- There is low-quality evidence showing that EMST may improve short-term swallowing outcomes in patients with dysphagia secondary to acute/subacute stroke, compared to no active treatment. The benefits observed in the sham therapy groups may suggest that the EMST has a placebo effect, or that dysphagia may improve as a natural recovery of the condition and not due to the intervention.
- The benefits observed in the sham therapy groups in neurogenic conditions other than stroke may also indicate a placebo effect of the EMST, or that expiratory breathing alone without the positive pressure load can improve the MEP.

- There is insufficient evidence to determine whether the short-term benefits observed with EMST therapy compared to sham treatment would last after treatment cessation.
- Adverse outcomes were not reported in any of the trials.

The use of Expiratory Muscle Training Therapy (EMST150) for Patients with Dysphagia due to Neurologic Diseases or Disorders doesn't meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Extracorporeal Photopheresis for Acute and Chronic Graft vs. Host

Medical necessity review no longer required for this service.

Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma (CTCL)

Must meet **ALL** of the following:

- The extracorporeal device must be FDA approved;
- The patient has cutaneous t-cell lymphoma that has not responded to other forms of treatment;
- The use is for palliative treatment of associated skin manifestations.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Extracorporeal photopheresis (ECP) is a treatment modality for graft-versus-host disease (GVHD) and cutaneous t-cell lymphoma (CTCL). CTCL refers to several clonal t-cell malignancies that primarily manifest as skin conditions. GVHD is a complication of allogeneic stem cell transplantation.

Extracorporeal photopheresis (ECP) is one of the treatment options for refractory acute and chronic GVHD. ECP involves removing the patient's peripheral blood and separating it into leukocyte-depleted blood and leukocyte-enriched plasma. The leukocyte-depleted blood is returned to the patient. The leukocyte-enriched plasma is exposed to ultraviolet light in the presence of an extracorporeally administered photosensitizing agent, 8-methoxypsoralen (8-MOP). The cells are then re-infused into the patient and die in one-week period. During that week, they are capable of stimulating an anti-idiotypic t suppressor response. The exact mechanism of action of ECP is not known. The Therakos Photopheresis System is FDA approved as a class III medical device specifically for photopheresis (Greinix et al., 2000; Woltz et al., 2006).

There are no agreed-upon standards for the optimal frequency and duration for ECP treatment in patients with chronic GVHD, and there is wide variability in practice. Patients may be treated two or three days a week every two to three weeks for 3 to 30 months (Woltz et al., 2006).

Extracorporeal photopheresis (ECP) is also a treatment option for CTCL. ECP involves removing a portion of the patient's blood and separating into red and white blood cells by centrifugation. The red cells are returned to the patient. The white cells are mixed with a photosensitizing agent, 8-methoxypsoralen or methoxsalen (Uvadex, Therakos), and irradiated with ultraviolet light (UVA light, 320-400 nm). When activated, the photosensitizing agent binds with the cellular DNA of the white cells and accelerates their death. The altered cells are then re-infused into the patient. The intention is that these cells will stimulate an immune response against the damaged pathogenic t cell clones. In the pivotal study upon which FDA approval was based, a case series with 37 patients by Edelson and colleagues, a greater treatment effect was seen in patients with erythrodermic CTCL (later-stage disease) compared to those with plaques or tumors. This distinction has been difficult to confirm in later case series because studies generally include patients at different stages of clinical disease and do not report findings separately by disease stage. The effectiveness of ECP for treating CTCL, particularly Sezary Syndrome, continues to be debated in the literature. Some of the controversies are whether prior treatment with systemic corticosteroids and systemic chemotherapy reduces the effectiveness of ECP and which sub-groups of patients are most likely to benefit from ECP treatment. To date, there have not been any randomized controlled trials comparing ECP to other treatments for CTCL (Apisarnthanarax et al., 2002; Russell-Jones, 2000; FDA Web site; Therakos Web site).

The FDA has approved the photopheresis device UVAR and the photosensitizing Uvadex (both by Therakos) for the palliative treatment of skin manifestations of cutaneous t-cell lymphoma that has not responded to other forms of treatment. ECP is covered by Medicare for the same indication.

Medical Technology Assessment Committee (MTAC)

Extracorporeal Photopheresis in the Treatment of Acute and Chronic Graft Versus Host Disease

BACKGROUND

Graft-versus-host disease (GVHD) is a complication of allogeneic stem cell transplantation (SCT). There are two forms of GVHD, acute and chronic. Acute GVHD occurs within the first 100 days of transplantation. In acute GVHD, the T-lymphocytes from the donor recognize tissues or cells in the recipient as foreign and produce a multi-organ (i.e. skin, liver, intestines) autoimmune-like syndrome. The T-lymphocytes use information from genetic markers known as human leukocyte antigens (HLA) to detect differences. Even when donors are matched for HLA markers, GVHD can occur because minor differences in these markers could still exist. Efforts to prevent acute GVHD include using closely matched donors, umbilical cord blood and/or post transplant immunosuppression with drugs including cyclosporine and methotrexate. Acute GVHD is commonly treated with corticosteroids which produce sustained responses in 50-80% of patients depending on the initial severity of disease. Second-line therapy includes different combinations of immunosuppressive agents. Newer treatments include infusion of mesenchymal stem cells (MSC), down-regulation of antigen-presenting cells (APC) and suicide gene transduced T cells (Bacigalupo, 2007). Chronic GVHD can occur after the first 100 days post-transplant, either in patients who experienced acute GVHD or a de novo onset. It is the main cause of late morbidity and mortality after allogeneic SCT. Chronic GVHD generally involves donor T cells expanding and attacking the host's immunologic system; its pathophysiology is poorly understood compared to acute GVHD (Woltz et al., 2006; Perez-Simon et al., 2006). Standard first-line treatment for chronic GVHD includes prednisone alone or in combination with a calcineurin inhibitor such as cyclosporin or tacrolimus. A recent review article (Perez-Simon et al., 2006) states that there is no generally accepted salvage treatment for patients with chronic GVHD who do not respond to prednisone. Treatments that have been used for refractory chronic GVHD include mycophenolate mofetil, anti-interleukin-2a receptor antagonists, sirolimus, pentostatin, CD20 antagonists, tumor necrosis factor- α antagonists and extracorporeal photopheresis. Other, newer treatments include anti-CD25 immunotoxin and inhibition of nuclear factor- κ B. The authors of the review article recommend that chronic GVHD patients enter clinical trials for salvage treatment if at all possible. Extracorporeal photopheresis (ECP) is one of the treatment options for refractory acute and chronic GVHD. ECP involves removing the patient's peripheral blood and separating it into leukocyte-depleted blood and leukocyte-enriched plasma. The leukocyte-depleted blood is returned to the patient. The leukocyte-enriched plasma is exposed to ultraviolet light in the presence of an extracorporeally administered photosensitizing agent, 8-methoxypsoralen (8-MOP). The cells are then re-infused into the patient and die in one-week period. During that week, they are capable of stimulating an antidiotypic T

suppressor response. The exact mechanism of action of ECP is not known. The Therakos Photopheresis System is FDA approved as a class III medical device specifically for photopheresis (Greinix et al., 2000; Woltz et al., 2006). There is no generally agreed-upon standards for the optimal frequency and duration for ECP treatment in patients with chronic GVHD, and there is wide variability in practice. Patients may be treated two or three days a week every two to three weeks for 3 to 30 months (Woltz et al., 2006). ECP for acute and chronic graft versus host disease was first reviewed by MTAC in 2002. At that time, the empirical evidence consisted of small case series, with sample sizes varying from 3 to 23. The item failed MTAC evaluation criteria, and the Health Plan Medical Directors decision was to review requests on a case-by-case basis. A new review is being requested due to the length of time since the previous review, and recent changes made to Medicare criteria. Medicare now covers ECP for patients with chronic GVHD whose disease is refractory to standard immunosuppressive drug treatment.

06/12/2002: MTAC REVIEW

Extracorporeal Photopheresis in the Treatment of Acute and Chronic Graft Versus Host Disease

Evidence Conclusion: There is not enough evidence to permit conclusions on the effectiveness of extracorporeal photopheresis for treating acute or chronic graft-versus-host disease.

Articles: The search yielded 16 articles. There were no randomized controlled trials. Seven of the articles were reviews or editorials, two were case reports and seven were small case series (varying in size from n=3 to n=23). Due to the low grade of evidence and the small size of the studies, no evidence tables were created.

The use of extracorporeal photopheresis in the treatment of acute and chronic graft versus host disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/20/2007: MTAC REVIEW

Extracorporeal Photopheresis in the Treatment of Acute and Chronic Graft Versus Host Disease

Evidence Conclusion: The published studies that evaluated actigraphy for the assessment of insomnia were conducted on selected groups of patients and used different actigraph models, software, and scoring algorithms. Most studies were conducted in sleep laboratories where recording conditions are standardized, and the artifacts controlled. These controls would be lost when the actigraphy devices are used in the home environment, where it is intended for use. Also, the algorithms that were validated for a specific model, mode of operation, or in a selected population may by not be equally accurate when used with a different brand of device, different gender or age group. The studies reviewed compared actigraphy to PSG, but the authors did not indicate whether the investigators interpreting the results of one test were blinded to the results of the other. The overall results of the studies reviewed, indicate that compared to polysomnography, actigraphy had a high sensitivity (92-98%) but very low specificity (28-48%) in detecting insomnia. It was also found to overestimate the total sleep time and sleep efficiency. Actigraphy tends to overestimate sleep in people with insomnia when they are lying quietly as quiet wakefulness could be miscoded as sleep. Insomnia patients can remain inactive for a period of time attempting to fall asleep on the other hand actigraphy may underestimate the amount of sleep and overestimate the duration awake among those who are asleep but are restless or have large amounts of movements during sleep. The use of actigraphy for the assessment of periodic leg movements in sleep was evaluated in only a few small studies with methodological limitations. It was compared with polysomnography with bilateral anterior tibialis electromyography (BATEMG). However, EMG and leg actigraphy are not interchangeable, and each measures a different event. One records electrical activity of a certain muscle and the other records leg acceleration. Leg activity may be due to movement artifacts produced by obstructive sleep apnea. Kemlink et al (2007) did not exclude patients with suspicious sleep apnea and did not adjust for it in the analysis. In conclusion there is insufficient evidence to determine that actigraphy would replace PSG or add to its value in the diagnosis and management of patients with sleep disorders.

Articles: No randomized or non-randomized controlled trials were identified. The empirical evidence continues to consist of case series. The largest case series on ECP for acute GVHD (n=59) and for chronic GVHD (n=71) identified in the search were critically appraised. In addition, a case series on ECP in pediatric patients with either acute or chronic GVHD (n=77) was critically appraised. There were additional smaller case series. The studies reviewed include: Greinix HT, Knobler RM, Worel N et al. The effect of intensified extracorporeal photochemotherapy on long-term survival in patients with severe acute graft versus host disease. *Stem Cell Transplant* 2006; 91: 405-408. See [Evidence Table](#). Couriel DR, Hosing C, Saliba R et al. Extracorporeal photochemotherapy for the treatment of steroid resistant chronic GVHD. *Blood* 2006; 107: 3074-3080. See [Evidence Table](#). Messina C, Locatelli F, Lanino e et al. Extracorporeal photochemotherapy for pediatric patients with graft versus host disease after hematopoietic stem cell transplantation. *Br J Hematol* 2003; 122 118-127. See [Evidence Table](#).

The use of extracorporeal photopheresis in the treatment of acute and chronic graft versus host disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma (CTCL)

BACKGROUND

Cutaneous T-cell lymphoma (CTCL) refers to several clonal T-cell malignancies that primarily manifest as skin conditions. The classical subsets of CTCL include mycosis fungoides (MF), the most common form, and Sezary Syndrome (SS). MF usually presents as chronic eczematous or psoriasiform patches or plaques whereas SS is characterized by erythroderma and leukemia. SS is sometimes viewed as an advanced form of MF. According to the CTCL disease staging system (stage IA-IVB), patients with Sezary Syndrome have stage IV disease. (Apisarnthanarax et al., 2002; Duvic et al., 2003; Russell-Jones et al., 2000). Therapeutic options differ according to clinical disease stage. Early patch-plaque MF (Stage 1 and IIA) is generally a benign and chronic condition and can be treated with conservative therapies such as topical corticosteroids, retinoids and mechlorethamine (nitrogen mustard). Early stage disease can also be treated with ultraviolet B (UVB) phototherapy or psoralen plus ultraviolet A photochemotherapy (PUVA). Some of the treatments used in early stage disease, such as PUVA or oral bexarotene, are also used for later stage disease but may be less effective. Historically, the most common treatment for late-stage disease (Stage IIB-IVB) is chemotherapy. No single-agent or multi-agent regimen has been shown to be clearly superior to the others. Disadvantages of systemic chemotherapeutic agents are that they have immunosuppressive effects which can lead to opportunistic infections, sepsis or death (Apisarnthanarax et al., 2002). Extracorporeal photopheresis (ECP) is another treatment option for CTCL. ECP involves removing a portion of the patient's blood and separating into red and white blood cells by centrifugation. The red cells are returned to the patient. The white cells are mixed with a photosensitizing agent, 8-methoxypsoralen or methoxsalen (Uvadex, Therakos), and irradiated with ultraviolet light (UVA light, 320-400 nm). When activated, the photosensitizing agent binds with the cellular DNA of the white cells and accelerates their death. The altered cells are then reinfused into the patient. The intention is that these cells will stimulate an immune response against the damaged pathogenic T cell clones. In the pivotal study upon which FDA approval was based, a case series with 37 patients by Edelson and colleagues, a greater treatment effect was seen in patients with erythrodermic CTCL (later-stage disease) compared to those with plaques or tumors. This distinction has been difficult to confirm in later case series because studies generally include patients at different stages of clinical disease and do not report findings separately by disease stage. The effectiveness of ECP for treating CTCL, particularly the following information was used in the development of this document and is provided as background only. Sezary Syndrome continues to be debated in the literature. Some of the controversies are whether prior treatment with systemic corticosteroids and systemic chemotherapy reduces the effectiveness of ECP and which sub-groups of patients are most likely to benefit from ECP treatment. To date, there have not been any randomized controlled trials comparing ECP to other treatments for CTCL (Apisarnthanarax et al., 2002; Russell-Jones, 2000; FDA website; Therakos website). The FDA has approved the photopheresis device UVAR and the photosensitizing Uvadex (both by Therakos) for the palliative treatment of skin manifestations of cutaneous T-cell lymphoma that has not responded to other forms of treatment. ECP is covered by Medicare for the same indication. Extracorporeal photopheresis for CTCL has not been reviewed previously by MTAC. ECP for the treatment of graft versus host disease was reviewed by MTAC in June, 2002.

06/05/2006: MTAC REVIEW

Extracorporeal Photopheresis for Cutaneous T-Cell Lymphoma (CTCL)

Evidence Conclusion: There are no randomized controlled trials evaluating the efficacy of extracorporeal photopheresis for treating patients with CTCL. The published literature consists of small, predominantly retrospective case series. The ECP treatment protocol was similar in the case series that were reviewed, generally consisting of treatment every 4 weeks with a tapering off by lengthening treatment intervals in patients who achieved a response. Data from case series suggests that ECP might be helpful for treating skin manifestations of CTCL, the FDA approved indication. However, there are no data on the efficacy of ECP for skin conditions compared to an alternative treatment or no treatment. In the single prospective study, 27/37 patients had a positive response to treatment, defined as at least a 25% reduction in the skin score. 24/29 patients with erythroderma had a positive response after a mean follow-up of 42 weeks (Edelson et al., 1987). A study published 5 years later on the 29 patients with erythroderma (Heald et al., 1992) found that most of the patients had at least some improvement in skin manifestations of CTCL and 6 had a complete remission. It is not possible to draw conclusions about survival after ECP treatment due to the lack of comparative data from RCTs. Predicted median survival using life-table analysis in the Heald/Edelson study was 60 months from time of diagnosis of the erythrodermic state. One of the case series (Fraser-Andrews et al. 1998) included a non-randomized comparison group of patients who did not receive ECP treatment. They did not find a statistically significant difference in median length of survival from time of SS diagnosis in the two groups (39 months in ECP-treated patients vs. 26.5 months in non-ECP treated patients, $p=0.12$). Other than a lack of randomization, limitations of the Fraser-Andrews study was the wide variety of other treatments patients received before, during and after ECP treatment, or instead of ECP treatment. It is difficult to attribute a response to the ECP treatment itself. The limited data on use of ECP for CTCL identified few adverse effects.

Articles: No randomized controlled trials were identified. The empirical studies were all case series, each with a sample size of less than 50. Desirable features of case series were prospective design, larger sample size, clear eligibility criteria, longer follow-up and survival included as an outcome. Three studies included survival as an outcome in addition to treatment response, had sample sizes $n > 25$ and had reasonably long-term follow-up; however, only one of them was prospective. These three studies were critically appraised. The prospective study reporting on patient survival was the original Edelson (1987) study, with follow-up data reported by Heald and colleagues in 1992. Excluded studies include a prospective study that included only 14 patients and a small ($n = 20$) study that included survival as an outcome but was retrospective and did not specify eligibility criteria. *Studies reviewed include:* Heald P, Rook A, Perez M et al. Treatment of erythrodermic cutaneous T-cell lymphoma with extracorporeal photochemotherapy. *J Am Acad Dermatol* 1992; 27: 427-433. (Follow-up of Edelson R et al. *NEJM* 1987; 316: 297-303). See [Evidence Table](#). Gottlieb SL, Wolfe JT, Fox FE et al. Treatment of cutaneous t-cell lymphoma with extracorporeal photopheresis monotherapy and in combination with recombinant interferon alfa: A 10-year experience at a single institution. *J Am Acad Dermatol* 1996; 35: 946-957. See [Evidence Table](#). Fraser-Andrews E, Seed, P, Whittaker S. et al. Extracorporeal photopheresis in Sezary syndrome. *Arch Dermatol* 1998; 134: 1001-1005. See [Evidence Table](#).

The use of extracorporeal photopheresis in the palliative treatment of cutaneous T-cell lymphoma lesions does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article (LCA)	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Medical Policy Clinical Review Criteria, <i>Fecal GI Infusion for the Treatment of C. Difficile Infection</i> , for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

Service	Criteria
Fecal GI Infusion	Fecal GI infusion is covered when ALL of the following are met: <ol style="list-style-type: none"> 1) Clostridium difficile infection confirmed by a positive stool test for C. difficile toxin 2) Has had at least two recurrences following adequate antibiotic therapy This would be defined as a symptomatic toxin-positive failure after at least one prolonged tapering course of vancomycin (generally over a 4-6-week period).
FMT capsule, G3 OpenBiome	If the above criteria are met, oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory clostridium difficile infection is covered.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Clostridium difficile (C difficile) is the leading cause of antibiotic associated diarrhea and its rates continue to rise. During the past several years, the incidence of C difficile infection (CDI) has increased to an epidemic level; it has become more severe, more refractory to standard treatment, and more likely to relapse. According to the CDC, the number of hospitalized patients with any CDI discharge diagnoses more than doubled from approximately

139,000 to 336,600, and the number with a primary CDI diagnosis more than tripled, from 33,000 to 111,000 from 2000 to 2009. This rise in incidence and severity of the disease is possibly associated with the emergence of the hypervirulent strain (NAPI/ribotype 027). CDI is responsible for a spectrum of infections including uncomplicated diarrhea, pseudomembranous colitis, and toxic megacolon, which may lead to sepsis and even death. It often occurs in patients in health-care settings where antibiotics are prescribed, and symptomatic patients are concentrated. The most common risk factor for CDI is the use of broad-spectrum antibiotics or the concomitant use of multiple and prolonged antimicrobials. Other risk factors include advanced age (65 years or older), recent organ transplantation, gastrointestinal surgery, inflammatory bowel disease, immunosuppressive drugs, presence of multiple co-morbidities, and others. Mature colonic bacterial microbiota (community of micro-organisms) in a healthy adult is generally resistant to *C difficile* colonization. Any factor altering the balance of intestinal microbiota leads to a selective advantage and colonization by *C difficile* colonization after exposure to the bacteria. The standard treatment for *C difficile* associated disease includes discontinuation of offending/inducing antibiotic and treatment with metronidazole or vancomycin. Most patients initially respond to this therapy, but 15-30% experience a symptomatic recurrence after discontinuation of the treatment. The risk of recurrence rises to 40% after a first recurrence and to more than 60% after two or more recurrences. The increased incidence and severity of CDI, and the high recurrence rate with conventional treatments have led researchers to explore alternative strategies and therapies with varying degrees of success. These include the use of additional courses of metronidazole and vancomycin, pulsed/tapered antibiotics, the use of new drugs as nitazoxanide and fidaxomicin, immune therapy such as IV immunoglobulin, active immunization, toxin binding, and alternative approaches as the use of probiotics (such as lactobacillus species, which is a low-virulent microorganism that could compete with *C difficile* for nutrients and sites of mucosal adherence), and fecal transplantation to recreate the colonic environment (Brandt 2012, Guo 2012, Kassam 2011, 2013).

Fecal transplantation (FT), also known as fecal microbiota transplantation (FMT), fecal bacteriotherapy, feco-therapy, fecal microbiota reconstitution, or human probiotics infusion, refers to the process of instilling a liquid suspension of stool from a healthy donor into the gastrointestinal (GI) tract of another person, theoretically to promote normalization of flora and restore the intestinal microbiota. It is of particular utility in recurrent or refractory *C difficile* infection. The exact mechanism of FMT in treating CDI is not clear but may involve the re-colonization of microbiota with missing components to generate colonization resistance or direct antagonistic activity of the normal microbiota to *C difficile*. There is also the possibility that the transplantation of donated flora results in an immunological response facilitating the eradication of *C difficile*. The re-establishment of the normal composition of the intestinal flora by the use of human fecal microbiota was first used by Ben Eiseman in 1958 for the treatment of four patients with pseudomembranous colitis. Lately, FMT has received more attention with the publication of promising results of case series. It is however, not widely accepted as a therapeutic tool due to lack of published trials with long-term outcomes and concerns regarding its safety and acceptability (Guo 2012, Matilla 2012).

There is no clear definition of CDI, its recurrence, relapse or re-infection, and there is no standardized protocol for FMT as regards the choice of donor (family member or volunteer donor), screening of donors, quantity and preparation of stools collected, form of infusion, and measurement of outcomes. There is also no consensus on the most appropriate form of delivery for the fecal microbiota. Until 1989 retention enema was the most common route for FMT; subsequently it was infused via nasogastric tube, colonoscopy and more recently self-administered enemas. The colonoscopic approach seems to be the most common and favored approach as it allows the examination of the disease extent and inoculation of the entire colon and ileum. Regardless of the delivery method, the steps of the procedure are similar and include evaluating the patient eligibility, patient consent, identification and screening of donors, preparation of the sample, and infusion of the suspension prepared. Donor stool is most often used within 8 hours of passage, but frozen samples have been thawed and used 1-8 weeks after passage. Stool is commonly suspended in saline; however, water, milk, and yogurt have also been used as diluents. The suspension is filtered through gauze pads or strainer, and then aspirated into syringes for use. The volume of stool suspension used for FMT varied between studies from less than 200 ml to 500 ml or more. Patients undergoing FMT typically remain on their CDI antimicrobials until 2-3 days prior to the procedure. Bowel preparation is performed regardless of the route. If infused via nasogastric tube, the suspension is applied after fitting the tube in place. After the infusion the tube is rinsed with saline solution and removed. If applied via colonoscopy, the colonoscope is inserted and advanced to the terminal ileum, and then working backwards the stool suspension is administered, most in the terminal ileum and ascending colon. The aftercare requires regular clinical checkups and testing the stools for *C difficile*. The risk of the procedure includes risks associated with application as perforation and hemorrhage, as well as the risk of microbial translocation and sepsis. FMT is relatively contraindicated in patients with severe comorbid conditions or those taking immunosuppressants, though such patients have been successfully treated with the fecal transplant (Brandt 2011, Gough 2011, Postigo 2012, Rohlke 2012, Kleger 2013, Aroniadis 2013).

Fecal transplantation is not regulated by FDA, to date, as fecal matter is organic. According to the FDA the complex nature of FMT products presents specific scientific and regulatory challenges. The Center for Biologics Evaluation and Research (CBER), together with the National Institute of Allergy and Infectious Disease (NIAID) are holding a public workshop in May 2013, to facilitate clinical development of FMT.

Medical Technology Assessment Committee (MTAC)

Fecal GI infusion for the Treatment of C. Difficile infection

04/15/2013: MTAC REVIEW

Evidence Conclusion: There is some evidence from one small RCT that fecal transplantation has a significantly higher success rate than vancomycin in treating patients with recurrent C difficile infection. Meta-analyses of case series with no control groups also show a high cure rate of recurrent CDI with FMT. There is insufficient evidence to determine whether FMT is effective for the treatment of patients with the more virulent strain ribotype 027 C difficile. There is insufficient evidence to determine the most effective and safe modality for delivering the FMT. There is insufficient evidence to determine the long-term efficacy and safety of FMT.

Articles: The literature search for studies on fecal transplantation for the treatment of *C difficile* infection revealed one recent RCT (van Nood 2013), and four systematic reviews (Gough 2011, Guo 2012, Kassam 2013 and Sofi 2013). The latter two pooled the results of the published studies in meta-analyses. Sofi and colleague's analyses combined the results of case series and case reports, while Kassam and colleagues excluded the small case series (<10 subjects) and case reports in an attempt to minimize bias. The search also identified a review comparing nasogastric versus colonoscopic FMT (Postigo 2012), and a protocol for a Cochrane review, which is still being prepared. van Nood 2013 RCT, and the Kassam and colleagues' meta-analysis that had a more valid methodology were selected for critical appraisal: van Nood E, Vrieze A, Nieuwdorp M, et al. Duodenal infusion of donor feces for recurrent *Clostridium difficile*. *N Engl J Med*. 2013; 368:407-415. [See Evidence Tables](#). Kassam Z, Lee CH, Yuan Y et al. Fecal Microbiota Transplantation for *Clostridium difficile* Infection: Systematic Review and Meta-Analysis. *Am J Gastroenterol* 2013; Mar 19. doi:10.1038/ajg.2013.59 [See Evidence Tables](#).

The use fecal GI infusion for the treatment of *C. difficile* infection meets the *Kaiser Permanente Medical Technology Assessment Criteria*.

Oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory clostridium difficile infection

BACKGROUND

Clostridium difficile (*C difficile*) infection (CDI) is one of the most prevalent hospital acquired infections in the United States and is the leading cause of antibiotic associated diarrhea. The incidence of CDI has increased to an epidemic level; it has become more severe, more refractory to standard treatment, and more likely to relapse. According to the CDC, CDI was estimated to have caused almost half a million infections in the United States in 2011, and 29,000 deaths within 30 days of the initial diagnosis. It is believed that the rise in incidence and severity of the disease may be related to the emergence of the hypervirulent strain of the organism (NAP1/BI/027) that is particularly associated with higher rates of treatment failure and recurrence (Youngster 2014, Hirsch 2015, CDC webpage accessed November 2015). CDI is responsible for a spectrum of infections including uncomplicated diarrhea, pseudomembranous colitis, and toxic megacolon, which may lead to sepsis and even death. It often occurs in patients in health-care settings where antibiotics are prescribed, and symptomatic patients are concentrated. The most common risk factor for CDI is the use of broad-spectrum antibiotics or the concomitant use of multiple and prolonged antimicrobials. Other risk factors include advanced age (65 years or older), recent organ transplantation, gastrointestinal surgery, inflammatory bowel disease, immunosuppressive drugs, presence of multiple co-morbidities, and others. Mature colonic bacterial microbiota (community of micro-organisms) in a healthy adult is generally resistant to colonization and overgrowth of pathogenic bacteria. Any factor altering the balance of intestinal microbiota allows pathogens such as *C difficile* to proliferate and dominate the gut ecosystem (Matilla 2012, Rohlke 2012, Sofi 2012, Brandt 2012, Kassam 2013, Hirsch 2015). The standard management of CDI includes discontinuation of offending/inducing antibiotic and treatment with metronidazole or vancomycin. Most patients initially respond to this therapy, but 15-30% experience symptomatic recurrence after discontinuation of the treatment. It is reported that antibiotics targeting CDI may eradicate the active infection, but do not restore the long-lasting dysbiosis of the microbiota, which is the major risk factor for relapse. This risk rises to 40% after a first recurrence and to more than 60% after two or more recurrences. The increased incidence and severity of CDI, and the high recurrence rate with conventional treatments have led researchers to explore alternative strategies and therapies with varying degrees of success. These include the use of additional courses of metronidazole and vancomycin, pulsed/tapered antibiotics, the use of new drugs as nitazoxanide and fidaxomicin, immune therapy such as IV immunoglobulin, active immunization, toxin binding, and alternative approaches such as use of probiotics as lactobacillus species, which is a low-virulent microorganism that could compete with *C difficile* for nutrients and sites of mucosal adherence, and fecal microbiota transplantation (Brandt

2012, Guo 2012, Kassam 2013, Hirsch 2015). Fecal microbiota transplantation (FMT), also known as fecal transplantation (FT), fecal bacteriotherapy, fecotherapy, fecal microbiota reconstitution, or human probiotics infusion, refers to the process of transplantation of stools from a healthy individual into the gastrointestinal (GI) tract of the affected patient, theoretically to promote normalization of flora and restore the intestinal microbiota. It may be particularly useful in recurrent or refractory *C. difficile* infection. The exact mechanism of FMT in treating CDI is not clear but may involve the re-colonization of microbiota with missing components to generate colonization resistance or direct antagonistic activity of the normal microbiota to *C. difficile*. There is also the possibility that the transplantation of donated flora results in an immunological response facilitating the eradication of *C. difficile*. The re-establishment of the normal composition of the intestinal flora by the use of human fecal microbiota was first used by Ben Eiseman in 1958 for the treatment of four patients with pseudomembranous colitis. Lately, FMT has received more attention with the publication of promising results of a small RCT and a number of case series (Guo 2012, Matilla 2012, van Nood 2013). There is no standardized protocol for FMT as regards the choice of donor (family member or volunteer donor), screening of donors, quantity and preparation of stools collected, form of infusion, and measurement of outcomes. There is also no consensus on the most appropriate form of delivery for the fecal microbiota. Traditionally FMT has been performed by transplanting a liquid suspension of feces from a related healthy donor into the gastrointestinal tract of the affected patient through nasogastric tube, endoscopy, enema, or colonoscopy. The traditional methods are time-consuming, may be technically challenging, unaesthetic, and not accepted by many patients (Brandt 2011, Gough 2011, Postigo 2012, Rohlke 2012, Kleger 2013, Aroniadis 2013). More recently, orally administered capsules containing cryopreserved fecal material have been described. The capsules are generally prepared using fecal material harvested from unrelated healthy donors fulfilling strict criteria including screening negative for HIV, hepatitis A, B, and C as well as *Treponema pallidum*. Fecal matter is collected under sterile conditions, combined with saline, processed, sieved, centrifuged, and mixed again with saline along with glycerol, to protect the biological material from becoming damaged when frozen. The fecal material is then dispensed into double or triple capsules and stored at -80°C (-112°F). The capsules should be kept frozen until the time of administration and ingested as quickly as possible after extraction from the freezer. Capsules may be kept at room temperature for up to 90 minutes for patient comfort and ease of swallowing. Another described method is the immediate freezing and storing of the fecal suspension or slurry in 5- or 10-ml syringes at -80°C then thawing and triple encapsulating it prior to its use. Capsules should never be refrozen and should be disposed of if not used within 90 minutes. OpenBiome (Boston, MA) a stool bank that created a fecal transplant pill (G3) recommends the intake 30 capsules, swallowed consecutively in a single session for the treatment of CDI (OpenBiome website, Youngster 2014, Hirsch 2015). FMT capsule G3 (OpenBiome) are size 00 (approximately the size of a large multivitamin) and are provided with two placebo test capsules. The patient is asked to ingest one test capsule prior to the start of treatment, under direct observation of the physician, to ensure the patient's ability to swallow. Any clinical concerns suggesting an aspiration risk is an absolute contraindication to capsule administration. Other contraindications include severe complicated CDI, dysphagia, history of gastroparesis, allergy to any of the ingredients, adverse events attributable to a previous FMT, and any condition that the treatment may pose a health risk (OpenBiome website). According to OpenBiome, FMT Capsule G3 may be used as a treatment for *C. difficile* infection not responsive to standard therapies in accordance with the FDA's guidance on the use of fecal microbiota for transplantation, and in clinical trials under an Investigational New Drug (IND) application.

12/21/2015: MTAC REVIEW

Oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory *clostridium difficile* infection

Evidence Conclusion: There is a lack of published studies on the use of oral cryopreserved FMT capsules for patients with relapsing or refractory CDI. Currently the literature on oral FMT capsules for patients with relapsing *C. difficile* infection (CDI) consists of two small case series and one case report. Youngster and colleagues (2014) (evidence table 1), evaluated the safety and rate of resolution of diarrhea following the administration of cryopreserved FMT capsules in 20 patients (11-89 years of age) with refractory *C. difficile* infection. The oral capsulized FMT was prepared from stool samples gathered from healthy adult volunteers who had been comprehensively screened for infectious diseases and avoided eating common allergens for several days before donating. Each patient ingested 15 FMT capsules consecutively each day for two successive days. If their symptoms did not improve within 72 hours, they were offered a second course of treatment with fecal material from the same donor. They were followed-up for 6 months and the primary outcomes were safety and clinical resolution of diarrhea with no relapse at 8 weeks. The results of the study show that after the first 2 days of treatment, 14 of the 20 patients (70%) experienced clinical resolution of diarrhea, defined as less than 3 bowel movements /24 hours, and remained symptom free for 8 weeks. After a second course of treatment, four of the remaining patients became symptom free, resulting in an overall 90% rate of symptom resolution. No serious adverse events were reported. The study was a small observational study with no control or comparison group and relied on patient report on clinical outcomes. Patients with symptomatic improvement were not retested for *C. difficile*. The authors indicated that it was a pilot feasibility study that only provides preliminary data on the safety

and effectiveness of this the oral capsulized FMT. Hirsch et al, 2015 (Evidence table 2), conducted a chart review of 19 patients treated with orally administered FMT capsules for recurrent CDI. FMT was prepared from stools donated by healthy volunteers unrelated to the recipients. Before receiving the FMT, the patients were required to discontinue any CDI antimicrobial treatment for 24 hours and were given a proton pump inhibitor on the evening and morning prior to the therapy. After a light breakfast, they received 6-22 capsules of FMT under supervision in an outpatient setting and were instructed to sit upright and not eat for an hour after ingesting the capsules. Patients were encouraged to drink 4 oz. of fermented milk product twice daily and to consume pro-biotic nutrients for at least 3 days after the FMT. They were followed-up by phone interviews within 2 days, 3 weeks, and after 90 days to assess the response to the therapy and adverse events. Those with recurrent CDI were retreated with antimicrobial therapy and subsequently offered repeat FMT (approximately 6 weeks after the initial FMT) and followed up for an additional 90 days. The primary outcome was resolution of CDI associated diarrhea without relapse assessed at 90 days after the last FMT. 13 of the 19 patients treated (68%) responded to a single course, and four responded to the second course of therapy with a total response rate of 89%. No serious adverse events were reported. The study was a small retrospective case series with no control or comparison group and relied on patient and family report on clinical outcomes. In addition, the follow-up duration was insufficient to determine the long-term safety and effectiveness of the orally ingested FMT capsules. It is also worth noting that the authors have financial ties to Symbiotic Health Inc. Conclusion: There is insufficient evidence to determine that orally ingested FMT capsules prepared from stools provided by volunteer donors is safe and effective for the treatment of patients with CDI. There is insufficient evidence to determine that orally ingested FMT capsules prepared from stools provided by volunteer donors is safe and effective for the treatment of patients with CDI with the more virulent strain *C difficile* (NAP1/B1/027). There is insufficient evidence to determine the long-term efficacy and safety of orally ingested FMT capsules. Case series may only generate hypothesis and large RCTs with long-term follow up are studies are needed to support the observed findings and determine the optimal donor, optimal dose of FMT, long-term safety, and long-term efficacy of cryopreserved oral capsulized FMT.

Articles: The literature search revealed two small cases series (one prospective and one retrospective) and a case report on the use of oral cryopreserved FMT capsules for patients with relapsing CDI. There are no published meta-analyses or randomized controlled trials, to date, that compared the use of the oral FMT capsules to standard therapy or to other traditional methods of delivering FMT for the treatment of refractory or relapsing CDI.

The following two case series were critically appraised. Youngster I, Russell G, Pindar C, et al. Oral, capsulized, frozen fecal microbiota transplantation for relapsing *Clostridium difficile* infection. *JAMA*. 2014 Nov 5; 312(17):1772-1778. See [Evidence Table 1](#). Hirsch BE, Saraiya N, Poeth K, et al. Effectiveness of fecal-derived microbiota transfer using orally administered capsules for recurrent *Clostridium difficile* infection. *BMC Infect Dis*. 2015 Apr 17; 15:191 See [Evidence Table 2](#).

The use of Oral, capsulized, frozen fecal microbiota transplantation (FMT capsule, G3 OpenBiome) for the treatment of recurrent or refractory *clostridium difficile* infection does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
44705	Preparation of fecal microbiota for instillation, including assessment of donor specimen
G0455	Preparation with instillation of fecal microbiota by any method, including assessment of donor specimen

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

MDCRPC Medical Director Clinical Review and Policy Committee

MPC Medical Policy Committee

Revision History	Description
01/06/2016	MTAC review was discussed at MPC and approved to adopt criteria for FMT capsule, G3 OpenBiome
05/02/2017	Revised criteria language so it is specific on how to manage care after two recurrences
05/02/2017	Adopted Kaiser Permanente policy for Medicare members

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Fertility Services

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

Non-Medicare Members

Effective until November 1, 2023

For baseline policy for all plans, [click here to view the criteria. \(Internal use only\)](#)

*Individual groups may provide additional benefits or exclusions – see current coverage agreement or contact member services for specific exceptions and limitations.

Based on Kaiser Permanente policy, a member is considered infertile if they are unable to conceive or produce conception:

- After 1 year of frequent, unprotected heterosexual sexual intercourse for members 35 and under
- After 6 months of frequent, unprotected heterosexual sexual intercourse if the female partner is over age 35 years.
- Alternately, a woman without a male partner may be considered infertile if she is unable to conceive or produce conception after at least 12 trials of medically supervised donor insemination (6 cycles for women aged 35 or older).
 - The initial 12 trials of medically supervised donor insemination (6 cycles for women aged 35 or older) to establish an infertility diagnosis, are not covered under the infertility benefit.
- A member is not considered “infertile” if they have had a voluntary sterilization (e.g. tubal ligation, vasectomy). Infertility treatment post-voluntary sterilization is not covered, even if the plan has an SI rider.

As of 1/1/2022, the following plans waived the requirement for a diagnosis of infertility but may still require prior authorization or clinical review based on individual benefits and plan riders.

Association of Washington Cities (AWC)

Boeing

City of Seattle

Meta (Facebook) – for cryopreservation only

SEIU

For *only* Kaiser Permanente Individual & Family (I&F) and Small Business Group (SBG) contracts

In addition to base infertility/sterility services listed in the Infertility and Sterility policy, member is eligible for:

- Tubal patency/uterine irregularities- HSG (radiology)
- TSH, prolactin (lab)
- Testing for Ovarian reserve –Day 3 FSH
- Semen analysis (if member has Kaiser coverage) (lab)
- Member must use in-network lab

Effective November 1, 2023

Referrals to Reproductive Endocrinology and Infertility (REI) specialists and associated services are not covered as a base benefit and are only eligible for coverage when the member has a sterility and infertility (SI) rider or other evidence of coverage in their contract. **When a Sterility/Infertility (SI) rider is present, initial consultation with an REI specialist is covered without additional criteria review. However, tests and procedures are subject to clinical criteria (as elaborated below).**

Please note that individual riders/contracts may vary in benefit design either excluding or waiving criteria for some services. These may include, but are not limited to, fertility-promoting medications, medications for erectile dysfunction, artificial insemination, in vitro fertilization, long-term cryopreservation, surrogacy services and tubal reanastomosis. The member's rider/contract should be reviewed before making a final coverage determination and supersedes clinical review criteria.

