition, ECMO was not available in Chile at the study period. The overall results of the trial show that early use of iNO given at a 20 ppm concentration to newborns who are ≥35 weeks gestation, <48 hours old, with birth weights >2000 g, and with moderate hypoxemic failure (OI between 10 and 30), increases oxygenation and decreases the risk of developing severe hypoxemic respiratory failure. Early iNO therapy was also found to significantly reduce oxygen therapy days, but not the mechanical ventilation. The difference in survival between the two treatment groups was statistically insignificant, but the study was not powered to detect a difference in survival. No adverse effects of iNO were reported. Treatment of pulmonary hypertension in pre-term newborns:

Several RCTs were conducted among preterm infants to determine whether iNO reduces the rates of death and/or chronic lung disease. The studies had differences in their inclusion criteria, design, indications and protocols or iNO therapy, and outcomes. The majority enrolled the preterm infants in the first 48 hours after birth; two trials

enrolled them after 3 days of preterm birth, and one after 7 days. Two studies used iNO in all intubated preterm infants with relatively low oxygen requirement and severity of illness, while two other studies enrolled only preterm infants with severe hypoxic respiratory failure. The results of the studies varied and were contradictory at times. The majority showed no effect, few showed a reduction in lung injury, and in one there was a reduction in cerebral injury. Barrington and Finer, 2010 conducted a meta-analysis of 14 published trials on iNO for respiratory failure in preterm infants. The authors did not perform an overall analysis of all trials, but grouped them into three categories depending on inclusion criteria: 1. Entry in the first 3 days of life based on oxygenation criteria (N=9 trials), 2. Later enrollment based on increased risk bronchopulmonary dysplasia (BPD) (N=two trials), and 3. Routine use in preterm babies with pulmonary disease (N=3 trials). The results of the analysis showed that inhaled nitric oxide had no effect on death or BPD at 36 weeks whether it was used routinely, in the first 3 days based on oxygenation criteria, or after 3 days based on BPD risk. Askie and colleagues (2011), performed an individual patient data meta-analysis of 12 trials (all included in the Barrington's meta-analysis except for 2 small trials whose authors could not be contacted or were unable to provide individual patient data. The results of the meta-analysis showed no statistically significant effect of iNO on death, chronic lung disease, or severe neurologic events among preterm infants. Post-hoc analysis did not show any significant difference in outcomes between iNO given to infants in different birth weight /illness severity categories, or between infants who were started on the gas earlier vs. later (using 3-or 7-day cut off). A subanalysis on the starting dose of iNO of >5 vs. < 5 ppm showed a statistically significant improvement in the primary outcome (p=.02). However, this was driven by one study which also differed according to duration, timing and indication of treatment). Based on these results, the authors of the meta-analysis concluded that the routine use of iNO in preterm infants cannot be recommended for the treatment of respiratory failure in preterm infants. Donahue and colleagues' 2011 meta-analysis of the same 14 trials included in Barrington's meta-analysis also showed no survival benefit of using iNO in preterm infants. There was no difference between preterm infants treated with iNO vs. controls in the incidence of cerebral palsy, neurodevelopmental or cognitive impairment. The NIH Consensus Development Conference Statement (Cole 2011) on inhaled nitric oxide therapy for premature infants also concluded that the available evidence does not support use of iNO in early routine, early rescue, or later-rescue regimens in the care of premature infants of <34 weeks gestation who require respiratory support. The statement also concluded, "On the basis of the currently available data, hospitals, clinicians, and the pharmaceutical industry should avoid marketing iNO for the premature infants of <34 weeks' gestation". Conclusion: There is fair evidence that the use of iNO for preterm infants does not improve their survival, reduce chronic pulmonary disease, cerebral injury and/or other neurodevelopmental impairments. Treatment of acute respiratory distress syndrome (ARDS) in adults and children: Afshari and colleagues (2010, 2011) conducted a meta-analysis of 14 RCTs (N=1,303 patients) on inhaled nitric oxide therapy for acute respiratory distress syndrome (ARDS) and acute lung injury (ALI) in children and adults (three pediatric studies, one combined pediatric and adults, and the rest included only adults). The meta-analysis had generally valid methodology and analysis. However, only four of the included trials had low risk of bias. There were also some variations between the studies in patient population, type, dose and duration of iNO therapy, as well as length of follow-up. The results of the meta-analysis suggest that iNO may only transiently improve oxygenation. It was not found to have a survival benefit, increase ventilation-free days, or improve other clinical outcomes in adults with ALI or ARDS. There was a significantly higher risk of renal impairment in the adult patients treated with iNO. Adhikari and colleagues meta-analysis (2007) of 12 RCTs also showed no survival benefit of iNO therapy, but an increased risk of renal dysfunction patients with ALI/ARDS. Conclusion: There is fair evidence that inhaled nitric oxide therapy for adult patients with acute respiratory distress syndrome or acute lung injury does not improve survival or other clinical outcomes, and may increase the risk of renal impairment. There are insufficient published pediatric trials to determine any benefit or harm of iNO therapy in children with ARDS or ALI.

## Clinical Review Criteria

### Injectable Poly-L-Lactic Acid (PLA) for Facial Lipoatrophy Sculptra

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

National Coverage Determinations (NCD)

[Dermal Injections for the Treatment of Facial Lipodystrophy Syndrome \(LDS\) \(250.5\)](#)

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies. In addition, this service is considered cosmetic and therefore excluded in all contracts.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

HIV-associated lipodystrophy has been reported in the literature starting in the late 1990s. This condition involves loss of subcutaneous fat or fat accumulations in particular regions of the body. It can include fat accumulation around the abdomen, dorsocervical area (buffalo hump) and breast hypertrophy. Regions affected by fat loss (lipoatrophy) include the limbs, buttocks and face, especially the nasiolabial regions, the temples and the eye sockets. The condition is different from HIV wasting syndrome that is mainly due to loss of muscle mass. HIV-associated lipodystrophy is also associated with insulin resistance, hyperglycemia and low levels of high-density lipoprotein (HDL) (James et al., 2002).

Although the cause of HIV-associated lipodystrophy is not well understood, some investigators believe there is a link with HIV protease inhibitors (PI). The condition started being reported in the literature around the time that protease inhibitors were introduced and prescribed to HIV-infected patients. In addition, the prevalence of lipodystrophy is higher in HIV-infected patients who received PIs compared to PI-naïve patients (James et al., 2002). Lipoatrophy may be associated with the use of specific nucleosides such as stavudine and didanosine in treatment while lipoaccumulation may be associated with protease inhibitors, especially ritonavir (Dr. Wayne Dodge, personal communication).