Reproductive services are also subject to lifetime coverage limits which vary by rider/contract and service category.

Exclusions

Unless otherwise stated in the members rider/contract, the following services are not covered

- Reproductive services after voluntary sterilization of a male or female partner (e.g., tubal ligation, vasectomy), including tubal reanastomosis, vas reanastomosis, sperm extraction, artificial insemination and in vitro fertilization
- Long-term cryopreservation (i.e., apart from real-time efforts to conceive)
- Costs related to donor genetic material used for artificial insemination or invitro fertilization
- Services for the purpose of surrogacy
- Routine use of pre-implantation genetic testing (with IVF); medical necessity criteria for pre-implantation genetic testing can be found in a separate clinical criteria - see PGD criteria [here](#)

The following services are subject to clinical review criteria unless the services have been specifically excluded or the criteria has been waived in the member's rider/contract.

Definition of Infertility	<p>The definition of infertility is used to determine eligibility for infertility workup (e.g., diagnostic laboratory or imaging studies) apart from other reproductive services enumerated below.</p> <p>Based on Kaiser Permanente policy, a member is considered infertile if they are unable to conceive or produce conception:</p> <ul style="list-style-type: none"> • Inability to achieve conception after frequent unprotected heterosexual intercourse lasting 12 months for members under 35 years of age or 6 months for members 35 years of age and older • Inability to achieve conception after 6 cycles of artificial insemination (of which at least 3 cycles must be medically supervised) for members under 35 years of age or 3 cycles of
----------------------------------	---

	<p>medically supervised artificial insemination for members 35 years of age and older</p> <ul style="list-style-type: none"> A member is not considered “infertile” if they have had a voluntary sterilization (e.g., tubal ligation, vasectomy) <p><i>*Some members may be eligible for reproductive services without meeting the definition of infertility. Please refer to specific criteria listed below.</i></p>
Pharmaceutical Therapy to Promote Fertility	<ul style="list-style-type: none"> Both oral and injectable medications to promote ovulation for the purpose of fertility require evidence of coverage (SI rider or contract language) and are covered under the pharmacy benefit subject to any applicable prior auth requirements. Medications for erectile dysfunction are not covered under this policy but may or may not be covered under the pharmacy benefit subject to any applicable prior auth requirements.
Artificial insemination (AI)	<p>AI including intravaginal, intracervical, and intrauterine insemination techniques and associated medications, laboratory, imaging, and procedure codes may be covered for the purpose of conception. This includes hysterosalpingogram that would confirm tubal patency necessary for the success of such techniques. Members are eligible for coverage when they have a SI rider that does not specifically exclude these services, have not exceeded their lifetime maximum and meet ONE OR MORE of the following criteria:</p> <ul style="list-style-type: none"> Natal female member without a male partner (applies to single members and same-sex female couples) Natal female member’s male partner is unable to participate in natural insemination due to a physical condition. Erectile dysfunction responsive to medical therapy is excluded even when such medication is not a covered benefit. Inability to achieve conception after frequent unprotected heterosexual intercourse lasting 12 months for members under 35 years of age or 6 months for members 35 years of age and older Documentation of an infectious disease that would make unprotected heterosexual intercourse unsafe according to the medical opinion of the member’s treating clinician Documentation of a heritable genetic trait in the male partner (such as an autosomal dominant trait in the male or co-occurrence of an autosomal recessive trait in both partners) would jeopardize the future health of naturally inseminated offspring according to the medical opinion of the member’s treating clinician and the member intends to use donor genetic material that does not pose the same risk
In Vitro Fertilization (IVF)	<p>IVF techniques including egg retrieval, fertilization, short-term storage, implantation and associated medications, laboratory, imaging, and procedure codes are eligible for coverage when the member has an SI rider that does not specifically exclude these services, has not exceeded their lifetime maximum and meets ONE OR MORE of the following criteria:</p> <ul style="list-style-type: none"> Inability to achieve conception after frequent unprotected heterosexual intercourse lasting 12 months for members under

	<p>35 years of age or 6 months for members 35 years of age and older</p> <ul style="list-style-type: none"> • Presence of previously diagnosed male-factor infertility that is reasonably expected to prevent conception (with heterosexual intercourse or artificial insemination). Mild to moderately reduced sperm count and/or motility are not included. • Inability to achieve conception after 6 cycles of artificial insemination (of which at least 3 cycles must be medically supervised) for members under 35 years of age or 3 cycles of medically supervised artificial insemination for members 35 years of age and older • Presence of previously diagnosed female factor infertility that is reasonably expected to prevent conception with heterosexual intercourse or artificial insemination (e.g., fallopian tubes are not patent) • Member has coverage and meets criteria for Preimplantation Genetic Testing
Surgical Procedures of the Fallopian Tube(s) to Promote Fertility	<p>Surgical therapy of the fallopian tube(s) to promote fertility may be covered when the patient has an SI rider or evidence of coverage in their contract and meets ALL of the following criteria:</p> <ul style="list-style-type: none"> • Member meets the definition of infertility above • Imaging (HSG) confirms scarring of the fallopian tube(s) or the patient has undergone prior surgery of the fallopian tube(s) not for the purpose of voluntary sterilization (e.g. ectopic tubal pregnancy) • The member intends to become pregnant once tubal patency is re-established • The member has not had a voluntary tubal ligation for the purpose of sterilization

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Infertility is a common problem. According to the Centers for Disease Control and Prevention (CDC), about 10 percent of U.S. women ages 15 through 44 years have difficulty getting pregnant or staying pregnant.¹

Both women and men can have problems that cause infertility. About one-third of infertility cases can be connected to the woman. Another third of the cases of infertility can be connected to the man. In the remainder of instances, a cause can't be found.

Applicable Codes

Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Kaiser Permanente Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " Hip Surgery Procedures for Femoroacetabular Impingement Syndrome " for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for these services, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Femoroacetabular impingement (FAI) syndrome is a recently recognized diagnosis in primarily younger individuals where relatively minor abnormalities in the joint (orientation or morphology) are thought to cause friction/impingement and pain. It is theorized that FAI starts the breakdown of cartilage, leading to osteoarthritis. There are two types of FAI: cam impingement (non-spherical femoral head or abnormality at the head-neck junction) and pincer impingement (deep or retroverted acetabulum resulting in over coverage of the femoral head). Proponents believe that surgical correction of the impinging deformities will alleviate the symptoms and retard the progression of OA degeneration. Surgery to correct FAI includes arthroscopy, open dislocation of the hip, and arthroscopy combined with a mini-open approach. The purpose of the surgery is to remove abnormal outgrowths of bone and damaged cartilage, and to reshape the femoral neck to ensure that there is sufficient clearance between the rim of the acetabulum and the neck of the femur.

Medical Technology Assessment Committee (MTAC)

Femoroacetabular Impingement Syndrome

06/17/2013: MTAC REVIEW

Evidence Conclusion: There is no new evidence that would change or add to the recommendations of the HTA review as regards the conservative or surgical treatment of femoroacetabular impingement. The results of these non-randomized observational studies as well as other published retrospective series with or without a comparison group should be interpreted with caution. Due to the nature of the study design, they are subject to selection bias, observation bias, confounding and other limitations, and only provide the lowest grade of evidence.

Articles: Larson CM, Givens R, Stone RM, et al. Arthroscopic debridement versus refixation of the acetabular labrum associated with femoroacetabular impingement. Mean 3.5 –year follow-up. *Am J Sports Med.* 2012; 40:1015-1021. Larson and colleagues (2012) reported on outcomes of two cohorts of patients with femoroacetabular impingement who were treated with either arthroscopic debridement or refixation of the acetabular labrum in one center, but at different time periods. The mean follow-up ranged between 24 and 72 months with a mean of 42 months. The results indicate that the labral fixation was associated with better Harris Hip Scores (HHS), Short Form-12 (SF-12) and visual analog scale (VAS) for pain outcomes compared to arthroscopic focal debridement. Zingg PO, Ulbrich EJ, Buehler TC, et al. Surgical hip dislocation versus hip arthroscopy for femoroacetabular impingement. Clinical and morphological short-term results. *Arch Orthop Trauma Surg.* 2013; 133:69-79. Zingg and colleagues (2013) compared surgical hip dislocation versus hip arthroscopy in 38 patients presenting with clinically FAI that was morphologically verified with plain radiographs and MRI. In 28 of the 38 participants the selection of the procedure was based on the patient's decision, and only 10 agreed to be randomly allocated to either procedure. There were statistically significant differences in the morphological pathology (in terms of acetabular coverage angle, and head-neck offset ratio) between the two groups at baseline. The primary outcome of the study was the alpha angle on a cross-table view. The results of the study showed that patients in the hip arthroscopy group had faster recovery and better short-term outcomes compared to those treated with surgical hip dislocation. However, the hip arthroscopy showed some overcorrection of the cam deformity and limited frequency of labrum refixations, which the authors indicate that they may lead to negative impact on long-term outcomes.

The use of FIS does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Per the Washington State Health Care Authority Health Technology Clinical Committee (HTCC) coverage determination following Femoroacetabular Impingement Syndrome re-review (adopted 1/17/2020):

Hip surgery for femoroacetabular impingement syndrome is not a covered benefit.

Applicable Codes

Considered not medically necessary:

CPT® Codes	Description
27299	Unlisted procedure, pelvis or hip joint
29914	Arthroscopy, hip, surgical; with femoroplasty (i.e., treatment of cam lesion)
29915	Arthroscopy, hip, surgical; with acetabuloplasty (i.e., treatment of pincer lesion)

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

For Non-Medicare Members

I. For the purpose of the Clinical Review Criteria foot care* is defined as:

- A. Cutting or removal of corns or calluses;
- B. Trimming, cutting, clipping, or debriding of nails;
- C. Other hygienic and preventative maintenance care, such as cleaning and soaking the feet, the use of skin creams to maintain skin tone of either ambulatory or bedfast patients, and any other service performed in the absence of localized illness, injury, or symptoms involving the foot;
- D. Asymptomatic foot care is not typically a covered service unless certain complications are present. It is not provided more frequently than every 60 days. The criteria below identify when foot care is covered. They are divided into sections of foot care for the asymptomatic and symptomatic foot.

II. Kaiser Permanente covers foot care services as medically necessary when **EITHER** of the following criteria is met:

- A. The foot care services that are associated with systemic conditions that are significant enough to result in severe circulatory insufficiency and/or areas of severe desensitization in the lower extremities, including, but not limited to, **ANY** of the following:
 - Marked diabetic neuropathy documented on physical exam*
 - Peripheral vascular disease*
 - Marked peripheral neuropathy documented on physical exam*
 - Non-traumatic partial amputation of a foot

*For neuropathies chart must record the physical findings of severe loss of sensation such that non-professional services might pose a danger to the patient. For peripheral vascular disease, the diagnosis and severity must have been confirmed by a vascular surgery evaluation.

- B. In the absence of a systemic condition, treatment of mycotic nails may be covered.
 - The treatment of mycotic nails for an **ambulatory** patient is covered only when the physician attending the patient's mycotic condition documents that (1) there is clinical evidence of mycosis of the toenail, and (2) the patient has marked limitation of ambulation, pain, or secondary infection resulting from the thickening and dystrophy of the infected toenail plate.
 - The treatment of mycotic nails for a **non-ambulatory** patient is covered only when the physician attending the patient's mycotic condition documents that (1) there is clinical evidence of mycosis of the toenail, and (2) the patient suffers from pain or secondary infection resulting from the thickening and dystrophy of the infected toenail plate.

III. Exclusions

- A. General diagnoses such as arteriosclerotic heart disease, circulatory problems, vascular disease, and venous insufficiency are not sufficient to permit coverage of routine foot care. Likewise, incapacitating injuries or illness such as rheumatoid arthritis, CVA, fractured hip and blindness which make trimming the nails difficult, **are not** diagnoses for which routine foot care is payable.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Asymptomatic foot care or routine foot care is usually not covered for members in the absence of localized illness, injury or symptoms involving the foot. Most Kaiser Permanente coverage contracts exclude routine foot care coverage. Kaiser Permanente developed criteria consistent with the Medicare those published by Medicare.

Foot care includes:

- Cutting or removal of corns or calluses
- Trimming, cutting, clipping, or debriding of nails
- Other hygienic and preventative maintenance care, such as cleaning and soaking the feet, the use of skin creams to maintain skin tone of either ambulatory or bedfast patients, and any other service performed in the absence of localized illness, injury, or symptoms involving the foot.

- Debridement of nails is a procedure that is needed to remove excessive material (reduce thickness and length) from a dystrophic nail but not a non-dystrophic nail. In contrast, trimming of nails is a procedure that may be directed at either type of nail.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
11055	Paring or cutting of benign hyperkeratotic lesion (eg, corn or callus); single lesion
11056	Paring or cutting of benign hyperkeratotic lesion (eg, corn or callus); 2 to 4 lesions
11057	Paring or cutting of benign hyperkeratotic lesion (eg, corn or callus); more than 4 lesions
11719	Trimming of nondystrophic nails, any number
11720	Debridement of nail(s) by any method(s); 1 to 5
11721	Debridement of nail(s) by any method(s); 6 or more
G0127	Trimming of dystrophic nails, any number
G0247	Routine foot care by a physician of a diabetic patient with diabetic sensory neuropathy resulting in a loss of protective sensation (LOPS) to include the local care of superficial wounds (i.e., superficial to muscle and fascia) and at least the following, if present: (1) local care of superficial wounds, (2) debridement of corns and calluses, and (3) trimming and debridement of nails
S0390	Routine foot care; removal and/or trimming of corns, calluses and/or nails and preventive maintenance in specific medical conditions (e.g., diabetes), per visit

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Galectin-3 Blood Assay Test" for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies for congestive heart failure (CHF).

The use of Galactin-3 for all other indications does not meet medical necessity because its clinical utility has not been established.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Heart failure (HF) is one of the most frequent and challenging medical disorders. It is a complex progressive disease with high morbidity and mortality. The prognosis of patients with HF is poor despite the advances made in the diagnosis, medical management, and device therapies. It is thus important to diagnose HF early and to identify the patients at higher risk of poor outcomes (Lok 2013, Browners 2014).

Accurate risk stratification of HF patients may help in the decision making for managing the disease; including individualizing the therapeutic approach and the proper use of invasive and costly therapies. However, risk prediction in acute, chronic, and new onset HF remains a challenge. Clinical parameters, such as advanced age, higher New York Heart Association (NYHA) functional class, reduced left ventricular ejection fraction (LVEF), lower body mass index, renal dysfunction, and anemia, have all been associated with poor outcomes in HF, but are not significant predictors of mortality. In recent years efforts were made to find biomarkers that might help in the risk stratification, and prognostication of acute and chronic heart failure. Brain natriuretic peptide (BNP) and its N-terminal part (NT-proBNP) have become well-established markers used in the diagnosis and management of HF patients. Both are released in response to myocyte stretch and provide useful information for HF diagnosis,

prognosis, and response to therapy. However, natriuretic peptides only indicate ventricular loading conditions and may not reveal other important mechanisms for HF. Other novel biomarkers from different physiopathological pathways such as soluble ST2, growth differentiation factor-15, highly sensitive troponins, and Galectin-3, have recently emerged and are being evaluated for their potential use in adding value to the risk stratification of HF patients. For a biomarker to be useful to a clinician, it should be available, accurate, and reliable. It also should add incremental value to the clinical variables or other established markers, provide prognostic information, have an impact on patient management, and be responsive to interventions (Carrasco-Sanchez 2014, Coburn 2014, Filipe 2014, Gruson 2014, Pouleur 2014, Schmitter 2014, Srivatsan 2014).

Galectin-3 (Gal-3) is a member of a family of proteins comprising soluble β -galactoside-binding lectins that have regulatory roles in fibrogenesis, inflammation, tissue repair, and cell proliferation. It is mainly known for its role as a mediator of tumor growth, progression, and metastases. Gal-3 is also associated with increased age, diabetes, nephropathy, and fibrotic conditions such as liver fibrosis, renal fibrosis, idiopathic lung fibrosis, and chronic pancreatitis. Recently, it has been suggested that Gal-3 may play a role in the pathophysiology of HF through promotion of inflammation, myocardial fibrosis and myocardial remodeling, which are key processes for the development and progression of HF. It was thus suggested that an increased Gal-3 level in the circulation may reflect active and excessive myocardial fibrogenesis in patients with HF and can thus be used as a marker for poor prognosis related to excessive and potential irreversible myocardial fibrosis (Lok 2010, Gullestad 2013, Carrasco-Sanchez 2013, Suarez 2014).

GAL-3 is measured in the circulation by manual or automated assays. The enzyme linked immunosorbent assay manual assay (ELISA) is the most frequently used method in the published studies. Manual assays are, however, laborious and take considerable time for sampling, handling, incubation, and washing steps. More recently, several automated assays with faster delivery of the results, have been developed and are commercially available. A number of manual and automated assays have received FDA approval for measuring circulating Gal-3. Others are still seeking approval. The ARCHITECT Galectin-3 assay, BGM Galectin -3TM are among those approved by the FDA to be used in conjunction with clinical evaluation as an aid in assessing the prognosis of patients diagnosed with chronic heart failure.

Galectin-3 testing in HF patients has not been previously reviewed by MTAC. It is being reviewed for its use as a prognostic marker in patients with heart failure based on requests from contracted providers for its coverage.

Medical Technology Assessment Committee (MTAC)

Galectin-3 Blood Assay Test

02/09/2015: MTAC REVIEW

Evidence Conclusion: 1. Prognostic value of galectin-3 in patients with acute or chronic heart failure: The published studies on the prognostic value of Gal-3 in patients with HF are mainly secondary studies analyzing data from existing databases for RCTs examining the effect of drug therapy or other interventions on outcomes of patients with HF. In these studies, blood samples were obtained once at baseline and the plasma was stored for years at temperatures below 70o-80oC. Baseline plasma Gal-3 levels were then correlated with the incidence of CVD, HF, rehospitalization, and mortality during follow-up. The results were not validated in external cohorts and could be related to specific characteristics of the patients studied, or other unmeasured cofounders. There are several other issues with these kinds of analyses that would limit generalization of their results. Retrospective analyses may only suggest correlation and not causality; blood samples were obtained only once in the majority of studies, with no serial measurements of Gal-3 and thus cannot determine whether it varies by time and the effects of this variation if any, the plasma samples were frozen, and it is unknown if Gal-3 would degrade over the years. In addition, a number of these studies used arbitrary cutoff levels for Gal-3 to categorize patients into subgroups in order to test for interactions and associations. It was also questioned whether the detection of Gal-3 in the circulation accurately reflects activity in the tissues. The ideal study for evaluating the prognostic value of a novel biomarker would be a prospective study with long-term follow-up that examines the additive or incremental value of the new biomarker on top of existing established prognostic markers or clinical variables. The results should then be externally validated in other patient populations. In general, the analyses of the published studies suggest that the plasma concentration of Gal-3 is high in patients with HF. There is insufficient evidence however, to determine that the high plasma level of Gal-3 in these patients is an independent prognostic marker for poorer outcomes. The results of the published analyses are conflicting; some suggest that after adjusting for many clinical variables including NT-proBNP, elevated Gal-3 levels may be associated with higher rates of all-cause mortality, CV events and /or rehospitalization in patients with heart failure. Other analyses, on the other hand, show that after adjusting for similar or additional clinical variables including NT-proBNP, Gal-3 is not a significant independent prognostic marker for any of the outcomes studied (Table 3 shows the differences in the variables adjusted for). There were variations between the studies in their inclusion criteria, patient characteristics, cause,

type, severity, duration, and therapies used for managing the heart failure. There were also differences in population sizes, duration of follow-up, number of covariables used in the multivariate analyses, and the cutoff for Gal-3, which was mainly arbitrarily selected. Studies that showed a significant association between Gal-3 and outcomes tended to be smaller studies that adjusted for less clinical variables in their analyses. The two largest studies HF-ACTION (Felker et al, 2012) and CORONA (Gullestad et al, 2014) showed that Gal-3 was significantly associated with the risk of primary outcomes in the univariate analyses performed, but the association observed was no longer significant when series of multivariable models including NT-proBNP were performed. Chen and colleagues (2015) performed a meta-analysis of 11 studies with 8,419 participants (Evidence table 1) to assess the association between Gal-3 and adverse outcomes in HF patients. The pooled results of the analysis suggest that increased serum Gal-3 was associated with higher all-cause mortality or CV mortality after adjusting for other established factors. These results, however, have to be interpreted with caution due to several limitations. The meta-analysis pooled the results of studies including patients with acute or chronic, and with systolic or diastolic heart failure, and conducted among different patient populations. Two of the 11 studies included in the analysis were performed by the same principal authors among the same group of patients. There was significant heterogeneity between the studies as well as significant publication bias. The population sizes varied between the included studies from 240 to 1,440 patients, and the follow-up duration ranged between 1 and 8.7 years. There were also differences between the studies in the cutoff values for Gal-3 and the variables adjusted for in calculating the hazard ratios (table 3). Meijers et al's (2014) pooled analysis (Evidence table 2) of three clinical trials showed that patients with elevated Gal-3 (>17.8 ng/mL) were more likely to be re-hospitalized for HR at 30, 60, 90, and 120 days after discharge. Gal-3 was found to be an independent predictor for re-hospitalization after adjusting for age, gender, NYHA class, renal function, LVEF, and BNP. Addition of Gal-3 to the clinical risk model comprising these variables significantly improved the net risk classification of patients for postdischarge rehospitalization and fatal events at each time point. The pooled analysis had its limitations and its results should be interpreted with caution.

2. Incremental value of galectin-3: The most commonly used way to evaluate the ability of a prognostic HF biomarker in predicting an event is to assess the area under the Receiver Operator Curve (AUC) which is a balance of sensitivity and specificity of the test or tool, and to compare it with a gold standard (C-statistics). However, a small but statically significant difference between the AUC for the gold standard and biomarker studied, may be clinically irrelevant, and there is no generally agreed upon clinically improvement in the C-statistics (Januzzi 2014). Area under Receiver Operator Curve (AUC) for Gal-3, NT-proBNP, and combinations

Author/ Study	N of patients	Outcome	AUC						
			Clinical model	Ref. † model	Gal- 3	NT- proBNP Or BNP	Clinical or Reference model +Gal-3	Clinical model +BNP	Gal-3 +BNP
Zhang et al, 2015	1,440	All-cause death CV death		0.82	0.71	0.79	0.83		0.81
				0.83			0.83		
Ahmad et al 2014/ HF-ACTION	813	Pump failure SCD	0.82		0.76	0.83	0.83	0.87	
			0.68		0.66	0.67	0.71	0.73	
De Boer et al, 2010/C OACH	592	Death or HF hospitalization			0.67	0.65 (BNP)			0.69
Lok, et al, 2010/ DEAL-HF* 2013	232 209	All-cause mortality			0.61 2	0.611			
					0.68	0.63			0.69
Van Kimmenda de 2006**	599	Mortality			0.74	0.67			

†Reference model included sex, age, DM, ischemic HD, SBP, NYHA functional class, LVEF, ARB/ACE I, B-blocker, hemoglobin, sodium, and NT-proBNP.

*Patients with high baseline levels of both markers were observed to have approximately 1.5-2-fold higher mortality rate compared to those in other categories.

** The combination of an elevated galectin-3 with NT-proBNP was a better predictor of mortality than either of the 2 markers alone.

oCutoff values for Gal-3 were: 22.4 for in-hospital death in Zhang et al's study (sensitivity =0.69 and specificity =0.62), 13.9 ng/mL in HF-ACTION, and 18.05 ng/mL in DEAL-HF

oCutoff values for NT-proBNP were: 2,472 pg/mL in Zhang et al's study, and 852 pg/mL in HF-ACTION.

Accuracy of Gal-3 in the diagnosis of HF was studied in a small study with N= 35 patients with HF and 43 controls (Sheng et al, 2014) showing the following results:

	Sensitivity %	Specificity %	Accuracy %	PPV %	NPV %	AUC
Gal-3	94.3	65.1	78.2	68.8	93.3	0.891
NT-proBNP	77.1	90.7	84.6	87.1	83.0	0.896

At a cutoff of 17.8 ng/mL for Gal-3 and 100 pg/mL for NT-proBNP

90.7 84.6 87.1
83.0 0.896

3. Clinical utility of Galectin-3: The literature search did not identify any randomized controlled trial that examined the use of Gal-3 as a target in HF therapy, or that evaluated its impact on selecting a management strategy for patients with HF. Published studies on the disruption of galectin-3 gene to block myofibroblast activation are experimental, with the hypothesis that direct inhibition of Gal-3 may be possible by N-acetyl-seryl-aspartyl-lysyl-proline (Ac-SDKP), a naturally occurring tetrapeptide that prevents and reverses inflammation and collagen deposition in heart after hypertension or myocardial infarction (Hrynchyshyn 2013). Studies on anti-galectin-3 therapy for heart failure are ongoing. The effect of measuring the concentration of circulating Gal-3 on patient management was indirectly examined in post hoc analyses of data obtained from RCTs evaluating different therapies for HF; rosuvastatin in the CORONA study and valsartan in the Val-HeFT.

The CORONA study (Kjekshus et al, 2007) aimed at examining the beneficial effects of rosuvastatin among patients with chronic, symptomatic, systolic, ischemic heart failure. The trial randomized 5,011 patients over the age of 60 years, with chronic ischemic heart failure to receive 10 mg of rosuvastatin or placebo per day. The primary composite outcome was death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke. Secondary outcomes included death from any cause, any coronary event, death from cardiovascular causes, and the number of hospitalizations. After a median follow-up of 32.8 months the results of the trial showed that rosuvastatin did not reduce the primary outcome or the number of deaths from any cause in these older patients with systolic heart failure but reduced the number of cardiovascular hospitalizations. In a post hoc analysis of CORONA study, Gullestad and colleagues (2012) investigated whether plasma Gal-3 can identify patients with chronic HF for whom statins are effective. Of the 5,011 patients enrolled in the CORONA study, 1,462 (29%) patients had baseline plasma specimens available for measuring Gal-3. These were obtained from nonfasting blood samples obtained at baseline and stored at -80oC. There were significant baseline differences between this subset of patients and the entire CORONA participants. For this secondary analysis, the investigators categorized patients into two groups based on the median Gal-3 baseline level (19.0 ng/mL) and found that after a median follow-up of 32.8 months, patients with Gal-3 below the median level who were assigned to rosuvastatin had significantly lower primary event rate, lower total mortality, and lower rates for the composite outcome of all-cause mortality and HF hospitalization, compared to placebo. No benefits were observed for patients with Gal-3 above the median level. The authors noted that the combination of Gal-3 and NT-proBNP (at cutoff of 102.7 pmol/L) identified patients with a large benefit from rosuvastatin treatment. Val-HeFT trial (Cohn et al, 2001) was a randomized placebo-controlled trial that enrolled 5,010 patients >18 years of age with symptomatic HF to evaluate the efficacy of valsartan. Blood was sampled, and the separated plasma was stored at -70oC. The primary outcomes of Val-HeFT were all-cause mortality and the first morbid event (defined as death, sudden death with resuscitation, hospitalization for HF, or the administration of intravenous inotropic drug or vasodilator for four or more hours without hospitalization). The results of the trial showed that after a median follow-up duration of 23 months, valsartan had no effect on mortality, but reduced the first morbid event by 13% and hospitalization for HF by 28%. These 3 endpoints were analyzed in the Galectin-3 substudy by Anand and colleagues (2013). This post hoc analysis of Val-HeFT trial examined whether circulating Gal-3 levels can predict the response to valsartan. Baseline samples for measuring Gal-3 were available for 1,650 patients (~30% of the participants). The overall results of this secondary analysis indicate that the use of valsartan was not associated with a beneficial effect on any outcome in this subgroup of patients with available baseline Gal-3 measurements. The authors then arbitrarily categorized patients into two groups based on the median level of Gal-3 (16.2 ng/mL) and found that valsartan treatment was associated with a significant decrease in hospitalization only among patients with Gal-3 below the median level and not for those with levels above the median. This is a posthoc analysis with several limitations and does not directly examine the impact of measuring Gal-3 levels on patient management, and/or treatment outcomes. The results of these post hoc analyses should be interpreted with caution due to several limitations. The studies did not directly examine the impact of

measuring Gal-3 levels on patient management, and/or treatment outcomes. They were secondary analyses that included less than one third of the population in each of the two trials, there were some significant baseline differences between the patients with Gal-3 measurements and the entire participants in each of the studies, Gal-3 was measured from specimens obtained at baseline and stored for years, and the results of the trials did not show any significant effect of either drug used (rosuvastatin or valsartan) on the primary outcomes studied.

Conclusions: There is insufficient evidence from longitudinal studies with long-term follow-up and serial measurements of Gal-3 to determine that elevated circulating Gal-3 levels are independent prognostic markers for poor outcomes in patients with HF. There is insufficient evidence to determine that Gal-3 adds clinically significant incremental value to established markers and clinical variables. There is insufficient evidence to determine that circulating Gal-3 has an impact on management decisions made for patients with HF.

Articles: The literature search revealed over 200 articles on Galectin-3 and heart failure. The great majority were unrelated to the current review. There were several published studies on the prognostic value of Gal-3 in patients with heart failure. These were mainly secondary analyses of data or subsets of data collected for patients enrolled in large cohort studies or randomized controlled trials that investigated different other therapies or interventions. The search also identified a pooled analysis of the results of 3 trials (Meijers 2014), and a more recent meta-analysis (Chen et al, 2015) that pooled the results of 11 studies. The literature search did not identify any RCT that directly studied the impact of using the plasma levels Gal-3 on the management of patients with HF. The two meta-analyses were selected for critical appraisal (Evidence tables 1 & 2). The characteristics of the studies included in the larger meta-analysis as well as selected studies published in the last 5 years and not included in the meta-analyses were reviewed and summarized in [Evidence Table 3](#). Chen A, Hou W, Zhang Y et al. Prognostic value of serum galectin-3 in patients with heart failure: a meta-analysis. *Int J Cardiol* 2015; 182:168-170. See [Evidence Table 1](#). Meijers WC, Januzzi JL, de Filippi C, et al. Elevated plasma galectin-3 is associated with near-term rehospitalization in heart failure: a pooled analysis of 3 clinical trials. *Am Heart J*. 2014 Jun;167(6):853-60.e4. See [Evidence Table 2](#).

The use of Galectin-3 Blood Assay Test does not meet the Kaiser Permanente *Medical Technology Assessment Criteria*.

Applicable Codes

Considered Not Medically Necessary:

CPT® or HCPC Codes	Description
82777	Galectin-3

Clinical Review Criteria Gender Affirming Surgeries

Kaiser Foundation Health Plan of Washington

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Gender Dysphoria and Gender Reassignment Surgery (140.9) . CMS has deferred to the local MAC for decision coverage (Noridian for Washington State. Currently Noridian has no policy as of 04/05/2022)
Local Coverage Determinations (LCD)	None
Local Coverage Article	MM9981 - Gender Dysphoria and Gender Reassignment Surgery
Kaiser Permanente Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " Gender Affirming Surgeries " for medical necessity determinations. Use the Non-Medicare criteria below.

Self-Funded Groups:

Coverage may vary for members of self-funded groups and may provide additional exclusions – see member's specific contract or contact member services for specific exceptions and limitations.

Self-Funded Group	Policy
For Microsoft employees	See the member's contract for specific coverage details
For Sound Health and Wellness	See Non-Medicare policy below for coverage details, with the exception of the following exclusions: <ul style="list-style-type: none"> • Facial contouring and other facial reconstructive surgeries; and • Procedures including but not limited to hairline advancement and transplantation; and • Body hair removal (<i>except face/neck and preop genital hair removal</i>); and • Voice modification including speech therapy; and • Collagen injections • Liposuction • Abdominoplasty; and • Other cosmetic procedures are not covered services under the plan <p>Per the Summary of Material Modifications dated March 31, 2023</p>
For Washington State Teamsters Trust	See the member's contract for specific coverage details
For King County employees	See the member's contract for specific coverage details. Coverage

	criteria are based on the Standards of Care published by the World Professional Association for Transgender Health.
--	---

Effective until November 1, 2023

For Non-Medicare Members:

Members must be enrolled in the Kaiser Permanente of Washington Gender Health Case Management Program to qualify for the gender health services benefit.

All referrals must be submitted by the Gender Health Case Management team.

I. Requirements for hair removal to treat gender dysphoria

Kaiser Permanente of Washington will cover hair removal for members with documented gender dysphoria according to the criteria below. Member can have either electrolysis or laser hair removal or both. The member must work with the Kaiser Permanente of Washington Gender Health Case Manager to determine the best provider for the service and arrange for either insurance billing or member reimbursement for services.

Procedures:

Facial Hair Removal*

- 16+ with parental consent or 18+ years old
- Currently on antiandrogens (spironolactone, leuprolide) unless contraindicated OR testosterone <100 OR hx of orchiectomy

Body Hair Removal*

- 16+ with parental consent or 18+ years old
- Treatment with antiandrogens for 2-3 years unless contraindicated AND testosterone <100 OR hx of orchiectomy

**Hair removal for non-binary patients reviewed on a case-by-case basis.*

Preoperative hair removal for genital reconstructive surgery – as indicated based on surgical plan, see element V below.

Note: Patients who have not had gender reassignment surgery (gonadectomy or vaginoplasty) should continue hormone/anti-androgen therapy unless contraindicated during and after hair removal to prevent recurrence.

II. Requirements for Mastectomy (i.e., initial mastectomy, with nipple sparing or tattooing) for members assigned female at birth or non-binary members. Member must meet **ALL of the following**:

- Age 18 years or older (Note: age requirement will not be applied to mastectomy for members assigned female at birth or non-binary members if the surgeon, the primary care provider, and the qualified mental health professional unanimously document the medical necessity of earlier intervention)
- Single letter of referral from a qualified mental health professional*; *and*
- Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; *and*
- Capacity to make a fully informed decision and to consent for treatment; *and*
- If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question.
- Twelve months of living in a gender role that is congruent with their gender identity (real life experience).

❖ Note that a trial of hormone therapy is not a pre-requisite to qualifying for a mastectomy for members.

If the referring medical provider or mental health provider requests surgical intervention prior to the patient's completion of 12 months of living in desired gender, the surgeon, the primary care provider, and the qualified mental health professional must submit evidence of medical necessity and clear rationale for the proposed surgical intervention to be done early. The three providers must submit written documentation to the plan that includes:

- A comprehensive, coordinated treatment plan with evidence that all treatment plan criteria for surgery and treatment goals have been met; *and*
- Clear rationale for the variation from the 12-month period of living in desired gender; *and*

- c. Patient understands the treatment plan, risks and benefits of surgery prior to completing the 12-month period; and
- d. The plan will determine authorization and consent to care based on medical necessity from the documentation outlined in A-F above.

III. Requirements for breast augmentation for members assigned male at birth:

- A. Single letter of referral from a qualified mental health professional; and
- B. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; and
- C. Capacity to make a fully informed decision and to consent for treatment; and
- D. Age 18 years or older (Note: age requirement will not be applied to augmentation for members assigned male at birth if the surgeon, the primary care provider, and the qualified mental health professional unanimously document the medical necessity of earlier intervention)
- E. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; and
- F. Twelve months of living in a gender role that is congruent with their gender identity (real life experience) and
- G. Twelve months of continuous hormone therapy as appropriate to the member's gender goals.

If the referring medical provider or mental health provider requests surgical intervention prior to the patient's completion of 12 months of hormone therapy and/or living in desired gender, the surgeon, the primary care provider, and the qualified mental health professional must submit evidence of medical necessity and clear rationale for the proposed surgical intervention to be done early. The three providers must submit written documentation to the plan that includes:

- a. A comprehensive, coordinated treatment plan with evidence that all treatment plan criteria for surgery and treatment goals have been met; and
- b. Clear rationale for the variation from either the 12-month period of hormone therapy and/or living for 12 months in desired gender; and
- c. Patient understands the treatment plan, risks and benefits of surgery prior to completing the 12-month period; and
- d. The plan will determine authorization and consent to care based on medical necessity from the documentation outlined in A-G above.

The criteria above apply for only initial augmentation mammoplasty for members assigned male at birth, any additional breast augmentation after an initial mammoplasty is considered a cosmetic procedure, and therefore, a contract exclusion.

IV. Requirements for gonadectomy (hysterectomy and oophorectomy for members assigned female at birth and orchiectomy in members assigned male at birth):

- A. Two referral letters from qualified mental health professionals*, one in a purely evaluative role. (At least one letter should be an extensive report. Two separate letters or one letter with two signatures is acceptable. One referral letter can be from a Kaiser Permanente of Washington Gender Health Case Manager and the other needs to be from a qualified mental health professional*); and
- B. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; *and*
- C. Capacity to make a fully informed decision and to consent for treatment; *and*
- D. Age of majority (18 years or older); *and*
- E. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; *and*
- F. Twelve months of continuous hormone therapy as appropriate to the member's gender goals (unless the member has a medical contraindication or is otherwise unable or unwilling to take hormones – chart notes must describe the contraindications in detail)

V. Requirements for genital reconstructive surgery (including, but not limited to: vaginectomy, vulvectomy, colpocleisis, colpectomy, metoidioplasty, vaginoplasty, perineoplasty, colovaginoplasty, penectomy, clitoroplasty, labioplasty, phalloplasty, scrotoplasty, urethroplasty, testicular prosthesis (expanders and implants), penile prosthesis, hair removal in the pubic surgical area for members assigned male at birth, hair removal on the

forearm prior to phalloplasty for members assigned female at birth, Mons Resection)

- A. Two referral letters from qualified mental health professionals*, one in a purely evaluative role (At least one letter should be an extensive report. Two separate letters or one letter with two signatures is acceptable. One referral letter can be from a Kaiser Permanente of Washington Gender Health Case Manager and the other needs to be from a qualified mental health professional*); and
- B. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria; and
- C. Capacity to make a fully informed decision and to consent for treatment; and
- D. Age 18 years and older; and
- E. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; and
- F. Twelve months of continuous hormone therapy as appropriate to the member's gender goals (unless the member has a medical contraindication or is otherwise unable or unwilling to take hormones); and
- G. Twelve months of living in a gender role that is congruent with their gender identity (real life experience)

VI. Eligibility for laryngochondroplasty for members assigned male at birth is based on meeting **ALL of the following** criteria:

- A. Member is at least 18 years old
- B. Member has been diagnosed with persistent, well documented gender dysphoria.
- C. Member has the capacity to make fully informed decisions and to consent to treatment.
- D. If significant medical or mental health concerns are present, they are reasonably well controlled.
- E. Member has a current referral letter for laryngochondroplasty surgery or other gender reassignment surgery from a qualified mental health professional who has independently assessed the patient. This assessment must be current within the past 12 months. For providers working within a multidisciplinary specialty team, the assessment and recommendation can be documented in the patient's chart. The referral is expected to cover the following recommended content:
 - a. The client's general identifying characteristics.
 - b. Results of the client's psychosocial assessment, including any diagnoses.
 - c. The duration of the mental health professional's relationship with the client, including the type of evaluation and therapy or counseling to date.
 - d. An explanation that the criteria for surgery have been met and a brief description of the clinical rationale for supporting the patient's request for surgery.
 - e. A statement about the fact that the patient has the capacity to provide informed consent.
 - f. A statement that the mental health professional is available for coordination of care and welcomes a phone call to establish this.
- F. Member has had a mental health evaluation and a medical evaluation and has been deemed to have no medical or psychological contraindications for surgery.

VII. Requirements for gender affirming voice modification surgery

- A. Pitch lowering surgery (eg Type III thyroplasty) is considered medically necessary if the voice fails to deepen below speaking F₀ 150Hz after 1.5 years of consistent masculinization hormone therapy

OR

- B. Pitch elevation surgery is considered medically necessary when speaking F₀ < 150Hz

AND

C. ALL of the following are met:

- a. Age 18 years of age or older
- b. Persistent, well-documented gender dysphoria per DSM 5 Gender Dysphoria
- c. Capacity to make a fully informed decision and to consent for treatment
- d. Single letter of referral from a qualified mental health professional in support of the requested procedure(s)*
- e. Established with a Speech Language Pathologist (SLP) with experience working with Transgender patients for voice therapy and has engaged with voice therapy techniques with consistent follow-up, documented as attendance at ≥ 75% of sessions for at least 6 months
- f. Voice/speech therapy has been ineffective – member has ongoing voice complaints including inability to reliably maintain speaking F₀ above 150 Hz (feminizing) or speaking F₀ below 150Hz (masculinizing)
- g. Member agrees to follow-up post-operatively with their surgeon and voice therapist/SLP on a regular

cadence (1 week, 1 month, 3 months, 6 months, 1 year, 2 years, etc.)

- h. Patient has none of the following contraindications:
 - 1. No active laryngeal pathology, except for muscle tension
 - 2. No medical diagnoses that would impair wound healing
 - 3. No medical diagnoses that would seriously impair breathing or swallowing
 - 4. No planned upcoming surgeries within 2 months after pitch modification surgery
 - 5. If significant medical or mental health concerns are present, they must be reasonably well controlled. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question.

VIII. Requirements for gender affirming facial surgery– member must meet **ALL** of the following:

- A. Member is at least 18 years old
- B. Member has been diagnosed with persistent, well documented gender dysphoria
- C. Member has the capacity to make fully informed decisions and to consent to treatment
- D. If significant medical or mental health concerns are present, they are reasonably well controlled
- E. Member is undergoing or has undergone other treatments to transition gender
- F. Member has a current referral letter for gender-affirming procedure(s) from a qualified mental health professional who has independently assessed the patient within the past 12 months. For providers working within a multidisciplinary specialty team, the assessment and recommendation can be documented in the patient's chart. The referral letter is expected to cover the following content:
 - a. The client's general identifying characteristics.
 - b. Results of the client's psychosocial assessment, including any diagnoses.
 - c. The duration of the mental health professional's relationship with the client, including the type of evaluation and therapy or counseling to date.
 - d. A statement about the fact that the patient has the capacity to provide informed consent.
 - e. A statement that the mental health professional is available for coordination of care and welcomes a phone call to establish this.

With regard to requested gender affirming facial surgery– must meet **ALL** of the following:

- A. For each requested procedure, documentation from an ABMS board-certified facial surgeon (Facial Plastic Surgery, Plastic Surgery, or Oral Maxillofacial Surgery) that the member experiences dysphoria specifically associated with that facial element is required (e.g., documentation of dysphoria related to a stereotypically masculine nose for a requested rhinoplasty); **AND**
- B. The goal of each procedure is to alter or reshape the facial feature to an appearance that is within the range of normal for the member's identified gender, as determined by an ABMS board-certified facial surgeon (Facial Plastic Surgery, Plastic Surgery, or Oral Maxillofacial Surgery)

Procedures for gender affirming facial surgery may include (but are not limited to): mandible contouring, brow lift, and forehead reduction, among others. See below for a list of common procedures* which may or may not be covered for a particular patient.

Procedures intended solely to reduce the appearance of aging that will not result in significant improvement of the condition being treated are considered not medically necessary.

*Procedures considered for gender affirming facial surgery when medical necessity criteria in the applicable policy statement listed above are met – this list represents common procedures; others will be reviewed on a case-by-case basis:

Typically covered:

- Brow lift
- Hairline advancement
- Lip lift
- Mandible contouring
- Forehead reduction and contouring

Sometimes covered:

- Rhinoplasty

Typically not covered:

- Blepharoplasty
- Lip augmentation
- Cheek implants
- Facelift

IX. The following procedures are **not covered** as a part of this benefit:

- Abdominoplasty
- Calf implants
- Collagen injections
- Cryopreservation of fertilized embryos
- Drugs for hair loss or growth
- Facials
- Hair implant
- Liposuction
- Mastopexy
- Neck tightening
- Pectoral implants
- Removal of redundant skin
- Reversal of prior genital surgery or reversal of surgery to revise secondary sex characteristics
- Sperm preservation in advance of hormone treatment or gender surgery
- Ultrasonic Assisted Lymphatic Massage
- All other cosmetic procedures that do not meet medical necessity

* Characteristics of a Qualified Mental Health Professional:

1. Master's degree or equivalent in a clinical behavioral science field granted by an institution accredited by the appropriate national accrediting board. The professional should also have documented credentials from the relevant licensing board or equivalent; and
2. Competence in using the Diagnostic Statistical Manual of Mental Disorders and/or the International Classification of Disease for diagnostic purposes; and
3. Ability to recognize and diagnose co-existing mental health concerns and to distinguish these from gender dysphoria;
4. Knowledgeable about gender nonconforming identities and expressions, and the assessment and treatment of gender dysphoria; and
5. Continuing education in the assessment and treatment of gender dysphoria. This may include attending relevant professional meetings, workshops, or seminars; obtaining supervision from a mental health professional with relevant experience; or participating in research related to gender nonconformity and gender dysphoria.

Effective November 1, 2023

For Non-Medicare Members:

Members must be enrolled in the Kaiser Permanente of Washington Gender Health Case Management Program to qualify for the gender health services benefit. **To be considered in network all *initial* referrals for gender affirming services including surgical consults (excluding GAHT and/or blockers) must be submitted by the Gender Health Case Management team (Not applicable for options patients utilizing out of network benefit. Out of network provider to place referral and request authorization from the health plan).**

I. Requirements for hair removal to treat gender dysphoria

Kaiser Permanente of Washington will cover hair removal for members with documented gender dysphoria according to the criteria below with a goal of hair removal to align with identified gender. Member can have either electrolysis or laser hair removal or both. The member must work with the Kaiser Permanente of Washington Gender Health Case Manager to ensure prior authorization is obtained for the service and arrange for either insurance billing or member reimbursement for services.

Procedures:

Facial Hair Removal*

© 2018 Kaiser Foundation Health Plan of Washington. All rights reserved.

[Back to Top](#)

- 16+ with parental consent or 18+ years old **AND**
- Six months of maximally tolerated Gender Affirming Hormone Therapy (GAHT) (including but not limited to antiandrogens such as spironolactone; T blockers such as leuprolide; and hormones such as: estrogen) appropriate to their desired gender, unless medically contraindicated (e.g., GAHT may be contraindicated when not consistent with members gender identity such as non-binary) **OR**
- In testicular bodied patients, testosterone <100 **OR**
- History of orchiectomy

NOTE: Hair removal is not covered for members using exogenous testosterone, as hair growth is expected

Body Hair Removal*

- 16+ with parental consent or 18+ years old **AND**
- Taking Gender Affirming Hormone Therapy (GAHT) (including but not limited to antiandrogens such as spironolactone; T blockers such as leuprolide; and hormones such as: estrogen) appropriate to their desired gender, for 2-3 years unless medically contraindicated (e.g., GAHT may be contraindicated when not consistent with members gender identity such as non-binary) **AND**
- In testicular bodied patients, testosterone <100 **OR**
- History of orchiectomy

NOTE: Hair removal is not covered for members using exogenous testosterone, as hair growth is expected

Preoperative hair removal for genital reconstructive surgery – as indicated based on surgical plan, see element IV below.

Note: Patients who have not had gender reassignment surgery (gonadectomy or vaginoplasty) should continue hormone/anti-androgen therapy unless contraindicated during and after hair removal to prevent recurrence.

- II. **Requirements for Mastectomy** (i.e., initial mastectomy, with nipple sparing or tattooing) for members assigned female at birth. Member must meet **ALL of the following**:
- A. Age 18 years or older (Note: age requirement will not be applied to mastectomy for members assigned female at birth if the surgeon, the primary care provider, and the qualified mental health professional unanimously document the medical necessity of earlier intervention)
 - B. Single letter of referral from a qualified mental health professional** within the past 18 months; and the letter should include:
 - i. Gender incongruence is marked and sustained;
 - ii. Meets diagnostic criteria for gender incongruence prior to gender-affirming surgical intervention in regions where a diagnosis is necessary to access health care;
 - iii. Demonstrates capacity to consent for the specific gender-affirming surgical intervention;
 - iv. Understands the effect of gender-affirming surgical intervention on reproduction and they have explored reproductive options;
 - v. Other possible causes of apparent gender incongruence have been identified and excluded;
 - vi. Mental health and physical conditions that could negatively impact the outcome of gender-affirming surgical intervention have been assessed, with risks and benefits have been discussed;
 - C. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question.
 - D. Stable on their gender affirming hormonal treatment regime (which may include at least 6 months of hormone treatment or a longer period if required to achieve the desired surgical result, unless hormone therapy is either not desired or is medically contraindicated). **Note:** a trial of hormone therapy is not a pre-requisite to qualifying for a mastectomy for members.
 - E. Patient has already undergone social transition*** or has a plan to do so after surgery

© 2018 Kaiser Foundation Health Plan of Washington. All rights reserved.

[Back to Top](#)

III. **Requirements for breast augmentation** for members assigned male at birth:

- A. Age 18 years or older
- B. Single letter of referral from a qualified mental health professional** within the last 18 months; and this letter should include:
 - i. Gender incongruence is marked and sustained;
 - ii. Meets diagnostic criteria for gender incongruence prior to gender-affirming surgical intervention in regions where a diagnosis is necessary to access health care;
 - iii. Demonstrates capacity to consent for the specific gender-affirming surgical intervention;
 - iv. Understands the effect of gender-affirming surgical intervention on reproduction and they have explored reproductive options;
 - v. Other possible causes of apparent gender incongruence have been identified and excluded;
 - vi. Mental health and physical conditions that could negatively impact the outcome of gender-affirming surgical intervention have been assessed, with risks and benefits have been discussed;
- C. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; and
- D. Patient has already undergone social transition*** or has a plan to do so after surgery and
- E. Stable on their gender affirming hormonal treatment regime (which may include at least 6 months of hormone treatment or a longer period if required to achieve the desired surgical result, unless hormone therapy is either not desired or is medically contraindicated)

The criteria above apply for only initial augmentation mammoplasty for members assigned male at birth, any additional breast augmentation after an initial mammoplasty is considered a cosmetic procedure, and therefore, a contract exclusion.

IV. **Requirements for gonadectomy (hysterectomy, oophorectomy or orchiectomy) and genital reconstructive surgery** (including, but not limited to: vaginectomy, vulvectomy, colpocleisis, colpectomy, metoidioplasty, vaginoplasty, perineoplasty, colovaginoplasty, penectomy, clitoroplasty, labioplasty, phalloplasty, scrotoplasty, urethroplasty, testicular prosthesis (expanders and implants), penile prosthesis, hair removal in the pubic surgical area for members assigned male at birth, hair removal on the forearm prior to phalloplasty for members assigned female at birth, mons resection:

- A. Age 18 years and older; and
- B. One referral letter from a qualified mental health professional** within the last 18 months; and this letter should include:
 - i. Gender incongruence is marked and sustained;
 - ii. Meets diagnostic criteria for gender incongruence prior to gender-affirming surgical intervention in regions where a diagnosis is necessary to access health care;
 - iii. Demonstrates capacity to consent for the specific gender-affirming surgical intervention;
 - iv. Understands the effect of gender-affirming surgical intervention on reproduction and they have explored reproductive options;
 - v. Other possible causes of apparent gender incongruence have been identified and excluded;
 - vi. Mental health and physical conditions that could negatively impact the outcome of gender-affirming surgical intervention have been assessed, with risks and benefits have been discussed;

- C. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; and
- D. Stable on their gender affirming hormonal treatment regime (which may include at least 6 months of hormone treatment or a longer period if required to achieve the desired surgical result, unless hormone therapy is either not desired or is medically contraindicated); and
- E. Twelve months of living in a gender role that is congruent with their gender identity (real life experience) Patient has undergone social transition*** and has been living in gender congruent identity for at least twelve months

V. Requirements for gender affirming voice modification surgery

- A. Requirements for gender affirming voice modification surgery
- B. Pitch lowering surgery (e.g., Type III thyroplasty) is considered medically necessary if the voice fails to deepen below speaking F0 150Hz after 1.5 years of consistent masculinization hormone therapy

OR

- C. Pitch elevation surgery is considered medically necessary when speaking F₀ < 150Hz

AND

D. ALL of the following are met:

- a. Age 18 years of age or older
- b. The health plan may require a second opinion regarding the patient's stability prior to surgery if in question; and
- c. Patient has already undergone social transition*** or has a plan to do so after surgery
- d. Stable on their gender affirming hormonal treatment regime (which may include at least 6 months of hormone treatment or a longer period if required to achieve the desired surgical result, unless hormone therapy is either not desired or is medically contraindicated)
- e. Single letter of referral from a qualified mental health professional** in support of the requested procedure(s) in the last 18 months; and the letter should include:
 - i. Gender incongruence is marked and sustained;
 - ii. Meets diagnostic criteria for gender incongruence prior to gender-affirming surgical intervention in regions where a diagnosis is necessary to access health care;
 - iii. Demonstrates capacity to consent for the specific gender-affirming surgical intervention;
 - iv. Understands the effect of gender-affirming surgical intervention on reproduction and they have explored reproductive options;
 - v. Other possible causes of apparent gender incongruence have been identified and excluded;
 - vi. Mental health and physical conditions that could negatively impact the outcome of gender-affirming surgical intervention have been assessed, with risks and benefits have been discussed;
- f. Established with a Speech Language Pathologist (SLP) with experience working with Transgender patients for voice therapy and has engaged with voice therapy techniques with consistent follow-up, documented as attendance at ≥ 75% of sessions for at least 6 months
- g. Voice/speech therapy has been ineffective – member has ongoing voice complaints including inability to reliably maintain speaking F0 above 150 Hz (feminizing) or speaking F0 below 150Hz (masculinizing)
- h. Member agrees to follow-up post-operatively with their surgeon and voice therapist/SLP on a regular cadence (1 week, 1 month, 3 months, 6 months, 1 year, 2 years, etc.)
- i. Patient has none of the following contraindications:
 - i. No active laryngeal pathology, except for muscle tension
 - ii. No medical diagnoses that would impair wound healing
 - iii. No medical diagnoses that would seriously impair breathing or swallowing
 - iv. No planned upcoming surgeries within 2 months after pitch modification surgery

VI. Requirements for gender affirming facial surgery– member must meet ALL of the following:

- A. Member is at least 18 years old; and
- B. One referral letter from a qualified mental health professional** in the last 18 months; and this letter should include:
 - i. Gender incongruence is marked and sustained
 - ii. Meets diagnostic criteria for gender incongruence prior to gender-affirming surgical intervention in regions where a diagnosis is necessary to access health care;
 - iii. Demonstrates capacity to consent for the specific gender-affirming surgical intervention;
 - iv. Understands the effect of gender-affirming surgical intervention on reproduction and they have explored

- reproductive options;
- v. Other possible causes of apparent gender incongruence have been identified and excluded;
- vi. Mental health and physical conditions that could negatively impact the outcome of gender-affirming surgical intervention have been assessed, with risks and benefits have been discussed;
- C. Member is undergoing or has undergone other treatments to transition gender

With regard to requested gender affirming facial surgery– must meet **ALL** of the following:

- A. For each requested procedure, documentation from an ABMS board-certified facial surgeon (Facial Plastic Surgery, Plastic Surgery, or Oral Maxillofacial Surgery) that the member experiences dysphoria specifically associated with that facial element is required (e.g., documentation of dysphoria related to a stereotypically masculine nose for a requested rhinoplasty); **AND**
- B. The goal of each procedure is to alter or reshape the facial feature to an appearance that is within the range of normal for the member's identified gender, as determined by an ABMS board-certified facial surgeon (Facial Plastic Surgery, Plastic Surgery, or Oral Maxillofacial Surgery)

Procedures for gender affirming facial surgery may include (but are not limited to): mandible contouring, brow lift, and forehead reduction, layrngochrondroplasty among others. See below for a list of common procedures* which may or may not be covered for a particular patient.

Procedures intended solely to reduce the appearance of aging that will not result in significant improvement of the condition being treated are considered not medically necessary.

*Procedures considered for gender affirming facial surgery when medical necessity criteria in the applicable policy statement listed above are met – this list represents common procedures; others will be reviewed on a case-by-case basis:

Typically covered:

- Brow lift
- Hairline advancement
- Lip lift
- Mandible contouring
- Forehead reduction and contouring
- Tracheal Shave

Sometimes covered:

- Rhinoplasty

Typically not covered:

- Blepharoplasty
- Lip augmentation
- Cheek implants
- Facelift

VIII. The following procedures are **not covered** as a part of this benefit:

- Abdominoplasty
- Calf implants
- Collagen injections
- Cryopreservation of fertilized embryos
- Drugs for hair loss or growth
- Facials
- Hair implant
- Liposuction
- Mastopexy
- Neck tightening
- Pectoral implants

- Removal of redundant skin
- Reversal of prior genital surgery or reversal of surgery to revise secondary sex characteristics
- Sperm preservation in advance of hormone treatment or gender surgery
- Ultrasonic Assisted Lymphatic Massage
- All other cosmetic procedures that do not meet medical necessity

****Characteristics of a Qualified Mental Health Professional for:**

1. Master's degree or equivalent in a clinical behavioral science field granted by an institution accredited by the appropriate national accrediting board. The professional should also have documented credentials from the relevant licensing board or equivalent; and
2. Competence in using the Diagnostic Statistical Manual of Mental Disorders and/or the International Classification of Disease for diagnostic purposes; and
3. Ability to recognize and diagnose co-existing mental health concerns and to distinguish these from gender dysphoria;
4. Knowledgeable about gender nonconforming identities and expressions, and the assessment and treatment of gender dysphoria; and
5. Continuing education in the assessment and treatment of gender dysphoria. This may include attending relevant professional meetings, workshops, or seminars; obtaining supervision from a mental health professional with relevant experience; or participating in research related to gender nonconformity and gender dysphoria.

*****Social Transition:** (e.g., name change, pronoun change, communication of affirmed gender identity to others) in place or judged by clinician to be unnecessary (e.g., nonbinary gender identity). This requirement is based on evidence of mental health benefits from social transition and lack of evidence to support gender affirming surgical therapy in the absence of social transition. Coverage may still be considered after additional mental health evaluation and/or explanation of not pursuing social transition.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Gender Dysphoria refers to discomfort or distress that is caused by a discrepancy between a person's gender identity and that person's sex assigned at birth. Gender dysphoria is only experienced by some gender-nonconforming people.

Transgender individuals usually present to the medical profession with a sophisticated understanding of their identity, and a desired course of treatment, including hormone therapy and potentially gender-realignment surgery. The therapeutic approach to gender dysphoria consists of three elements: hormones, real life experience and, finally, surgery for some patients.

The use of hormone therapy and surgery for gender transition/affirmation is based on many years of experience treating transgender people. Research on hormone therapy is providing us with more and more information on the safety and efficacy of hormone therapy, but all of the long-term consequences and effects of hormone therapy may not be fully understood. Therefore, a careful diagnosis, differential diagnosis, and exploration of identity is absolutely vital to the patient's best interest and the patient provider relationship. A vital part of the long-term diagnostic therapy is the so-called real-life experience, in which the patient lives as a member of the desired gender continually and in all social spheres in order to accumulate necessary experience.

Hormone therapy and gender-realignment surgery are superficial changes in comparison to the major psychological adjustments necessary in affirming gender identity. One aspect of treatment should concentrate on the psychological adjustment, with hormone therapy and gender-realignment surgery being viewed as confirmatory procedures dependent on adequate psychological adjustment. Many providers and organizations are moving to an informed consent model for hormones, but surgery still needs involvement of psychology and psychiatry. Psychiatric care may need to be continued for many years after gender-realignment surgery. The overall success of treatment depends partly on the technical success of the surgery, but more crucially on the psychological adjustment of the patient, and the support from family, friends, employers and the medical profession.

Evidence and Source Documents

There was no evidence review conducted for these criteria. They were developed in response to the Washington

State RCW for the coverage of gender affirming services.

Applicable Codes (not all-inclusive) – all requests require clinical review

Members Assigned Male at Birth:

CPT® or HCPC Codes	Description
55970	Intersex Surgery; male to female
15830	Excision, excessive skin and subcutaneous tissue (includes lipectomy); abdomen, infraumbilical panniculectomy
With diagnosis codes	
F64.0	Transsexualism
F64.1	Dual role transvestism
F64.2	Gender identity disorder of childhood
F64.8	Other gender identity disorders
F64.9	Gender identity disorder, unspecified

Members Assigned Female at Birth:

CPT® or HCPC Codes	Description
55980	Intersex Surgery; female to male
With diagnosis codes	
F64.0	Transsexualism
F64.1	Dual role transvestism
F64.2	Gender identity disorder of childhood
F64.8	Other gender identity disorders
F64.9	Gender identity disorder, unspecified

Electrolysis:

CPT® or HCPC Codes	Description
17380	Electrolysis epilation, each 30 minutes

Gender Affirming Facial Surgery

Forehead Recontouring/Augmentation:

CPT® or HCPC Codes	Description
21137	Reduction forehead; contouring only
21138	Reduction forehead; contouring and application of prosthetic material or bone graft (includes obtaining autograft)
21139	Reduction forehead; contouring and setback of anterior frontal sinus wall

Brow Lift:

CPT® or HCPC Codes	Description
15824	Rhytidectomy; forehead
67900	Repair of brow ptosis (supraciliary, mid-forehead or coronal approach)

Hairline Correction/Scalp Advancement:

CPT® or HCPC Codes	Description
15839	Excision, excessive skin and subcutaneous tissue (includes lipectomy); other area

Jaw Contouring:

CPT® or HCPC Codes	Description
21299	Unlisted craniofacial and maxillofacial procedure
21209	Osteoplasty, facial bones; reduction

Chin Augmentation:

CPT® or HCPC Codes	Description
21120	Genioplasty; augmentation (autograft, allograft, prosthetic material)
21121	Genioplasty; sliding osteotomy, single piece
21122	Genioplasty; sliding osteotomies, 2 or more osteotomies (e.g., wedge excision or bone wedge reversal for asymmetrical chin)
21123	Genioplasty; sliding, augmentation with interpositional bone grafts (includes obtaining autografts)
21296	Reduction of masseter muscle and bone (e.g., for treatment of benign masseteric hypertrophy); intraoral approach

Fat Transfer:

CPT® or HCPC Codes	Description
15773	Grafting of autologous fat harvested by liposuction technique to face, eyelids, mouth, neck, ears, orbits, genitalia, hands, and/or feet; 25 cc or less injectate
15774	Grafting of autologous fat harvested by liposuction technique to face, eyelids, mouth, neck, ears, orbits, genitalia, hands, and/or feet; each additional 25 cc injectate, or part thereof (List separately in addition to code for primary procedure)

Rhinoplasty:

CPT® or HCPC Codes	Description
30400	Rhinoplasty, primary; lateral and alar cartilages and/or elevation of nasal tip
30410	Rhinoplasty, primary; complete, external parts including bony pyramid, lateral and alar cartilages, and/or elevation of nasal tip
30420	Rhinoplasty, primary; including major septal repair
30430	Rhinoplasty, secondary; minor revision (small amount of nasal tip work)
30435	Rhinoplasty, secondary; intermediate revision (bony work with osteotomies)
30450	Rhinoplasty, secondary; major revision (nasal tip work and osteotomies)

Blepharoplasty:

CPT® or HCPC Codes	Description
15820	Blepharoplasty, lower eyelid;
15821	Blepharoplasty, lower eyelid; with extensive herniated fat pad
15822	Blepharoplasty, upper eyelid;
15823	Blepharoplasty, upper eyelid; with excessive skin weighting down lid

Dermal Filler:

CPT® or HCPC Codes	Description
11950	Subcutaneous injection of filling material (eg, collagen); 1 cc or less
11951	Subcutaneous injection of filling material (e.g., collagen); 1.1 to 5.0 cc
11952	Subcutaneous injection of filling material (e.g., collagen); 5.1 to 10.0 cc

11954	Subcutaneous injection of filling material (e.g., collagen); over 10.0 cc
--------------	---

Suction Assisted Lipectomy:

CPT® or HCPC Codes	Description
15876	Suction assisted lipectomy; head and neck

Rhytidectomy:

CPT® or HCPC Codes	Description
15829	Rhytidectomy; superficial musculoaponeurotic system (SMAS) flap
15838	Excision, excessive skin and subcutaneous tissue (includes lipectomy); submental fat pad

Voice Modification Surgery

CPT® or HCPC Codes	Description
No specific codes – commonly submitted with CPT code 31599 Unlisted procedure, larynx	

***Note:** Codes list is not all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

^{MDCRPC} Medical Director Clinical Review and Policy Committee

^{MPC} Medical Policy Committee

Revision History	Description
11/2/2015	Added Providence Health & Services and link to Sound Health & Wellness Policy & ICD-10 codes
03/08/2016	Added PEBB link
09/02/2016	Added FtM Mastectomy criteria for adolescents 16 years and older
11/01/2016	MPC approved revised indication for Electrolysis
10/02/2017	Removed the requirement for testosterone treatment for members 16-18
02/06/2018	Added criteria for M-F breast augmentation
05/01/2018	Added facials and ultrasonic assisted lymphatic massage to the non-covered list
06/05/2018	Changed the mastectomy and breast augmentation criteria
06/11/2018	Added coverage language for facial hair removal
07/10/2018	Added coverage and revised criteria language for facial hair removal
10/02/2018	Updated evaluation criteria under genital reconstructive surgery requirements
12/04/2018	Added MtF criteria to add coverage for Layrngochondroplasty (Tracheal Shave)
04/12/2019	Added Mons Resection code to genital reconstructive surgery
01/22/2020	Minor changes to Facial Hair removal criteria
05/4/2020	Added the following procedures to section V "Requirements for genital reconstruction surgery": vulvectomy, colpocleisis and perineoplasty
12/18/2020	MPC approved to adopt clinical criteria for Facial Harmonization and updated exclusions for the non-covered list.
02/19/2021	Included non-binary patients for facial hair removal and mastectomy indications.

10/04/2021	Updated terminology from female to male and male to female to assigned male at birth or assigned female at birth.
03/01/2022	MPC approved changes to criteria for hair removal, including the addition of criteria for coverage of body hair removal and updates to facial hair removal criteria.
04/05/2022	MPC approved to adopt coverage for voice modification surgery.
05/02/2023	Updated self-funded SHWT policy coverage details statement
05/08/2023	Updated additional exclusions provided by SHWT
06/06/2023	MPC has approved revisions to the clinical criteria for Gender Affirming Services, ensuring alignment with the updated guidelines from the World Professional Association for Transgender Health (WPATH). Requires 60-day notice, effective date 11/01/2023

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Genetic Screening and Testing

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Preferred Lab for Genetic Testing for Kaiser Permanente non-Medicare enrollees (for in-network coverage).

Prevention and Invitae Corporation are the preferred labs for genetic testing, when the test(s) is/are available at Prevention or Invitae and medical necessity criteria are met.*

Invitae's test catalog can be found here: [Invitae Test Catalog](#)

Prevention test catalog can be found here: [Prevention Test Catalog](#)

**Note: This does not affect processing of tumor or other pathology specimens as they are not performed by Invitae*

PPO/POS members may use non-preferred labs at the out of network cost share.

Exceptions

For the genetic test(s) listed below, please use the lab specified/refer to the link attached:

- **Cell Free Fetal DNA testing – Any of these three labs can be used:**
 - Ariosia (Bioreference) Diagnostics, Inc. (81507) or
 - Invitae (81420) or
 - LabCorp (81420)
 - Quest-QNatal (81420)
- **Next Generation Sequencing for Advanced Cancer—Any of these three labs can be used:**
 - CellNetix SymGene Panel
 - Oncoplex (University of Washington)
 - Caris Life Sciences
- Prenatal Chromosomal Microarray (samples typically obtained via amniocentesis/CVS)—Either of these two labs can be used:
 - Prevention
 - LabCorp
- Fetal diagnostic testing in cases of recurrent intrauterine fetal demise (definition)—Either of these two labs can be used:
 - Prevention
 - LabCorp
- Carrier Screening for Preconception Counseling—Either of these two labs can be used:
 - Prevention
 - Invitae
- Non-prenatal Chromosomal Microarray (sample obtained by blood draw)—Any of these three labs can be used:
 - Prevention
 - LabCorp

- Invitae

General Coverage Rules – LCD 24308 (retired)

1. Genetic tests for cancer are only a covered benefit for a beneficiary with a personal history of an illness, injury, or signs/symptoms thereof (i.e. clinically affected). A person with a personal history of a relevant cancer is a clinically affected person, even if the cancer is considered cured. Genetic testing is considered a non-covered screening test

for patients unaffected by a relevant illness, injury, or signs/symptoms thereof.

2. Predictive or pre-symptomatic genetic tests and services, in the absence of past or present illness in the beneficiary, are not covered under national Medicare rules. For example, Medicare does not cover genetic tests based on family history alone.
3. A covered genetic test must be used to manage a patient. Medicare does not cover a genetic test for a clinically affected individual for purposes of family planning, disease risk assessment of other family members, when the treatment and surveillance of the beneficiary will not be affected, or in any other circumstance that does not directly affect the diagnosis or treatment of the beneficiary.
4. The results of the genetic test must potentially affect at least one of the management options considered by the referring physician in accordance with accepted standards of medical care (e.g. surgery, the extent of surgery, a change in surveillance, hormonal manipulation, or a change from standard therapeutic or adjuvant chemotherapy).
5. Pre-test genetic counseling must be provided by a qualified and appropriately trained practitioner.
6. An informed consent form signed by the patient prior to testing which includes a statement that he/she agree to post-test counseling is required. This consent form must be available on request by Medicare.
7. Genetic analysis must be provided through a laboratory which meets the American Society of Clinical Oncology (ASCO) recommended requirements:

The MoIDX Program has determined certain gene tests do not meet Medicare's medical necessary requirements, and that the inclusion of these genes will result in an entire panel to be denied. MoIDX has determined that testing for the below genes is a statutorily excluded service. Unless indicated otherwise, panels that include these genes will be denied. Please see the individual Test Coding and Billing Guidelines for each gene.

Palmetto GBA is the Medicare contractor for Molecular Diagnostic Testing – this site has the most up to date Medicare coverage guidelines for genetic testing.

For Non-Medicare Members

Members must meet **ALL** the following criteria:

© 2010, Kaiser Foundation Health Plan of Washington. All Rights Reserved.

[Back to Top](#)

1. The member is at clinical risk for a genetic condition because of current documented symptoms being displayed or a strong family history of the condition.
2. The test is scientifically valid and can be adequately interpreted.
3. The results will directly affect a member's clinical management or reproductive decisions.
4. After appropriate clinical work-up, and informed consent by the appropriate practitioner, the genetic test is indicated.

Genetic testing is not covered for the medical management of a family member who does not have Kaiser Permanente coverage.

Carrier Screening is limited to once per lifetime.

*For **specific tests listed** below the member must meet the criteria above **AND** the specific test criteria below:*

*For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access

Cardiology	Criteria
Arrhythmogenic Right Ventricular Cardiomyopathy – ARVC Genes	MCG* A-0627
Brugada Syndrome Channelopathy Genes	MCG* A-0594
Catecholaminergic Polymorphic Ventricular Tachycardia Genes	MCG* A-0636

Coronary Artery Disease - KIF6 Gene	MCG* A-0656: This is not covered per MCG*
Coronary Artery Disease Genetic Panel	MCG* A-0658: This is not covered per MCG*
Familial Dilated Cardiomyopathy – Gene and Gene Panel Testing	MCG* A-0648
Familial Hypertrophic Cardiomyopathy, Nonsyndromic – Gene and Gene Panel Testing	MCG* A-0633
Thoracic Aortic Aneurysm and Aortic Dissection (Hereditary) - Gene Panels	There is insufficient evidence in the published medical literature to show clinical utility.
Ehlers-Danlos Syndrome (Vascular) - COL3A1 Gene	MCG* A-0910
Loeys-Dietz Syndrome - Gene and Gene Panel Testing	MCG* A-0909
Long QT Syndrome (Hereditary) - Gene Panel	MCG* A-0918

Endocrinology	Criteria
Diabetes Mellitus, Type 2 - KCNJ11, KCNQ1, PPARG, SLC16A11 and TCF7L2 Genes	MCG* A-0826: This is not covered per MCG*
Diabetes Mellitus (Maturity-Onset Diabetes of the Young) - ABCC8, APPL1, BLK, CEL, GCK, HNF1A, HNF1B, HNF4A, INS, KCNJ11, KLF11, NEUROD1, PAX4, and PDX1 Genes	MCG* A-0598

Gastroenterology	Criteria
HLA Testing for Celiac Disease:	<ol style="list-style-type: none"> 1. Is medically appropriate for symptomatic patients <ol style="list-style-type: none"> a. Despite being on a gluten free diet OR b. With indeterminate serology/biopsy results 2. It is not covered for <ol style="list-style-type: none"> a. Asymptomatic people OR b. Screening

Gastroenterology	Criteria
Hemochromatosis - HFE Gene	Medical necessity review no longer required.
Pancreatitis, Hereditary – CFTR, CPA1, CTRC, PRSS1, and SPINK1 Genes	MCG* A-0646

Genomic Testing Methods and Technologies	Criteria
Broad Spectrum Tumor Molecular Profiling – Next Generation Sequencing (NGS)	There is insufficient evidence in the published medical literature to show clinical utility.
Tacrolimus Pharmacogenetics - CYP3A4 and CYP3A5 Genes	MCG* A-0775: This is not covered per MCG*
Chromosomal Microarray Testing	<ol style="list-style-type: none"> Chromosomal microarray testing may be considered medically necessary for genetic evaluation of an individual when ALL of the following criteria are met: <ol style="list-style-type: none"> Testing has been requested following evaluation and genetic counseling by a medical geneticist, pediatric neurologist, or neurodevelopment pediatrician; and Results have the potential to affect clinical management of the patient; and The patient meets one or more of the following: <ul style="list-style-type: none"> Multiple anomalies not specific to a well-delineated genetic syndrome Apparently non-syndromic developmental delay/intellectual disability Autism spectrum disorder Dysmorphic facial features Abnormal growth not otherwise explained Chromosomal microarray testing (CPT 81228, 81229) may be considered medically necessary for patients undergoing invasive prenatal genetic testing (i.e., amniocentesis, chorionic villus sampling (CVS), or fetal tissue sampling), or a patient who has had recurrent (two or more) intrauterine fetal demise. Genetic counseling is required. Prior authorization is not required if done at Invitae, Labcorp or Prevention but is required for all other vendors in advance of submitting a claim for payment. Chromosomal microarray testing may be considered medically necessary for testing of one or both parents when a chromosomal deletion or duplication has been identified in one or more of their offspring and: <ol style="list-style-type: none"> Parental testing is necessary to guide a reproductive decision, or Parental testing is necessary to determine the clinical significance of the chromosome abnormality found in the child, and The result is expected to directly affect clinical management of the child <p>The following are not covered:</p> Chromosomal microarray testing to confirm the diagnosis of a disorder or syndrome that is routinely diagnosed based on clinical evaluation alone.
Genome-Wide Association Studies	Does not require medical review

Genomic Testing Methods and Technologies	Criteria
MicroRNA Detection - Cancer	MCG* A-0705: This is not covered per MCG*
MicroRNA Detection – Heart Failure	MCG* A-0838: This is not covered per MCG*
MicroRNA Detection - Inflammatory Bowel Disease	MCG* A-0839: This is not covered per MCG*
MicroRNA Detection - Ischemic Heart Disease	MCG* A-0840: This is not covered per MCG*
MicroRNA Detection – Kidney Disease	MCG* A-0841: This is not covered per MCG*
Molecular Profiling	MCG* A-0789: This is not covered per MCG*
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Microdeletion Syndromes <i>81331 not medically necessary when performed using cell-free fetal DNA, 81422</i>	MCG* A-0848: This is not covered per MCG*
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Monogenic Disorders	MCG* A-0849: This is not covered per MCG*
Noninvasive Prenatal Testing (Cell-Free Fetal DNA) - Sex Chromosome Disorders	MCG* A-0850: This is not covered per MCG*
Septin 9 (SEPT9) DNA Methylation Testing	MCG* A-0706: This is not covered per MCG*
Telomere Analysis	MCG* A-0672: This is not covered per MCG*
Integrated Molecular Pathology Testing (Topographic Genotyping) - PathFinderTG	MCG* A-0632: This is not covered per MCG*
Whole Exome Sequencing (WES)	<p>Whole exome sequencing (WES) is considered medically necessary for a phenotypically affected individual when ALL of the following criteria are met:</p> <ol style="list-style-type: none"> 1. Individual has been evaluated by a board-certified medical geneticist (MD) or other board-certified physician specialist with specific expertise in the conditions and relevant genes for which testing is being considered 2. Results have the potential to directly impact clinical decision-making and clinical outcome for the patient 3. A genetic etiology is the most likely explanation for the phenotype as demonstrated by EITHER of the following: <ol style="list-style-type: none"> A. multiple abnormalities affecting unrelated organ systems OR B. TWO of the following criteria are met: <ol style="list-style-type: none"> a. abnormality affecting a single organ system b. significant intellectual disability, symptoms of a complex neurodevelopmental disorder (e.g. self-injurious behavior, reverse sleep-wake cycles), or severe neuropsychiatric condition (e.g. schizophrenia, bipolar disorder, Tourette syndrome) c. family history strongly implicating a genetic etiology d. period of unexplained developmental regression (unrelated to autism or epilepsy) e. dysmorphic facial features f. abnormal growth not otherwise explained 4. No other causative circumstances (e.g. environmental exposures, injury, infection) can explain symptoms 5. Clinical presentation does not fit a well-described syndrome for which single-gene or targeted panel testing is available 6. The differential diagnosis list and/or phenotype warrant testing of multiple genes and ONE of the following: <ol style="list-style-type: none"> a. WES is more practical than the separate single gene tests or panels that would be recommended based on the differential diagnosis

Genomic Testing Methods and Technologies	Criteria
	<p>b. WES results may preclude the need for multiple and/or invasive procedures, follow-up, or screening that would be recommended in the absence of testing</p> <p><i>All requests must be approved by a KP geneticist, regardless of whether they have seen the patient.</i></p>

Hematology	Criteria
Alpha Thalassemia - HBA1 and HBA2 Genes	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0808
Beta Thalassemia - HBB Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0815
Fetal and Neonatal Alloimmune Thrombocytopenia - Human Platelet Antigen (HPA) Genotyping	MCG* A-0793
Factor V Leiden Thrombophilia-F5 gene	Does not require medical review
Fanconi Anemia - FANC Genes and Gene Panel Testing	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0683
Hemoglobin C and E – HBB Gene	MCG* A-0604
Hyperhomocysteinemia - MTHFR Gene	MCG* A-0629
Post-Transfusion Purpura - Human Platelet Antigen (HPA) Genotyping	MCG* A-0800: This is not covered per MCG*

Hematology	Criteria
Prothrombin Thrombophilia - F2 Gene	Does not require medical review
Sickle Cell Disease - HBB Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0864
Von Willebrand Disease-VWF Gene	MCG* A-0688