The treatment of facial lipoatrophy is the subject of the current MTAC review. There is little published literature on this topic, but anecdotal information suggests that facial lipoatrophy negatively affects HIV-infected individuals' body image and self-esteem and can lead to social and sexual problems. The long-term natural history of lipoatrophy is also not well known. Lipoatrophy does not appear to resolve on its own, or after discontinuation of PIs and other medication (James et al., 2002; Huff, 2004).

Sculptra, an injectable form of poly-L-lactic acid (PLA) is the first FDA-approved treatment for HIV-associated facial lipoatrophy. PLA is a biocompatible, biodegradable substance that is synthetically derived from natural components. It was been used in surgical products such as dissolvable stitches and bone screws. PLA was approved in Europe in 1999 for cosmetic treatment of scars and wrinkles, under the brand name New-Fill. The FDA did not approve Sculptra for the treatment of wrinkles. FDA approval of Sculptra for facial lipoatrophy was based on unpublished data submitted by the manufacturer Dermik Laboratories. A condition of FDA approval was that Dermik agreed to conduct a registry study for five years to evaluate Sculptra's long-term safety (FDA press release; James et al., 2002). Potential limitations of injectable PLA for severe cases of facial lipoatrophy are that large quantities of material are needed to fill the defects and there may be high maintenance costs (Binder & Bloom, 2004).

## Medical Technology Assessment Committee (MTAC)

### Injectable Poly-L-Lactic Acid (PLA)

#### 12/08/2004: MTAC REVIEW

**Evidence Conclusion:** There was one randomized controlled trial with 30 patients (Moyle, 2004) and this compared immediate treatment with PLA to delayed treatment after 12 weeks. The 12-week follow-up is the appropriate point in the study to compare treatment with no treatment. At 12 weeks, there were no significant differences between groups in depression or anxiety scores. A significantly greater proportion of patients in the immediate treatment group perceived “less thinness” in the face. The study was limited by the short follow-up period, small sample size with no statistical power analysis and lack of clear primary outcomes. The other empirical study reviewed was a case series with 50 patients (Valentin, 2003). Although there was no comparison group, advantages of the Valentin study were that there was objective measurement of changes in facial thickness and follow-up was longer, 96 weeks. There was a significant increase in total cutaneous thickness (TCT) of the face after a series of treatments with PLA and the increase in TCT persisted until the 96-week follow-up. There was a significant increase in the quality of life score compared to baseline at the 24- and 48 weeks follow-ups, but not at the 72- or 96-week follow-ups. No serious adverse effects were reported in either study. Safety and efficacy beyond 96 weeks is not known. The generalizability of Valentin study has been criticized because one dermatologist performed all of the injections; it is not known whether there would be similar results with other dermatologists. In summary, there is some evidence from an uncontrolled case series that treatment with Sculptra can reduce facial lipoatrophy for up to 96 weeks and has no serious adverse effects, when used by a trained dermatologist. There are no good data from controlled studies. The impact on quality of life is less clear. There are no published data on safety and efficacy of Sculptra beyond 96 weeks.

**Articles:** The search yielded 10 articles. Several were reviews or opinion pieces. Three empirical studies were identified. The ideal study would have the following characteristics: Randomized controlled trial, Comparison of Sculptra to alternative treatment, or placebo, Long-term follow-up, Sufficiently large sample size, Important outcomes include whether treatment with Sculptra is effective at increasing facial fat and reduces any adverse psychosocial effects. In this case, there is no standard alternate treatment and no other FDA-approved new treatments for HIV-associated facial lipoatrophy. No placebo-controlled studies were identified. There was one randomized controlled trial that compared immediate treatment with PLA to delayed treatment. There was also a case series with 96 weeks’ follow-up. Case series can provide important long-term safety data. The RCT and case series were critically appraised. Both used New-Fill, the European version of PLA. The third empirical study was a case report presenting data on 4 patients and was excluded from review. The following studies were critically appraised: Valantin M-A Aubron-Olivier C, Ghosn J et al. Poly lactic acid implants (New-Fill) to correct facial lipoatrophy in HIV-infected patients: results of the open-label study VEGA. *AIDS* 2003; 17: 2471-2477. **See Evidence Table.** Moyle GJ, Lysakova L, Brown S et al. A randomized open-label study of immediate versus delayed poly lactic acid injections for the cosmetic management of facial lipoatrophy in persons with HIV infection. *HIV Medicine* 2004; 5: 82-87. **See Evidence Table.**

The use of injectable poly-L-lactic acid (PLA) in the treatment of facial lipoatrophy does not meet the *Group Health Medical Technology Assessment Criteria*.

##### Local Coverage Article

[Injectable Bulking Agents for the Treatment of Fecal Incontinence \(A52923\)](#)

##### For Non-Medicare Members, see below.

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Fecal incontinence occurs when a person loses the ability to control his/her bowel movements and is unable to retain feces in the rectum. It can be caused by a wide variety of conditions that affect either the anatomy or function of the anal sphincter. Perineal injury during childbirth is a common cause of fecal incontinence in women. It can also be caused by neurological disorders such as spinal injury and multiple sclerosis, or it can result from anorectal surgery. In any case, fecal incontinence is common and, due to its association with considerable physical and social disability, is often under-reported (Tjandra, Chan et al. 2009).

First line treatment for fecal incontinence is usually conservative and includes antidiarrheal medication and pelvic floor muscle training. In patients for whom conservative treatment fails, alternative treatments include surgery to tighten the anal sphincter, sacral nerve stimulation, creation of a new sphincter from other suitable muscles, implantation of an artificial sphincter or a permanent colostomy. Injectable bulking agents offer an additional, less invasive, second line treatment for fecal incontinence. The concept is to inject a biocompatible material to close the anal canal to avoid fecal incontinence (Siproudhis, Morcet et al. 2007; Maeda, Vaizey et al. 2008; Graf, Mellgren et al. 2011).

At least ten different materials have been used as bulking agents for fecal incontinence including autologous fat, Teflon, bovine glutaraldehyde, cross-linked collagen, carbon coated zirconium beads, polydimethylsiloxane elastomer, dextranomer in nonanimal stabilized hyaluronic acid, hydrogel cross-linked with polyacrylamide, porcine dermal collagen, synthetic calcium hydroxylapatite ceramic microspheres and polyacrylonitrile in cylinder form (Maeda, Laurberg et al. 2013). The material can be injected either via the perianal skin or via the anal mucosa. The procedure may be performed under local, regional or general anesthesia and the injection may be guided by the surgeon's finger in the anal canal or by ultrasound. This treatment is potentially attractive in its simplicity and minimal invasiveness and can be performed in an outpatient setting.

Several injectable bulking agents have been approved by the U.S. Food and Drug Administration (FDA) in recent years for the treatment of fecal incontinence in patients 18 years and older who have failed conservative therapy.

The Medical Technology Assessment Committee (MTAC) previously reviewed and failed bulking agents for the treatment of GERD in 2003. Currently, the committee has been asked to review the literature on the safety and efficacy of injectable bulking agents for the treatment of fecal incontinence compared to standard treatment for fecal incontinence. This is the first time that bulking agents have been reviewed for this indication. The topic is being reviewed for decision making guidance.

#### Medical Technology Assessment Committee (MTAC)

## **Injectable Bulking Agents for Fecal Incontinence**

### **10/21/2013: MTAC REVIEW**

**Evidence Conclusion: EFFICACY** The Cochrane Collaboration identified five randomized trials for inclusion in their review to determine if the injection of bulking agents is better than currently available treatments or no treatments for faecal incontinence in adults. Only two of the trials compared a bulking agent to sham treatment and none of the studies made a comparison of bulking agents versus other therapies. On the whole, the studies were of poor quality with only two providing adequate information to reliably assess bias. In addition, most of the studies were small and limited to short-term follow up. Two of the trials reported on the short-term benefit from injections as outcome measures improved with time but neither trial had follow up beyond 12 months (Siproudhis, Morcet et al. 2007; Graf, Mellgren et al. 2011). In addition, there appeared to be some short-term benefits from injections given with ultrasound guidance compared with digital guidance (Tjandra, Han et al. 2004). Two of the studies compared different types of bulking agents with the larger trial reporting that silicone material was better than the carbon coated beads in terms of faecal incontinence at six and 12 months (Tjandra, Chan et al. 2009). The smaller trial, which was not included in this critical appraisal, compared the injection of Bulkamid™ with Permacol™ and showed some improvement in outcomes in both groups but ultimately was too small to detect differences between groups (Maeda, Vaizey et al. 2008). Currently the literature addressing the efficacy of injectable bulking agents is limited for a variety of reasons. First and foremost, outcome measures and the definition of response to treatment are varied, and as a result, problematic for this indication. Furthermore, it is unclear how severity of incontinence at baseline affects outcomes data. Finally, there is a lack of information regarding the volume, the precise location where the agent should be placed, and the choice of guidance of the needle track. Several different techniques were employed with various bulking agents used across all studies making comparisons complicated. **SAFETY** Four of the five studies reported on adverse effects (Tjandra, Han et al. 2004; Siproudhis, Morcet et al. 2007; Tjandra, Chan et al. 2009; Graf, Mellgren et al. 2011). Overall, the observed adverse events were similar across all the studies with few complications reported and the most commonly reported complication being pain at injection site. Safety data collected from these trials is limited as it is not clear if complications were recorded systematically. The severity and duration were not always mentioned and in many cases adverse events were recorded with no information on the number of patients reporting these events. (For example, Graf and colleagues reported 128 adverse events in patients treated with NASHA Dx and 29 events in the sham treatment group but do not detail the number of patients reporting these adverse events.) Furthermore, the safety of injectable bulking agents has not been studied past 12 months. Other studies not included in this review also reported experiencing pain or minor ulceration at the injection site or in the anal canal for up to 10 weeks after the procedure (Malouf, Vaizey et al. 2001). Further complications included leakage of the bulking agent in 1 of 10 patients and, in a different study, passing of the bulking agent in 2 of 18 patients (Davis, Kumar et al. 2003). Conclusion: There is evidence from one large randomized trial to suggest that injectable bulking agents are effective up to 12 months. There is evidence to suggest that injectable bulking agents are reasonably safe in the short term. There is no evidence to permit conclusions about long term safety or efficacy of injectable bulking agents for fecal incontinence.

**Articles:** A literature search was conducted revealing a variety of publications including multiple case-series reports as well as case-control and cohort studies. One recent Cochrane review was also revealed which included five randomized trials measuring the effects of bulking agents versus placebo, bulking agents versus other types of bulking agents and bulking agents versus other minimally invasive interventions. No studies that compared the injection of bulking agent versus conservative treatment were revealed. Four of the studies included reporting of adverse events up to 12 months post treatment. The Cochrane review did not pool the results of the trials due to their heterogeneity. Four of the five trials included in the Cochrane Review were selected for appraisal:

Graf W, Mellgren A, Matzel KE, Hull T et al. Efficacy of dextranomer in stabilized hyaluronic acid for treatment of faecal incontinence: a randomized, sham-controlled trial. *Lancet* 2011; **377**(9770):997-1003.

[See Evidence Table 1.](#) Siproudhis, L., J. Morcet, et al. Elastomer implants in faecal incontinence: a blind, randomized placebo-controlled study. *Alimentary Pharmacology & Therapeutics* 2007;**25**(9):1125-1132.

[See Evidence Table 2.](#) Tjandra, J., W. Han, et al. (2004). "Injectable silicone biomaterial for faecal incontinence due to internal sphincter dysfunction is effective." *Diseases of the Colon & Rectum* **47**(12): 2138-2146. [See Evidence Table 3.](#)

## Clinical Review Criteria

### Inpatient Rehabilitation

- Admission guidelines

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

### Criteria

#### For Medicare Members

Source	Policy
CMS Coverage Manuals	<a href="#">See the Medicare Benefit Policy Manual</a> Chapter 1 - Inpatient Hospital Services Covered Under Part A 110 - Inpatient Rehabilitation Facility (IRF) Services
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