Metabolic and Developmental Disorders	Criteria
Angelman Syndrome - UBE3A Gene <i>Note: Guideline indications are related to tests performed using amniocentesis or chorionic villus sampling. Not medically necessary when performed using cell-free fetal DNA (see MCG A-0848).</i>	MCG* A-0708
Ashkenazi Jewish Genetic Panel	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0592
Autism Spectrum Disorders – Gene Panels	MCG* A-0914 This is not covered per MCG*
Beckwith-Wiedemann Syndrome - CDKN1C Gene	MCG* A-0765
Bloom Syndrome - BLM Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0682
Canavan Disease - ASPA Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0595
Deafness and Hearing Loss, Nonsyndromic - Microarray and Multigene Panels	MCG* A-0823
Deafness and Hearing Loss, Nonsyndromic - GJB2, MT-RNR1, MT-TS1, POU3F4, PRPS1, and SMPX Genes	MCG* A-0596
Developmental Delay - Gene Panels	MCG* A-0925 This is not covered per MCG*

Metabolic and Developmental Disorders	Criteria
Fragile X-Related Disorders-FMR1 Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0602
Fragile X-Associated Primary Ovarian Insufficiency - FMR1 Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0829
Fragile X-Associated Tremor/Ataxia Syndrome - FMR1 Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0830
Gaucher Disease - GBA Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0603
Glycogen Storage Disease, Type 1 G6PC and SLC37A4 Gene	MCG* A-0684
Intellectual Disability - Gene Panels	MCG* A-0923 This is not covered per MCG*
Joubert Syndrome – Gene Testing and Gene Panels	MCG* A-0785
Lesch-Nyhan Syndrome - HPRT1 Gene	MCG* A-0606
Maple Syrup Urine Disease, Type 1 or Type 2 – BCKDHA, BCKDHB, and DBT Genes	MCG* A-0681
Maple Syrup Urine Disease, Type 3 - DLD Gene	MCG* A-0776
Mucopolidosis IV - MCOLN1 Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0686
Niemann-Pick Disease (Acid Sphingomyelinase Deficiency) - NPC1, NPC2, and SMPD1 Genes	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0611
Noonan Syndrome – Gene and Gene Panel Testing	MCG* A-0915
Prader-Willi Syndrome DNA Methylation Testing <i>Note: Guideline indications are related to tests performed using amniocentesis or chorionic villus sampling. Not medically necessary when performed using cell-free fetal DNA (see MCG A-0848).</i>	MCG* A-0707
Rett Syndrome – CDKL5, FOXP1 and MECP2 Genes	MCG* A-0687
Tay-Sachs Disease and Variants - HEXA Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0614
Usher Syndrome - ADGRV1 (GPR98), CDH23, CIB2, CLRN1, DFNB31, HARS, MYO7A, PCDH15, USH1C, USH1G, and USH2A Genes	MCG* A-0802
Fabry Disease - GLA Gene	MCG* A-0916

Miscellaneous	Criteria
Autosomal and X-Linked Recessive Disease Carrier Screening - Expanded Gene Panels	MCG* A-0768: This is not covered per MCG*
Familial Mediterranean Fever - MEFV Gene	MCG* A-0689
Hereditary Hemorrhagic Telangiectasia - ACVRL1, ENG, GDF2, and SMAD4 Genes	MCG* A-0704
Male Infertility - Y Chromosome Microdeletion Analysis	MCG* A-0803
Malignant Hyperthermia Susceptibility - CACNA1S and RYR1 Genes	MCG* A-0690

Nephrology	Criteria
Donor-derived cell-free DNA testing (e.g., Allosure)	*Please see separate criteria for Donor-derived cell-free DNA testing for Kidney Transplant Rejection (e.g., AlloSure)
Polycystic Kidney Disease (Autosomal Recessive) – DZIP1L and PKHD1 Genes and Gene Panels	MCG* A-0852

Neurology	Criteria
Alzheimer Disease – (Early Onset) APP, PSEN1, and PSEN2 Genes	MCG* A-0590
Alzheimer Disease (Late Onset) - APOE Genotyping	MCG* A-0809: This is not covered per MCG*
Amyotrophic Lateral Sclerosis (ALS) - SOD1 Gene	No additional criteria need to be met beyond numbers 1 - 4 at the top of the Non-Medicare criteria (page 4).
Ataxia-Telangiectasia - ATM Gene	MCG* A-0593
CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) - NOTCH3 Gene	MCG* A-0668
Charcot-Marie-Tooth Hereditary Neuropathy – Gene and Gene Panel Testing	MCG* A-0691
Epilepsies (Hereditary) - Gene Panels	MCG* A-0905 This is not covered per MCG
Epilepsies, Hereditary - SCN1A Gene	MCG* A-0904
Familial Dysautonomia - ELP1 Gene	Does not require medical review in the prenatal setting. For all other indications refer to MCG* A-0685
Familial Frontotemporal Dementia - C9orf72, GRN, and MAPT Genes	MCG* A-0906 This is not covered per MCG
Friedreich Ataxia - FXN Gene	MCG* A-0907
Huntington Disease - HTT Gene	MCG* A-0605
Muscular Dystrophies (Duchenne, Becker) - DMD Gene	MCG* A-0608
Myotonic Dystrophy – Type 1 - DMPK Gene	MCG* A-0609
Myotonic Dystrophy, Type 2 - CNBP Gene	MCG* A-0844
Narcolepsy - HLA Testing	MCG* A-1005 This is not covered per MCG
Nemaline Myopathy – Gene and Gene Panel Testing	MCG* A-0792
Parkinson Disease – Gene Testing and Gene Panels	MCG* A-0671 This is not covered per MCG
<p>Spinal Muscular Atrophy - SMN1 and SMN2 Genes</p> <p>Spinal Muscular Atrophy – Carrier Testing</p> <p>References: American College of Obstetricians and Gynecologists (2017). Carrier screening for genetic conditions. Committee Opinion No. 691. <i>Obstet Gynecol.</i> 129:e41-45. R., Aarabi, M., Klugman, S., Leach, N. T., Bashford, M. T., Goldwasser, T., Chen, E., Sparks, T. N., Reddi, H. V., Rajkovic, A., & Dungan, J. S. (2021). Screening for autosomal recessive and X-linked conditions during pregnancy and preconception: a practice resource of the American College of Medical Genetics and Genomics (ACMG). <i>Genetics in Medicine</i>, 23(10), 1793–1806. Retrieved 10/20/21 from: https://doi.org/10.1038/s41436-021-01203-z</p>	<p>Preconception or prenatal carrier testing for spinal muscular atrophy (SMA) with analysis of the SMN1 gene (CPT code 81329), as described by the American College of Medical Genetics (ACMG) and the American College of Obstetricians and Gynecologists (ACOG), is considered medically necessary for a prospective biologic parent with the capacity and intention to reproduce. Testing is covered once in a lifetime.</p> <p>Kaiser Permanente will cover carrier testing for SMA (CPT 81329) without prior authorization when performed at a Kaiser Permanente lab, Invitae, or Prevention. Prior authorization will still be required for SMA carrier testing at any other lab in advance of submitting a claim for payment.</p> <p>All other spinal muscular atrophy genetic testing: Medical necessity review will be required for all other indications for SMN1/SMN2 gene testing using MCG* KP-0659. <i>Note – this is a KP hybrid, not MCG A-0659</i> (Includes CPT codes: 81336, 81337, 0236U)</p>
Spinocerebellar Ataxia - Gene Testing and Gene Panels	MCG* A-0908

Neurology	Criteria
Transthyretin Amyloidosis - TTR Gene	MCG* A-1010

Oncology	Criteria
Acute Lymphoblastic Leukemia - BCR-ABL1 Fusion Gene Testing	Does not require medical review
Acute Promyelocytic Leukemia - PML-RARA Fusion Gene Testing	Does not require medical review
Breast Cancer - HER2 Testing	MCG* A-0766
Breast Cancer Gene Expression Assays CPT - 81519	See Oncotype Dx
Breast Cancer - PALB2 Gene	MCG* A-0989
Breast or Ovarian Cancer, Hereditary - BRCA1 and BRCA2 Genes CPT 81211, 81212, 81213, 81162	MCG* A-0499
Cancer of Unknown Primary: Gene Expression Profiling – 81540; CancerTYPE ID	MCG* A-0673 This is not covered per MCG
Chronic Eosinophilic Leukemia/Hypereosinophilic Syndrome - FIP1L1-PDGFRα Fusion Gene Testing	MCG* A-0770
Chronic Myelogenous Leukemia - BCR-ABL1 Fusion Gene Testing	Does not require medical review
ClonoSEQ (often billed with miscellaneous code 81479)	ClonoSEQ is a new test whose current use is confined to clinical trials. It is not currently covered by KPWA
Cologuard	See Fecal DNA Testing
Colon Cancer - Oncotype DX	MCG* A-0651: This is not covered per MCG*
Colon Cancer Gene Expression Assay - GeneFx Colon	MCG* A-0821: This is not covered per MCG*
Colorectal Cancer (Hereditary) – Gene Panel	MCG* A-0774: This is not covered per MCG*
Cowden Syndrome - PTEN Gene	MCG* A-0585
DecisionDx - Choroidal/Uveal Melanoma	DecisionDX is covered for dx of choroidal/uveal melanoma
DecisionDx - Cutaneous Melanoma	There is insufficient evidence in the published medical literature to show clinical utility.
Familial Adenomatous Polyposis - APC Gene	MCG* A-0534
Gastric Cancer, Hereditary - CDH1 Gene	MCG* A-0779
Gastrointestinal Stromal Tumor (GIST) - KIT and PDGFRA Genes	Does not require medical review
Ovarian Cancer (Hereditary) - Gene and Gene Panel Testing	Criteria currently under revision to be completed by 9/1/2022. Send to MD for review.
Li-Fraumeni Syndrome - TP53 Gene	MCG* A-0584
Lymphoma - T-Cell Antigen Receptor (TCR) Gene Rearrangement Testing	Does not require medical review
Lynch Syndrome – EPCAM, MLH1, MSH2, MSH6, and PMS2 Genes (see Genetic Panel Testing policy)	MCG* A-0533
Malignant Melanoma (Uveal) - BAP1 Gene	MCG* A-0836: This is not covered per MCG*
Malignant Melanoma (Cutaneous) – BAP1, CDK4 and CDKN2A Genes	MCG* A-0601: This is not covered per MCG*

Oncology	Criteria												
Melanoma (Cutaneous) - Gene Expression Profiling	MCG* A-0837: This is not covered per MCG*												
Melanoma (Uveal) - Gene Expression Profiling	MCG* A-0670: This is not covered per MCG*												
Multiple Endocrine Neoplasia (MEN) Syndrome, Type 2 - RET Gene	MCG* A-0842												
Multiple Endocrine Neoplasia (MEN) Syndromes - MEN1 Gene	MCG* A-0582												
MUTYH-Associated Polyposis - MUTYH Gene	MCG* A-0828												
Myelodysplastic Syndromes (Somatic) - Gene Panels	MCG* A-0791: This is not covered per MCG*												
Myeloproliferative Neoplasms - JAK2 Genes	Does not require medical review												
Myeloproliferative Neoplasms - MPL Gene	Does not require medical review												
Neuroblastoma - ALK, MYCN, and PHOX2B Genes and Gene Expression Profiling	MCG* A-0610												
Neurofibromatosis - NF1 Gene	MCG* A-0581												
Neurofibromatosis - NF2 Gene	MCG* A-0846												
Non-Small Cell Lung Cancer – Gene Testing (Somatic or Therapeutic)	MCG* A-0795 Includes indications for: Anaplastic Lymphoma Kinase (ALK) Fusion Gene Testing – medically necessary when indications met EGFR Gene Testing – medically necessary when indications met KRAS Gene Testing – not medically necessary for NSCLC per MCG*												
OVA1- Assessment for Ovarian Cancer	There is insufficient evidence in the published medical literature to show clinical utility.												
Pancreatic Cancer (Hereditary) - Gene Panel	MCG* A-0797												
Paraganglioma-Pheochromocytoma (Hereditary) - Gene Testing and Gene Panel	MCG* A-0798												
Peutz-Jeghers Syndrome - STK11 Gene	MCG* A-0799												
Prostate Cancer - BRCA1 and BRCA2 Genes	MCG* A-0612												
Prostate Cancer – ConfirmMDx (CPT Code 81551)	<p>ConfirmMDx (81551) for men with prior negative biopsy when repeat biopsy is being considered, and the following criteria are met (must be ordered by treating urologist):</p> <ul style="list-style-type: none"> The beneficiary would benefit from treatment of prostate cancer and has greater than 10-year life expectancy Previous biopsy within the past 12 months negative or atypical small acinar proliferation (ASAP) Meets Age/PSA per table below Serial testing not covered (this is a one-time test) Concurrent testing with multiple assays is not medically necessary <table border="1"> <thead> <tr> <th colspan="2">TABLE 1. Background

Genetic screening is used to identify the genetic disorders or the potential for transmission of genetic disorders in populations at risk for a particular genetic disorder. Genetic screening is only appropriate when the natural history of the disease is understood; the screening tests are valid and reliable; sensitivity, specificity, false-negative, and false-positive rates are acceptable; and effective therapy is available. A sufficient benefit must be derived from a screening program to justify its cost.

Medical Technology Assessment Committee (MTAC)

Afirma

BACKGROUND

Thyroid nodules are clinically identified in 5-7% of the population, and incidentally on ultrasonography in up to 50% of women and 20% of men over the age of 50. Thyroid nodules are typically benign, but 5-15% prove to be malignant. It is thus recommended that any identified nodule measuring one centimeter or more in diameter be diagnostically evaluated. Ultrasound-guided fine needle aspiration (FNA) biopsy is the most widely used method for clinical evaluation of a suspicious thyroid nodule. FNA is a safe and simple outpatient procedure that yields cellular material suitable for cytological analysis. It can identify approximately 50% of malignant nodules and 70% of benign nodules without the need to perform a diagnostic surgery. However, 15-30% of the biopsied nodules have indeterminate cytology and cannot be conclusively diagnosed by FNA biopsy alone. Most patients with indeterminate lesions or lesions suspicious for malignancy, according to the Bethesda classification* system, are referred to surgery for both diagnostic and therapeutic purposes. Surgery is the recommended and appropriate treatment for thyroid cancer, however 70-75% of the nodules with indeterminate FNA cytology are found to be benign on final surgical pathology. Thus, a large proportion of these patients may undergo unnecessary partial or complete thyroidectomy with its potential surgical complications and risk of long-term morbidity (Alexander 2012, Duick 2012, Walsh 2012, Ali 2013, Labourier 2015, Sacks 2016).

Molecular markers and assays have been investigated for their ability to preoperatively classify the indeterminate thyroid nodules. Each has its performance characteristics and diagnostic values. Ideally a molecular marker or panel of markers is accurate in differentiating benign from malignant in any lesion that is considered suspicious or indeterminate. Molecular tests should also be simple to use, reproducible by the different institutions/laboratories, and cost-effective.

Molecular genetic testing for cytologically indeterminate thyroid nodules fall in two approaches: the “rule in” and the “rule-out” disease approach. Tests that rule-in malignancy (such as BRAF, RAS mutations, RET/PTC and PAX8-PPAry) have high specificity and positive predictive values (PPVs) for malignancy by identifying specific mutations or gene rearrangements known to be present in thyroid cancer. However, they have limited sensitivity and negative predictive values (NPVs) and fail to detect as many as 30% of malignancies. Tests that rule-out the disease on the other hand, should have a high sensitivity and negative predictive value in order to exclude malignancy when the test results are benign. Because a majority of nodules with indeterminate cytology are found to be benign on surgical resection, a test that can preoperatively rule-out malignancy may spare a subset of these patient’s unnecessary diagnostic surgeries (Alexander 2012, Kouniavsky 2012, Ward 2013, Chaudhary 2016, Nishino 2016).

*2008 Bethesda classification system for thyroid cytology: Class I: Nondiagnostic or unsatisfactory, Class II. Benign, Class III: atypia or follicular lesion of undetermined significance (AUS/FLUS), Class IV: follicular neoplasm or suspicious for follicular neoplasm (FN), Class V: suspicious for malignancy (SUSP) and Class VI: malignant) (Kuo, 2016)

Afirma gene expression classifier (GEC) is a molecular test developed by Veracyte Inc. (San Francisco, CA) with the intention of reducing unnecessary diagnostic surgeries in patients with thyroid nodules with indeterminate FNA cytopathologic results. It represents the “rule-out” approach by preoperatively identifying the benign thyroid nodules and ruling-out malignancy. Afirma GEC uses a proprietary diagnostic algorithm that analyses the mRNA expression of 167 genes to identify the signature of benign thyroid nodules. 142 of the 167 genes are in the main classifier, and 25 genes filter out rare neoplasms. The selected gene profile is based on the gene expression identified from FNAs of surgically proven benign and malignant thyroid nodules. During the Afirma GEC test RNA is extracted from the FNA sample, amplified and hybridized to a custom microarray to examine for gene patterns. These are compared with the GEC proprietary panel, which molecularly classifies them as either ‘benign’ or ‘suspicious’. Insufficient RNA in the sample leads to ‘no result’ conclusion in approximately 10% of cases. Nodules with benign results, in addition to clinical judgement, are typically followed up clinically and ultrasonography, while those with suspicious results undergo diagnostic thyroid lobectomy with possible total thyroidectomy (Alexander 2012, Kim 2012, Ward 2013, Kuo 2016, Witt 2016).

Afirma GEC is a proprietary test commercially owned by Veracyte Corporation and is offered through a sole source, which is a Clinical Laboratory Improvement Amendments certified [CLIA] reference laboratory. During a routine FNA of a thyroid nodule, after the aspirates are obtained for cytopathologic examination, two more needle passes are obtained for Afirma analysis and immediately stored in a preservative. These are either 1. Sent to a Veracyte independent industry partner (Thyroid Cytopathology Partners [TCP], Austin, TX) that performs cytopathologic exam of the FNA sample, and only runs the Afirma test for indeterminate diagnoses on cytopathology, or 2. In Thyroid Cytopathology Medical centers designated as “Enabled centers” cytopathology is done in-house and specimens with indeterminate results based on the Bethesda criteria are sent for Afirma GEC testing. Afirma test is run only on nodules with indeterminate cytology. If the cytopathologic evaluation reveals any other diagnosis or is nondiagnostic due to insufficient FNA samples, the preserved samples are discarded. The goal of the test is to identify the benign nodules from among those with indeterminate cytopathology. It is not intended to assist with clinical decision making for patients who have an indication for surgery or meet criteria for surgical interventions (Alexander 2012, Duick 2012, Ward 2013, Kuo 2016, Yip 2016).

03/20/2017: MTAC REVIEW

Evidence Conclusion: Analytic validity of Afirma GEC (From an earlier MTAC review)

Evaluating the analytic performance of Afirma GEC includes studying the stability of RNA in FNAs during collection, storage, and shipment; reproducibility of the test; and its analytic sensitivity and specificity under various conditions e.g. interference of the assay with bloody FNA and genomic DNA. The literature search revealed one study (Walsh and colleagues, 2012) that evaluated the analytic performance of Afirma GEC in a number of sub-studies. The investigators obtained prospective FNA samples aspirated in vivo from 43 patients from outpatient clinics, preoperatively, or immediately after surgical excision. The samples were placed in FNAProtect preservative solution and shipped chilled or frozen, then stored at -80°C upon receipt. The RNA was extracted, and its yield examined for quantity and quality using positive (tissue lysate) and negative (water) as controls. Three different lots of controls were tested over several weeks of independent runs by 3 different operators to determine reliability of the test. Multiple lots of benign and malignant total RNA were manufactured and used as process controls to determine the analytic sensitivity of the test using different RNA input quantity and under different dilution of malignant FNA content. These studies indicated tolerance to variation in RNA input across a range of 5-25 ng. as well as dilution of malignant FNA material down to 20%. Analytic specificity of the test using malignant samples mixed with blood (up to 83%) and genomic DNA (up to 30%) showed minimal assay interference. However benign FNA samples mixed with relatively high proportions of blood had a potential for yielding false positive results. The investigators examined the stability of RNA in FNAs during collection and shipment and found that RNA content within FNAs preserved in FNAProtect was stable for up to 6 hours at room temperature with no change in RNA yield, and that the FNA storage and shipping temperatures had no significant effect on GEC scores. They also examined the reproducibility of the test and indicated that it was reproducible from extraction through GEC results, including variation across operators, runs, reagent lots, and laboratories. The investigators concluded that the analytical performance and reproducibility of the Afirma Gene Expression Classifier was successfully verified. The research was supported by Veracyte Corporation (the maker of Afirma GEC), and the authors of the study had financial ties to the corporation.

Clinical validity of Afirma GEC an ideal diagnostic test would have high sensitivity and specificity to correctly detect or exclude a condition. A molecular diagnostic test with high sensitivity offers a high negative predictive value (NPV) when the risk of malignancy is low and can “rule out” malignancy. Conversely, a test with high specificity offers high positive predictive (PPV) value and can “rule in” malignancy. A preoperative diagnostic test would ideally have a high sensitivity in order not to miss a malignant nodule and have a high NPV to avoid surgery in patients

with benign nodules. Predictive values do not only depend on the sensitivity and specificity of the test, but also on the prevalence of the disease; e.g. as the disease prevalence increases, the NPV decreases and vice versa. Afirma GEC test was validated in a. a double-blind prospective multicenter study (Alexander 2012 (Evidence table 1, reviewed earlier by MTAC). The study involved 265 nodules with indeterminate cytology that were selected for GEC analysis. Molecular results were compared to the gold standard of post-surgical histopathology. The malignancy rate was 32% and the Afirma sensitivity and specificity were 92% and 52% respectively with a NPV of 94-95% and PPV of 27-38% for Bethesda III/IV nodules. In the subgroup in patients with nodules suspicious for malignancy (SUSP) the NPV was only 85%, based on which, the authors concluded that GEC should not be used for cytology SUSP nodules. The study was conducted to validate the GEC accuracy by comparing it to surgical histopathology and did not compare its performance to repeat FNA or other immunochemical or molecular testing. A number of post-validation analyses were conducted by independent or industry supported investigators. In the initial validation study (Alexander 2012) the decision to resect the nodule was made independently of the GEC test results, while in the post-validation studies GEC was a factor influencing the decision whether to recommend a diagnostic surgical intervention. The published studies and analyses showed a wide variation in the NPVs and PPVs of Afirma GEC test results. The NPV and PPV of a test are neither absolute nor inherent in the test but depend on the pre-test probability of malignancy in the population studied, i.e. prevalence of malignancy in indeterminate nodules. This is made clear by Marti and colleagues (2014) who retrospectively analyzed all indeterminate thyroid nodules (ITNs) evaluated with GEC at two centers with widely different prevalence of malignancy in ITNs (Memorial Sloan Kettering Cancer Center [MSK] and Mount Sinai Beth Israel [MSBI]) (see table below).

The results of the validation study as well as post-validation studies are summarized in the following table.

Performance of GEC in the validation study and selected post-validation studies

Study	N FNA ITN undergoing GEC	Afirma results Suspicious	Benign	Inadequate RNA/ no result	Cancer prevalence in indeterminate FNA	NPV‡	PPV‡‡	Operative rate in GEC benign results
Alexander 2012 (multicenter Validation study)	265	62%	38%		32%	94-95%	27-38%	NA
Alexander, 2014 (5 centers)***	339	40%	55%	5%	--	99.4%	--	6.3%*
Harrell, 2014 (One practice)	58	62%	35%	3%	33-36%	88.3-89.6%	56%	25%**
Mclver, 2014	72	61%	22%	17%	17%	94%	15.6%	25%
Marti, 2015 MSK center(tertiary) MSBI comprehensive health system)	94	74%	26%	--	30-38%	86-92%	57.1%	8%
	71	48%	52%	--	10-19%	95-98%	14.3%	14%
Chaudhary, 2016†	158	54%	40%	6%		100%	38%	13%
Witt, 2016 (single-practice)	32	47%	44%	9%	21%	100%	--	0
Samulski, 2016 (single institution)	294	46%	49%	5%		81% for resected nodule, 98% for unrested benign GEC	39%	12%
Sacks, 2016 (single medical center)	140	55.7%	37.1%	7.1%	31.5%	92%††	33.3%	

All studies were performed in Institutional Enabled Centers, except for Harrell (2014) study where the cytology specimens were sent to Thyroid cytopathology partners (TCP).

* 1/11 (9.1%) was malignant (false negative)

** Of the 20 benign GEC patients 5 underwent surgery 2 of which (40%) were found to be malignant (False negative),

*** There were variation between the 5 study sites in the cytology distribution and Afirma GEC performance. GEC suspicious cases proved to be cancerous in 44% of cases (False positive in 56% of cases)

‡ The NPVs (the probability of cancer in GEC benign nodules) were all estimates and could not be directly assessed because not all patients had undergone surgery to determine surgical pathology or had long-term follow-up of the GEC benign nodules.

‡‡ The reported PPVs ranged between studies from 14-57% which limits the utility of the test as a rule-in test i.e. to predict the risk of malignancy.

† A comparison between pre- and post-GEC era showed no significant difference in surgical excision rates of FNA ITN. There were differences in the accuracy and predictive values of the GEC according to the cytomorphological features of the nodules. The authors concluded that the GEC test was found to reduce surgical excision of nodules with suspicious for follicular neoplasm (SFN), but not with FLUS / AUS or Hurthle cell neoplasm (HCN). They recommended repeating FNA rather than performing Afirma GEC test for FLUS/AUS, and be cautious when ordering GEC on HCN cases. 8 (13%) of the benign affirm underwent surgery and all were found benign

†† Estimated based on the prevalence. Could not be calculated due to the low number of GEC-benign cases with surgical pathology

-- Not provided

Based on the results of the published studies, some investigators suggest that Afirma GEC may provide useful information in practice settings where the prevalence of malignancy in indeterminate thyroid nodules is 15-21%. At this range and using the sensitivity and specificity data from the multicenter validation study the NPV would be >95% and the PPV >25%. It is suggested that GEC may also provide some useful information with the prevalence of malignancy ranging from 12-25% but is not expected to be useful in altering management if the prevalence is outside this range (Marti 2015, Zhang 2016). The Afirma GEC performance was found to be suboptimal for Hurthle cell neoplasms (HCNs). Wu and colleagues (2016) examined the clinical factors influencing the performance of GEC testing and found that the test has a limited clinical validity for HCNs due to the high rate of false positive results (specificity 22.7-26.1% and PPV 29.2%). Other studies also showed inconsistent and low performance of GEC testing for HCN nodules. In the clinical validation study only 4 of 21 (19%) FNA samples from Hurthle adenomas were classified as benign with GEC.

Limitations in the published studies These include but are not limited to the following:

- All analyses were retrospective with potential bias and confounding.
- There were intra- and inter-observer differences within and between studies in the histological interpretations.
- Only data for patients with GEC testing were analyzed and with the exception of one study, the results were not compared to repeat FNA or other tests.
- The NPVs were all estimates as only a very limited number of GEC benign nodules underwent surgery, and the follow-up duration was too short to determine the true benign nature of the GEC benign nodules.
- The majority of the published studies were industry sponsored.
- The predictive values of a test vary with the prevalence of the disease in a population studied and may not be generalized to other groups. A better analysis would be the likelihood ratios which are not affected by prevalence.

Santhanam and colleagues' meta-analysis (2013, Evidence table 2) pooled the results of 7 prospective and retrospective studies to determine the sensitivity and specificity of the GEC test in classifying FNA indeterminate thyroid nodules and evaluate its clinical utility. The results of the meta-analysis are summarized in the following table:

Pooled results

Pooled values	Value (95% CI)	P value
Sensitivity	95.7% (92.2-97.9)	0.09
Specificity	30.5% (26.0-35.3)	<0.01
Positive likelihood ratio*	1.20 (0.99-1.44)	<0.01
Negative likelihood ratio**	0.2 (0.11-0.36)	0.56
Diagnostic odds ratio	7.86 (4.1-15.01)	0.42
Prevalence of malignancy	37.1%	
Positive predictive value	44.8 (40.4-49.4)	

*A good test for ruling-in a disease is the one with the largest positive likelihood ratio (LR) A positive LR of 1 means that the test does not provide any information on ruling in the disease, LR >1<5 indicates a small effect, and LR>10 indicates a large effect on increasing the probability of a disease is presence.

** The better test to rule-out a disease is the one with the smaller negative likelihood ratio. LR <0.1 indicates that the result has a large effect on decreasing the probability of the disease (rule out), LR 0.1-0.5 indicates moderate effect, and >0.5 indicates a small effect. The meta-analysis had valid methodology, but a meta-analysis is as good as the studies it includes. Due to the lack of RCTs and comparative prospective studies Santhanam and colleagues pooled the results of observational prospective and retrospective studies. There was significant heterogeneity between the studies as they were performed at different institutions and included a wide distribution of patients with different indeterminate cytology results (the test may perform better for one type of neoplasm/cancer versus the other). The meta-analysis had the advantage of calculating likelihood ratios which are not affected by prevalence the condition as

the predictive values. However, likelihood ratios are calculated based on the sensitivity and specificity of the test, which may have not been accurate as the majority of GEC benign cases did not undergo surgery or were followed up for a sufficient duration to assess the actual accuracy of the test, and not all GEC suspicious cases underwent surgery. More recently in 2016, an international panel of pathologists and clinicians reclassified a clinically indolent malignant tumor (encapsulated follicular variant of papillary thyroid carcinoma [EFVPT]) as a benign neoplasm (noninvasive follicular thyroid neoplasm with papillary-like nuclear features [NIFTP]) (Nikiforov 2016). This reclassification may affect the calculated performance of the current Afirma GEC as it has not been validated with these changes. In one study Samulski and colleagues (2016) reported that of 11 NIFTP cases in their cohort, only one was classified as benign with the GEC test.

Clinical utility of Afirma GEC the clinical utility of Afirma GEC would be guiding the management decisions by clearly ruling out malignancy in FNA indeterminate nodules to avoid unnecessary diagnostic surgery. The published studies on the impact of Afirma GEC on the management of patients with FNS ITNs were retrospective in nature, performed in different sites with intra- and inter-rater variability, which are potential sources of selection and performance bias. In addition, the studies only focused on nodules that underwent Afirma GEC testing and did not investigate the effect of FNA results on overall thyroidectomy rates, or include a comparison group to examine the impact of a repeat FNA or other tests for nodules with indeterminate cytopathology. [Santhanam and colleagues \(2013, Evidence table 2\)](#) discussed in the previous section on clinical validity of Afirma GEC also evaluated its clinical utility of the test. The authors calculated that for patients with FNA indeterminate nodule, one thyroid surgery can be avoided for every two Afirma GEC tests, assuming that >90% of the patients with benign GEC are followed conservatively. They noted however, that according to the American Cancer Society, the 5-year survival of stage I and stage II follicular and papillary thyroid cancer is 100%. The morbidity and mortality rates in patients with FNA indeterminate thyroid nodules are reported to be more likely low, and thus the diagnosis of suspicious nodules with GEC testing may represent a lead-time bias with little change in overall survival.

[Sacks and colleagues \(2016 Evidence table 3\)](#) performed a retrospective analysis to evaluate the impact of Afirma GEC testing on cytopathology diagnosis, rate of surgery, and the rate of malignancy on all indeterminate nodules (ITNs) before and after the introduction of Afirma GEC testing at a high-volume thyroid center. The study was a retrospective analysis of patient data from one institution, with no direct comparison to a control group. However, it had the advantage of reporting on outcomes of repeat FNAs, comparing two cohorts' pre-and post-Afirma, and reporting on thyroidectomy rates among all cases irrespective of GEC testing. The calculated PPV for the test was 33.3%, and the estimated NPV was 92% (an accurate NPV could not be calculated due to small number of GEC benign cases with surgical pathology). There was a significant increase Bethesda III-IV diagnosis in the post Afirma cohort compared to the pre-Afirma cohort (13.4% vs. 10.7%, $p<0.005$), with a corresponding significant decrease in benign cytology (Bethesda II) post-Afirma (74.6% compared to 68.8% pre-Afirma, $p<0.001$), despite the use of the same guidelines, practice, reporting scheme, and personnel. In an attempt to explain the reason for this shift, the authors supposed that cytopathologists, especially those with less experience, may be less likely to classify nodules as Bethesda II knowing that the GEC testing will help stratify them. No significant changes were observed for Bethesda I, V, or VI, or in the rate of repeat FNA for ITNs. The author noted that while Afirma may reduce the rate of thyroidectomy for nodules with benign GEC results, the "suspicious label" may increase it. Only 33.3% of GEC suspicious cases were found to be malignant. The analysis shows that 35.2% of patients with ITNs who underwent a repeat FNA were classified as non-ITN and avoided Afirma testing. Overall, the results of the analysis indicate that the use of Afirma GEC testing was associated with an increase in the rate of FNA indeterminate diagnosis, and a decrease in the incidence of benign diagnosis. GEC testing did not reduce the overall rate of thyroidectomies which is its main goal. As indicated earlier the study had its disadvantages, which may limit generalization of the results.

[Abeykoom and colleagues \(2016\)](#), performed a similar respective analysis in a single endocrine clinic comparing the rate of surgeries pre-and post GEC testing for nodules with indeterminate cytopathology (N=61 [27 before and 34 after GEC implementation]). The results were however, inconsistent with Sack's 'findings. The analysis showed no significant difference before and after GEC implementation in the rate of ITNs, but there was a significant decrease in the recommendation for surgery for patients with ITNs from 81.5% pre-GEC implementation to 50% post GEC ($p=0.01$). The surgical pathology for those who underwent an operation was read as malignant in 20% and 85.7%. of patients before and after Afirma GEC respectively ($p<0.01$). The study was retrospective, small, included patients from a single center over two-time periods with different pathologists analyzing the specimens, which are potential sources of confounding and bias that may limit generalization of the results.

[Duick and colleagues \(2012, Evidence table 4, from an earlier MTAC review\)](#) performed a chart review for 21 endocrinology practices in 11 states. They analyzed data for 368 patients with 395 cytologically indeterminate thyroid nodules with Afirma GEC benign results. 7.6% of these patients underwent surgery and 94.4% were

managed nonoperatively.

The study did not have a comparison group, but the authors compared the 7.6% surgical rate in nodules with benign GEC results to a 74% historical rate of diagnostic surgery ($P < 0.001$). The main indications for surgery for those with GEC benign results were the rapid growth or larger size of the nodules, local pressure symptoms, or the presence of a second suspicious nodule or malignant nodule.

The study was retrospective, used a historical comparison, and investigated the decision-making of endocrinologists experienced in managing patients with thyroid nodules, which may differ from that made by primary care providers or other specialists. In addition, the authors of the study did not provide data on long-term follow-up of those who were managed by watchful waiting rather than surgery.

Sipos and colleagues (2016), retrospectively analyzed data recorded for 98 patients with a benign GEC over a mean duration of 36 ± 3 months (range 0-44 months) treated at multiple centers. 17 of these 98 patients (17.3%) underwent surgery during this period. 88% of the surgeries were performed in the first 2 years after the benign GEC results with the rate leveling after the first year. The most common indications for surgery were the nodules rapid growth and large size. The authors concluded that the study shows that benign GEC test results are associated with low operative rates. The study had its limitations and the authors did not provide data on the pathology results of the resected nodules.

Articles: The updated literature search revealed a number of retrospective analyses performed after the Afirma GEC validation study, a meta-analysis that pooled the results of selected studies, and three retrospective studies on the clinical utility of the test. The study on the analytic validity, the two clinical validation studies as well as two retrospective studies on clinical utility were reviewed earlier by MTAC. The meta-analysis and the more recent studies on the clinical validity and clinical utility of Afirma GEC test were reviewed and their results summarized.

04/12/2022: MTAC Review

Thyroid Nodule Molecular Testing

Evidence Conclusion: Analytical validity: One study showed that Afirma GSC test has a strong analytic performance and is reproducible. Clinical validity: Low quality evidence suggests that: Afirma GSC test has a good diagnostic performance. Comparison to ThyroSeq v3 and ThyraMIR/ThyGeNEXT: the diagnostic performance cannot be ranked due to lack of head-to-head comparisons. Clinical utility: The evidence is insufficient (very low quality) for or against the use of Afirma GSC to reduce unnecessary surgery in patients with indeterminate thyroid nodules.

Articles: PubMed was searched through October 26, 2021. The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. Search terms included: (Afirma Genomic Sequencing Classifier OR Genomic Sequencing Classifier OR GSC OR Afirma OR Veracyte) AND (thyroid) through 10/21/21.

For Thyroseq v3, search terms included ThyroSeq v3 Regarding ThyGeNEXT and ThyraMIR, search terms included Interpace or ThyGeNEXT or ThyraMIR. Afirma GSC: The search yielded several articles. After screening through abstracts and/or full text, 9 studies were retained and reviewed. The studies consisted of 1 analytical validity study, four clinical validity studies, and four clinical utility studies. Thyroseq v3: The search yielded several articles. Studied retained are critically appraised. ThyGeNEXT and ThyraMIR: The search yielded several articles. Studied retained are critically appraised. See Evidence tables.

The use of Thyroid Nodule Molecular Testing does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Array Comparative Genomic Hybridization (aCGH) for the Genetic Evaluation of Patients with Intellectual Disability

BACKGROUND

Intellectual disability, also termed mental retardation or cognitive disability, affects approximately 1-3% of the general population and is defined as a significant impairment in cognitive and adaptive functions, with the age of onset before 18 years. It is a serious and lifelong condition that presents significant challenges to families and to public health. Determining the specific etiology of intellectual disability may help to provide answers related to prognosis, recurrence risk, and treatment. Intellectual disability can be caused by anything that damages or interferes with the growth or maturation of the brain; however, genetic (chromosomal) abnormalities are one of the main causes of intellectual disability (Galasso 2010, Sagoo 2009). Chromosomal abnormalities are deletions and duplications of genomic material and are commonly referred to as copy number variations. Conventional methods for detecting these abnormalities include karyotyping and fluorescent in situ hybridization (FISH). Karyotyping

involves visualizing the chromosome for large gains or losses in chromosomal material and is generally the first step in cytogenetic analysis. Karyotyping can detect chromosomal abnormalities such as deletions, duplications, inversions, and translocations across the entire genome; however, it lacks the resolution necessary to detect abnormalities smaller than 3-5 megabases (Mb; 3-5 million base pairs). FISH uses florescent-labeled chromosome-specific probes to detect chromosomal abnormalities. FISH can detect submicroscopic abnormalities and is often used in situations where the karyotype is normal, but there is a high clinical suspicion of a deletion syndrome. However, FISH is a targeted method and requires prior knowledge of the chromosome region(s) of interest to request the appropriate FISH test. Additionally, FISH can only screen a limited number of genomic regions at a time (Bremner 2009, Fruhman 2010, Galasso 2010, Gropman 2010). Array comparative genomic hybridization (aCGH) is a more recent technology used to identify copy number variations by comparing patient DNA with reference DNA. It is currently used as an adjunct to conventional methods. There are two types of aCGH: targeted and whole-genome. Targeted arrays are designed to interrogate areas of the genome with known clinically significant abnormalities. Whole genome arrays provide high resolution coverage of the entire genome. This can lead to the discovery of new copy number variations. Compared to conventional methods, aCGH has a higher resolution and is able to simultaneously detect copy number variations in multiple regions of the genome. Additionally, unlike FISH, knowledge of the chromosome region(s) of interest does not need to be determined in advance because a single array assay detects all genomic variants represented on the array. Array CGH is not without limitations. It cannot detect totally balanced translocations or inversions; it performs suboptimally for polyploidy; and has not been optimized for prenatal diagnosis of point mutations. Because aCGH cannot identify the exact location of a duplicated chromosome, further testing with karyotype or FISH may be necessary. Another limitation is the potential to identify novel copy number variants with unknown clinical significance (Fruhman 2010, Moeschler 2008). Array CGH is a laboratory-developed test and is commercially available from several different laboratories. Laboratory-developed tests are licensed under the Clinical Laboratory Improvement Amendments (CLIA) and do not require clearance from the FDA.