#### For Non-Medicare Members

**Inpatient Rehabilitation Facility (IRF - acute rehabilitation)** admission is indicated by **ALL of the following**:

- 1) No acute hospital care needs.  
The inpatient rehabilitation benefit is not to be used as an alternative to completion of the full course of treatment in the referring hospital. (e.g. for completion of antibiotics or to observe renal failure)
- 2) A preadmission screening assessment must be completed. A preadmission screening assessment is an evaluation of the patient's condition and need for rehabilitation therapy and medical treatment that must be conducted by licensed or certified clinician(s) (Registered Nurse, Physical or Occupational Therapist, Nurse Practitioner, or Medical Doctor) within the 48 hours immediately preceding the IRF admission. A preadmission screening that includes all of the required elements, but that is conducted more than 48 hours immediately preceding the IRF admission, will be accepted as long as an update is conducted in person or by telephone to document the patient's medical and functional status within the 48 hours immediately preceding the IRF admission in the patient's medical record at the IRF.
- 3) There must be documentation in the preadmission screening assessment (a copy of the assessment must be available for review) that includes **ALL of the following**:
  - a) Must indicate the patient's prior level of function (prior to the event or condition that led to the patient's need for intensive rehabilitation therapy),
  - b) Expected level of improvement and
  - c) Expected length of time necessary to achieve that level of improvement.
  - d) Nature and degree of improvement identified with practical goals established for patient's condition
  - e) Conditions that caused the need for rehabilitation,
  - f) Treatments needed (i.e., physical therapy, occupational therapy, speech-language pathology, or prosthetics/orthotics),
  - g) Expected frequency and duration of treatment in the IRF,
  - h) Discharge plan that includes **ALL of the following**:
    - Anticipated discharge destination including documentation that patient will be appropriate for discharge to home or to a community based environment. (not to a SNF or LTC facility)
  - i) Any anticipated post-discharge treatments and any other information relevant to the care needs of the patient.
- 4) In order for IRF care to be considered reasonable and necessary, the documentation must demonstrate a reasonable expectation that **ALL of the following** criteria will be met at the time of admission to the IRF:
  - a) The patient must require the active and ongoing therapeutic intervention of more than two therapy disciplines (physical therapy, occupational therapy, speech-language pathology, or prosthetics/orthotics), one of which must be physical or occupational therapy.
  - b) Need for an intensive rehabilitation therapy program that includes **ONE or more** of the following:

- Therapy at least 3 hours per day for 5 days per week OR
- Therapy at least 15 hours per week consecutive days
- c) Therapy must not exceed the patient's need or tolerance or compromise the patient safety.
- d) The patient must reasonably be expected to actively participate in, and benefit significantly from, the intensive rehabilitation therapy program
- e) Close physician involvement with need for treating rehabilitation physician face-to-face assessment at least 3 days per week (e.g. monitoring of uncontrolled pain, bowel and bladder issues, and complex rehabilitation needs such as adapting mobility devices.)
- f) The patient must require an intensive and coordinated interdisciplinary approach to providing rehabilitation

5) Document must state why an equivalent outcome will not be achieved in a Skilled Nursing Facility.

The following indications are not covered:

- Coma stimulation
- Custodial care
- Routine services for maintenance of medication administration, routine enteral feedings, routine colostomy care, ongoing straight catheterization for chronic conditions.
- Single joint replacement unless the individual has significant comorbidity(ies) resulting in functional deficits which would necessitate an acute inpatient level of rehabilitation in order to achieve a satisfactory outcome within a reasonable time period.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## Background

Inpatient rehabilitation hospital admissions provide intensive rehabilitation to patients with various neurological, musculo-skeletal, orthopedic and other medical conditions following stabilization of their acute medical issues. The inpatient rehabilitation bed is specifically licensed for the rehabilitation services and is sometimes part of an acute hospital or a separate facility.

Rehabilitation hospitals were created to meet a perceived need for facilities which were less costly on a per diem basis than general hospitals but which provided a higher level of professional therapies such as speech therapy, occupational therapy, and physical therapy than can be obtained in a "skilled nursing care" facility. Prior to admission to an inpatient rehabilitation facility an evaluation is conducted by a physiatrist to determine appropriateness for this level of admission.

##### For Non-Medicare Members

###### Initial Insulin Pump:

- A. To qualify for an insulin pump the member must meet **ALL of the following**:
1. Patient has Type 1 diabetes of at least six months' duration or Type 2 diabetes requiring a basal/bolus insulin regimen of multiple daily injections using long-acting basal insulin and a rapid-acting analogue
  2. Referral initiated by a Diabetes specialist\* that will manage therapy with an insulin pump.
  3. Documentation from the Diabetes specialist\* that includes **ALL of the following**:
    - a. Assessment for clinical therapeutic value of an insulin pump.
    - b. Assessment of patient pump education and skill training preparation prior to pump start (either one-on-one or within a group).
    - c. Assessment of the patient's (or caregiver's) ability to safely and appropriately participate in an insulin-pump self-management plan.
  4. Has been on a treatment regimen of multiple daily injections (MDI) of insulin that includes a trial of both a long-acting insulin analog (Lantus, or Detemir) and a short-acting insulin analog (Aspart™ (Novolog), Glulisine (Apidra) or Lispro™ (Humalog), with a plan for pre-meal short acting insulin dose adjustment for at least 3 – 6 months prior to initiation of the insulin pump.
  5. Require less than 200 units of total insulin per day prior to pump therapy.
  6. Has documented logs of glucose self-testing - at least 4 times per day during the 2 months prior to consideration of an insulin pump.
  7. Meets **ONE or more of the following** while on an MDI regimen:
    - a. Recent history (within last six months) of significant, recurring hypoglycemia (blood glucose < 70 mg/dl).
    - b. Wide fluctuations (well below and above the set glycemic targets) in blood glucose before and after meal times, despite appropriate MDI using up to date insulins (analogs) and dose adjustments to affect control.
  8. Patient has advanced carbohydrate counting skills and actively uses this information for insulin dosing
  9. Patient demonstrates ability to recognize their glucose patterns and safely problem-solve these
  10. Has no other illness that could impede use of the pump (i.e. alcohol/chemical abuse, psychological instability, difficulty with digital dexterity, visual impairment).

###### Ongoing Coverage of Pump and Supplies:

- A. To qualify for ongoing coverage of an insulin pump the member must meet **ALL of the following**:
1. There is documentation that patient monitors glucose at least four times daily, or appropriately uses a continuous glucose monitor.

2. Patient maintains advanced carbohydrate counting skills and actively uses this information for insulin dosing
3. Patient maintains ability to recognize their glucose patterns and safely and appropriately problem-solve these, including troubleshooting pump malfunction
4. Patient does not have other conditions or psychosocial stressors which might impede safe use of an insulin pump
5. Patient has at least one visit per year with Diabetes specialist\* (face-to-face, secure message, or telephone encounter)

A treating provider may order ongoing pump supplies in the interval between annual visits with the Diabetes specialist\*

#### **Continuous Glucose Monitor: Initial request**

- A. The use of a CGM may be indicated when **ALL of the following** are present:
1. The monitor is being requested by a Diabetes specialist\*.
  2. There is medical record documentation of recurrent symptomatic hypoglycemia (blood glucose measurements less than 70 mg/dl; previous criteria was less than 50 mg/dl) despite best practice management OR Patient has hypoglycemia unawareness
  3. Intensive insulin regimen (3 or more insulin injections per day, or receiving insulin via an insulin pump)
  4. Patient is motivated, and has monitored and documented blood glucose 4 or more times per day for 2 months

#### **Sensor-Augmented Insulin Pumps (artificial pancreas):**

For coverage the member must meet both the criteria for insulin pumps (see above) and the [Continuous Glucose Monitor criteria](#).

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

## **Background**

In January 1998, the state of Washington passed the Diabetes Cost Reduction Act that requires that major health carriers provide coverage (all, or in part) for diabetes supplies (insulin, syringes, and delivery devices) and education. This new law includes insulin pumps.

Insulin pumps are high technology infusion devices, about the size of a small tape cassette. Flexible tubing connects to the pump that contains the insulin, and then to the patient via a needle that is put in place and changed every 2 to 3 days. The pump itself can then be programmed to deliver 'background' insulin on a continuous basis, and also allow pre-meal "boluses" to accommodate meals. The pump is NOT a system that a patient can just plug into and forget diabetes.

In fact, patients who use the pump have to learn how to program and trouble-shoot the technology, and also learn how to do complex decision-making. This intensive management approach requires multiple daily blood testing, learning how to recognize and use types of food in a very sophisticated way, keeping records, and learning to use the information for complex problem solving. This education is an absolute prerequisite to being on the insulin pump, so special education classes and supervised care are required.

## **Medical Technology Assessment Committee (MTAC)**

### ***Insulin Pump Type II Diabetes***

#### **04/20/2015: MTAC REVIEW**

**Evidence Conclusion:** *Effectiveness* At baseline, the mean HbA1c was 9.0% (75 mmol/mol) in both groups. At six months, both groups saw a decrease in HbA1c (7.9% in the pump group vs. 8.6% in the MDI group) with a -0.7% (95% CI -0.9 to -0.4; -8 mmol/mol, 95% CI -10 to -4 mmol/mol, adjusted p<0.0001) difference between groups favoring pump treatment. Reduction in HbA1c in the pump group was also associated with a 20% lower daily dose of insulin compared with the MDI group, and was not accompanied by an increase in hypoglycemia or weight gain. Ultimately, the investigators concluded that patients with poorly controlled T2DM who received CSII over six months achieved significantly greater reductions in HbA1c. In a separate analysis, the investigators retrospectively stratified the study population according to concentrations of two different biomarkers determined from plasma collected at baseline. The first biomarker, anti-glutamic acid decarboxylase (anti-GAD) antibody

(Ab), was present in 18% of the population at baseline indicating that the study population may include patients with T1DM. The investigators attribute this high rate to false-positives, relatively low cutoff values or a combination of both. The second biomarker, C-peptide, a measure of insulin production, did not appear to be associated with A1C level. Ultimately, the analysis demonstrated that HbA1c values were independent of both biomarkers (Reznik and Huang 2014). *Safety* The investigators reported five episodes of hyperglycemia related to the device or study procedure in the pump group and two diabetes related serious adverse events (SAE) resulting in hospital admission. Comparison with the MDI group is not possible as the collection of safety data appears to be incomplete. The investigators noted that data on self-reported mild hypoglycemia and hyperglycemia were not collected, nor were data for hyperglycemia in the MDI group. The studies strengths include randomization, sufficient sample size and the utilization of an intent-to-treat (ITT) analysis. To add to this, the study was conducted across 36 hospitals in five different countries. Methodological limitations of the study can be attributed to the nature of the treatments preventing blinding of patients and assessors. In addition, the investigators acknowledge that the average number of daily glucose self-monitoring tests in both groups was below the generally recommended standard of care, however, this may be consistent with real-life experiences. Finally, the investigators note that due to the inclusion/exclusion criteria and run-in phase, the results of the study may not be generalizable. As a final note, the study was designed and sponsored by Medtronic, the manufacturer of the device. Although they had no role in data collection, the analysis was carried out by statisticians employed by Medtronic. *Conclusions:* There is evidence to support the efficacy of CSII in achieving glycated hemoglobin targets in highly motivated patients with T2DM with have poor glycemic control, who are taking a total daily dose of insulin less than 220 units. There is limited evidence to support the safety of CSII patients with T2DM.

**Articles:** The literature was searched for studies assessing the effectiveness of CSII for glycemic control in patients with T2DM. A variety of publications were revealed including several observational studies and four small randomized controlled trials (RCT) with conflicting results. The best available evidence was a recent RCT comparing CSII with multiple daily injections (MDI). The following articles were selected for critical appraisal: Reznik Y, Cohen O, Aranson R, et al. Insulin pump treatment compared with multiple daily injections for treatment of type 2 diabetes (opT2mise): a randomized open-label controlled trial. *The Lancet*. 2014;384(9950):1265-1272. See [Evidence Table 1](#)

The use of Insulin Pump for Type II diabetes does meet the *Group Health Medical Technology Assessment Criteria*.

## **Artificial Pancreas**

### **BACKGROUND**

Diabetes mellitus is a metabolic disorder resulting from a defect in insulin secretion, insulin action or both. More specifically, in type 1 diabetes, the pancreas is unable to produce insulin which results in increased blood glucose levels, and ultimately, leads to complications which may affect the eyes, kidneys, nerves, heart and blood vessels. As a result, an essential part of diabetes management is to maintain blood glucose levels to as near normal as possible over all hours of the day. Implementation of this approach requires the individual to be capable of and committed to a day-to-day medical program. It requires ongoing compliance with multiple daily glucose measurements accompanied by appropriate adjustments in insulin dose and insulin injection. Additionally, successful intensive diabetic management requires response to a variety of external factors including changes in diet, exercise, and presence of infection.

Typically, patients self-monitor their blood glucose via fingerprick in an effort to optimize glycemic control, however, this technique is tedious and uncomfortable for the patient. In addition, this technique only provides information about a single point in time making it difficult to recognize trends. In any case, intensive glucose monitoring and insulin therapy can be challenging as they require obtaining, retaining, processing and applying vast amounts of information in the course of everyday life (Watkins, Connell et al. 2000; Boland, Monsod et al. 2001; Brauker 2009).