The use of Gene Expression Classifier (Afirma®) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

4/18/2011: MTAC REVIEW

Array Comparative Genomic Hybridization (aCGH) for the Genetic Evaluation of Patients with Intellectual Disability

Evidence Conclusion: Analytic validity The BCBS review identified several studies that evaluated the sensitivity of aCGH. The sensitivity of aCGH testing compared to conventional methods (karyotype and/or FISH) ranged from 73% to 100%. As false-positive rates were inconsistently reported, specificity could not be determined (BCBS 2009). Clinical validity

Articles: No studies were identified that evaluated the impact of conventional methods or aCGH on patient outcomes other than diagnostic yield. Results from the BCBS review suggest that diagnostic yield in patients with intellectual disability ranged from 5 to 16.7%, which represents a significant improvement compared to conventional methods. The number needed to test by aCGH to detect one clinically relevant abnormality ranged from 25 to 6 depending on the diagnostic yield. Limitations of these studies include: different aCGH resolution, patient selection criteria ranged from none too stringent criteria, and three different types of arrays were used (targeted, whole-genome, and those that combined targeted and whole-genome arrays) (BCBS 2009).

Diagnostic yield ¹ of aCGH, karyotype, and FISH			
	aCGH	FISH	karyotype
	4-7%	5-6%	
Diagnostic yield	(In those negative by karyotype and FISH)	(In those negative by karyotype)	3-5%

¹Estimates from Stankiewicz 2007.

Clinical utility The BCBS review included two small studies with a high risk of bias and found that there was insufficient evidence to determine the clinical utility of aCGH testing (BCBS 2009). Conclusion: Analytic validity: There is fair evidence that aCGH testing had good sensitivity compared to conventional methods; however, there is insufficient evidence to determine the specificity or reproducibility of this test. Clinical validity: There is fair evidence that aCGH increases diagnostic yield over conventional methods; however, this is an intermediate outcome. Clinical utility: There is insufficient evidence that patients managed with the genetic test had better outcomes than patients managed without the genetic test.

In 2009, Blue Cross and Blue Shield (BCBS) evaluated the use of aCGH for the genetic evaluation of patients with developmental delay/ mental retardation. Studies were selected for review if they were published after the 2009 review and did not support the BCBS recommendations. No studies were identified that would

change the BCBS recommendations. The following review was critically appraised: Blue Cross and Blue Shield Association.

Special report: aCGH for the genetic evaluation of patients with developmental delay/mental retardation or autism spectrum disorder. Assessment Program. Volume 23, No. 10. April 2009.

The use of Array Comparative Genomic Hybridization (aCGH) for the genetic evaluation of patients with intellectual disability does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

HLA Testing for Celiac Disease

BACKGROUND

Celiac disease is a chronic, autoimmune disorder that affects approximately 1% of children and adults in the United States. In individuals with celiac disease, the ingestion of gluten proteins found in wheat, rye, and barley lead to an autoimmune reaction that causes small intestine mucosal injury. Damages in the small intestine can cause gastrointestinal symptoms and interfere with the absorption of nutrients from food. This may lead to malnutrition-related problems such as anemia, vitamin deficiencies, osteoporosis, and neurological disorders. A gluten-free diet typically resolves symptoms and can prevent long-term consequences (Tack 2010). There are a variety of tests available to diagnose celiac disease. The gold-standard for diagnosing celiac disease is a small intestine biopsy. However, this test is not a perfect gold-standard as false positive and false-negative results may occur due to interobserver variability, patchy mucosal damage, low-grade histological abnormalities, and technical limitations. Additionally, histological features are not unique to celiac disease. Serum antibody tests are used as an initial screening tool to detect and support the presence of celiac disease and to select which patients should undergo a biopsy. Two of the most sensitive and specific serological tests for diagnosing celiac disease are tests that assess the presence of IgA autoantibodies against the endomysium of connective tissue (EMA) (sensitivity 62-81%, specificity 80-99%) and against tissue transglutaminase (tTGA) (sensitivity 81-88%, specificity 84-99%). While these tests are accurate, they are not without limitations. For example, the EMA test correlates with the degree of mucosal damage. As such, the sensitivity of this test is lower in patients with milder cases (higher chance of false negative results). Additionally, false negative results may occur in patients with an IgA deficiency and in patients who are already on a gluten-free diet. In patients with an IgA deficiency, serum IgA testing can be replaced by using IgG assays, which are less sensitive than IgA assays. Another test that can be used to rule out the diagnosis of celiac disease is human leukocyte antigen (HLA) genotyping. It has been reported that approximately 90-95% of patients with celiac disease are carriers of the HLA-DQ2 heterodimer and most of the remaining patients carry the HLA-DQ8 heterodimer. Since virtually all patients with celiac disease carry one of these heterodimers, celiac disease is highly unlikely when both are absent. It has been proposed that using HLA genotyping as an initial screening tool may avoid future concerns about the condition and eliminate further diagnostic testing. However, HLA typing is not a perfect solution since around 25-40% of the general population carries either HLA-DQ2 or DQ8, of which the majority never develop the disease. Other situations where HLA genotyping may be useful is when the diagnosis of celiac disease is unclear based on serological and/or histological findings. Additionally, HLA genotyping can be performed in patients who are already on a gluten free diet (Tack 2010, Hadithi 2010).

4/18/2011: MTAC REVIEW

HLA Testing for Celiac Disease

Evidence Conclusion: Analytic validity There are a variety of methods used for HLA genotyping. Each of these assays has its advantages and limitations (Monsuur 2008, Lavant 2009). Clinical validity A recent prospective cohort study evaluated the accuracy of serologic tests and HLA-DQ genotyping used alone and in combination for diagnosing celiac disease compared to small intestine biopsy. Results from this study suggest that both tTGA and EMA are sensitive and specific tests for diagnosing celiac disease. HLA-DQ testing was also highly sensitive but was not as specific as serologic testing. The addition of HLA-DQ genotyping to serum antibody tests did not increase test performance compared to serologic testing alone. Results should be interpreted with caution as only 16 patients were diagnosed with celiac disease (Hadithi 2007). Sensitivity and specificity of serologic testing and HLA-DQ typing for diagnosing celiac disease

	Sensitivity (95% CI)	Specificity (95% CI)
HLA-DQ testing		
HLA-DQ2 or DQ8	100 (79-100)	57 (52-62)
Serologic testing using IgA		
tTGA	81 (54-95.9)	99.1 (97.7-99.7)
EMA	81 (54-95.9)	99.1 (97.7-99.7)
tTGA & EMA	81 (54-95.9)	99.3 (98-99.9)

Both serologic testing & HLA-DQ testing		
tTGA & HLA-DQ	81 (54-95.9)	99.3 (98-99.3)
EMA & HLA-DQ	81 (54-95.9)	99.1(97.7-99.8)
tTGA, EMA, & HLA-DQ	100 (79-100)	99.3 (98-99.9)

Abbreviations: EMA= antiendomysium antibody; tTGA= antitransglutaminase antibody.

Another observational study investigated whether HLA genotyping would be useful to identify first-degree relatives of patients with celiac disease who do not need further screening for celiac disease. Fifty-four families with at least two siblings with celiac disease were selected to participate in the study. In total, 245 (52.5%) first-degree relatives agreed to participate. The diagnosis of celiac disease was based on duodenal biopsy and medical records. Of all of the first-degree relatives, 17.6% (N=43) did not carry any of the celiac disease risk alleles. Of these relatives, only one was diagnosed with celiac disease (Karinen 2010). Clinical utility Because of its low specificity HLA genotyping may not be an ideal initial screening test for diagnosing celiac disease. However, HLA genotyping may be useful in certain situations, such as when the diagnosis of celiac disease is unclear based on serologic and histologic findings and when patients are already on a gluten free diet, to rule out celiac disease. Additionally, as negative serologic or histologic test results do not exclude the development of celiac disease later in life, the use of HLA genotyping in patients who are at increased risk for celiac disease may prevent unnecessary serologic and histologic testing. Conclusion: Analytic validity: There are a variety of methods used for HLA genotyping. Each of these assays has its advantages and limitations. Clinical validity: There is fair evidence that HLA genotyping may be a useful adjunct in the diagnosis of celiac disease as it has a high negative predictive value. Clinical utility: No studies were identified that addressed the clinical utility of HLA genotyping for celiac disease; however, early identification and treatment of the disease can prevent short- and long-term complications.

Articles: Articles were selected for review if they included at least 25 subjects and assessed the accuracy of HLA genotyping compared to the small intestine biopsy. A prospective cohort study was selected for review. The following study was critically appraised: Hadithi M, von Blomberg ME, Crusius BA, et al. Accuracy of serologic tests and HLA-DQ typing for diagnosing celiac disease. *Ann Intern Med* 2007; 147:294-302. See [Evidence Table](#)

The use of HLA testing for celiac disease does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Micro Array for Evaluation of Intellectual Disability

BACKGROUND

Intellectual disability, also termed mental retardation or cognitive disability, affects approximately 1-3% of the general population and is defined as a significant impairment in cognitive and adaptive functions, with the age of onset before 18 years. It is a serious and lifelong condition that presents significant challenges to families and to public health. Determining the specific etiology of intellectual disability may help to provide answers related to prognosis, recurrence risk, and treatment.

Intellectual disability can be caused by anything that damages or interferes with the growth or maturation of the brain; however, genetic (chromosomal) abnormalities are one of the main causes of intellectual disability (Galasso 2010, Sagoo 2009).

Chromosomal abnormalities are deletions and duplications of genomic material and are commonly referred to as copy number variations. Conventional methods for detecting these abnormalities include karyotyping and florescent in situ hybridization (FISH). Karyotyping involves visualizing the chromosome for large gains or losses in chromosomal material and is generally the first step in cytogenetic analysis. Karyotyping can detect chromosomal abnormalities such as deletions, duplications, inversions, and translocations across the entire genome; however, it lacks the resolution necessary to detect abnormalities smaller than 3-5 megabases (Mb; 3-5 million base pairs).

FISH uses florescent-labeled chromosome-specific probes to detect chromosomal abnormalities. FISH can detect submicroscopic abnormalities and is often used in situations where the karyotype is normal, but there is a high clinical suspicion of a deletion syndrome. However, FISH is a targeted method and requires prior knowledge of the chromosome region(s) of interest to request the appropriate FISH test. Additionally, FISH can only screen a limited number of genomic regions at a time (Bremann 2009, Fruhman 2010, Galasso 2010, Gropman 2010).

Array comparative genomic hybridization (aCGH) is a more recent technology used to identify copy number variations by comparing patient DNA with reference DNA. It is currently used as an adjunct to conventional methods. There are two types of aCGH: targeted and whole-genome. Targeted arrays are designed to interrogate areas of the genome with known clinically significant abnormalities. Whole genome arrays provide high resolution coverage of the

entire genome. This can lead to the discovery of new copy number variations. Compared to conventional methods, aCGH has a higher resolution and is able to simultaneously detect copy number variations in multiple regions of the genome. Additionally, unlike FISH, knowledge of the chromosome region(s) of interest does not need to be determined in advance because a single array assay detects all genomic variants represented on the array. Array CGH is not without limitations. It cannot detect totally balanced translocations or inversions; it performs suboptimally for polyploidy; and has not been optimized for prenatal diagnosis of point mutations.

Because aCGH cannot identify the exact location of a duplicated chromosome, further testing with karyotype or FISH may be necessary. Another limitation is the potential to identify novel copy number variants with unknown clinical significance (Fruhman 2010, Moeschler 2008).

Array CGH is a laboratory-developed test and is commercially available from several different laboratories.

Laboratory-developed tests are licensed under the Clinical Laboratory Improvement Amendments (CLIA) and do not require clearance from the FDA.

Date: 07/09/2018 MTAC REVIEW***Chromosomal microarray for Intellectual Disability (ID)/ Developmental delay (DD)*****BACKGROUND**

Intellectual disability is a disorder marked by deficits in intellectual and adaptive functioning and starts before 18 years of age. Its management requires early diagnosis and extensive supports. Intellectual disability is caused by any conditions disrupting brain development. Of these conditions, genetic abnormalities are the most common known etiologies (Rauch et al., 2012) with Down syndrome being the leading cause. Conventional cytogenetics (karyotype analysis and fluorescence in situ hybridization (FISH)) can identify the cause but detect less than 10% of chromosomal abnormalities in patients with intellectual disability (ID) or developmental delay (DD) (Shaffer, Beaudet, et al., 2007; Shaffer, Bejjani, et al., 2007). Chromosomal microarray analysis (CMA) has become the primary test for most patients with intellectual disability (Miller et al., 2010). CMA includes array-based comparative genomic hybridization (aCGH) or single nucleotide polymorphism (SNP) microarray analysis.

Array-based comparative genomic hybridization (aCGH), also known as oligonucleotide array comparative genomic hybridization utilizes both patient and control genomes. These DNAs are marked with fluorescent dyes and applied to the microarray. This step is followed by hybridization. Hybridization occurs when patient and control DNAs compete to attach to the microarray which is comprised of thousands of DNA segments (bacterial artificial chromosome clones of > 10 kilobases or oligonucleotides of 50–70 base pairs). Fluorescent signals are assessed by a scanner and a computer analyzes the data and generates a plot. This results in the identification of copy number changes (Theisen et al., 2008(Shaffer et al., 2008)). It is believed that the aCGH concurrently detects copy number variants (CNVs) (deletions, duplications), and/or amplifications across the genome. However, the array-based comparative genomic hybridization cannot detect low-level mosaicism or balanced chromosomal rearrangements (Brady & Vermeesch, 2012). The results of the CMA are interpreted as benign with no impact on phenotype, or pathogenic/clinical significant, or uncertain clinical significance. In the latter category, samples from parents are required for assessment of the clinical significance (Miller et al., 2010; Paciorkowski & Fang, 2009). If the CMA does not detect a cause, whole exome sequencing (WES) may be performed. Single nucleotide polymorphism (SNP) arrays is a variation of DNA sequence that occurs when there is a discrepancy between a single nucleotide and a reference sequence in the same person. Single nucleotide polymorphism is used as the probes. Only the patient sample is hybridized onto the array(Das & Tan, 2013). SNP can detect copy number changes, uniparental disomy, consanguinity, and balanced translocations (Conlin et al., 2010; Schaaf, Wiszniewska, & Beaudet, 2011; Wiszniewska et al., 2014). No FDA regulatory information was found on FDA website on March 12, 2018. However, genetic tests are controlled under the Clinical Laboratory Improvement Amendments (CLIA). The technology is being assessed for the first time on Medical Technology Assessment Committee (MTAC).

Evidence Conclusion:**Conclusion:**

- **Analytic validity:** Four studies were reviewed and showed high sensitivity and specificity with high concordance in comparison to FISH or karyotyping. This suggests that chromosomal microarray can accurately detect copy number variants in children and adolescents with developmental delay or intellectual disability. The studies were retrospective in design or case series resulting in low evidence.
- **Clinical validity:** Nine studies (please refer to “other studies table” and table 2) in addition to those included in Milliman review (evidence table 1) were evaluated. In children and adolescents with unexplained developmental delay or intellectual disability, chromosomal microarray (aCGH) diagnosed genomic alterations that were not detected by conventional cytogenetic tests including karyotype or FISH. This suggests that the

detection rate of chromosomal microarray is higher than conventional cytogenetic tests. However, the studies reviewed were case series or retrospective chart review resulting in low evidence.

- **Clinical utility:** Two studies (please refer to “other studies table” and table 2) in addition to those included in Milliman review (evidence table 1) were evaluated. The clinical utility revolved around referrals to specialists, recommendation for screening of other anomalies, provision of recurrent risk for affected subsequent pregnancies, and avoidance of unnecessary testing. However, the studies were surveys and retrospective review with small sample size resulting in low evidence.
- Milliman Care guidelines indicated that there is a net benefit in evaluating children and adolescents with intellectual disability with chromosomal microarray analysis (CMA). The use of CMA to detect copy number variants affects medical management and this includes referrals to specialists, treatment intervention for special findings, reduction of unnecessary procedures, and screening for associated anomalies. However, the evidence is of low certainty.

The use of Chromosomal microarray for Intellectual Disability (ID)/ Developmental delay (DD) meets the *Kaiser Permanente Medical Technology Assessment Criteria*.

04/18/2011: MTAC REVIEW

Array Comparative Genomic Hybridization (aCGH)

Evidence Conclusion: Analytic validity - The BCBS review identified several studies that evaluated the sensitivity of aCGH. The sensitivity of aCGH testing compared to conventional methods (karyotype and/or FISH) ranged from 73% to 100%. As false-positive rates were inconsistently reported, specificity could not be determined (BCBS 2009). Clinical validity - No studies were identified that evaluated the impact of conventional methods or aCGH on patient outcomes other than diagnostic yield. Results from the BCBS review suggest that diagnostic yield in patients with intellectual disability ranged from 5 to 16.7%, which represents a significant improvement compared to conventional methods. The number needed to test by aCGH to detect one clinically relevant abnormality ranged from 25 to 6 depending on the diagnostic yield. Limitations of these studies include: different aCGH resolution, patient selection criteria ranged from none to stringent criteria, and three different types of arrays were used (targeted, whole-genome, and those that combined targeted and whole-genome arrays) (BCBS 2009).

Diagnostic yield ¹ of aCGH, karyotype, and FISH			
	aCGH	FISH	karyotype
	4-7%	5-6%	
Diagnostic yield	(In those negative by karyotype and FISH)	(In those negative by karyotype)	3-5%

¹Estimates from Stankiewicz 2007.

Clinical utility- The BCBS review included two small studies with a high risk of bias and found that there was insufficient evidence to determine the clinical utility of aCGH testing (BCBS 2009).

Conclusion:

1. Analytic validity: There is fair evidence that aCGH testing had good sensitivity compared to conventional methods; however, there is insufficient evidence to determine the specificity or reproducibility of this test.
2. Clinical validity: There is fair evidence that aCGH increases diagnostic yield over conventional methods; however, this is an intermediate outcome.
3. Clinical utility: There is insufficient evidence that patients managed with the genetic test had better outcomes than patients managed without the genetic test.

Articles: In 2009, Blue Cross and Blue Shield (BCBS) evaluated the use of aCGH for the genetic evaluation of patients with developmental delay/ mental retardation. Studies were selected for review if they were published after the 2009 review and did not support the BCBS recommendations. No studies were identified that would change the BCBS recommendations. The following review was critically appraised: Blue Cross and Blue Shield Association.

Special report: aCGH for the genetic evaluation of patients with developmental delay/mental retardation or autism spectrum disorder. Assessment Program. Volume 23, No. 10. April 2009.

The use of Array Comparative Genomic Hybridization (aCGH) for the genetic evaluation of patients with intellectual disabilities does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Risk Prognosticator Test**BREVAGen****BACKGROUND**

According to the American Cancer Society, breast cancer is the second leading cause of death in women in the United States after lung cancer. Current methods of assessing breast cancer risk include the Breast Cancer Risk Assessment Tool (BCRAT) otherwise known as the Gail model. This model incorporates individual risk factors such as basic demographic information, reproductive history and medical history. Recent genome wide association studies have identified several single nucleotide polymorphisms (SNPs) associated with an increased risk of breast cancer leading to an additional dimension and understanding of risk (Easton, Pooley et al. 2007; Stacey, Manolescu et al. 2007; Stacey, Manolescu et al. 2008). The BREVAGen™ (Phenogen Sciences, Inc., Charlotte, NC) is a risk stratification test for sporadic breast cancer. Intended for use as an adjunct to the Gail model, the test consists of two parts, the first, a series of questions to determine clinical risk and the second, a buccal swab to analyze specific genetic markers. The latter part of the test, includes a panel of seven SNPs associated with breast cancer risk and does not include either of the BRCA mutations. Ultimately, a patient's risk is calculated by multiplying the product of the individual SNP risks by the Gail model risk. According to the BREVAGen™ website, the test is only suitable for women of European descent aged 35 years or older. No test combining the results of SNP analysis with clinical factors to predict breast cancer risk has been approved or cleared by the U.S. Food and Drug Administration (FDA). BREVAGen™ is offered as a laboratory developed tests and only requires oversight under the Clinical Laboratory Improvement Amendments of 1988 (CLIA). The development and use of this laboratory developed test is restricted to laboratories certified as high complexity under CLIA. Under the current regulatory program, CLIA requires that laboratories demonstrate quality systems which includes validation and proficiency testing.

12/16/2013: MTAC REVIEW**BREVAGen****Evidence Conclusion:**

Conclusion: There is no evidence to determine the analytic validity of the BREVAGen™. There is some evidence to suggest that the addition of the BREVAGen™ panel is superior in determining breast cancer risk compared to Gail score alone. There is no evidence to determine the clinical utility of the BREVAGen™.

Articles: A search of PubMed was completed for the period through November 2013 for studies on the accuracy of BREVAGen™ for detecting the absence or presence of certain common genetic variations associated with an increased risk for developing breast cancer. The search strategy used the terms BREVAGen, Breast Cancer Risk Tool, Gail Model, genetic risk, single nucleotide polymorphism, breast cancer, and sporadic with variations. To identify ongoing clinical trials, a search of the National Institute of Health Clinical Trials website was also conducted using the same methodology. Articles were limited to those published in the English language with human subject enrollment. The search was supplemented by an examination of article reference lists in addition to the PubMed related articles function. The literature search for BREVAGen™ revealed one publication that clinically validates the Breast Cancer Risk Model in combination with the genetic and clinical information. The following study was selected for review: Mealiffe ME, Stokowski RP, Rhees BK, et al. Assessment of clinical validity of a breast cancer risk model combining genetic and clinical information. *Journal of the National Cancer Institute*. 2010;102(21):1618-1627. [See Evidence Table](#).

The use of BREVAGen does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Fibroblast Growth Factor Receptor 3 (FGFR3) for Urothelial Carcinoma**BACKGROUND**

It is estimated that approximately 70,530 new cases of bladder cancer will be diagnosed in the United States in 2010, and 14,680 will die of the disease (Jemal 2010). The most commonly occurring form of bladder cancer in the United States is urothelial carcinoma (also known as transitional cell carcinoma). The clinical spectrum of urothelial carcinoma can be divided into 3 categories: non-muscle-invasive, muscle-invasive, and metastatic disease. This review will focus on non-muscle-invasive urothelial cancer (NMIUC), which makes up approximately 75-80% of urothelial carcinoma. NMIUC includes stage Ta (noninvasive papillary carcinoma), Tis (carcinoma in situ), and T1 (tumor invades subepithelial connective tissue) tumors. The standard treatment for stage Ta, Tis, and T1 tumors is transurethral resection of bladder tumor (TURBT). Depending on prognosis adjuvant intravesical chemotherapy or immunotherapy may also be considered. However, despite treatment a significant number of patients will develop recurrence within 1 to 2 years of the initial treatment. Because of the high risk of recurrence careful surveillance is required for patients with NMIUC (Chou 2010, Cheng 2011, NCCN 2011, Pollard 2010). Assessing the risk of progression and recurrence is important for planning therapy. The risk for tumor progression

and recurrence is estimated using factors such as histological grade, stage, depth of invasion, and extent of disease; however, the ability of these factors to predict clinical outcome is limited (Burger 2008, Cheng 2011, NCCN 2011). Recently, it has been suggested that molecular biomarkers such as fibroblast growth factor receptor 3 (FGFR3) may be useful for predicting clinical outcome and planning therapy. FGFR3 regulates cell growth, differentiation, and angiogenesis. More than 70% of low-grade noninvasive papillary urothelial carcinomas harbor FGFR3 mutations. Studies suggest that urothelial carcinomas that harbor FGFR3 mutations may be associated with improved prognosis (Cheng 2011). The CertNDx molecular grading assay (Predictive Biosciences, Inc.) was designed as a tool to be used in conjunction with clinical and histological parameters to aid in the clinical management of NMIUC. This test uses two biomarkers to determine molecular grade. The first biomarker is FGFR3 and the second is Ki-67, which is a marker of cell proliferation (Cheng 2011). Patients with molecular grade 1 (mG1) have FGFR3 mutations and low Ki-67 levels. Patients with molecular grade 2 (mG2) have FGFR3 mutations with high Ki-67 levels or wild-type FGFR3 and low Ki-67 levels. Patients with molecular grade 3 (mG3) are FGFR3 wild-type and have high Ki-67 levels. Patients with molecular grade 1 have favorable prognosis, patients with molecular grade 2 have intermediate prognosis, and patients with molecular grade 3 have poor prognosis.

10/17/2011: MTAC REVIEW

Fibroblast Growth Factor Receptor 3 (FGFR3) for Urothelial Carcinoma

Evidence Conclusion: Analytic validity- No studies were identified that addressed the analytic validity of the CertNDx molecular grading assay. Clinical validity - A recent prospective observational study evaluated the prognostic value of both WHO 1973 and 2004 grading systems, markers CK20, FGFR3, and Ki-67, and molecular grade (combination of FGFR3 and Ki-67) in 221 patients with urothelial carcinoma. In univariate analysis, WHO grade 1973, WHO grade 2004, pathological stage, FGFR3, Ki-67 status, and molecular grade were significantly associated with progression in stage; however, in a multivariate model, only WHO grade 1973 and 2004 remained significantly associated with progression in stage. None of the variables measured were significantly associated with recurrence-free survival (Burger 2008). Another study that included 255 patients with primary urothelial carcinoma also found that the combination of FGFR3 and Ki-67 status was not an independent predictor of recurrence-free or disease-specific survival (van Oers 2007). However, an observational study that included 286 patients with urothelial carcinoma found that in a multivariate analysis, the combination of FGFR3 and Ki-67 status predicted progression, recurrence rate, and disease-specific survival (van Rhijn 2003). Clinical utility - No studies were identified that addressed the clinical utility of the CertNDx molecular grading assay. Conclusion: Analytic validity: No studies were identified that addressed the analytic validity of the CertNDx molecular grading assay. Clinical validity: Results from observational studies regarding the prognostic value of molecular grade (FGFR3/Ki-67) are mixed. Clinical utility: No studies were identified that addressed the clinical utility of the CertNDx molecular grading assay.

Articles: No studies were identified that addressed the analytic validity or clinical utility of the CertNDx molecular grading assay. Several studies were identified that evaluated the clinical validity of the CertNDx molecular grading assay. The most recent study was selected for review. The following study was critically appraised: Burger M, van der Aa MN, van Oers JM, et al. Prediction of progression of non-muscle-invasive bladder cancer by WHO 1973 and 2004 grading and by FGFR3 mutation status: a prospective study. *Eur Urol*. 2008;54:835-843. See [Evidence Table](#).

The use of FGFR3 for urothelial carcinoma does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

MammaPrint Test

BACKGROUND

Breast cancer affects almost 10% of women in western countries and is a major cause of morbidity and mortality. Most patients with lymph node negative disease may be successfully treated with surgery and local irradiation. Those with more aggressive disease may benefit from adjuvant chemotherapy and hormone therapy which could significantly improve their overall and disease-free survival. It is generally accepted that breast cancer patients with the poorer prognosis would gain the most benefits from systemic adjuvant therapy. The use of this adjuvant therapy is thus one of the most critical treatment decisions during the clinical management of breast cancer patients. Currently those with aggressive breast cancer are identified according to a combination of criteria including age, clinical stage and size of the tumor, histological type and grade of cancer, axillary node status, and hormone-receptor status. The ability of these criteria to predict outcome and disease progression is imperfect. Within a given patient population at a specific predicted risk of recurrence, there are some patients whose actual clinical outcome does not match that predicted by the indicators. As a result, some of those who need adjuvant therapy do not receive it, while others may receive unnecessary toxic therapy (Kallioniemi 2002, DeVigier 2002).

To overcome these issues, scientists are attempting to identify more accurate prognostic indicators. Microarray technology is revolutionizing researchers' understanding of cancer biology through the simultaneous study of the expression of tens of thousands of genes. Molecular profiling is the classification of tissue or other specimens for diagnostic, prognostic, and predictive purposes based on multiple gene expression. The potential value of gene expression profiling in assessing the risk of post-surgical breast cancer recurrence has been extensively investigated over the last few years. This has led to important insights in the molecular heterogeneity of cancers by revealing biologically and clinically relevant subtypes of tumors previously indistinguishable by the conventional approaches (Bertucci 2005). Due to the biological heterogeneity of breast cancers, women with the same stage of the disease may vary widely in their response to treatment and prognosis. Several gene expression-based predictors for breast cancer have been developed but have not been used in routine clinical practice. According to researchers, this is mainly due to the limited validation and the limited clinical description of the molecular subtypes. Validation is a major challenge for microarray studies especially those with clinical implications as it requires a large sample size and because the results are influenced by the patient selection and by choice of the methods used to analyze gene expression data (Calza 2006, Hu 2006, Ioannidis 2007). The Amsterdam 70-gene profile (MammaPrint®) was first developed using supervised gene expression profiling analysis of frozen tumor samples from two distinct patient populations. All were <55 years of age and had lymph node negative disease. 44% had distant metastases within 5 years of completing treatment and 56% did not. By comparing the gene expression profile of patients with or without metastases, a signature 70-gene set that correlated with the outcome was identified and internally validated with the same group (van't Veer 2002), and externally validated in two retrospective groups (Van De Vijver 2002 and Buyse 2006, see evidence tables). MammaPrint® from Agendia is a qualitative in vitro diagnostic test service performed in a single laboratory using the gene expression profile of breast cancer tissue samples to assess a patient's risk for distant metastases. The MammaPrint assay uses a panel of the Amsterdam 70-gene profile described above. It is a microarray-based gene expression analysis of RNA extracted from breast tumor tissue. The MammaPrint® analysis is designed to determine the activity of specific genes in a tissue sample compared to a reference standard. Its index ranges from -1.0 to +1.0. Tumor samples with an index above the threshold of +0.4 are classified as low risk, and those with an index equal to or less than the threshold is classified as high risk. The test requires fresh frozen samples which are shipped to the Agendia reference laboratory in the Netherlands. It is performed for breast cancer patients <61 years old, with Stage I invasive breast cancer or Stage II node negative invasive breast cancer, with tumor size <5 cm. It is indicated for use by physicians as a prognostic marker only, along with other clinicopathological factors. It is not intended for diagnosis, or for predicting or detecting response to therapy, or to help select the optimal therapy for patients (FDA).

08/06/2007: MTAC REVIEW

MammaPrint Test

Evidence Conclusion: The identification and validation of gene expression panels to improve risk prediction or treatment outcomes is a multistep process that starts by 1. Identifying the candidate genes (analytic validity), followed by 2. Evaluating the genetic panel associations with risk prediction or treatment outcomes in preliminary performance studies in relevant population (clinical validity), and 3. Determining whether the use of the multigenetic assay would direct the management of patients and improve outcomes (clinical utility). The most reliable method for validation is to derive a prognostic/predictive gene set from a training set and then apply it to a completely independent set, the test set, (Simon 2003, Ioannidis 2006, and Hu 2006). The MammaPrint test was developed based on research performed in the Netherlands Cancer Institute. The training set was derived from a study by van't Veer and colleagues that included 98 women < 55 years of age at diagnosis, with primary breast cancer (34 developed distant metastases within 5 years, 44 were disease free after at least 5 years). All patients were lymph node negative. 5 µg total RNA was isolated from frozen tumor material for each patient. The authors used inkjet-synthesized oligonucleotide microarrays that included 25,000 genes. Following several techniques 5000 genes were selected from the microarray, and then optimized to 70 genes with which a prognosis profile was established. The authors conducted a cross validation and concluded that a classification system based on these 70 genes outperformed all clinical variables in predicting the likelihood of distant metastases within five years. They noted however, that a selection of the patients based on the outcome (distant metastases or disease free in 5 years) was a limitation to the study. The same research team followed the initial study with a validation study (Van De Vijver, 2002) that included 295 women with either lymph node negative or lymph node positive breast cancer. The authors calculated the correlation coefficient of the level of expression of the 70- predictor genes identified in their initial study. They then classified the women with a correlation coefficient > 0.4 as having a good prognosis gene expression signature, and all the others as having a poor prognosis gene expression signature. In this validation set however the authors included 61 patients from the original training group used to derive the RNA expression signature, which could overestimate the relative risk and inflate the discriminating power of the test. The validation study included women < 55 years of age, with small tumors and at stage I or II of the disease which

may not represent the entire spectrum of patients with breast cancer. Adjuvant hormone therapy or chemotherapy or both were given to most of the patients with lymph node positive disease. The Translational Research Network of the Breast International group (TRANSBIG) also conducted an independent validation study of the prognostic signatures in a retrospective series of 302 untreated patients in five European countries. The study included only women node negative early stage breast cancer who had not received systemic adjuvant therapy, and thus may not represent the all patients with breast cancer. Its overall results showed that the 70-gene signature provided prognostic information on time to distant metastases and overall survival independent of the other clinical predictors. In conclusion, the selection of the 70- predictor genes were based on analyses of tumors from patients < 55 years of age with lymph node negative cancer who do not represent all women with breast cancer. The test proved to perform well as an independent prediction tool among the selected women studied. This, however, does not necessarily indicate that it would predict treatment response. To date there are no published studies that show if modification of adjuvant therapy based on this test would improve disease free or overall survival. A large randomized controlled trial (Microarray for Node negative Disease may Avoid Chemotherapy [MINDACT]) that will evaluate the clinical utility of MammaPrint is underway. The trial will directly compare the use of prognostic information provided by the standard clinicopathological criteria vs. the MammaPrint test to decide whether to offer adjuvant chemotherapy to node-negative breast cancer patients. The MINDACT plans to prospectively include 6000 women and follow-them up for a long duration in order to determine 5-year disease free-survival rate.

Articles: The literature search revealed multiple articles on molecular and gene-expression profiling in general. For the MammaPrint test in particular, there was a published study on the training set (to develop or derive the predictive classifier or model) by Van't Veer and colleagues, and three validation studies to evaluate the predictive accuracy of the model (Van De Vijver 2002, Buyse 2006, and Glas 2006). All studies were reviewed but only the first two validation studies were critically appraised, Glas, et al's study was not selected for critical appraisal due to patient overlap with the van De Vijver study. It is to be noted that Van De Vijver, van't Veer, and several other principal authors are named inventors on a patent application for the 70-gene signature used in the studies. All studies also had financial ties to the manufacturer. *The following studies were critically appraised:*

Van De Vijver MJ, He YD, van't Veer LJ, et al. A gene expression signature as a predictor of survival in breast cancer. *N Engl J Med* 2002;347:1999-2009. See [Evidence Table](#). Buyse M, van't Veer, L, Viale G et al on behalf of the TRANSBIG Consortium. Validation and clinical utility of a 70-gene prognostic signature for women with node negative breast cancer. *J Natl Cancer Inst* 2006;98:1183-1192. See [Evidence Table](#).

The use of the MammaPrint test in the treatment of recurring cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

OVA1™ Test for the Assessment of Suspected Ovarian Cancer

BACKGROUND

In the United States, ovarian cancer is the fifth leading cause of all cancer-related death among women. It is estimated that in 2010, there were 21,880 new cases of ovarian cancer and 13,850 deaths from ovarian cancer (Jemal 2010). The incidence of ovarian cancer increases with age with approximately two thirds of cases being diagnosed in women over the age of 55. Women with a family history of ovarian or breast cancer or who are carriers of the BRCA gene mutations are also at increased risk for ovarian cancer (Clarke-Pearson 2009). For patients with early stage disease, survival rates are greater than 90%; however, they are less than 30% for patients with advanced disease. Because of the lack of specific symptoms during the early stage approximately 70% of cases are diagnosed with advanced disease (Carter 2011). The most commonly used tests for the detection of ovarian cancer are transvaginal ultrasound (TVS) and serum CA-125. Recently, the FDA approved the OVA1™ test (Quest Diagnostics, Inc.) to be used as an adjunct to clinical/radiological evaluations for women planning surgery for an adnexal mass. This test measures the serum levels of 5 potential biochemical markers for ovarian cancer (transferrin, apolipoprotein A1, transferrin, CA-125, and β 2-microglobulin). The results of the test are then interpreted using a proprietary algorithm to yield a single score ranging from 0 to 10 to indicate the likelihood that the adnexal mass is benign or malignant. A high probability for malignancy is defined as a score of at least 5.0 in premenopausal women or 4.4 in postmenopausal women. The goal of the OVA1™ test is to provide additional information to aid in identifying patients who should be referred to a gynecologic oncologist for surgery (Carter 2011, Muller 2010). Studies suggest that women who receive their initial surgical care from an experienced gynecologic oncologist have improved outcomes and greater overall survival. Because of this the National Comprehensive Cancer Network (NCCN) recommends that all patients should undergo surgery by an experienced gynecologic oncologist (NCCN 2011). It is important to emphasize that this test is not approved for ovarian cancer screening and is not intended for use as a standalone test. Another limitation of this test is that assay interference may occur in patients with rheumatoid factor levels of at least 250 IU/mL and triglyceride levels greater than 4.5 g/L (Muller 2010). In 2009, the FDA approved the use of this test for women over the age of 18 with an ovarian adnexal mass for which surgery is planned and have not yet been referred to an oncologist.

10/17/2011: MTAC REVIEW**OVA1™ Test for the Assessment of Suspected Ovarian Cancer****Evidence Conclusion:**

Conclusion: Analytic validity: No studies were identified that evaluated analytic validity of the OVA1™ test. Clinical validity: Results from a recent observational study suggest that the when added to physician assessment or substituted for CA 125, the OVA1™ test increased the sensitivity and negative predictive value of these assessments but decrease the specificity and positive predictive value. Clinical utility: No studies were identified that evaluated the clinical utility of the OVA1™ test.

Articles: No studies were identified that assessed the analytic validity or clinical utility of the OVA1™ test. Two studies were identified that addressed the clinical validity of the OVA1™ test. Both of these studies were selected for review. The following studies were selected for critical appraisal: Ueland FR, Desimone CP, Seamon LG, et al. Effectiveness of a multivariate index assay in the preoperative assessment of ovarian tumors. *Obstet Gynecol* 2011; 117:1289-1297. See [Evidence Table](#). Ware Miller R, Smith A, DeSimone CP, et al. Performance of the American College of Obstetricians and Gynecologists' ovarian tumor referral guidelines with a multivariate index assay. *Obstet Gynecol*. 2011; 117:1298-1306. See [Evidence Table](#).

The use of OVA1 for ovarian tumors does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Hayes Review**SelectMDx for Prostate Cancer (MDxHealth Inc.)**

According to the testing laboratory, the SelectMDx test is a noninvasive, urine-based molecular screening test that, when combined with patient clinical risk factors, can aid physicians in determining if a patient is at higher risk (defined by laboratory as detecting GS \geq 7 prostate cancer upon biopsy) or lower risk for prostate cancer and can avoid biopsy (MDxHealth, 2019a). The test is intended for men who have not been previously diagnosed with prostate cancer. The SelectMDx test requires a first void post-digital rectal examination (DRE) urine sample, which is analyzed for the mRNA level of 2 cancer-related biomarkers, DLX1 and HOXC6 (MDxHealth, 2016; MDxHealth, 2019b).

Hayes Rating: D2

For use of the SelectMDx for Prostate Cancer test to aid physicians in determining if a patient is at higher risk (defined by laboratory as detecting Gleason score (GS) \geq 7 prostate cancer upon biopsy) or lower risk for prostate cancer and can avoid biopsy.

Conclusion: There is insufficient evidence supporting use of the SelectMDx test. Additional studies are needed to demonstrate the clinical validity and, ultimately, clinical utility of the test and whether the test results would improve patient management outcomes, including avoiding unnecessary prostate biopsies.