Evolving technologies such as continuous subcutaneous insulin infusion (CSII), and continuous glucose monitoring (CGM) have allowed patients to safely maintain glycemic goals and prevent other related complications. While there is evidence to support the efficacy of CSII (Misso, Egberts et al. 2010), the reliability and robustness of CGMs leaves much to be desired. Even with the aid of these devices, maintaining blood glucose concentrations within a suggested optimal range is a constant struggle.

Most recent technologic advancements have integrated these components into an Artificial Pancreas Device System (APDS). In addition to CSII and CGM, the APDS incorporates a control algorithm designed to facilitate

communication between the different components thus automating the process of maintaining blood glucose concentrations at or near a specified target or range and, ultimately, improving glucose control, preventing complications, and decreasing disease burden. With a wide range of current products available on the market, there is potential for a large variety of different types and designs of ADPSs.

In an effort to help advance the development of the diabetes technologies, the U.S. Food and Drug Administration (FDA), in 2011, established three new product classifications for APDSs including threshold suspend, single hormonal control, and bihormonal control, all of which are regulated as class III device systems (general controls and premarket approval). In September of 2013, Medtronic's MiniMed® 530G was the first system approved under this new product classification. ADPSs have not previously been reviewed by the Medical Technology Assessment Committee (MTAC) and are currently being reviewed due to provider request.

The development of an "artificial pancreas" has been the "holy grail" for management of Type 1 diabetes for several decades. To understand why this is such a difficult task it helps to understand what the normal non-diabetic person's body actually does in response to changes in blood glucose. Within the pancreas we all have 1-2 million groups of cells called the Islets of Langerhans which function together to help maintain the blood glucose levels within a quite narrow range (of around 70-160mg/dl). The islets make two main hormones (insulin from the beta-cells and glucagon from the alpha cells) which work together in concert. These islet cells monitor the blood glucose flowing through them constantly. Whenever the blood goes up (after a meal, for example) the islets increase the amount of insulin that they are secreting from the beta-cells and decrease the amount of glucagon that they are secreting from the alpha cells. Whenever the blood glucose drops below normal the beta-cells turn off completely (so that no insulin is secreted) and the alpha cells crank out lots of glucagon. Glucagon (as well as other hormones like epinephrine, growth hormone and cortisol) stimulate the liver to release glucose into the blood stream (the liver stores about 300 grams of glucose in the form of a kind of starch called glycogen). The insulin and glucagon are released directly into the portal circulation of blood flowing from the pancreas to the liver. In other words, a non-diabetic person is functioning with millions of blood glucose measurements being done every day with the results connected to a continuously variable secretion of both insulin and glucagon released directly into the blood flowing to the liver. Even though the commercially made components of an "artificial pancreas" may seem very sophisticated they are a very crude and imprecise way of trying to do what the real non-diabetic person's pancreas can do.

First consider the delivery of insulin. Rather than having both insulin and glucagon being released directly into the blood flowing to the liver we have a continuous subcutaneous infusion of insulin alone. The insulin is absorbed out of the subcutaneous fat into the peripheral systemic circulation and only then gets to the liver. This can give a fairly accurate and stable basal delivery of insulin but when larger amounts of insulin are delivered immediately before meals (bolus insulin delivery) the rate of rise and fall of insulin in the bloodstream is a lot slower than in a healthy non-diabetic person's body.

Second, consider the measurement of blood glucose. Typically diabetic patients test the capillary glucose level in their fingertips 2-8 times per day. This can give useful information but does not show the constant rising and falling of blood glucose excursions throughout the day. If needle sensors are placed in the subcutaneous tissue this can give a reading of interstitial fluid glucose (similar to plasma glucose) every 10-20 minutes throughout the day and so can show the trends as the blood glucose rises and falls. Several companies now make these continuous glucose monitoring systems (CGMS). There are two practical issues with CGMS, however: a) the interstitial fluid glucose lags behind the actual plasma glucose by 15-20 minutes and so can give a falsely low or high value if it is measured at times when the blood glucose is rising rapidly (after a meal) or is falling rapidly (after exercise or after injecting a bolus of insulin), and b) the glucose oxidase enzyme system for measuring blood glucose can drift over time and so the readings from a CGMS will be inaccurate unless they are calibrated several times a day by doing a capillary blood glucose test at a time when the blood glucose is expected to be stable (not rising or falling rapidly).

The concept of an "artificial pancreas" is that a person could wear both an insulin pump and a CGMS device and that the insulin pump uses the information from the CGMS to automatically make adjustments to the rate of insulin infusion. The person would not need to worry about testing their blood glucose or of thinking about what they eat and when they exercise but could go about their day-to-day life safe in the knowledge that their blood glucose would stay within normal limits. It is because of the practical limitations of the technology (outlined above) that we are still a long way away from that idealized situation.

## **02/14/2014: MTAC REVIEW**

### **Artificial Pancreas**

Date Sent: February 28, 2017

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage. Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

**Evidence Conclusion:** In this review, the results of four RCTs were included. One of these studies compared sensor-augmented insulin pumps to multiple daily insulin injections while two of them compared threshold suspense systems with standard insulin pumps. The last study compared two closed-loop algorithms to patient self-control with CSII. *Effectiveness:* Comparison of the effectiveness of sensor augmented pump therapy versus multiple daily injections (MDI) was examined in a one year multicenter, randomized and controlled phase of the sensor-augmented pump therapy for hemoglobin A<sub>1c</sub> reduction (STAR-3) study. Compared with 241 subjects on MDI, those on pump therapy (n=244) experienced greater reductions in A<sub>1c</sub> levels by three months, with the trend continuing throughout the remainder of the study. By the end of the study, the baseline A<sub>1c</sub> level (8.3% in the two study groups) had decreased to 8.1% in the MDI group compared with 7.5% in the pump therapy group ( $P<0.001$ ). Participants were offered an optional six-month continuation phase which allowed subjects in the pump therapy group to continue therapy and allowed subjects in the MDI group to cross over to pump therapy. The continuation phase resulted in a sustained lower mean A<sub>1c</sub> value for patients in the pump therapy group and decreased the mean A<sub>1c</sub> values to 7.6% ( $P<0.001$ ) among MDI subjects who crossed over to pump therapy for the continuation phase. (Bergenstal, Tamborlane et al. 2010; Bergenstal, Tamborlane et al. 2011). See [Evidence Table](#). In the three-month automation to simulate pancreatic insulin response trial (ASPIRE), 247 patients with type 1 diabetes and nocturnal hypoglycemia were randomized to sensor augmented insulin pump therapy with the threshold suspend feature (Paradigm group) or to the standard sensor-augmented insulin pump therapy (control group). The primary efficacy outcome was the area under the curve (AUC) for nocturnal hypoglycemic events. At the end of three months, the mean AUC for nocturnal hypoglycemic events was found to be significant through supportive analysis at 37.5% lower in the Paradigm group than in the control group ( $P<0.001$ ) (Bergenstal, Klonoff et al. 2013). See [Evidence Table](#). In another trial, 95 adults and children with type 1 diabetes were randomized to use of a sensor-augmented insulin pump with threshold suspension or a standard insulin pump. After six months, the combined incidence of moderate and severe hypoglycemic events was significantly lower in patients using the pump with the threshold suspension compared with the standard insulin pump (9.5 vs. 34.2 per 100 patient-months) (Ly, Nicholas et al. 2013). See [Evidence Table](#). Most recently, Luijf and colleagues compared two validated closed-loop algorithms versus patient self-control with CSII in terms of glycemic control. The investigators concluded that both the algorithm developed by the University of Cambridge (CAM) and the algorithm developed by the University of Pavia, Padova, University of Virginia and University of California Santa Barbara (international artificial pancreas [IAP]) provide safe glycemic control. This study, however, occurred in a highly controlled environment for short periods of time. While the algorithms may have the benefit of less time in hypoglycemia, this came at the expense of higher mean glucose values when compared to self-management (open loop) and thus, more time spent in hyperglycemia (Luijf, DeVries et al. 2013). See [Evidence Table](#).

**Safety and Adverse Events:** Safety and adverse events were included as endpoints in two of the four selected studies. In the STAR 3 study, data on adverse events were collected at each follow up clinic visit. Severe

hypoglycemia was defined as an episode requiring assistance and was confirmed by documentation of a blood glucose value of less than 50 mg per deciliter (Bergenstal, Tamborlane et al. 2010). In the ASPIRE study, the primary safety endpoint was the change in glycated hemoglobin level. The change in the glycated hemoglobin level from randomization to study end was not significant in both groups, and the difference in hemoglobin level between groups was only 0.05 percentage points. Beyond that, no episodes of diabetic ketoacidosis occurred in either group and no severe hypoglycemic events occurred in the Paradigm group. During the study phase there were seven adverse events thought to be related to the study device which included skin irritation and device malfunction resulting in severe hyperglycemia (Bergenstal, Klonoff et al. 2013). Generally speaking, the studies had the advantage of randomization and control, however, the lack of blinding makes the evidence vulnerable to bias. In addition, the Ly et al. study relied on patient recall for their results and some of the experimental subjects may have had more contact with physicians opening up the results to recall and observation bias. Sample size ranged anywhere from 48 to 495 participants and most of the studies, with the exception of the STAR 3 Trail, did not report on the racial and ethnic composition of the study samples, and for those that did, participants were predominantly white. Furthermore, inclusion criteria were extremely selective with few studies including children younger than 12 years. In the same way, the data lack generalizability because management was limited to expert settings and among highly motivated patients. Further limitations include heterogeneity in definitions of hypoglycemia and short duration of follow-up ranging anywhere from 24 hours to 18 months. With many complications of diabetes developing over many years it would be ideal to see results allowing for multiple periods of sensor wear and to evaluate changes in subject needs over time. With that said, at the current point in time, APDSs are a rapidly evolving technology that should only be considered in select patients.

**Conclusion:**

- The results of the published studies suggest that APDS may be effective in reducing hypoglycemia in highly selected, motivated and compliant groups of individuals.
- There is some evidence to support the safety of APDS in highly compliant adult patients.

**Articles:** The search revealed over 500 articles many of which were commentary, discussion, or systematic review articles. Articles were screened for randomized, comparison studies of outcomes between patients using APDS and a control group of patients using currently available technology. The following articles were selected for critical appraisal: Bergenstal RM, Tamborlane WV, Ahmann A, et al. Effectiveness of sensor-augmented insulin-pump therapy for type 1 diabetes. *New England Journal of Medicine*. 2010;**363**(4):311-320. See [Evidence Table](#). Bergenstal RM, Klonoff DC, Garg SK, et al. Threshold-based insulin-pump interruption for reduction of hypoglycemia. *New England Journal of Medicine*. 2013;**369**(3):224-232. See [Evidence Table](#). Ly TT, Nicholas JA, Retterath A, et al. Effect of sensor-augmented insulin pump therapy and automated insulin suspensions vs standard insulin pump therapy on hypoglycemia in patients with type 1 diabetes a randomized clinical trial. *JAMA*. 2013;**310**:1240-1247. See [Evidence Table](#). Luijck YM, DeVries JH, Zwinderman K, et al. Day and night closed-loop control in adults with type 1 diabetes. *Diabetes Care*. 2013;**36**: 3882-3887. See [Evidence Table](#).

The use of Artificial Pancreas does meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### INTACS Inserts (Intrasomal Corneal Ring Segments)

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	<a href="#">Non-Covered Services (L35008)</a> . And for facility-based services billed using a UB form, see <a href="#">Non-Covered Services (L34886)</a> =
Local Coverage Article	None

Implantation of intrastromal corneal ring segments is identified as part of group 1, investigational, not proven effective or experimental. While use of this procedure has been largely for refractive and thus not medically necessary conditions, there is one notable exception. The FDA has approved use of these implantable devices for use in cases of the medical condition Keratoconus, and other conditions where corneal thinning causes ectasia.

NAS agrees with the comment that 0099T is appropriate for use with keratoconus. Thus, 0099T will be removed from the non-covered policy. However, 0099T will continue to be not covered for refractive surgery which is not a Medicare benefit.

##### For Non-Medicare Members

- 1) Implantation of intrastromal corneal ring segments may be considered medically necessary for the treatment of keratoconus when **ALL of the following** criteria are met:
  - Functional vision cannot be achieved with contact lenses or spectacles
  - Age 21 years or older
  - Clear central cornea
  - Corneal transplantation is the only other remaining option to improve functional vision
- 2) Implantation of intrastromal corneal ring segments is considered not medically necessary for the treatment of myopia.
- 3) Implantation of intrastromal corneal ring segments is considered investigational for all other conditions including, but not limited to, pellucid marginal degeneration.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Keratoconus is a progressive noninflammatory corneal disorder characterized by corneal thinning and protrusion of the central cornea. Signs and symptoms of keratoconus vary and depend on disease severity. In the early stages of keratoconus, individuals may be asymptomatic; however, as the disease progresses, there is considerable distortion of vision in the form of myopia and irregular astigmatism. For patients with mild to moderate keratoconus, vision may be corrected with spectacles or contact lenses. However, as the disorder progresses, or when the patients can no longer tolerate contact lenses, they are referred for corneal transplant (penetrating keratoplasty). The outcomes of this surgery are generally favorable; however, the surgery is not without complications. Complications of penetrating keratoplasty include graft rejection, intraocular damage, postoperative astigmatism, recurrence of keratoconus, and side effects from the long-term use of topical corticosteroids (Ambekar 2011, Ertan 2007, Romero-Jiménez 2010).