Thyroid Nodule Gene Expression Testing (Afirma)**BACKGROUND**

Thyroid nodules are very common; they are clinically identified in 5-7% of the population, and incidentally on ultrasonography in up to 50% of women and 20% of men over the age of 50. The thyroid nodules are typically benign, but 5-15% prove to be malignant. It is thus recommended that any identified nodule measuring one centimeter or more in diameter be diagnostically evaluated. Thyroid fine needle aspiration (FNA) biopsy is the most widely used method for clinical evaluation of a suspicious thyroid nodule. FNA is a safe and simple outpatient procedure that yields cellular material suitable for cytological analysis. However, 15-30% of the biopsied nodules has indeterminate cytology and cannot be conclusively diagnosed by FNA biopsy alone. Most patients with indeterminate lesions (defined in the Bethesda System as Atypia of Undetermined Significance or Follicular Lesion of Undetermined Significance, suspicious for Follicular or Hurthle Cell neoplasm and suspicious for malignancy) are referred to surgery. Currently, surgery is performed for both diagnostic and therapeutic purposes in these patients with indeterminate aspirates. Surgery has high operative efficacy in removal of thyroid cancer, however approximately three-quarters of the nodules with indeterminate FNA cytology are ultimately found to be benign on final surgical pathology. Thus, a large proportion of patients with indeterminate nodules may undergo unnecessary partial or complete thyroidectomy with its potential surgical complications and risk of long-term morbidity (Alexander 2012, Duick 2012, Walsh 2012, Ali 2013). In an attempt to preoperatively classify the indeterminate thyroid nodules

different novel diagnostic tests and molecular markers have been investigated. These include immunohistochemistry, mutation and gene rearrangement testing, and gene expression and microarray analysis. Each has its performance characteristics and diagnostic values. Ideally a molecular marker or panel of markers would be accurate in differentiating benign from malignant in any lesion that is considered suspicious or indeterminate. It should be simple to use, reproducible by all institutions, and cost-effective. Genetic markers associated with malignancy such as mutation markers (e.g. BRAF, RAS) and gene rearrangements (e.g. RET/PTC and PAX8-PPAry) have high specificity and positive predictive values; and when detected they can “rule in” the diagnosis of thyroid cancer. However, they have limited sensitivity and negative predictive values as they fail to detect a large proportion of malignant samples that do not contain one of the mutations or rearrangements being tested, i.e. mutation or rearrangement markers cannot ‘rule out’ malignancy when not detected (Alexander 2012, Kouniavsky 2012, Ward 2013). Microarray techniques seek to identify patterns of expressed RNA in the human genome that are predictive of benign or malignant thyroid disease. Unlike single gene mutations or rearrangements, microarray diagnostic tests involve tens to hundreds of expressed genes. The currently available diagnostic microarray for use in thyroid nodule analysis is the Afirma Gene Expression Classifier (GEC) recently developed by Veracyte, Inc. It is a genomic test designed with the intention of preoperative identification of benign thyroid nodules in patients with indeterminate FNA cytopathological results. The test assesses gene expression from mRNA isolated from thyroid FNA samples by comparing the mRNA expression detected in a thyroid FNA against a panel of 167 molecular genes. It uses a multidimensional algorithm to identify the thyroid FNA samples with a benign gene expression pattern (Alexander 2012, Kim 2012, Ward 2013). Afirma GEC is commercially owned by Veracyte Corporation; South San Francisco, California and is offered through a sole source, Clinical Laboratory Improvement Amendments (CLIA), a certified reference laboratory. Afirma CEC analysis is indicated only for nodules with indeterminate cytology, and is not performed on cytologically benign, malignant, or nondiagnostic (insufficient FNA samples) nodules. The assay classifies nodule as either benign or suspicious for malignancy. With a preoperative identification of a nodule that is benign rather than malignant, observation or ultrasound follow-up could be recommended instead of thyroid surgery, i.e. potentially avoids unnecessary surgery (Alexander 2012, Duick 2012, Ward 2013).

10/21/2013: MTAC REVIEW

Thyroid Nodule Gene Expression Testing (Afirma)

Evidence Conclusion: Analytic validity Evaluating the analytic performance of Afirma GEC includes studying the stability of RNA in FNAs during collection, storage, and shipment; reproducibility of the test; and its analytic sensitivity and specificity under various conditions e.g. interference of the assay with bloody FNA and genomic DNA. The literature search revealed one study (Walsh and colleagues, 2012) that evaluated the analytic performance of Afirma GEC in a number of sub studies. The investigators obtained prospective FNA samples aspirated in vivo from 43 patients from outpatient clinics, preoperatively, or immediately after surgical excision. The samples were placed in FNAProtect preservative solution and shipped chilled or frozen, then stored at -80°C upon receipt. The RNA was extracted, and its yield examined for quantity and quality using positive (tissue lysate) and negative (water) as controls. Three different lots of controls were tested over several weeks of independent runs by 3 different operators to determine reliability of the test. Multiple lots of benign and malignant total RNA were manufactured and used as process controls to determine the analytic sensitivity of the test using different RNA input quantity and under different dilution of malignant FNA content. These studies indicated tolerance to variation in RNA input across a range of 5-25 ng. as well as dilution of malignant FNA material down to 20%. Analytic specificity of the test using malignant samples mixed with blood (up to 83%) and genomic DNA (up to 30%) showed minimal assay interference. However benign FNA samples mixed with relatively high proportions of blood had a potential for yielding false positive results. The authors also examined the stability of RNA in FNAs during collection and shipment and found that RNA content within FNAs preserved in FNAProtect was stable for up to 6 hours at room temperature with no change in RNA yield, and that the FNA storage and shipping temperatures had no significant effect on GEC scores. They also examined the reproducibility of the test and indicated that it was reproducible from extraction through GEC results, including variation across operators, runs, reagent lots, and laboratories. The authors concluded that the analytical performance and reproducibility of the Afirma Gene Expression Classifier was successfully verified. The research was supported by Veracyte Corporation, (the maker of Afirma GEC), and the authors of the study were either employed by or were consultants to the corporation. Clinical validity A perfect test would have high sensitivity and high specificity in correctly detecting or excluding a condition. A molecular diagnostic test with high sensitivity offers a high negative predictive value when the risk of malignancy (ROM) is low and can “rule out” malignancy. Conversely, a test with high specificity offers high positive predictive value and can “rule in” cancer. To be of use in avoiding surgery, a test that better distinguishes benign from malignant nodules needs to have high sensitivity and high negative predictive value. The literature search identified two published studies on the validation of Afirma GEC (Chudova et al, 2010, and Alexander et al. 2012); both funded by Veracyte Corporation the maker of Afirma GEC. The more recent and larger validation study by Alexander and colleagues (evidence table 1), was a double-blind prospective multicenter validation study. 4,812

thyroid FNAs were obtained from 3,789 patients. 577 (12%) samples were classified as indeterminate, and less than half (46%) were ultimately selected for GEC analysis. Molecular results were compared to the gold standard of post-surgical histopathology interpreted by a panel of blinded endocrine histopathologists for clinical validation. The overall sensitivity of the Afirma test was 92% with a negative predictive value (NPV) of 93% (95% for atypical or follicular lesions of undetermined significance (AUS/FLUS), 94% for a follicular neoplasm, and 85% for a lesion suspicious for malignancy). It is to be noted that the predictive values of a test vary with the prevalence of the disease in the population studied and may not be generalized to other groups. A better analysis would be the likelihood ratios which are not affected by prevalence. Seven of the 85 (8.2%) overall cancers were diagnosed incorrectly by the GEC as benign (false negative). The authors attributed the false negative results to insufficient RNA in the FNA sample used for GEC. The test had an overall low specificity and positive predictive values (52% and 47% respectively). Atypical or follicular lesions of undetermined significance (AUS/FLUS) accounted for almost 50% of the indeterminate thyroid FNAs samples. 43% of these FNA were reclassified with the GEC as benign and 57% remained in their suspicious category. Other investigators showed that repeat FNAs without a molecular test can also accurately reclassify >50% of the nodules in the AUS/FLUS category as benign (Faquin 2013). The study was conducted to validate the GEC accuracy by comparing it to surgical histopathology, and the authors did not compare its performance to repeat FNA or other immunochemical testing. Clinical utility: The clinical utility of Afirma GEC was evaluated in a retrospective study by Duick and colleagues, 2012, (Evidence table 2). They obtained their data from 21 endocrinology practices in 11 states. The authors conducted a chart review of 368 patients with 395 cytologically indeterminate thyroid nodules that were GEC benign. 7.6% of these patients with Afirma GEC benign nodules underwent surgery and 94.4% were managed nonoperatively. The study did not have a comparison group, but the authors compared the 7.6% surgical rate to a 74% historical rate of diagnostic surgery ($P < 0.001$). The indications for surgery for those with GEC benign results included a large size or rapid growth of the nodules, local pressure symptoms, or the presence of a second suspicious nodule or malignant nodule. The authors explained that these were similar to indications for surgery on nodules with benign FNA cytologically. The study was retrospective, used a historical comparison, and investigated the decision-making of endocrinologists experienced in managing patients with thyroid nodules, which may differ from that made by primary care providers or other specialists. In addition, the authors of the study did not provide data on long-term follow-up of those who were managed by watchful waiting rather than surgery. In conclusion, there is insufficient evidence to determine whether Afirma GEC is more accurate than repeat FNA or immunochemical testing in reclassifying cytologically indeterminate thyroid nodules. There is also insufficient evidence to determine the impact of Afirma GEC on clinical management and net health outcomes in patients with indeterminate thyroid nodules.

Articles: The literature search for gene expression classifier for preoperative identification of benign thyroid nodules with indeterminate fine needle aspiration cytopathology revealed a number of articles on molecular diagnostic tests. Many were reviews, editorials, letters, or were unrelated to the current review. The search identified a study on the analytic validity of the test, two on its clinical validity, and retrospective study on its clinical utility. The following studies were selected for critical appraisal. Alexander EK, Kennedy GC, Baloch ZW, et al. Preoperative diagnosis of benign thyroid nodules with indeterminate cytology. *N Engl J Med*. 2012; 367:705-715. [See Evidence Table](#) Duick DS, Klopper JP, Diggans JC, et al. The impact of benign gene expression classifier test results on the endocrinologist-patient decision to operate on patients with thyroid nodules with indeterminate fine-needle aspiration cytopathology. *Thyroid*. 2012 22:996-1001. [See Evidence Table](#)

The use of does Afirma® Thyroid FNA Analysis (Gene Expression Classifier) for Thyroid Nodules with Indeterminate Fine Needle Aspiration Cytopathology not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

ConfirmMDx for Prostate Cancer

BACKGROUND

Prostate cancer is the second most leading cause of cancer in men around the globe (Fitzmaurice et al., 2017). In the United States, one in six men has a lifetime risk of prostate cancer (Siegel, Ward, Brawley, & Jemal, 2011). Prostate cancer screening is subject to controversy due to overdiagnosis, overtreatment, and harms. Major guidelines highlight the importance of informed decision-making. Despite the controversy, prostate specific antigen (PSA) and or digital rectal examination (DRE) can be performed.

After undetermined or abnormal results are reported on prostate cancer screening, more tests such as prostate biopsy is indicated for prostate cancer diagnosis. A high proportion (62%) of initial biopsies are negative and up to 43% will have second/repeat biopsies. Of these repeat biopsies, 26% – 35% will be diagnosed with prostate cancer (Auprich et al., 2012). False negative results are non-negligible since biopsy can miss cancer (Bhindi et al., 2017). In addition, prostate biopsies may result in several complications. As a result, it is crucial to find other ways to avoid or decrease repeat biopsies and predict with accuracy prostate cancer in patients with negative initial biopsies.

ConfirmMDx is an assay that evaluates molecular alterations of three genes to detect prostate cancer.

The following description of the test is from the manufacturer website (<https://mdxhealth.com/confirmmdx-physician/>). ConfirmMDx is a tissue test to enhance the detection of previously negative biopsy patients at high risk for clinically significant prostate cancer. It rules out patients with no cancer and prevent them from unnecessary repeat biopsies and screening procedures, thus alleviating stress and reduce complications. According to the manufacturer, ConfirmMDx is believed to be the most significant predictor of patient outcome among all currently available clinical factors.

ConfirmMDx uses methylation-specific PCR (MSP) and epigenetic biomarkers to detect prostate cancer. The MSP, unlike histopathology, can detect DNA methylation changes (molecular alterations) in tissues surrounding cancer foci. This epigenetic effect is the molecular mechanism by which MSP detects occult prostate cancer in men with negative initial biopsy. ConfirmMDx measures DNA methylation of 3 genes including GSTP1, APC, and RASSF1. In patients with negative prostate biopsies results, the test can enhance accuracy for predicting repeat biopsy outcome in comparison to the standard risk factors (Waterhouse et al., 2019). The test can also indicate the likelihood of detecting Gleason score ≤ 6 (low grade) and ≥ 7 (high grade) prostate cancer upon repeat biopsy. Patient report indicates if DNA methylation is positive, the likelihood of detecting prostate cancer, probability of detecting Gleason score ≤ 6 and ≥ 7 prostate cancer on repeat biopsy (<https://mdxhealth.com/wp-content/uploads/2020/07/MDX-C152-ConfirmMDx-Case-Study-1-v3.pdf>).

The test is indicated when there is a need to perform repeat biopsy on patients with initial negative biopsy result (benign, high-grade prostatic intraepithelial neoplasia (HGPIN), or atypical small acinar proliferation (ASAP)) within the past 24 months and high-risk clinical factors for occult prostate cancer. The results of the test should be interpreted in addition to clinical and other laboratory data.

Eligible patients include those with the following biopsy results:

- Negative/benign
- HGPIN (high-grade prostatic intraepithelial neoplasia)
- Atypia (atypical glands suspicious for malignancy)
- ASAP (atypical small acinar proliferation)
- PIA (proliferative inflammatory atrophy, or lesion)

07/11/2022: MTAC REVIEW

ConfirmMDx for Prostate Cancer

Evidence Conclusion:

- Analytical validity: Very low-quality study shows that the assay can measure the methylation status of the three genes including GSTP1, APC, and RASSF1.
- Clinical validity: Low quality evidence support ConfirmMDx in ruling out prostate cancer on repeat biopsy.
- Clinical utility: There is insufficient evidence for or against the clinical utility of ConfirmMDx for prostate cancer.
- **Overall, the evidence is insufficient for or against the use of ConfirmMDx.**

Articles: PubMed was searched on 03/29/2022 with the search terms ConfirmMDx OR Episcore OR MDxHealth OR (GSTP1 AND APC AND RASSF1 AND prostate) OR (Epigenetic assay AND prostate cancer) with variations. The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. The search yielded a number of articles. Seven studies were reviewed (1 analytical validity study, 4 clinical validity studies, and 2 clinical utility studies). See [Evidence Table](#).

The use of ConfirmMDx for Prostate Cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Hayes Review

ConfirmMDx for Prostate Cancer (MDxHealth Inc.)

According to the laboratory, ConfirmMDx is for men with a previous histopathologically cancer-negative prostate biopsy within the past 24 months who have clinicopathological risk factors for prostate cancer to (MDxHealth, 2017; MDxHealth, 2018a):

- Identify men at risk for undetected prostate cancer (a false-negative biopsy result).
- Rule out men who are prostate cancer free to prevent unnecessary repeat biopsies and screening procedures, resulting in reduced complications, patient anxiety, and healthcare expenses.

In addition, the ConfirmMDx test result claims to predict the likelihood of (MDxHealth, 2017):

- Detecting Gleason score ≤ 6 prostate cancer on repeat biopsy.
- Detecting Gleason score ≥ 7 prostate cancer on repeat biopsy.

Hayes Rating: D2

For use of ConfirmMDx test, using residual prostate biopsy specimens, to: (1) rule out men who are prostate cancer free; and (2) identify men at risk for undetected prostate cancer by predicting the likelihood of detecting Gleason score ≤ 6 and ≥ 7 prostate cancer on repeat biopsy in men with an initial negative biopsy yet high-risk clinicopathological features suggestive of prostate cancer.

Conclusion: There is positive but insufficient evidence supporting the use of the ConfirmMDx test to help rule-out prostate cancer in repeat biopsy and insufficient evidence for the use of the test to predict the likelihood of Gleason score ≤ 6 prostate cancer and Gleason score ≥ 7 prostate cancer on repeat biopsy. Available studies do not evaluate whether the test results, when used to influence patient repeat biopsy decisions, result in improved patient outcomes in men with high-risk clinicopathological features suggestive of prostate cancer.

Prolaris for Prostate Cancer

BACKGROUND

Prostate cancer is the second most leading cause of cancer in men around the globe (Fitzmaurice et al., 2017). In the United States, one in six men has a lifetime risk of prostate cancer (Siegel, Ward, Brawley, & Jemal, 2011). Its natural history varies and is difficult to predict. Some men have indolent disease that can be safely managed with active surveillance, whereas others have an aggressive cancer and are treated with a variety of therapeutic options. Accurate prediction of disease behavior is critical because radical treatment is associated with high morbidity (J. Cuzick et al., 2012).

Clinical variables including Gleason score, tumor stage, and PSA have been considered at the time of diagnosis to predict disease outcome. However, predictions based on these variables are not accurate, resulting in hesitation among physicians and patients about the best course for initial treatment (J. Cuzick et al., 2012). Tests to make accurate prediction and determine treatment decision are necessary.

Description:

Prolaris is a genetic test that measures the growth of tumor cell. In combination with PSA and Gleason score, the test determines the aggressiveness of prostate cancer. PSA and Gleason only show the progression of prostate cancer. However, when these tests are combined to Prolaris test, the aggressive progression of the cancer over the next ten years is determined. The information on the aggressiveness of cancer is specific to each individual.

Testing process:

The same tissue from the original biopsy is utilized to run the test. Therefore, additional biopsies are not required. The tissue sample is sent to Myriad to determine the aggressiveness of the prostate cancer. After the test is complete, the results are sent back to the provider. The result is comprised of a personalized Prolaris Score and a 10-year prostate cancer mortality risk and the risk of metastasis.

The Prolaris Molecular Score is computed by measuring the expression of 31 cell cycle progression (CCP) genes (measured by qRT-PCR and normalized by 15 housekeeping genes). Most of the scores range between 1-11. The higher the score, the more aggressive the cancer. Over- and under-expression of the 31 CCP genes results in positive and negative CCP score, respectively (Shangguan et al., 2021).

Benefits of Prolaris test:

The benefits are to identify mortality risk, the risk of metastasis, and to help determine the best course of treatment.

Prolaris is supported by NCCN guidelines as a 2A recommendation which is considered standard of care. Prolaris testing is indicated in men who have been diagnosed with localized prostate cancer.

07/11/2022: MTAC REVIEW

PROLARIS FOR PROSTATE CANCER

Evidence Conclusion:

➤ **PROLARIS BIOPSY TEST**

- Low quality evidence shows that CCP testing is reproducible and precise.
- Very low to low quality evidence indicate that CCP & CCR scores may help predict prostate cancer mortality and metastasis. It may help improve risk stratification in men with localized prostate cancer.
- Low quality evidence shows that Prolaris test may influence physician treatment decision.
- Overall, low quality evidence supports Prolaris test to predict prostate cancer related clinical outcomes.

➤ **PROLARIS POST-PROSTATECTOMY**

- The evidence is insufficient for or against the use of Prolaris test in patients with radical prostatectomy.

Articles: PubMed was searched through April 11, 2022 with the search terms (Prolaris OR cell cycle progression OR CCP OR cell cycle risk OR CCR) AND (prostate) with variations. The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. See [Evidence Table](#).

The use of Prolaris Prostate Cancer (Biopsy and Post-Prostatectomy) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

04/20/2015: MTAC REVIEW

DecisionDx - Melanoma

Evidence Conclusion:

DecisionDx - Melanoma

BACKGROUND

Skin cancer is extremely common accounting for nearly half of all cancers in the United States. Melanoma, the most aggressive type of skin cancer, occurs as a result of abnormal melanocytes, most often caused by over- exposure to ultraviolet radiation from the sun. When detected early, cutaneous melanoma can be surgically excised resulting in a 5-year overall survival rate of 91%-97%. Despite these odds, however, the clinical behavior of cutaneous melanoma is highly variable and some melanomas, that appear less risky, will develop into advanced disease and require extensive treatments such as additional surgery, immunotherapy, targeted therapy, chemotherapy and radiation therapy (ACS 2015). As with all cancers, a primary challenge is predicting prognosis. Conventional methods of melanoma staging are characterized by the American Joint Committee on Cancer (AJCC) TNM System. The TNM system specifically refers to Tumor thickness, spread to nearby lymph Nodes, and Metastasis. Based on history and physical exam, as well as, biopsy, imaging and pathology, the TNM system groups patients with melanoma into stages, 0-IV based on the advanced nature of the disease (Balch, Gershenwald et al. 2009). The stage of the melanoma is an estimate of prognosis and will ultimately guide treatment options. Recently, gene expression profiling (GEP) has been proposed for use in cancer management. The technique specifically analyzes the patterns of genetic material contained in tumor cells and has the potential ability to predict clinical outcomes associated with cancer. One such test, the DecisionDx-Melanoma™, developed by Castle Biosciences Inc. (Friendswood, TX), is described to more accurately classify stage I and II melanoma.

Proposed as an adjunct to conventional staging systems, the DecisionDX-Melanoma test includes 31 genes, 28 of which have previously been associated with melanoma and the remaining three, controls (Winnepeninckx, Lazar et al. 2006). The results of the DecisionDx-Melanoma test is further claimed to stratify stage I and II melanomas into one of two classes; class one identifying patients as low risk of metastasis, or class two indicating high risk. The developer claims that the information provided by the DecisionDx-Melanoma test enables physicians to tailor, patient specific, surveillance and treatment plans informing, for example, the intensity of surveillance, need for referral to specialists, evaluation of adjuvant treatments and clinical trial eligibility (CastleBiosciencesInc. 2015).

04/20/2015: MTAC REVIEW

DecisionDx - Melanoma

Evidence Conclusion: The study aimed to develop a prognostic genetic signature based on previous analyses of cutaneous melanoma tumors. To do this, the investigators included 268 archived tissue samples and divided the sample into two cohorts, development (n=164) or validation (n=104). The investigators compared the patient clinical outcomes at five years with the GEP test prediction. Overall, Kaplan-Meier analysis indicated that the five-year disease-free survival (DFS) rates in the validation cohort were 97% and 31% for predicted class 1 and 2, respectively (p<0.0001). These results were comparable to the DFS rated in the development cohort, 100% and 38% for class 1 and class 2, respectively (p<0.0001). The investigators ultimately concluded that in patients with

primary cutaneous melanoma, the GEP signature accurately predicts metastasis risk (Gerami, Cook et al. 2015). [Evidence Table 1] The investigators had the clear intent to develop and validate a GEP for predicting metastatic risk in stage I and II cutaneous melanoma. The patient sample was well defined and the study design, cohort, appeared to be appropriate for the development of the genetic signature. To validate the test, however, the study relied on archived tumor samples with at least five years of follow-up. While this is a sufficiently long time to detect the outcome of interest, and the investigators used an independent sample, a prospective study would be a more appropriate design for validation. With that said, the investigators report that samples were collected at a similar point in the course of the disease, diagnosis, however the diseases progression at diagnosis may have varied between patients and it is not clear if the investigators were blinded to prognostic factors. On a final note, the study was funded by the test manufacturer and at least two of the investigators have financial ties with Castle Biosciences, Inc. Conclusions: There is limited evidence to conclude that the DecisionDx-Melanoma test is valid. There is insufficient evidence to conclude that the DecisionDx-Melanoma test has prognostic accuracy in predicting metastatic risk. There is insufficient evidence to conclude that the DecisionDx-Melanoma test is not harmful to patients. There is insufficient evidence to establish the clinical utility and therapeutic impact of the DecisionDx-Melanoma test.

Articles: The literature search was carried out to identify studies relating to the prognostic value of the DecisionDx-Melanoma test. The search revealed a variety of publications discussing the use of GEP and one publication identifying the genes associated with melanoma progression and prognosis (Winnepeninckx, Lazar et al. 2006). No studies were identified in which the DecisionDX-Melanoma was prospectively analyzed and followed- up in populations with Stage I and II melanoma. A search of the NIH Clinical Trials database identified two manufacturer sponsored prospective studies currently in the enrollment stage. The best, currently available, evidence was a development and validation study published by Castle Biosciences, Inc. The following articles were selected for critical appraisal: Gerami P, Cook RW, Wilkinson J, et al. Development of a prognostic genetic signature to predict the metastatic risk associated with cutaneous melanoma. *Clinical Cancer Research*. 2015;21(1);175-183. See [Evidence Table](#).

The use of DecisionDx-Melanoma does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

OVA1 Assessment for Ovarian Cancer

BACKGROUND

Ovarian cancer is the most lethal gynecological malignant worldwide. The five-year overall survival is over 90% in patients with stage I disease and only 20-40% for stages III and IV. Unfortunately, because of the lack of specific symptoms during the early stage approximately 70% of cases present with an advanced stage disease. Detection of ovarian cancer at an early stage would have a significant impact on reducing mortality, however to date; there is no screening or biomarker test that meets the criteria for a beneficial screening test in asymptomatic women with early ovarian cancer (Carter 2011, Cohen 2014, Leung 2014). Serum CA-125, a high molecular weight glycoprotein, remains the most widely used biomarker for the confirmation of diagnosis and management of ovarian cancer. Serum CA-125 however, is more prominently expressed in patients with late stage serous tumors; it is elevated in 50-60% of women with stage I epithelial ovarian cancer, and in 75-90% of patients with advanced stage disease. Elevated circulating CA-125 has also been documented in uterine fibroids, endometriosis, pregnancy, menstruation, benign ovarian neoplasms, liver cirrhosis, and other malignancies making it a less useful marker for the detection of ovarian cancer (Autelitano 2012, Cohen 2014). Improvements have been made in the preoperative diagnosis of ovarian cancer by combining serum CA-125 concentration with ultrasound score and menopausal status, into a Risk of Malignancy Index (RMI) which was found to outperform CA-125 alone in discriminating between a benign and malignant pelvic mass. Over the past two decades diagnostic triage methods incorporating clinical algorithms, serum biomarkers, imaging, or a combination of these techniques have been investigated to improve its diagnostic efficiency in predicting ovarian malignancy in women with adnexal masses. The Risk of malignancy Algorithm (ROMA) and OVA1 test are two algorithms recently developed for the assessment of malignancy risk in these women. These are not screening tests but are potential tools to further triage women to the appropriate provider once the decision for surgical intervention has been made (Autelitano 2012, Bristow 2013, Cohen 2014). Combining multiple variables or markers in a single biomarker assay (in vitro diagnostic multivariate assay [IVDMIA, or MIA]) has the potential advantage of complementing the information provided by a single-valued index. The inclusion of biomarkers in an IVDMIA requires that they are complementary and collectively outperform a single marker with respect to its intended uses. CA-125 remains the best tumor marker, and the selection of additional biomarkers is based mainly on their ability to detect malignancy in cancer patients with low CA-125 level or to reduce false positive results among non-cancer patients with elevated serum CA-125 levels (Zhang 2012). Ova1™ test (developed by Vermillion and licensed to Quest Diagnostics, Inc.) is the first IVDMIA of protein biomarkers cleared by the FDA to be used as an adjunct to clinical and radiological evaluations for women over the age of 18 who have planned to undergo surgery for an adnexal mass and have not been referred to a gynecologic oncologist. Studies suggest that women who receive their initial surgical care

from an experienced gynecologic oncologist are more likely to have better outcomes including surgical staging, optimal debulking, and improved median and overall-5-year survival. Ova1™ test is a qualitative test that measures the serum levels of 5 potential biochemical markers for ovarian cancer (CA-125, prealbumin, apolipoprotein A-1, β 2-microglobulin, and transferrin). The results of the test are then interpreted using a proprietary algorithm to yield a single score ranging from 0 to 10 to indicate the likelihood that the adnexal mass is benign or malignant. A high probability for malignancy is defined as a score of ≥ 5.0 in premenopausal women or ≥ 4.4 in postmenopausal women. The decision for selecting these cutoff values was made to emphasize the need for high sensitivity to minimize the risk of false negative results for patients who actually have a malignant lesion. A limitation to OVA1™ is that all the included markers with the exception of CA-125 are acute phase reactants that may be nonspecific for ovarian cancer. Another limitation is interference of triglyceride levels greater than 4.5g/L or rheumatoid factor levels more than 250IU/mL with the biomarkers assay (Muller 2010, Carter 2011, Zheng 2012, Leung 2014).

04/20/2015: MTAC REVIEW

OVA1 Assessment for Ovarian Cancer

Evidence Conclusion: The main purpose of adding biomarkers to an established tumors biomarker as CA-125, in a multivariate index assay (MIA), is to achieve a very high sensitivity without sacrificing the specificity. However, the published studies evaluating OVA1™ showed the test improved the sensitivity of the physicians' assessment in predicting ovarian malignancy in women with adnexal masses, but at the cost of reducing the specificity and positive predictive value. The FDA cleared the OVA1™ test based on the results of Ueland and colleagues' study that was reviewed earlier by MTAC in 2011. The study compared the sensitivity, specificity, and predictive values of physician assessment with or without adding the multivariate index assay (MIA) in identifying high-risk ovarian tumors. The study enrolled 590 women (524 evaluable with both MIA and CA-125-II) with a documented ovarian mass on imaging and planned surgery within 3 months of imaging. 53% of the women were enrolled by non-gynecologic oncologists and the rest by gynecological oncologist. The MIA index assay test was performed on preoperative serum samples, and the results were correlated with preoperative physician assessment. There was no specific protocol for the clinical assessment. Using surgical pathology as the gold standard, 161 women were diagnosed with a malignant and 363 with a benign ovarian tumor. The results of the analysis showed that the sensitivity of non-gynecologic oncologists' assessment increased from 72% to 92% with the addition of the MIA test (78% and 99% respectively for gynecologic oncologists). The negative predictive value increased slightly with the addition of the MIA test. On the other hand, the specificity and positive predictive values dropped significantly with the addition of the assay (the specificity was reduced from 83% to 42% for non-gynecologic oncologists and from 75% to 26% for gynecologic oncologists and the positive predictive value dropped from 60% to 36% and from 63% to 43% in the two groups of respectively). The studies published after that pivotal study were conducted mainly by the same group of investigators who either analyzed the results of women enrolled in some or all 44 sites participating in the study. The studies were sponsored by Vermillion Inc., and the investigators had financial ties to the company. The largest and most recent of these studies (Longoria et al 2014) (Evidence table 1) compared the accuracy and predictive values of the multivariate index assay, OVA1™ to clinical assessment, CA-125-II, and the modified American Congress of Obstetricians and Gynecologists (ACOG) guidelines, for the detection of early-stage ovarian cancer in 1,016 women undergoing surgery for an adnexal mass. The authors did not indicate whether the assessors were blinded to the other tests and/or clinical evaluation results. The study did not include women without adnexal masses or with other disorders that may lead to elevated levels of CA-125 or any of the other biomarkers included in the assay. Overall, similar to the Ueland and colleagues' study, as well as the other published studies using MIA test, Longoria, et al's study showed that the addition of OVA1™ to clinical assessment may significantly improve the sensitivity of detecting early-stage ovarian cancer, but at the expense of reducing the specificity, which would result in referral of more patients with benign conditions to gynecologic oncologists for surgery. The overall results of the study show the following: **Comparative performance for evaluable women in all cancer cases (from evidence table 1)**

	Sensitivity %	Specificity %	PPV %	NPV %
OVA1	92.2%	49.4%	37.9%	94.9%
Clinical assessment*	74.5%	86.3%	64.6%	91.0%
OVA1 + clinical assessment	95.3%	44.2%	36.4%	96.6%
CA 125-II	70.6%	89.6%	69.5%	90.1%
Modified ACOG guidelines**	80.0%	76.5%	53.3%	91.9%

*The authors did not clearly explain that clinical assessment included CA125-II for all women

** Included: very elevated CA125 (>67U/mL), ascites, and evidence of abdominal or distant metastasis for premenopausal women.

For postmenopausal women the ACOG criteria were Elevated CA125 (>35 u/mL, nodular or fixed pelvic mass, ascites, and evidence of abdominal or distant metastasis.

The studies had enrolled selected groups of women with adnexal masses who were referred to surgery in multiple centers with no standardized process for data collection or referral practice. The referral pattern was retrospectively analyzed, and the impact of the test on health outcomes was not evaluated. In addition, the studies were funded by Vermillion Inc, the developer of the test, and the principal investigators had financial ties to the company. The performance of OVA1™ was not compared to other risk assessment algorithms as ROMA, ultrasound-based risk assessment models, or other diagnostic tools that may lead to similar sensitivity and superior specificity to OVA1™. Conclusion: The published studies do not provide sufficient evidence to determine the clinical utility and impact of using OVA1™ assay on health outcomes of women with ovarian tumors.

The use of OVA 1 does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Date: 07/09/2018 MTAC REVIEW

Whole Genome/Exome Sequencing for Developmental Delay (DD)/Intellectual Disability (ID)

BACKGROUND

Intellectual disability is a disorder marked by deficits in intellectual and adaptive functioning and starts before 18 years of age. Its management requires early diagnosis and extensive supports. Intellectual disability is caused by any conditions disrupting brain development. Of these conditions, genetic abnormalities are the most commonly known etiologies (Rauch et al., 2012) with Down syndrome being the leading cause. Conventional cytogenetics (karyotype analysis and fluorescence in situ hybridization (FISH)) can identify the cause but they detect less than 10% of chromosomal abnormalities in patients with intellectual disability (ID) or developmental delay (DD) (Shaffer, Beaudet, et al., 2007; Shaffer, Bejjani, et al., 2007). Chromosomal microarray analysis (CMA) has become the primary test for most patients with intellectual disability (Miller et al., 2010). However, if CMA fails to identify the etiology, whole genome/exome sequencing may be considered.

Whole genome sequencing (WGS) is a process that determines the complete DNA sequence of the entire genome. In contrast, whole exome sequencing (WES) determines the DNA sequence of a small part of the genome. The small part which is the coding part of the genome is 1% of the entire genome.

(Biasecker & Green, 2014) Genome and exome sequencing (GES) begins with extraction of DNA from white cells followed by disintegration of DNA and determination of sequences with sequencing instrument. Using computer, the sequences are placed into specific positions in the human genome reference sequence for assessment of similarities and differences. This results in the determination of the specific genotype at each position in the exome or genome. This leads in output file which is filtered for variants that explain the phenotype. Sequencing can be performed on unaffected or affected parents or affected siblings. Clinical GES can detect single-nucleotide substitutions and insertions or deletions of 8 to 10 nucleotides or smaller. However, it is less accurate for other types of genomic variation. GES is indicated in patients with suspicion of mendelian genetic disease. It is also considered when CMA fails to identify the cause of intellectual disability. (Biasecker & Green, 2014)

This review focuses on developmental delay (DD) or intellectual disability (ID).

As this is a laboratory test, no FDA approval is required. Genetic tests are controlled under the Clinical Laboratory Improvement Amendments (CLIA). The technology is being assessed for the first time on Medical Technology Assessment Committee (MTAC).

Evidence Conclusion:

Conclusion:

- **Analytical validity:** Studies assessing analytical validity were scarce. Only two studies reported that the performance of WES/WGS was high. However, the evidence is insufficient to draw conclusion on analytical validity.
- **Clinical validity:** Thirteen studies were evaluated. Most studies have included children with moderate to severe intellectual disability/developmental delay. In most studies, WES or WGS was performed in patients on whom previous genetic evaluations (molecular karyotyping, microarray) failed to diagnose the etiology or were negative. The diagnostic yield ranged from 21% to 60% (including new mutations) suggesting higher detection rate than traditional genetic tests including microarray. Nevertheless, the studies provide low evidence and demonstrate that WES/WGS has high detection rate overall and even in children with undiagnosed or unexplained intellectual disability or developmental delay.
- **Clinical utility:** The evidence on clinical utility is conflicting. More studies are warranted.
- Milliman Care Guidelines was reviewed and indicated that the evidence is poor, or conflicting, or insufficient to assess the net benefit of this test versus harm; additional research is recommended.

The use of Whole Genome/Exome Sequencing for Developmental Delay (DD)/Intellectual Disability (ID) doesn't meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Next Generation Sequencing (NGS) - Broad Spectrum Tumor Molecular profiling

Background

All cancers begin in cells. A normal become cancerous largely because of mutations in their genes. Often many mutations are needed before a cell becomes a cancer cell. Some gene changes may increase production of a protein that makes cells grow and others may result in the production of a misshape leading to a nonfunctional form of a protein that normally repairs cellular damage. Genetic changes that promote cancer may be inherited (germline) or more commonly acquired (somatic) during a person's lifetime, either because of errors that occur as cells divide or from exposure to DNA-damaging carcinogens. There are many types of DNA genetic changes; these may affect just one unit of DNA (a nucleotide) or involve larger stretches of DNA (NIH, American Cancer Society).

Somatic mutations include point mutations, small insertions/deletions, and copy-number alterations that direct therapeutic options. Thus, in some cases, knowledge of the genetic alterations in a cancer patient can help determine a treatment plan as some treatments, particularly targeted therapies, are effective only for people whose cancer cells have specific genetic alterations that cause the cells to grow out of control (Wagle 2011, National Cancer Institute).

In the past decade, investigators have focused on searching for oncogenes and tumor suppressor genes that drive cancer. This is moving systemic cancer treatment away from the paradigm of treating histologically defined disease with cytotoxic chemotherapy, towards the use of molecularly targeted drugs prescribed to selected subsets of patients across multiple tumor types. Theoretically targeted therapies that inhibit the abnormally activated proteins, are more specific to cancer cells, potentially safer and more efficacious than the cytotoxic agents that target cell replication (Frampton 2013, Uzilov 2016, Tournau 2015, Beaubier 2018).

To deliver personalized cancer targeted therapy, it is essential to use diagnostic tests that would accurately and comprehensively characterize the genomic alterations within individual tumors. Several technologies including Sanger sequencing (SGS, the gold standard), PCR, mass spectrometric genotyping, and other tests are currently used for the clinical assessment of a limited number of oncogenic markers. These tests may not perform parallel investigations of multiple targets and cannot address the increasing number and variety of therapeutically relevant genomic alterations that occur in hundreds of cancer related genes with the amount of material obtained from biopsies (Frampton 2013, Rehm 2013, Arsenic 2015, Beaubier 2018).

Next generation sequencing (NGS), is becoming an attractive clinical diagnostic technology to detect most genomic alterations in the therapeutically relevant cancer genes in a single assay. NGS is not a test, but is an umbrella term for massively parallel DNA sequencing technology. The term NGS is used to emphasize the difference from the initial traditional gold standard single gene-based sequencing approaches that involve sequencing of one DNA strand at a time. NGS encompasses a variety of technologies that permit rapid parallel sequencing of millions of DNA segments, up to the entire genomes. These can perform three main levels of analysis: exome sequencing, genome sequencing, and disease targeted gene panels (Frampton 2013, Regier 2018).

A NGS cancer panel involves a complex 2-step process: 1. Wet bench process, which includes the handling of patient samples, extraction of nuclei acid, fragmentation and barcoding, target enrichment, adaptor ligation, library preparation, and generation of sequence reads. 2. Bioinformatics analysis of sequence data. This includes mapping sequence reads to the human reference genome, variant calling, annotation, and reviewing data in the right clinical context. Each of these steps require separate standards (Behjati 2013, Frampton 2013, McCourt 2013, Rehm 2013, American College of Medical Genetics and Genomics).

The number and scope of genes to be tested depend on the purpose of the test. A companion diagnostic test for standard care would require a limited number of genes, whereas NGS-based tests used for stratifying patients require the interrogation of a broader range of genes. Currently, there are several NGS platforms that perform sequencing of millions of small fragments of DNA in parallel. The platforms use different sequencing technologies, and due to the complexity and amount of sequencing data, and concerns about the reliability of the different NGS panels, several working groups (including the College of American Pathologists (CAP) and the American College of Medical Genetics and Genomics [ACMG]) have issued guidelines for NGS clinical testing. The assays or platforms should have a high-test sensitivity as cancer specimens may have a low percentage of tumor cells, i.e.

high level of normal cell contamination. The test should also have a high specificity as a false positive result will have a negative impact on the choice of therapy (Frampton 2013, Kim 2017).

Cancer panel tests are mainly focused on actionable genomic alterations (variants) whose presence may help identify the most promising treatment approach. Different definitions of “actionable variants” have been used by researchers. While the majority defined it as the variant that can be targeted by a currently available drug (either FDA approved, off label use of an FDA approved drug, or a drug under investigation), others expanded the definition to include change in patient management on the prognostic implication or change in risk stratification. It is estimated that as many as one third of actionable changes in tumor analysis may be incorrectly classified as somatic changes. It is thus recommended to use matched tumor-normal DNA for genomic analysis to accurately identify and interpret actionable somatic and genetic changes that would have an important impact on the diagnosis and therapeutic management of cancer patients (Jones 2015, Kim 2017, Tan 2017, Regier 2018).

In recent years, several academic centers have adopted the use of NGS panels at the point of care to study cancer genomics and personalize patient care (precision oncology). However, the application of the NGS technology in the clinical context as a routine test to support the selection of therapy for cancer patients has its challenges. Most of cancer specimens are formalin-fixed paraffin embedded tissue (FFPE) which can degrade the DNA and RNA. This would require the application of robust nucleic acid extraction and sequencing library construction. In addition, many samples available for testing contain limited amount of tissue and in turn a limited amount of nucleic acid. The assays also need to be sensitive enough to detect gene alterations in specimens with a low tumor percentage. The use of the technology requires an infrastructure e.g. computer capacity and storage, as well as the application of rigorous statistical and analytical approaches to validate the accuracy of NGS technology for use in the clinical setting. An additional reported challenge is the personnel expertise required to comprehensively analyze and interpret the subsequent data, as well as skillfully extract and manage the clinically important information from the volume of data obtained. NGS has the potential to uncover a significant quantity of complex clinically and non-clinically actionable results with wide ranging implications for the patients and their families. Targeted therapies are limited by several factors including the availability, effectiveness and /or specificity of molecular inhibitor (targeted drug therapies) based on patients' genetic information, heterogeneity the disease, resistance to a targeted therapy, and access to the treatment. It has also been reported that targeted therapies may be successful for some tumor types but not for others (Behjati 2013, Frampton 2013, Radovich 2016, Beaubier 2018).

FoundationOne CDx™ (F1CDx, Foundation Medicine, Inc.) a NGS test, was granted marketing approval by the US Food and Drug Administration (FDA) on November 30, 2017 to detect genetic mutations in 324 genes and two genomic signatures in any solid tumor type. The test can also identify which patients with non-small cell lung cancer (NSCLC), melanoma, breast cancer, colorectal cancer, or ovarian cancer may benefit from 15 different FDA-approved targeted treatment options (FDA website).

01/14/2019: MTAC Review

Evidence Conclusion:

- As indicated earlier in the report, it is difficult to set standards for assuring the analytical validity of NGS tests due to the amount and complexity of cancer genome sequencing and the different NGS technologies used. In general, however, the published validation studies suggest that NGS tests may have a high analytic validity, and lower clinical validity.
- There is insufficient evidence from published randomized clinical trials to determine that incorporating NGS into cancer care improves patient outcomes, such as treatment response and disease-free survival, or to support the use of molecularly targeted agents outside their indications based on tumor molecular profiling.
- More RCTs are needed to provide evidence on the utility of cancer genomics in clinical practice.

Articles: The literature search identified over 1,000 articles on NGS; the great majority of which were reviews, abstracts or articles not related to the current review. The search was filtered and narrowed down according the inclusion criteria based on PICO. Selected studies comparing the performance of NGS versus Sanger sequencing as well as randomized or nonrandomized studies evaluating the effectiveness and safety of applying the technology to cancer patients were included in the review. See [Evidence Table](#)

The use of Broad-Spectrum Tumor Molecular Profiling - Next Generation Sequencing (NGS) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Decipher Prostate Genomic Classifier

10/10/2022: MTAC Review

Evidence Conclusion:**Decipher genomic testing using biopsy specimen**

- There is insufficient evidence for or against the analytical validity and clinical utility of Decipher test. Low quality evidence supports the clinical validity of Decipher test. Overall, the evidence is insufficient for or against the use of Decipher genomic testing using biopsy specimen.

Decipher genomic testing using radical prostatectomy specimen

- Analytical validity: There is a lack of studies.
- Clinical validity: Low quality evidence from retrospective studies demonstrate that the Decipher Genomic Classifier is consistently superior in its prognostic and discriminatory ability in comparison to clinicopathologic variables for metastasis & prostate cancer-specific mortality.
- Clinical utility: Low quality evidence supports the clinical utility of Decipher testing. Decipher may influence treatment recommendations change in post prostatectomy patients with adverse pathologic characteristics.
- Overall, low quality evidence supports the use of Decipher genomic testing using radical prostatectomy specimens.

Articles: PubMed was searched through September 2022 with the search terms (Decipher OR genomic classifier OR 22-gene) AND (prostate). The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. The search yielded several studies. See [Evidence Table](#).

The use of Decipher Prostate Genomic Classifier does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

***Note:** Codes listed in the criteria above may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

^{MDCRPC} Medical Director Clinical Review and Policy Committee

^{MPC} Medical Policy Committee

Revision History	Description
05/11/2015	Array-Based Comparative Genomic Hybridization (aCGH): Removed MCG and reactivated GHC insufficient evidence criteria
06/02/2015	MPC approved MTAC recommendation of insufficient evidence for OVA1 & DecisionDx-Melanoma Testing
06/04/2015	Added Cologuard
06/30/2015	Added LCD link for cytogenetic studies
08/27/2015	Add LCD for CYP Genes
09/08/2015	Revised LCD CYP2C19 (CPT-81225), CYP2D6 (CPT-81226), CYP2C9(CPT81227), and VKORC1(CPT-81355) Genetic Testing (L36311), Cytogenetic Studies L34067

10/13/2015	Added Medicare molecular testing LCD
10/27/2015	Added codes that do not need review
11/18/2015	Added Medicare MoIDX links
03/01/2016	Discontinue review for Factor II & V
08/30/2016	Combined Risk Prognosticator Test to Genetic Screening criteria
09/06/2016	Added Prostate Cancer Gene Expression Testing- Oncotype DX MCG A-0712 to criteria
10/24/2016	Changed Veristrat to match Pharmacogenomic policy
11/01/2016	MPC approved to accept the genetic testing recommendations from the MCG 20 th edition as outlined
01/23/2017	Added LCD 36544 & LCD 36186
04/04/2017	Added MTAC Review
05/16/2017	Added Percepta LCD
08/28/2017	Added ThyGeNEXT Oncogene Panel
09/18/2017	HFE gene – review no longer required CPT 81256
10/03/2017	Adopted MCG 21 st ed. guidelines: A-0910, A-0909, A-0916, A-0907, A-0904, A-0908, A-0918, A-0926
10/11/2017	Removed MCG A-0917
12/05/2017	Adopted clinical criteria for Cystic Fibrosis testing
02/06/2018	MPC approved to adopt criteria for Decision Dx- Choroidal/Uveal Melanoma
03/26/2018	Added Decision Memo for Next Generation Sequencing (NGS) for Medicare Beneficiaries with Advanced Cancer
04/25/2018	Added language to BRAF testing
05/03/2018	Updated name changes with the MCG 22 nd Edition
06/05/2018	MPC approved to adopt MCG* A-0823 and MCG* A-0957
08/07/2018	Added MTAC review from 7/9/18 for Microarray and Whole Exome for DD/ID
08/29/2018	Move code 81301 to no review at this time.
10/02/2018	Updated Micro Array for Evaluation of Intellectual Disability criteria
12/04/2018	MPC approved to adopt MCG* A-0598 Diabetes Mellitus (Maturity-Onset Diabetes of the Young)
01/08/2019	MPC approved to adopt criteria for Whole Exome Sequencing
02/05/2019	MPC approved to adopt policy of no coverage for Next Generation Sequencing (NGS) - Broad Spectrum Tumor Molecular profiling; added 01/2019 MTAC review
02/26/2019	Mammaprint: Send all cases to MD for review until criteria has been developed
04/02/2019	MPC approved to adopt criteria for Mammaprint
12/03/2019	MPC approved a non-coverage policy for Donor-derived cell-free DNA testing (e.g., Allosure)
04/07/2020	MPC approved non-coverage policy for 81540 CancerTYPE ID
04/29/2020	Removed code 81528
06/02/2020	Added section: "Preferred Lab for Genetic Testing for Kaiser Permanente non-Medicare enrollees.". Requires 60-day notice, effective date 10/01/2020. Moved CPT codes 81402, 81403 and 81270 under Applicable Codes section that do not need review.
06/23/2020	Added CPT codes 81277, 81307, 81308, 81309, 81522, 81542, 81552, 875630087U, 0080U, 0081U, 0088U, 0089U, 0090U, 0091U, 0092U, 0105U, 0106U, 0107U, 0108U, 0109U, 0110U, 0111U, 0112U, 0113U, 0114U, 0115U, 0116U, 0117U, 0118U, 0119U, 0120U, 0121U, 0122U, 0123U, 0124U, 0125U, 0126U, 0127U, 0128U, 0129U, 0130U, 0131U, 0132U, 0133U, 0134U, 0135U, 0136U, 0137U, 0138U
07/22/2020	Removed CPT codes that do not require review: 81220, 81221, 81240, 81241, 81261, 81340, 81341, 81342, 81372, 81374, 81375, 81376, 81377, 81378, 81379, 81380, 81381, 81402, 81403, 81270.

10/06/2020	MPC approved to adopt MCG 24 th ed. guidelines for the following: Narcolepsy - HLA Testing: A-1005, Transthyretin Amyloidosis - TTR Gene: A-1010, Retinal Dystrophy - RPE65 Gene: A-1011, Breast Cancer- PALB2: A-0989, Alpha-1 Antitrypsin Deficiency - SERPINA1 Gene: KP-1006, Paraganglioma-Pheochromocytoma (Hereditary) - Gene Testing and Gene Panel: A-0798; added exception for NGS for Advanced Cancer (CellNetix lab) to Invitae as preferred lab section. Removed codes section; will defer to pre-authorization code check tool.
05/04/2021	Updated Medicare LCD links, MCG Guideline information, and applicable codes. MPC approved to adopt MCG 25 th edition guidelines for the following: Malignant Melanoma (Cutaneous) – BAP1, CDK4, and CDKN2A; Malignant Melanoma (Cutaneous) – BRAF V600 Testing; Renal Cancer (Hereditary) – Gene Panel; and Noonan Syndrome – Gene and Gene Panel Testing. Requires 60-day notice, effective date 10/1/2021.
08/03/2021	Updated Nephrology section, referencing separate criteria for Donor-derived cell-free DNA testing for Kidney Transplant Rejection (e.g., AlloSure).
11/02/2021	MPC approved to expand coverage for Spinal Muscular Atrophy (SMA) Carrier Testing. Requires 60-day notice, effective date 04/01/2022.
12/07/2021	MPC approved to adopt expansion of coverage for Chromosomal Microarray testing to members who are undergoing invasive prenatal genetic testing (i.e., amniocentesis). Requires 60-day notice, effective date 05/01/2022.
12/07/2021	MPC approved to adopt a policy of non-coverage for the ConfirmMDx and SelectMDx genetic tests for prostate cancer. Requires 60-day notice, effective date 05/01/2022.
04/05/2022	MPC approved to adopt MCG* A-0782 with new indications in the 26 th edition. Gene/gene panel testing for hereditary ovarian cancer criteria are in the process of being updated and will all be reviewed by the Medical Director on a case-by-case basis until finalized.
06/07/2022	MPC approved to adopt MTAC's recommendation of non-coverage and to continue the existing policy of insufficient evidence.
08/16/2022	MCG* A-0822 and A-0847 were deleted from the 26 th edition guidelines; deleted from criteria
09/22/2022	Added Oncoplex (University of Washington) and Caris Life Sciences as preferred lab vendors for NGS
311/01/2022	Updated criteria for Chromosomal Microarray Testing to remain compliant with revisions to the WAC; also updated other related prenatal genetic testing that were mandated to no longer require medical review. Effective immediately to comply with WAC 246-680-010. 60-day notice required.
11/01/2022	MPC approved to adopt criteria for Thyroid Nodule Gene Expression Testing (ThyraMIR/ThyGeNEXT CPT 0245u+0018U), Prostate Cancer Gene Expression Testing (Prolaris 81541) and Prostate Cancer (ConfirmMDx CPT 81551). Requires 60-day notice, effective date 04/01/2023.
11/14/2022	Added the July 2022 MTAC reviews for ConfirmMDx and Prolaris for Prostate Cancer. Replaced SelectMDx temporary CPT code 81479 with new CPT code 0339U, effective 10/1/22.
12/06/2022	MPC approved to remove NRAS genetic test from this page as it is currently on pharmacogenomic page. MPC approved to remove BRAF testing from genetic screening page and move to Pharmacogenomic page. Effective immediately.
12/12/2022	Added ClonoSEQ 81479 to flag for medical director review.
01/03/2023	Clarified language on ClonoSEQ indications. Added Medicare LCD L38816 and LCA A58997.
01/18/2023	Added the MTAC review for Decipher Prostate Genomic Classifier.
01/25/2023	For Prolaris-clarified use in setting of radical prostatectomy.
04/03/2023	Updated Medicare links and applicable code 0340U for Medicare LCD L38816.
04/24/2023	Added Quest-QNatal as a preferred vendor for Cell Free Fetal DNA testing.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Genetic Panels using Next Generation Sequencing (germline/blood testing, excluding Advanced Cancer)

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Preferred Lab for Genetic Testing for Kaiser Permanente non-Medicare enrollees (for in-network coverage).

Prevention and Invitae Corporation are the preferred labs for genetic testing, when the test(s) is/are available at Prevention or Invitae and medical necessity criteria are met.*

Invitae's test catalog can be found here: [Invitae Test Catalog](#)

Prevention test catalog can be found here: [Prevention Test Catalog](#)

**Note: This does not affect processing of tumor or other pathology specimens as they are not performed by Invitae*

PPO/POS members may use non-preferred labs at the out of network cost share.

Exceptions

For the NGS testing for Advanced Cancer, see below:

Local Coverage Determinations (LCD)	<p>9/30/2015 - Noridian retired LCD for Genetic Testing (L24308). These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an LCD. Most LCDs are not retired because they are incorrect. The criteria should be still referenced when making an initial decision. However, if the decision is appealed, the retired LCD cannot be specifically referenced. Maximus instead looks for "medical judgment" which could be based on our commercial criteria or literature search.</p> <p>MolDX: Next-Generation Sequencing for Solid Tumors (L38121) (Applies to diagnostic lab tests using NGS for solid tumors.)</p>

General Coverage Rules – LCD 24308

1. Genetic tests for cancer are only a covered benefit for a beneficiary with a personal history of an illness, injury, or signs/symptoms thereof (i.e. clinically affected). A person with a personal history of a relevant cancer is a clinically affected person, even if the cancer is considered cured. Genetic testing is considered a non-covered screening test for patients unaffected by a relevant illness, injury, or signs/symptoms thereof.
2. Predictive or pre-symptomatic genetic tests and services, in the absence of past or present illness in the beneficiary, are not covered under national Medicare rules. For example, Medicare does not cover genetic tests based on family history alone.
3. A covered genetic test must be used to manage a patient. Medicare does not cover a genetic test for a clinically affected individual for purposes of family planning, disease risk assessment of other family members, when the treatment and surveillance of the beneficiary will not be affected, or in any other circumstance that does not directly affect the diagnosis or treatment of the beneficiary.
4. The results of the genetic test must potentially affect at least one of the management options considered by the referring physician in accordance with accepted standards of medical care (e.g. surgery, the extent of surgery, a change in surveillance, hormonal manipulation, or a change from standard therapeutic or adjuvant chemotherapy).
5. Pre-test genetic counseling must be provided by a qualified and appropriately trained practitioner.
6. An informed consent form signed by the patient prior to testing which includes a statement that he/she agree to post-test counseling is required. This consent form must be available on request by Medicare.
7. Genetic analysis must be provided through a laboratory which meets the American Society of Clinical Oncology (ASCO) recommended requirements:

The MolDX Program has determined certain gene tests do not meet Medicare's medical necessary requirements, and that the inclusion of these genes will result in an entire panel to be denied. MolDX has determined that testing for the below genes is a statutorily excluded service. Unless indicated otherwise, panels that include these genes will be denied. Please see the individual Test Coding and Billing Guidelines for each gene.

Palmetto GBA is the Medicare contractor for Molecular Diagnostic Testing – this site has the most up to date Medicare coverage guidelines for genetic testing.

L36891	MolDX: Percepta® Bronchial Genomic Classifier	81479

For Non-Medicare Members

Kaiser Permanente considers genetic testing panels medically necessary when the results are expected to directly affect treatment, management, surveillance or reproductive decisions and when all genes or genetic variants included in the panel have high quality, evidence-based guidelines established to direct clinical management based on results.

Testing for individual components of a panel may be medically necessary in some clinical situations. Separate clinical criteria for these components may apply.

Members must meet ALL the following criteria:

1. The member is at clinical risk for a genetic condition because of current documented symptoms being displayed or a strong family history of the condition.
2. The test is scientifically valid and can be adequately interpreted.
3. The results will directly affect a member's clinical management or reproductive decisions.
4. After appropriate clinical work-up, and informed consent by the appropriate practitioner, the genetic test is indicated.

Genetic testing is not covered for the medical management of a family member who does not have Kaiser Permanente coverage.

- 1.) If Kaiser Permanente Clinical criteria for BRCA genetic testing using MCG* A-0499 are met AND
 - a. Member has had consultation with a medical geneticist or certified genetic counselor who is recommending the test and who has documented the indication for testing, as well as its expected impact on clinical management or surveillance
 - b. One of the following NGS panels can be covered:
 - i. Invitae Breast Cancer STAT Panel
 - ii. Invitae Breast Cancer Guidelines – Based Panel
 - iii. Invitae Breast and Gynecological Cancers Guidelines – Based Panel
 - iv. Prevention – Breast Cancer- High Risk Panel
- 2.) If Kaiser Permanente Clinical Review Criteria for Lynch syndrome genetic testing using MCG* A-0533 are met AND
 - a. Member has had consultation with a medical geneticist or certified genetic counselor who is recommending the test and who has documented the indication for testing, as well as its expected impact on clinical management or surveillance
 - b. One of the following NGS panels can be covered:
 - i. Invitae Lynch Syndrome Panel
 - ii. Invitae Colorectal Cancer Guidelines – Based Panel
 - iii. Prevention Lynch Syndrome Panel

- 3.) If Kaiser Permanente Clinical Review Criteria for both BRCA and Lynch syndrome genetic testing are met

- a. Member has had consultation with a medical geneticist or certified genetic counselor who is recommending the test and who has documented the indication for testing, as well as its expected impact on clinical management or surveillance
- b. The following NGS panel can be covered
 - i. Invitae Breast and Gynecological Cancers Guidelines – Based Panel
 - ii. Prevention Hereditary Breast and Ovarian Cancer – High Risk and Lynch Syndrome Panel

***If a member has had prior negative BRCA1 & 2 gene testing:** In most cases, further genetic testing would not be considered necessary. However, in cases where there is a very strong personal or family history suggesting a genetic disposition, testing for additional evidence-based cancer susceptibility genes is warranted. One of the Invitae NGS panels listed in section 1b above could be covered.

Criteria for other Genetic Panel Tests:

Refer to the [Genetic Screening and Testing](#) clinical review criteria to see information about review criteria for specific genetic tests *not* described above; please also check [Invitae Test Catalog](#) or [Prevention Test Catalog](#)

*For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

*MCG are proprietary and cannot be published and/or distributed. However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Last 6 months of radiology if applicable

The following genetic panels are **not considered medically necessary** because the current scientific evidence is not yet sufficient to establish how test results from all components of these panels should be used to direct treatment decisions. There is also insufficient evidence to establish that use of these genetic panels to guide treatment decisions results in improved patient health outcomes.

This list is not all-inclusive as new genetic panel tests are frequently being developed.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

The emergence of new genetic testing technology, including next generation sequencing and chromosomal microarray, has made possible the ability to examine many genes simultaneously. This in turn has resulted in a proliferation of new genetic testing panels. The intended use for these panels varies.

For example, for hereditary disorders, a clinical diagnosis may already be established, in which case genetic testing is performed to determine the specific causative mutation and a diagnostic genotype. In other cases, the clinical findings may suggest a number of possible etiologies, in which case genetic testing is performed in the hope of making a specific diagnosis.

For cancer panels, intended uses also differ. Some panels may be intended to identify the presence of a hereditary syndrome predisposing to the development of certain cancers. Other panels look for somatic mutations in a tumor biopsy specimen with the intent of identifying a cancer's primary site of origin and/or identifying a molecular target to help in selecting treatment.

Panels using next generation sequencing technology are currently available in the areas of cancer, cardiovascular disease, neurologic disease, and for prenatal testing and screening. These panels are intuitively attractive to use in clinical care because they can analyze multiple genes quickly and may lead to greater efficiency in the work-up of genetic disorders. It is also possible that in some cases these “bundled” gene tests can be performed more cost efficiently than individual sequencing, although this may not be true in all cases.

On the other hand, the use of newer sequencing techniques is associated with a higher rate of results which may be of uncertain clinical significance and/or for which there are no reliable evidence-based guidelines regarding management or surveillance. This can potentially lead to unnecessary follow-up testing and procedures, which have their own inherent risks and cost.

The design and composition of genetic panel tests are not standardized. The make-up of each panel is determined by the specific laboratory that has developed the test. In addition, the composition of any individual panel is likely to change over time, as new genetic variations are discovered and added to the existing panels.

Medical Technology Assessment Committee (MTAC)

Ambry Genetics' Next-Generation Panels (BreastNext, OvaNext, CancerNext)

BACKGROUND

Understanding the underlying genetic contribution to cancer can give insight to individual and familial risk. This is especially important with hereditary cancer since risk-reducing strategies for additional primary cancers can vary based on molecular diagnosis. Identifying an underlying genetic cause can also aid in the diagnostic process since relying on family history alone can be challenging. Numerous genetic mutations are associated with certain types of hereditary cancer. Traditionally, Sanger sequencing has been considered the gold standard in mutation detection and is still the method of choice for most diagnostic labs. However, since multiple genes are implicated in each type of cancer, testing by traditional sequencing can be burdensome and expensive. Advancements in sequencing technologies have made it possible to generate a large amount of data quickly and cost effectively (Choi, Scholl et al. 2009). Next generation sequencing (NGS) provides investigators with the required capacity to analyze large panels of genes or whole genomes in a single run (panel testing) (Previati, Manfrini et al. 2013). As a result, these technologies are enabling new tailor-made approaches to diagnostic testing with an increasing number of commercially available genetic panels (Walsh, Lee et al. 2010; Michils, Hollants et al. 2012). Ambry Genetics offers four different genetic testing panels for hereditary cancers (Keiles 2013). These panels address three specific types of cancer that may be inherited including breast, ovarian and colorectal. The mutations included in these panels are associated with varying levels of risk of developing cancer, and only some of the mutations are associated with well-defined cancer syndromes which have established clinical management guidelines (Burke, Petersen et al. 1997).

TABLE 1: PANEL NAME AND DESCRIPTION	
PANEL NAME	DESCRIPTION
<i>BreastNext™</i>	Next-generation sequencing panel that simultaneously analyzes 16 genes that contribute to increased risk for breast cancer including BRCA1 and BRCA2.
<i>OvaNext™</i>	Next-generation sequencing panel that simultaneously analyzes 21 genes that contribute to increased risk for breast ovarian and/or uterine cancers.
<i>Colonext™</i>	Next-generation sequencing panel that simultaneously analyzes 14 genes that contribute to increased risk for colon cancer.
<i>CancerNext™</i>	Next-generation sequencing panel that simultaneously analyzes 24 genes that contribute to increased risk for breast colon, ovarian, uterine and other cancers.

There is no standardization to the make-up of genetic panels. Composition of the panels is variable, and different commercial products for the same condition may test a different set of genes. The make-up of the specific panels is determined by the specific lab that has developed the test. In addition, the composition of any individual panel is likely to change over time, as new mutations are discovered. The majority of cancer panel tests are laboratory derived tests that are not subject to U.S. Food and Drug Administration (FDA) approval. Labs are subject to Clinical Laboratory Amendment (CLIA) regulations that monitor high-complexity testing.

10/21/2013: MTAC REVIEW

Ambry Genetics' Next-Generation Panels (BreastNext, OvaNext, CancerNext)

Evidence Conclusion: Analytic Validity According to Ambry Genetics, the analytic sensitivity for the 22 genes analyzed on their cancer susceptibility panels by next generation sequencing is 96-99% (Keiles 2013), however, no publications were found to support these claims. No published literature addressed the analytic validity of the Ambry Genetics' Next-Gen Cancer Panels. Clinical Validity While it may be possible to evaluate the clinical validity of sequencing of individual genes found on these panels, the clinical validity of Ambry Genetics' Next-Gen Cancer Panels, which include mutations associated with unknown or variable cancer risk, is uncertain. No published literature addressed the clinical validity of panel testing for cancer susceptibility with NGS. Clinical Utility Theoretically, identifying an individual with a genetic mutation that indicates a high risk of developing cancer could lead to changes in clinical management and improved health outcomes including modifications in cancer surveillance and treatment guidance. However, identifying mutations that have intermediate or low risk of developing cancer is of limited clinical utility. With potential harms, such as psychological stress and unnecessary prophylactic intervention, the management for patients found to have one of these mutations is not well defined. No published literature addressed the clinical utility of the Ambry Genetics' Next-Gen Cancer Panels. Conclusion There is insufficient evidence to determine the analytic validity, clinical validity or clinical utility of the Ambry's Next-Gen Cancer Panels.

Articles: A search of PubMed was completed for the period through August 2013 for studies on the accuracy of NGS for predicting risk of hereditary breast ovarian and colon cancer. The search strategy used the terms *next*

generation, cancer panel, BreastNext, breast cancer, ColoNext, colon cancer, OvaNext, ovarian cancer and CancerNext with variations. To identify ongoing clinical trials, a search of the National Institute of Health Clinical Trials website was also conducted using the same methodology. Articles were limited to those published in the English language with human subject enrollment. The search was supplemented by an examination of article bibliographies in addition to the PubMed *related* articles function.

The use of Ambry next generation does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Coloseq™ Colon Cancer Panel

BACKGROUND

Approximately 2% to 5% of colorectal cancer (CRC) can be attributed to inherited syndromes such as Lynch syndrome (also known as hereditary non-polyposis colon cancer), familial adenomatous polyposis (FAP), and MUTYH-associated polyposis. Patients with these syndromes are at higher risk for CRC and, therefore, require more intensive surveillance programs. Lifetime CRC risk is 50-80% for patients with Lynch syndrome, 100% for patients with FAP, and 80% for patients with MUTYH-associated polyposis compared to 5-6% for patients without these syndromes (Kaz and Brentnall 2006; Jasperson, Tuohy et al. 2010). There are several different strategies used to identify families at high-risk for developing these syndromes, however, genetic testing is the gold standard for diagnosing Lynch syndrome and FAP. To date, clinical diagnostic criteria for MUTYH-associated polyposis have not been fully established; however, genetic testing may be warranted in individuals with more than 10 colorectal adenomas who are negative for APC mutations (Jasperson, Tuohy et al. 2010). Genetic testing of high-risk families allows for a more accurate diagnosis and more specific targeting of clinical screening and surveillance protocols to gene carriers in the family. Additionally, genetic testing allows for the identification of family members who did not inherit the mutation and therefore do not warrant intensive surveillance programs. Coloseq™ is a comprehensive genetic test for the prediction and diagnosis of hereditary colon cancer that uses next generation sequencing to detect mutations in multiple genes associated with Lynch syndrome, FAP, and MUTYH-associated polyposis. Initially, the panel was developed to include seven genes that have a well-established role in clinical decision making for patients with Lynch or polyposis syndromes. Since then, however, the panel has undergone several evolutions to include four additional genes in June of 2012, two more genes in January of 2013 and, most recently, the addition of six genes in October of 2013. With a total of 19 genes now included, the panels utility has now expanded into the realms of endometrial, breast, and thyroid cancer, to name a few. Coloseq is not approved by the Food and Drug Administration (FDA) but clinical laboratories that develop and validate tests for in-house use are regulated under the Clinical Laboratory Improvement Amendments (CLIA) of 1988.

10/16/2013: MTAC REVIEW

Coloseq™ Colon Cancer Panel

Evidence Conclusion: *Analytic Validity* One publication from the Journal of Molecular Diagnostics was identified that addressed the analytic validity of ColoSeq™ (Pritchard, Smith et al. 2012). The study presents 99.4%-100% sensitivity and 99.4%-100% specificity. The paper was limited to the seven genes that were included on the original panel and thus does not provide sufficient evidence for the 19 gene panel that is currently used. No publications were identified that validated the entire 19 gene panel that has since evolved. *Clinical Validity* Pritchard and colleagues present that the clinical validity is achieved by targeting and validating only genes that, when mutated, are well-established causes of hereditary colon cancer leading to the conclusion that incorporating the results of the ColoSeq™ testing into clinical-decision making was now straightforward. The addition of new genes and inclusion of additional cancers compromise this claim. No publications were identified that addressed the clinical validity of the ColoSeq™ cancer panel. *Clinical Utility* Originally, the ColoSeq panel was designed to focus only on genes that have a well-established role in clinical decision making and patient management. The recent expansion of the ColoSeq panel compromises the overall clinical utility. No published literature addressed the clinical utility of the ColoSeq™ cancer panel.

Conclusion: There is insufficient evidence to determine the analytic validity, clinical utility and clinical validity of Coloseq™ for the identification of hereditary colon cancer.

Articles: A search of PubMed was completed for the period from April 2012 to November 5th, 2013 for studies on the accuracy of ColoSeq™ for detecting hereditary colon cancer. The search strategy used the terms *Coloseq™*, *genetic testing*, *Lynch syndrome*, *familial adenomatous polyposis (FAP)*, *MUTYH-associated polyposis*, and *colon cancer* with variations. To identify ongoing clinical trials, a search of the National Institute of Health Clinical Trials website was also conducted using the same methodology. Selected articles were limited to those published in the English language enrolling human subjects. The search was supplemented by an examination of article reference lists in addition to the PubMed *related articles* function. **Screening of articles:** The literature search for ColoSeq™ revealed one July 2012 publication on the development and validity of the assay (Pritchard, Smith et al. 2012). Due to recent additions (October 2013) to the Coloseq™ cancer panel, this publication is no longer applicable and was not reviewed.

The use of Coloseq™ does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

^{MPC} Medical Policy Committee

Revision History	Description
06/30/2015	Added Medicare LCD links and PROOVE® panels.
08/27/2015	Added LCD 35850 and LCD 35504
09/08/2015	Revised LCD Circulating Tumor Cell Marker Assays LCD L35096 and L34066, Breast Cancer Genetic Assay L35500 and L36316, GeneSight® Assay for Refractory Depression L36324 and L36325, Genetic Testing L34101, LCD for ConfirmMDx Epigenetic Molecular Assay (L36328),
12/06/2016	Added Cx Bladder & My Risk Panel to the non-covered list
05/16/2017	Added Percepta LCD
06/15/2017	Added Invitae Stat Panel coverage
10/19/2017	Added Health Diagnostics to the non-covered panel list
03/26/2018	Added Decision Memo for Next Generation Sequencing (NGS) for Medicare Beneficiaries with Advanced Cancer
06/13/2018	Moved 81381 to the no review list
08/29/2018	Moved 81307 to no review at this time
06/02/2020	Added section: "Preferred Lab for Genetic Testing for Kaiser Permanente non-Medicare enrollees." Requires 60-day notice, effective date 10/01/2020. Moved CPT codes 81402, 81403 and 81270 under Applicable Codes section that do not need review.
06/24/2020	Added CPT codes 0084U, 0085U, 0093U, 0094U, 0095U, 0097U, 0098U, 0099U, 0100U, 0101U, 0102U, 0103U, 0104U
07/07/2020	MPC approved to adopt updates to the clinical indications for Non-Medicare. Requires 60-day notice, effective date 12/01/2020. Removed CPT codes that do not require review: 81220, 81221, 81240, 81241, 81261, 81340, 81341, 81342, 81372, 81374, 81375, 81376, 81377, 81378, 81379, 81380, 81381, 81402, 81403, 81270.
10/06/2020	Removed codes section; will defer to pre-authorization code check tool.
05/04/2021	Removed genetic panel tests that are no longer available. Updated Medicare LCD links and applicable codes.
09/27/2022	Added Prevention as a preferred lab vendor for genetic panel testing. Removed Caris and Oncoplex from the non-inclusive list of genetic panel tests. 60-day notice required; effective 03/01/2023.
01/19/2023	Removed Prolaris from the non-covered list. MPC approved to adopt criteria for Prostate Cancer Gene Expression Testing (Prolaris 81541) and Prostate Cancer (ConfirmMDx CPT 81551), effective 4/1/2023- see Genetic Screening Criteria for details.
03/08/2023	Added Signatera to the non-covered panel list
05/15/2023	Updated Medicare Links including—newly retired policies L36163, L36329 and L36374

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Treatment of Gastroesophageal Reflux Disease - GERD

- CR BARD's Endoscopic Suturing System
- Endoscopic Placement of a Bulking Material at the Lower Esophageal Sphincter
- LINX Reflux Management System
- Stretta Procedure
- Transoral (Endoluminal) Gastroplication or Suturing (Esophyx)

Background

Gastroesophageal reflux disease (GERD) is a common disease worldwide with an estimated prevalence of 10-20% in the Western population. It is defined as a condition which develops when the reflux of stomach contents causes troublesome symptoms and/or complications. GERD has a wide clinical spectrum ranging from mild reflux symptoms to severe regurgitation but is typically characterized by heartburn and acid regurgitation. Other symptoms of GERD include epigastric pain, dysphagia, chronic cough, chronic laryngitis, and asthma (Vakil 2006, Zhang 2016, Savarino 2017).

Therapeutic approaches to GERD included lifestyle modification, medical therapy with gastric acid secretion inhibitors, and surgical interventions. Proton pump inhibitors (PPIs) are the standard medical therapy and aim at suppressing the normal acid production in the stomach to alleviate the acid reflux symptoms. PPIs can only inhibit gastric acid secretion, but do not prevent reflux nor address the incompetent lower esophageal sphincter (LES). It is reported that up to 40% of the GERD patients fail to respond either partially or completely to PPIs and will continue to have reflux symptoms or endoscopic evidence of esophagitis (Reynolds 2016, Saino 2016, Chen 2017).

Laparoscopic Nissen fundoplication (LNF) is currently the gold standard surgical treatment for patients who fail medical therapy. Nissen fundoplication reconstructs the defective LES to restore its normal function as an anti-reflux barrier. The surgery is safe and very effective in reducing GERD symptoms. However, the procedure is technically demanding and requires significant anatomical disruption to mobilize the gastric fundus and wrap it around the esophagus. It may also be associated with side effects including difficulty swallowing, bloating, early satiety, and inability to vomit or belch. As a result, only very few GERD patients will opt for the surgery (Saino 2015, Reynolds 2016, Zadeh 2018).

The Magnetic sphincter augmentation device (MSA) (LINX®, Torax Medical Shoreview, MN) was introduced in 2008 as a potential less invasive anti-reflux surgical option for patients with uncomplicated GERD who do not respond to PPIs, and still have some LES function. I.e. it is not indicated for patients with complete LES failure or with complicated GERD. The MSA device is a small expandable bracelet-like string of consisting of 10 or more beads with a magnetic core and interlinked with independent titanic wires. The device is laparoscopically placed around the gastroesophageal junction (GEJ) with minimal dissection of the hiatus to preserve the native LES. The magnetic attraction between the beads augments the existing LES barrier function to prevent reflux, and the mobile wires connecting the beads allow the device to expand during swallowing, belching, or vomiting (Reynolds 2017, Siddiqi 2017, Zadeh 2018, Guidozzi 2019).

The LINX® device should not be placed in patients with suspected or known allergies to titanium, stainless steel, nickel or ferrous material, or in those with pacemakers, defibrillators or metallic implants in the abdomen. In addition, it may not be appropriate for patients with a history of dysphagia, previous upper abdominal surgery, previous endoluminal anti-reflux procedures, large sliding hiatal hernia, or Barrett's esophagus. Reported adverse events and complications associated with magnetic sphincter augmentation include inability to belch or vomit, bloating, and dysphagia. The latter is the most common complication of the MSA, and severe cases may require a second surgery for dilatation, and removal of the device if endoscopic dilatation fails. Other reported adverse events include device failure, device migration, device erosion, and ring eroding into the esophageal lumen (Fass 2017, Chen 2017, Zadeh 2018, Guidozzi 2019).

The LINX® Reflux Management System received U.S. Food and Drug Administration (FDA) approval on March 22, 2012 for patients with GERD as defined by abnormal pH testing, and who continue to have chronic symptoms despite the use of a maximum medical therapy.

Medical Technology Assessment Committee (MTAC)

CR BARD's Endoscopic Suturing System (EndoCinch Therapy, Endoluminal Plication) for the Treatment of GERD

BACKGROUND

Gastroesophageal reflux disease (GERD) is a chronic disorder that affects as many as 14 million Americans. It is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett's esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture. Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up (Lafullarde, 2001). More recently endoscopic or endoluminal approaches for treating GERD have either been FDA approved or are still under investigation. These various methods can be divided in three broad categories: 1. Methods that attempt to create a fundoplication (plicating techniques), 2. Methods that create a controlled stricture (radio frequency), and 3. Methods that bulk the gastroesophageal junction (injecting bulking agents). The ideal procedure should be safe, effective over a long term, and would not affect future surgical options. Currently, there are three plicating devices: The EndoCinch (C.R. Bard's endoscopic suturing system, the ESD, and the Full-Thickness Plicator. The first two have been approved by the FDA, and the last was not approved to date. Endoluminal plication uses mechanical techniques to hinder reflux by approximation of tissue at or below the gastroesophageal junction. The EndoCinch (CR BARD Endoscopic technologies, Massachusetts, USA) system was the first FDA approved endoscopic sewing machine method for treating GERD. It was developed by Swain CP et al in London UK, in the mid-1980s. In the Bard method, an oroesophageal tube (19.7 mm in diameter and 30 cm long) is placed to facilitate passage of the suturing device. The suture capsule, which is similar to a sewing machine, is attached to an endoscope and loaded with a suture. After placing the suture capsule, under vision, over the selected site at the gastroesophageal junction, suction through the external vacuum line is applied. This pulls a fold of tissue into the capsule cavity, and the needle driver places the suture. Suction is released, and the tissue is withdrawn from the capsule. The procedure is repeated on an adjoining site. Drawing two sutured sites together creates a plication. It is reported that the procedure is technically difficult, has a steep learning curve, and that the results are likely to be operator dependent. Conscious sedation might not be sufficient, and a general anesthesia may be needed. Adverse effects associated with the procedure include pharyngitis, vomiting, abdominal pain, chest pain, mucosal tear, hypoxia, and bleeding. The Bard's Endoscopic Suturing system was FDA approved in March 2000, for the treatment of GERD. The ESD (Wilson-Cook Medical, Winston-Salem, N.C.) another endoscopically assisted endoluminal suturing device was also approved by the FDA for soft-tissue apposition. The Full-Thickness Plicator (Ndo Surgical, Inc, Mansfield, Mass) is another plication device that had not been approved by the FDA at time the search was made.

02/13/2003: MTAC REVIEW

Endocinch Therapy in the Treatment of GERD

Evidence Conclusion: The studies reviewed show that the procedure is associated with a reduction in the frequency and severity of heartburn and regurgitation symptoms. Patients had an improved quality of life, and

there was a significant reduction in the use of antisecretory medications in two of the studies. However, the procedure was performed on a highly selected group of patients (those with hiatal hernia >3 cm, esophageal stricture and Barrett's esophagus were excluded). Moreover, the follow-up duration of all studies was short, and insufficient to determine the recurrence rate and long term-efficacy of the procedure. Filipi's study was an RCT, yet the patients were randomized to two different suture configurations of the same procedure and not to an alternative treatment. Randomized controlled studies with long-term follow-up are needed to compare the procedure with other medical and surgical anti reflux therapies and assess the sustained effect of the procedure and the long-term relief from symptoms without using antisecretory medications.