Intrasomal corneal ring segments (Intacs®) inserts are an alternative treatment strategy for patients with mild to moderate keratoconus who are no longer able to achieve adequate vision using contact lenses or glasses and for whom corneal transplant is the only remaining option. Intacs® inserts are small rings of synthetic material that are implanted in the deep corneal stroma with the aim of generating modifications of corneal curvature in an attempt to improve visual acuity, contact lens tolerance, and prevent or delay corneal transplant. The procedure is performed outside the corneal visual axis and the inserts may be removed or replaced if the desired outcome is not achieved. Intacs® inserts should not be used in patients who can achieve functional vision on a daily basis using contact lenses, are younger than 21 years of age, do not have clear corneas, or have corneal thickness less than 450 microns at the proposed incision site. Complications associated with Intacs® inserts include patient dissatisfaction with visual quality, discomfort, and ring segment extrusion or migration (Ambekar 2011, Bromley 2010, Ertan 2007, Romero-Jiménez 2010).

Intacs® inserts received FDA approval in 2004.

## Medical Technology Assessment Committee (MTAC)

### **INTACS Inserts in the Treatment of Keratoconus**

#### **10/03/2005: MTAC REVIEW**

**Evidence Conclusion:** The studies reviewed, as well as others revealed by the literature search, were all case series comparing the postoperative results to the preoperative values among the same groups of patients. Case series have potential selection and observation biases as well as other threats to internal validity. The results of these series may indicate some improvement in visual acuity after the implantation of Intacs in patients with keratoconus with a clear central cornea and intolerance to contact lenses. However, the technology was not compared to penetrating keratoplasty or other alternative therapies, and the follow-up duration was insufficient to determine the stability of the observed outcomes and the long-term harms that could be associated with Intacs inserts. Moreover, these studies do not provide evidence to determine if this technology would prevent the progression of keratoconus and eliminate the need for penetrating keratoplasty (PK). In conclusion, larger studies with longer follow up and that compare the outcomes of the technology with those achieved with PK are needed to determine the efficacy and long-term stability, benefits, and harms of the technology.

**Articles:** The search revealed 18 articles. There were no meta-analyses or randomized controlled trials. All published studies identified were prospective or retrospective case series and had no control groups. Two prospective series on the use of Intacs for the management of keratoconus were selected for critical appraisal. Selection was based on the sample size, duration of follow-up, and quality of study. *Evidence tables were created for the following studies:* Hellstedt T, Makela J, Uusitalo R, et al. Treating keratoconus with Intacs corneal ring segments. *J Refract Surg.* 2005; 21:236-246. See [Evidence Table](#). Siganos CS, Kymionis GD, Kartakis N, et al. Management of keratoconus with Intacs. *AM J Ophthalmol* 2003;135:64-70. See [Evidence Table](#).

The use of INTACS Inserts in the treatment of keratoconus does not meet the *Group Health Medical Technology Assessment Criteria*.

#### **12/19/2011: MTAC REVIEW**

### **INTACS Inserts in the Treatment of Keratoconus**

**Evidence Conclusion:** The study reviewed for the 2011 update, as well as those reviewed in the original 2005 MTAC review, were all case series comparing postoperative results to the preoperative values among the same groups of patients. Results from case series should be interpreted with caution as this type of study design is prone to bias. The results of these studies may indicate some improvement in visual acuity after the implantation of Intacs® inserts in patients with keratoconus with a clear central cornea and intolerance to contact lenses. However, the technology was not compared to other alternative therapies, and the follow-up duration was insufficient to determine the stability of the observed outcomes and the long-term harms that could be associated with Intacs inserts. Moreover, these studies do not provide evidence to determine if this technology would prevent the progression of keratoconus and eliminate the need for penetrating keratoplasty (Colin 2007, Hellstedt 2005, Siganos 2003). Conclusion: There is insufficient evidence to determine the safety and efficacy of Intacs® inserts for the treatment of keratoconus.

**Articles:** The literature search did not reveal any meta-analyses or randomized controlled trials. The published studies identified were prospective or retrospective case series. The largest prospective case series with the longest duration of follow-up was selected for review.

The following study was critically appraised: Colin J and Malet F. Intacs for the correction of keratoconus: two-year follow-up. *J Cataract Refract Surg.* 2007;33:69-74. See [Evidence Table](#).

The use of INTACS Inserts in the treatment of keratoconus does not meet the *Group Health Medical Technology Assessment Criteria*.

## Clinical Review Criteria

### Intermittent Pneumatic Compression for the Treatment of Peripheral Arterial Occlusive Disease

- ArtAssist Device
- ArterialFlow™ System
- Flow Medic™ System

Group Health Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Group Health reserves the exclusive right to modify, revoke, suspend or change any or all of these Review Criteria, at Group Health's sole discretion, at any time, with or without notice. **Member contracts differ in their benefits. Always consult the patient's Medical Coverage Agreement or call Group Health Customer Service to determine coverage for a specific medical service.**

#### Criteria

##### For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	<a href="#">Pneumatic Compression Devices (280.6)</a>
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

##### For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

#### Background

Peripheral arterial disease (PAD) is a common condition that affects approximately 8-12 million people in the US. The prevalence of the disease increases rapidly with age, and is associated with significant morbidity and mortality. PAD commonly affects the arteries supplying the leg and is mostly caused by atherosclerosis. Restriction of blood flow due to arterial stenosis or occlusion is commonly clinically presented as intermittent claudication which is pain in the calf muscles that occurs on walking or exercising, and is rapidly relieved by resting.

The clinical course of patients with intermittent claudication is variable. Most patients either improve or have a stable condition, but over one fourth will experience deterioration in symptoms. These patients may eventually develop critical leg ischemia or gangrene which can lead to amputation. Fontaine classified chronic leg ischemia into four stages: Stage I: asymptomatic, stage II: intermittent claudication, stage III: ischemic rest pain, and stage IV: ulceration, gangrene, or both (Hirsch 2001, Leng 1993, Delis 2000, 2005, Beard 2000).