Articles: The search yielded 12 articles, all on the Bard technique. There was one randomized controlled trial, one case-control study and one case series. The rest were reviews, tutorials, letters or dealt with the technical aspect of the procedure. There were no published studies on the Wilson-Cook ESD, or the Ndo Full-Thickness Plicator. Evidence tables were created for the three studies identified in the search:

Filipi CJ, Lehman GA, Rothstein RI, et al. Transoral flexible endoscopic suturing for treatment of GERD. A multicenter trial. *Gastrintest Endosc* 2001; 53:416-422. See [Evidence Table](#). Mahmoud Z, McMahon BP, Arfin Q, et al. Endocinch therapy for gastro-esophageal reflux disease: a one-year prospective study. *Gut* 2003, 52:34-39. See [Evidence Table](#). Velanovich V, Ben-Menachem T, and Goel S. Case-control comparison of endoscopic gastroplication, with laparoscopic fundoplication in the management of gastroesophageal reflux disease. Early symptomatic outcomes. *Surg laparosc Endosc Percutan Tech* 2002, 12:219-223. See [Evidence Table](#).

The use of Endocinch therapy in the treatment of GERD does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Endoscopic Placement of a Bulking Material at the Lower Esophageal Sphincter for the Treatment of GERD

BACKGROUND

Gastro-esophageal reflux disease (GERD) is a chronic disorder that affects as many as fourteen million Americans. It is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett's esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture. Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up ((Lafullarde, 2001). More recently endoscopic or endoluminal approaches for treating GERD have either been approved or are still under trial. These various methods can be divided in three broad categories: 1. Methods that create a controlled stricture (radiofrequency), 2. Methods that attempt to create a fundoplication, and 3. Methods that bulk the gastroesophageal junction (injecting bulking agents). The ideal procedure should be safe, effective, with long-term effects, and do not affect future surgical options. Endoscopic injection of an inert material into the submucosa of the distal esophagus has been tried with the intention to impede the reflux. The bulking effect results from both the material injected and the tissue response. Examples of the bulking agents used are bovine collagen, ethylene vinyl alcohol, polytetrafluoroethylene and others. These are injected through long catheters and small gauge needles under endoscopic guidance. In the experiments conducted the resulting improvement in reducing the LES pressure and GERD symptoms were temporary, and did not last long, either due to the biodegradation or migration of the injected material. Other non-biodegradable substances injected into the submucosa or muscle, and with the use of different application techniques are still under trial. These methods are still in the investigational stage and are not approved by the FDA.

02/13/2003: MTAC REVIEW

Bulking Material in the Treatment of GERD

Evidence Conclusion: There is insufficient evidence to determine the efficacy and safety of endoscopic injection of bulking material for the treatment of GERD.

Articles: The search did not yield any study. Two studies were revealed from review articles. Both were pilot studies with no comparison groups. One included only a series of 15 patients (10 in Brussels and 5 in Rome), and the other was a case series with only ten participants.

The use of bulking material in the treatment of GERD does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Magnetic Sphincter Augmentation – (LINX® Reflux Management System)

BACKGROUND

Gastroesophageal Reflux Disease (GERD) is an extremely common clinical manifestation of excessive reflux of acidic gastric components. Also referred to as chronic acid reflux, GERD is characterized by a chronic, often progressive dysfunction of the lower esophageal sphincter (LES) allowing acids and bile from the stomach to flow back into the esophagus. Common symptoms include heartburn, regurgitation and dysphagia and can adversely impact the quality of life by interfering with daily activities, disturbing sleep, and reducing productivity. Left untreated GERD can lead to more serious complications such as esophageal stricture, Barrett's esophagus and esophageal cancer (Gorecki 2001). Simple diet and lifestyle modifications can ease some of the symptoms associated with GERD, however, more severe or frequent cases may require pharmaceutical treatment with antacids, H₂-receptor antagonists or proton pump inhibitors (PPIs). Some cases of GERD, however, will not respond to medications and may require surgical intervention. Laparoscopic fundoplication (LF), has long been considered the gold standard of antireflux surgery. The technique involves wrapping the upper part of the stomach (gastric fundus) around the lower end of the esophagus in an effort to reinforce the LES. Although LF has a high success rate, the procedure is non-reversible and has been associated with a variety of potential side-effects such as dysphagia, loss of belching and vomiting and increased flatulence and bloating. The LINX® Reflux Management System, developed by Torax® Medical (St. Paul, MN), was designed to prevent back flow into the esophagus and is suggested as an alternative to anti-reflux surgery. More specifically, the magnetic sphincter augmentation (MSA) device is a series of interlinked magnetic beads implanted laparoscopically at the junction between the esophagus and stomach that acts as a reinforcement of the LES. The device relies on small wires that allow the magnetic beads to expand and allow the flow of foods and liquids into the stomach while preventing reflux at the same time. According to the manufacturer, the LINX Reflux Management System requires less recovery time, provides immediate relief and faster return to solid foods compared with other surgical interventions. To add to this, the device can be removed if side-effects, such as dysphagia, pain and bloating, become unbearable. The LINX® Reflux Management System received US Food and Drug Administration (FDA) approval on March 22, 2012. The device is intended for use in patients with GERD who continue to have symptoms despite the use of a maximum medical therapy for the treatment of reflux. More specifically, it is intended for use in patients who would be considered candidates for anti-reflux surgery. This topic has not previously been reviewed by the Medical Technology Assessment Committee (MTAC) and is currently under consideration due to coverage decision support.

12/15/2014: MTAC REVIEW

LINK Reflux Management System

Evidence Conclusion: A feasibility trial by Lipham and colleagues, included 44 patients and aimed to assess the long-term safety and effectiveness of the LINX Reflux Management System (up to 3.7 years). In this study, patient's baseline measurements were used as the control for comparison with post-implant measurements. In all outcome measures improvements were seen with reduced esophageal acid exposure, improved GERD-HRQL scores and decreases in use of PPIs. As a result, the investigators concluded that sphincter augmentation with LINX provides long-term clinical benefits with no safety issues (Lipham, DeMeester et al. 2012). [Evidence Table 1](#) In the second study, a pivotal trial by Ganz and colleagues, the investigators sought to evaluate the safety and effectiveness of the LINX Reflux Management System. The study included 100 patients with GERD and assessed esophageal pH as well as manometry and barium esophagography. The investigators report that 64% (95% CI, 54%-73%) of patients achieved success with normalization of esophageal acid exposure, or a ≥50% reduction in exposure at one year. Additional endpoints were also promising with 50% or more improvements seen in 92% of patients on the GERD-Health Related Quality of Life (HRQL) questionnaire. Although the authors concluded that the LINX device resulted in a decreased exposure to esophageal acid, improved reflux symptoms and allowed cessation of PPIs in the majority of patients, they also noted that additional prospective RCTs with appropriate controls are necessary for confirmation. (Ganz, Peters et al. 2013). Finally, the third study, by Riegler and colleagues, evaluated 249 patients who had undergone MSA and LF and completed one-year follow-up. With the overall goal to compare the clinical experience of each procedure, the investigators evaluated patients reflux symptoms, PPI use, side effects and complications. At one year, both groups showed improvement in total GERD-HRQL score (20 vs. 3 in the MSA group and 23 vs. 3.5 in the LF group) and discontinuation of PPIs was higher in the MSA group with 81.8% of patients abstaining and only 63% in the LF group ($P=0.009$). The investigators concluded that both MSA and LF were comparable but that MSA should be considered as the first-line surgical option [Evidence Table 3](#). Adverse events and complications were documented in all three of the critically appraised publications. In addition, a recent publication from Lipham and colleagues provides a safety

analysis of the first 1,000 patients treated with the MSA device. The analysis included safety related events collected from the published literature, FDA databases for device related complications and information provided by the manufacturer for over 1,000 patients treated worldwide between February 2007 and July 2013. This paper was not critically appraised, however, the safety data is generally summarized in table one, below. (Lipham, Taiganides et al. 2014).

Table 1. Summary of events by source		
Source of data	# of events included in analysis	Breakout
Clinical literature	32	<ul style="list-style-type: none"> • 9 device removal • 20 esophageal dilation • 3 hospital readmissions
MAUDE database	20	<ul style="list-style-type: none"> • 19 device removal (includes US and OUS) • 1 device erosion
Manufacturer's database	59	<ul style="list-style-type: none"> • 8 device removal • 1 intra/perioperative complication • 11 hospital readmissions • 39 esophageal dilation

Generally speaking, the body of evidence is limited by small sample sizes, short-term follow-up, as well as a lack of randomization and adequate comparators. Selection bias may be an issue in the third study as the selection of intervention was ultimately made by the surgeon at the time of surgery. It should also be noted that the majority of studies assessing the LINX Reflux Management System are either funded by the device manufacturer or authored by consultants to the manufacturer. Ultimately the body of evidence provides insufficient evidence to support the safety and effectiveness of the LINX Reflux Management System. Conclusions: There is insufficient evidence to support the effectiveness of the LINX Reflux Management System in patients with refractory GERD. There is insufficient evidence to support the safety of the LINX Reflux Management System in patients with refractory GERD.

Articles: The literature search revealed just over 100 publications relating to treatment of GERD using sphincter augmentation many of which were not directly applicable to the objective at hand. No randomized controlled trials (RCTs) were revealed comparing the LINX Reflux Management System with alternative surgical interventions such as LF. The FDA's 2012 approval relied on two publications, a pivotal clinical trial and a feasibility study, which were selected for critical appraisal. Post-approval studies of the LINX Reflux Management System, required by the FDA, are currently ongoing. In addition to the pivotal and feasibility trial, two additional studies were considered. The first was a recent observational study comparing MSA to laparoscopic fundoplication (LF) and the latter, a safety analysis of the first 1,000 patients treated with MSA (this study was not critically appraised but discussed in the evidence summary). The following articles were selected for critical appraisal: Lipham JC, DeMeester TR, Ganz RA, et al. The LINX® reflux management system: confirmed safety and efficacy now at 4 years. *Surgical Endoscopy*. 2012; 26:2944-2949. [See Evidence Table 1](#). Ganz RA, Peters JH, Horgan S, et al. Esophageal Sphincter Device for Gastroesophageal reflux disease. *NEJM*. 2013;368(8):719-72. Reigler M, Schoppman, Bonavina L, et al. Magnetic sphincter augmentation and fundoplication for GERD in clinical practice: one-year results of a multicenter, prospective observational study. *Surgical Endoscopy*. 2014. [See Evidence Table 3](#).

The use of LINX Reflux Management System does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Stretta Procedure (Electro-Surgical Coagulation-Radiofrequency [RF] Application- Curon Medical Inc's CSM Stretta System) for the Treatment of GERD

BACKGROUND

Gastroesophageal reflux disease (GERD) is a one of the most common medical disorders in the United States. It is a chronic disorder that is primarily caused by transient inappropriate relaxation or abnormally low resting pressure of the lower esophageal sphincter (LES). This intermittently exposes the esophagus to gastric acid and enzymes. GERD usually manifests as heartburn, regurgitation, or dysphagia. Patients may have significant daily symptoms with a substantial effect on their quality of life. Complications of the disease include Barrett's esophagus, esophagitis, laryngeal injury, pneumonia, and esophageal stricture. Current therapy for GERD begins with lifestyle changes and medical treatment, which proved to be effective in more than three fourths of the patients. Pharmacotherapy reduces the frequency, duration and/ or potency of the refluxate. However, the long-term costs are high, and the recurrence of symptoms could be as high as 90% after the cessation of medication. Patients who do not tolerate, or respond well to medical treatment, as well as those who want to avoid life-long

treatment, may be candidates for surgery. Surgical approaches are used to create barriers to the reflux. Nissen fundoplication is the most commonly used surgical procedure with a response rate as high as 90% at 5-year follow-up (Lafullarde, 2001). More recently options include injection therapy to the lower esophageal sphincter, endoscopic sewing procedures, and radiofrequency ablation therapy. The ideal procedure should be safe, effective for a long time, and would not affect future surgical options. This review evaluates the radiofrequency techniques. Radiofrequency (RF) energy has been used for the general surgical application of tissue coagulation for more than 70 years. RF energy leads to collagen shrinkage, and in turn tissue contraction and tightening. Recently RF is being used for different clinical purposes, including its application to the gastroesophageal junction. The Stretta System (Curon Medical, Sunnyvale, CA) consists of a RF control module and a flexible Stretta catheter. The catheter has a 20F soft bougie tip and a balloon, which opens in a surrounding basket. On its widest area after balloon inflation, the catheter has four nickel-titanium needle electrodes (5.5 mm long), which can be extended in the LES muscle. The catheter is introduced transorally and positioned at the Z-line (squamocolumnar junction). It aspirates and irrigates the esophageal lumen with water to prevent surface injury. The four electrodes provide 60 to 300 J of RF energy to each needle, heating the surrounding muscle tissue to the target temperature between 65° and 85° C while cooling the mucosal with its irrigation system. 15 to 25 lesion sets are created in the region from 2 cm proximal to 1 cm distal to the Z-line by rotating the catheter 45 degrees and varying its linear position. The RF-induced burns eventually scar down and create a reflux barrier. The mechanism of action of RF is reported to be a reduction in the frequency of LES relaxations, as well as physical alteration in tissue compliance and wall thickness of the gastroesophageal junction. The Curon Medical Inc.'s CSM Stretta System was approved by the FDA on April 18, 2000. Curon recommends the device for mild or moderate cases of GERD only. The Stretta procedure is reported to be easy to learn and apply. However, there is a concern that if the scars continue to contract, at least some patients will develop a stricture that could be difficult to manage. Other adverse events that may be associated with the procedure include chest pains, fever, mucosal tear, and dysphagia.

12/10/2003: MTAC REVIEW

Electro-Surgical Coagulation (radio-frequency application) in the treatment of GERD

Evidence Conclusion: Of the studies reviewed, an RCT compared Stretta procedure to sham treatment, and a non-randomized longitudinal study compared it to laparoscopic fundoplication. The third was just a survey from a registry with no control or comparison group. Corley et al's trial was randomized and controlled however, it was a small study, with a high dropout rate, and some baseline differences between the two groups, that were not adjusted for in the analysis. Moreover, the procedure was compared to a sham treatment and not to another intervention e.g. laparoscopic fundoplication. The follow-up duration might have been insufficient to determine the long-term sustained effects, or potential late harms that could be associated with the procedure. In addition, the patients included in the study were highly selected for the trial and may not represent typical GERD patients. Richard et al's study was not randomized and patients were highly selected for each procedure. It was not blinded, not powered, and the follow-up duration was as short as 2 months for some patients, which is insufficient to determine the long-term durability of benefits or harms of the procedure. Both Corley's and Richard's studies were financially supported by Curon Medical, the manufacturer of the Stretta system. The third study reviewed was a retrospective survey of patients who underwent the Stretta procedure in several centers, with no reference to the inclusion/exclusion criteria, or techniques used for performing the procedure. Overall, the results of the studies show that radiofrequency application to the gastroesophageal junction to selected GERD patients is associated with improvement in symptoms and quality of life compared to sham treatment or laparoscopic fundoplication. The heartburn improvement associated with GERD vs. sham treatment was significant in the per protocol analysis but not with the ITT analysis in Corley's trial.

Articles: The search yielded 9 articles. There were no meta-analyses or randomized controlled trials. There were only three empirical studies all of which were case series. One had a very small sample, and only three months follow-up. The other two with relatively larger sample sizes, and longer follow-up duration were selected for critical appraisal. In December 2001, Curon Medical announced the completion of two major clinical trials, one of which is a RCT of the Stretta vs. sham treatment. To date these studies have not been published. *Evidence tables were created for the following studies:* Triadafilapoulos G, DiBaise JK, Nostrant T, et al. The Stretta procedure for the treatment of GERD: 6 and 12-month follow-up of the U.S. open label trial. *Gastrointest Endosc* 2002, 55:149-156. See [Evidence Table](#). Houston H, Khaitan L, and Richards WO. First year experience of patients undergoing the Stretta procedure. *Surg Endosc* 2002, Nov 20. See [Evidence Table](#).

The use of electro-surgical coagulation (radio-frequency application) in the treatment of GERD does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

02/13/2003: MTAC REVIEW

Electro-Surgical Coagulation (radio-frequency application) in the treatment of GERD

Evidence Conclusion: The two-case series reviewed show that the Stretta procedure may be a promising treatment for GERD. Patients had significant reduction in the esophageal acid exposure and use of antisecretory medication, as well as significant improvement in their quality of life scores, compared to those before the intervention. However, the studies were case series that provide the lowest grade of evidence. In the studies reviewed, participants were highly selected for the procedure. Only patients with small or no hiatal hernias, no dysphagia, stricture, or Barrett's disease as well as those whose symptoms are controlled by pharmacological treatment were included in the studies. Moreover, the interpreters of the results were not blinded to the treatment, the follow-up duration was insufficient, dropout rate was high, and there were no comparison or control groups. In conclusion, there is insufficient evidence to determine the efficacy of the Stretta procedure in the treatment of GERD. Prospective randomized studies with larger sample sizes, comparison to another intervention or treatment, and a long follow-up duration will be needed.

Articles: The search yielded seven review articles and two empirical studies: (1) An RCT comparing radiofrequency ablation to sham treatment, and (2) A longitudinal non-randomized study comparing the procedure to fundoplication. *Evidence tables were created for these two studies as well as a patient registry published prior to 2003 that was not included in the earlier review:* Corley DA, Katz P, Wo JM, et al. Improvement of gastroesophageal reflux symptoms after radiofrequency energy: A randomized, sham-controlled trial. *Gastroenterol* 2002; 125:668-672. See [Evidence Table](#). Richards WO, Houston HL, Torquati A, et al. Paradigm shift in the management of gastroesophageal reflux disease. *Ann Surg* 2003; 237:638-649. See [Evidence Table](#). Wolfson HC, and Richards WO. The Stretta procedure for the treatment of GERD: A registry of 558 patients. *J Laparoendosc Adv Surg Tech* 2002; 6:395-402. See [Evidence Table](#).

The use of electro-surgical coagulation (radio-frequency application) in the treatment of GERD does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

EndoGastric Solutions Stomaphy X™ Endoluminal Fastener, InScope™ Tissue Apposition System, Transoral Incisionless Fundoplication

BACKGROUND

Over the last two decades, several less invasive endoluminal /endoscopic techniques have been developed for the management of GERD. These procedures include radiofrequency ablation (Stretta system), magnetic sphincter augmentation (LINX procedure), and transoral incisionless fundoplication, among others.

Transoral incisionless fundoplication (TIF) using the (EndoGastric Solutions, Inc., Redmond, WA) has been proposed as a less invasive alternative to traditional surgical procedures. Similar to the NF, TIF attempts to decrease the reflux of stomach acid into the esophagus through the reconstruction of an anti-reflux barrier. It involves wrapping a portion of the stomach around the esophagus without requiring any incisions.

TIF is performed in an outpatient setting under general anesthesia, and involves inserting the EsophyX™ device transorally, under direct endoscopic visualization, into the stomach and positioning it at the junction of the stomach and the esophagus. Once positioned, the device uses suction and transmural fasteners to facilitate the recreation of the esophageal gastric valve. The fundus of the stomach is folded up and around the distal esophagus utilizing the tissue mold and chassis of the device. Next, an integrated suction apparatus grasps the distal esophagus and positions it below the diaphragm. H-shaped fasteners, made of polypropylene, are then delivered through apposed layers of esophageal and fundus tissue to anchor the repair. This process is repeated to create a full thickness, partial circumference, and gastroesophageal fundoplication. Approximately 20 fasteners are implanted during the procedure resulting in the recreation of an omega shaped full-thickness gastroesophageal valve from inside the stomach 3-5 cm in length and 200-300° in circumference. This procedure may also reduce hiatal hernias that are < 2 cm in size through the use of a built-in vacuum invaginator (Jafri 2009, Louis 2010, Hunter 2015, Testoni 2014, Trad 2014, Witteman 2015).

TIF 1.0 utilizing the EsophyX™ device was first performed in 2005 and received United States Food and Drug Administration (FDA) initial 510(k) clearance in 2007. The EsophyX device is indicated for endoluminal, transoral tissue approximation, full thickness plication and ligation in the GI tract for the treatment of symptomatic chronic gastroesophageal reflux disease in patients who require and respond to pharmacological therapy. It is also indicated to narrow the gastroesophageal junction and reduce hiatal hernia < 2cm in size in patients with symptomatic chronic gastroesophageal reflux disease (FDA website accessed June 2020).

The EsophyX technology underwent several modifications along the years. Currently, there are three generations of the device; the original EsophyX® device, EsophyX2®, EsophyX Z®. Over the same timeline, four different

fundoplication procedures using the EsophyX have emerged. The initial device was used to perform the endoluminal gastro-gastric fundoplication, called “ELF”. The second procedure TIF 1.0, was a longitudinally oriented plication of gastric cardia onto the distal esophagus just proximal to the gastroesophageal junction. The third procedure TIF 2.0, incorporated a rotational wrap of the cardia and fundus around the circumference of the distal esophagus in addition to providing a 2–4 cm length of the wrap over the intra-abdominal distal esophagus. This results in tightening and reinforcing the sling fibers of the proximal stomach (the lower portion of the LES), accentuating the cardiac notch, steepening the angle of His, and reestablishing the flap valve mechanism. The fourth procedure is a combined laparoscopic hiatal hernia repair with transoral incisionless fundoplication 2.0 (HH-TIF). Each of TIF procedures described is markedly different from the others and have different clinical outcomes. The TIF-2 procedure is believed to be the most similar procedure to NF morphologically and physiologically and is accomplished by using the third generation EsophyX® Z, launched in 2015 and cleared by the FDA in 2016 (Chang 2020, Ihde 2020).

Reported adverse events associated with the procedure include gastrointestinal bleeds, esophageal laceration, pleural effusion, mediastinal abscess, and potential failure of the procedure due to the pull on the fastener used to create the valve.

04/09/2008: MTAC REVIEW

Endoluminar Fasteners

Evidence Conclusion: There is insufficient published evidence to determine the efficacy and safety of the EndoGastric Solutions StomaphyX™ endoluminar fastener for weight loss. There is insufficient published evidence to determine the efficacy and safety of the InScope™ Tissue Apposition System for endoscopic gastric sutures.

Articles: The literature search did not reveal any published studies, on the EndoGastric Solutions StomaphyX™ endoluminar fastener and delivery system, or on the InScope™ Tissue Apposition System. Information about the systems was obtained from the FDA and the manufacturer’s Web sites.

The use of endoluminar fasteners in the treatment of obesity does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/15/2011: MTAC REVIEW

Endoluminar Fasteners

Evidence Conclusion: Two case-series were selected for review that evaluated the safety and effectiveness of transoral incisionless fundoplication (TIF) for the treatment of GERD. The first study followed 110 subjects for a median of 7 months and the second study followed 86 subjects for 12 months. The primary outcome in both of these studies was GERD Health-Related Quality of Life (GERD-HRQL). Both studies found significant reductions in GERD-HRQL compared to baseline. However, results from these studies should be interpreted with caution as both studies were case-series (lowest-quality evidence). Serious adverse events included two perforations and a post-TIF intraluminal bleeding that required a blood transfusion. Other adverse events included: left shoulder pain, abdominal pain, sore throat, nausea, and epigastric pain (Barnes 2011; Cadière 2008). **Conclusion:** There is insufficient evidence to determine the safety and efficacy of transoral incisionless fundoplication for the treatment of GERD.

Articles: To determine the safety and efficacy of transoral incisionless fundoplication using the EsophyX system for the treatment of GERD. Screening of articles: No randomized controlled trials were identified that addressed the safety or efficacy of transoral incisionless fundoplication using the EsophyX system for the treatment of GERD. Studies were not selected for review if they included less than 25 subjects. The largest studies with the longest duration of follow-up were selected for review. The following studies were critically appraised: Barnes WE, Hoddinott KM, Mundy S, Williams M. Transoral incisionless fundoplication offers high patient satisfaction and relief of therapy-resistant typical and atypical symptoms of GERD in community practice. *Surg Innov* 2011; 18:119-129. See [Evidence Table](#). Cadière GB, Buset M, Muls V, et al. Antireflux transoral incisionless fundoplication using EsophyX: 12-month results of a prospective multicenter study. *World J Surg* 2008; 32:1676-1688. See [Evidence Table](#).

The use of endoluminar fasteners in the treatment of GERD does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

07/13/2020: MTAC REVIEW

Transoral Incisionless Fundoplication with Esophyx

Conclusion:

- The published RCTs evaluating the safety and efficacy of TIF 2.0 using EsophyX compared the procedure versus a sham therapy or PPI and not to laparoscopic Nissen fundoplication (LNF), the most appropriate comparator.
- There is no direct published evidence, to date, to determine the safety and effectiveness of TIF 2.0 using EsophyX compared LNF, the gold standard for the management of patients with refractory GERD.
- Indirect comparison suggests the LNF is superior to TIF 2.0 in esophageal acid control, healing of esophagitis and increasing in LES pressure.
- There is insufficient published evidence to determine the effects of TIF using EsophyX on net health outcomes, and whether it will lead to protection from long-term adverse events of GERD and Barrett's esophagus.
- TIF may be superior to sham therapy (i.e. no therapy), but not PPIs in reducing percent time pH <4.
- TIF may be superior to sham therapy in improving the quality of life, but not in reducing the incidence of persistent esophagitis.
- The published studies and MAs indicate that the efficacy of TIF may decrease over time and that most patients may still need to use PPIs, but maybe at a lower dose.
- Open label trials found significant improvements with TIF 2.0 in subjective measures, but no difference in objective outcome measures of pH normalization and esophagitis when compared with PPI therapy. This may suggest a potential placebo effect of TIF 2.0.
- There is insufficient published data to determine the long-term safety of TIF 2.0 using EsophyX in patients with GERD.

Articles:

The literature search identified 6 RCTs, one non-randomized comparative study, and over 20 noncomparative observational studies published between 2011 and 2018. The search also revealed 4 meta-analyses (MAs) of exclusively RCTs or RCTs together with observational studies. One of the meta-analyses also included a network MA (NMA). Of the published RCTs, only one trial (Svoboda et al, 2011) compared TIF vs. LNF, 2 trials compared TIF to sham therapy, and two compared the procedure to different PPIs. The Svoboda trial was a small trial (N=52) that used 2 generations of the devices and different techniques for the TIF group along the study (Plicator® method for 18 patients, and the EsophyX® in 16 patients). The study was thus not included in any of the published meta-analyses as combining results of studies using different procedures and generations of the device would lead to incorrect conclusions on effectiveness of the procedure in treating reflux disease.

The meta-analysis with the more valid methodology and most inclusive of published RCTs (Huang et al, 2017) as well as the Richter and colleagues' systematic review with both a direct and network meta-analysis were selected for critical appraisal. The published RCTs that compared TIF 2.0 versus LNF, sham therapy, or PPIs were summarized in a table format. See [Evidence Table](#).

The use of Transoral Incisionless Fundoplication with Esophyx does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

07/08/2019: MTAC REVIEW**Magnetic Sphincter Augmentation (MSA) (LINX® Reflux Management System) for Gastroesophageal Reflux Diseases****Conclusion:**

- There is no published evidence, to date, from randomized controlled trials to determine the comparative safety and effectiveness of MSA and laparoscopic Nissen fundoplication in patients with GERD refractory to maximal medical therapy.
- Low quality evidence from short-term non-randomized comparative observational studies suggest that MSA may be associated with better postoperative ability to belch and vomit and less bloating compared to fundoplication in patients with GERD.
- There is insufficient evidence to determine the long-term safety or effectiveness of MSN in patients with medically refractory GERD.

Articles: The literature search for recently published studies after the December 2017 MTAC review did not identify any randomized controlled trial that compared magnetic sphincter augmentation (LINX® Reflux Management System) versus Nissen fundoplication. The search revealed only one RCT that compared MSA versus double-dose PPIs in patients with moderate to severe GERD who failed once daily PPI therapy for 8 weeks (Bell, 2019). One qualitative systematic review (Stanak 2018) and two more recent systematic reviews with meta-analyses (Ailofi 2018, and Guidozi 2019) that pooled the results of nonrandomized comparative observational studies, were also identified, as well as a small retrospective study (Richards 2018) of patients who underwent the procedure by a single surgeon. The RCT comparing magnetic sphincter augmentation to double-dose PPI was excluded as the aim of the review was to compare the device to Nissen fundoplication the gold standard procedure

for patients with GERD-related symptoms despite the use of a maximum medical therapy. The most recent meta-analyses of studies comparing LINX® reflux management system with Nissen fundoplication were reviewed. No evidence tables referenced for this report.

The use of Magnetic Sphincter Augmentation (MSA) in the treatment of GERD does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

LINX® Reflux Management System - Considered Not Medically Necessary:

CPT® Codes	Description
43284	Laparoscopy, surgical, esophageal sphincter augmentation procedure, placement of sphincter augmentation device (ie, magnetic band), including cruroplasty when performed
43285	Removal of esophageal sphincter augmentation device

Radiofrequency Energy Delivery to Gastroesophageal Junction/Transesophageal radiofrequency energy (Ex: CSM Stretta) - Considered Not Medically Necessary:

CPT® Codes	Description
43257	Esophagogastroduodenoscopy, flexible, transoral; with delivery of thermal energy to the muscle of lower esophageal sphincter and/or gastric cardia, for treatment of gastroesophageal reflux disease

Transoral (Endoluminal) Gastroplication or Suturing/Transoral incisionless fundoplication (TIF) (Ex: Esophyx) - Considered Not Medically Necessary:

CPT® Codes	Description
43210	Esophagogastroduodenoscopy, flexible, transoral; with esophagogastric fundoplasty, partial or complete, includes duodenoscopy when performed

Endoscopic placement of a bulking material at the lower esophageal sphincter - Considered Not Medically Necessary:

CPT® Codes	Description
43192	Esophagoscopy, rigid, transoral; with directed submucosal injection(s), any substance
43201	Esophagoscopy, flexible, transoral; with directed submucosal injection(s), any substance

CR BARD's Endoscopic Suturing System - Considered Not Medically Necessary:

CPT® Codes	Description
No specific codes

Hayes Technology Assessment

A nerve block is a form of regional anesthesia. The genicular nerve is a sensory nerve that innervates the knee. Genicular nerve blocks are performed to relieve pain in patients who may not be candidates for knee surgery or in advance of total knee replacement surgery. In a genicular nerve block procedure, an anesthetic agent, (e.g.,

lidocaine, bupivacaine, etc.), is injected on the genicular nerve. Genicular nerve blocks may be performed as a diagnostic step to ensure that blocking the nerve provides pain relief. In these cases, after a genicular nerve block demonstrates pain relief, genicular neurotomy or genicular nerve ablation may be performed as a more permanent solution.

Hayes Rating: D² - Insufficient Evidence: For use genicular nerve blocks combined with a corticosteroid or alone for treatment of pain and loss of function associated with osteoarthritis of the knee or persistent chronic pain following total knee arthroplasty.

This Rating reflects a very-low-quality body of evidence that does not consistently provide proof of benefit. Substantial uncertainty remains due to conflicting evidence and limited follow-up.

Hayes. Hayes Technology Assessment. *Genicular Nerve Block for the Management of Knee Pain*. Dallas, TX: Hayes; June 24, 2020. Retrieved July 13, 2020, from <https://evidence.hayesinc.com/report/htb.genicular3323>

Background

Osteoarthritis (OA) of the knee is a common chronic degenerative joint disorder and one of the leading causes of physical impairment and decline in the quality of life in older adults in the US and worldwide. It is a progressive condition in which the cartilage between bones in the joint wears away leaving the bones to rub more closely against one another resulting in pain, swelling, stiffness, and loss of function.

Conservative treatment for symptomatic knee OA includes physical therapy, aquatic therapy, weight loss, oral or topical non-steroidal anti-inflammatory drugs, bracing, and orthosis. Intraarticular injection of corticosteroids, hyaluronic acid, and other treatment modalities have also been used to alleviate the pain however, the analgesic effect is short-term with the steroid injection and unproven with some other therapies. Overall, conservative measures may relieve symptoms and improve function in some patients, but they do not restore the normal knee function, reverse the damage, or slow the progression of the disease. Knee joint arthroplasty is the most effective treatment for relieving pain and improving the knee function in patients with severe knee OA, but it is an invasive surgery that may be associated with medical and postsurgical complications. In addition, older individuals with comorbidities might not be good candidates for the surgery and others may be unable or unwilling to undergo the operation (El-Hakim 2018, Jamison 2018, Erdem 2019).

Over the years, researches have been investigating alternative less invasive therapies for the treatment of patients with refractory knee OA. Several existing and new therapies have thus been or are being evaluated for the alleviation of chronic pain in patients with musculoskeletal disorders including knee OA.

Radiofrequency ablation (RFA) is one of these modalities considered for the treatment of patients with symptomatic knee. RFA is a nonsurgical, minimally invasive procedure that uses radio waves to create an electrical current through the body. The created current delivers heat to the targeted tissue resulting in its destruction. Ablation of the nerve tissues disrupts the ability of the nerve to send pain signals. RFA was first used by a German surgeon in 1931 to treat trigeminal neuralgia and three decades later, the first radiofrequency ablation commercial machine was introduced in the market. The indications of RFA have expanded over the years and is currently being used for the treatment of a variety of medical conditions including chronic low back pain, cardiac arrhythmias, tumors, varicose veins, obstructive sleep apnea, and several other disorders. More recently RFA gained popularity in alleviating pain due to musculoskeletal disorders. In 2010 Choi and colleagues investigated its use for OA knee pain based on the theory that blocking the sensory innervation for a painful structure will result in pain relief (Choi 2011, Gupta 2017).

The knee joint is innervated by the articular branches of various nerves including the femoral, common peroneal, saphenous, tibial and obturator nerves known as the genicular nerves. Several of these nerves can be approached percutaneously under fluoroscopic or ultrasound guidance to identify the anatomical landmarks around the knee and locate the targeted genicular nerves (Choi 2011, Gupta 2017).

Conventional RFA treatment uses a high temperature probe to impair/destroy the targeted nerve fibers that carry the pain signals to the brain. The high heat originating from the RF probe may potentially damage adjacent tissues as the temperature reaches 70-90°C. In addition, it has been reported that the lesion produced by the heat is limited in size and thus may not reach some target areas. To overcome these limitations, two new techniques the (pulsed RFA (p-RFA) and the cooled RFA (C-RFA) have been investigated for GNRFA (Oladeji 2019).

Coolief™ RFA treatment (the focus of the current review) also known as cooled radiofrequency ablation or neurotomy, follows the same method as the conventional RFA neuronal tissue damage, but uses water-cooled technology to safely impair or destroy the sensory nerves. A radiofrequency generator transmits a small current of RF thermal energy through an insulated electrode placed within the tissue. Sterile water circulates continuously inside the Coolief™ probe to cool it and regulate its temperature while it delivers the RF thermal energy. According to the investigators of the technology, the circulating water modulates the thermal heat in the tissue to ≈60°C and alters the size, shape, and projection of the lesions compared to conventional RFA. It is postulated that delivering RF energy through water-cooled electrode enables more RF energy to be safely delivered to the targeted nerves creating larger spherical -shaped lesion that increases the area of denervation and minimizes the risk of excessive heating and damaging the adjacent tissues (Gupta 2017, Oladeji 2019, AVANOS report 2019).

The Cooled RFA (CRFA) procedure is performed in an outpatient setting under local anesthesia, conscious sedation and fluoroscopic or ultrasound guidance. It is performed in 2 stages (McCormick 2017, Davis 2018):

1. A diagnostic genicular nerves block procedure: After positioning the patient in a supine position on a fluoroscopy table, a 25-gauge 2.5-3.5-inch Whitacre needle is placed under fluoroscopic guidance at three unique anatomic sites to block the superior lateral, superior medial, and the inferior medial genicular nerves. Accurate placement of the needle is confirmed using fluoroscopy in the AP and lateral planes, then lidocaine is injected in order to numb each genicular nerve. Patients with a positive response (≥50% reduction in pain in the 24hrs following injection) are offered radiofrequency ablation (stage 2) for a more sustained response.
2. Genicular nerve radiofrequency ablation procedure performed under fluoroscopic visualization of the anatomical landmarks for probe placement. The patient is positioned supine on the fluoroscopy table (similar to the diagnostic nerve block procedure), and given conscious sedation, and local anesthesia at each of the 3 anatomic sites for RFA. An introducer needle (50 or 70 mm 17-gauge) is then placed to lesion the 3 genicular nerves after which the internally cooled RFA electrode (Coolief, 4-mm, 18-gauge active tip) is inserted in the introducer needle and its positioning verified with AP and lateral fluoroscopic views. Lidocaine is then injected through the introducer needle to numb the region before the thermal ablation. Each target undergoes CRFA for 150 seconds at a set temperature of 60°C which produces tissue temperature of 77°C-80°C surrounding the electrode. The needles are then removed, and the patients allowed to recover before they are discharged to home.

Medical Technology Assessment Committee (MTAC)

Coolief Cooled Radiofrequency Ablation for Knee and Hip Pain

10/14/2019: MTAC REVIEW

Evidence Conclusion:

- There is insufficient published evidence to determine the safety and efficacy of cooled RFA treatment for the management of moderate to severe chronic OA knee pain that is refractory to conservative therapy in patients who are not candidates for surgery.
- There is low to moderate quality evidence from one relatively small RCT showing that genicular RFA using Coolief™ system, performed prior to total knee replacement surgery had no significant effect compared to sham ablation, on reducing post-operative pain, use of pain medications, or improving function.

Articles: The literature search for studies on cooled genicular nerve ablation for symptomatic knee osteoarthritis, published after the March 2018 INCT review yielded less than 10 articles including a report on the 12 months follow-up results of the pivotal RCT (Davis et al 2019). The search also identified a RCT comparing the effect of CRFA versus a sham therapy performed prior to TKA, on postoperative pain. Among the other recently published articles was a randomized trial that evaluated the utility of genicular nerve blocks to predict the outcome of genicular nerve cooled radiofrequency ablation in patients with osteoarthritis (McCormick et al, 2018); a cost-effective analysis of CRFA based on Davis et al's trial (Desai 2019); one observational study with no control or comparison group (House et al, 2019), three technical reports, and a case presentation.

[See Evidence Table.](#)

The use of Coolief Cooled Radiofrequency Ablation for Knee and Hip Pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Thermal Genicular Nerve Radiofrequency Ablation (GNRFA) for continued chronic knee pain post total knee replacement

07/13/2020: MTAC REVIEW

Evidence Conclusion:

There is insufficient published evidence to support the use of genicular RFA for reducing postoperative pain after total knee replacement surgery.

Articles:

There is a paucity of published literature evaluating the use of thermal genicular nerve ablation for the management of persistent pain after a total knee replacement surgery. The only published randomized controlled trial identified by the literature search was a small double-blinded trial that compared the efficacy of genicular nerves RFA versus analgesic block with corticosteroids in alleviating pain and improving function and QoL in patients with pain after a TKA (Qudsi-Sinclair S et al, 2017 ([Evidence Table 1](#))).

This trial was randomized, controlled, and double-blinded, but had its limitations including the small sample size study (N=30 randomized and 28 included in the analysis), lack of power calculations, randomization method not discussed, and subjective outcomes. There were also some baseline differences between the study groups e.g. their ages, duration of a pain, knee function, QoL, and the use of medication including opioids before the intervention. The differences were not significant, but the numbers may be too small to detect statistically significant differences.

The overall results of the study show the following (details in the evidence table)

- A significant reduction in pain scores in each of the treatment arm compared to baseline values, this was more pronounced in day 1 after each of the two procedures but tended to increase during follow-up.
- At one year the NRS was almost 5 in the RFA group and >5 in the steroid group (a value of 5-10 indicates worst possible pain).,
- Knee functioning also improved vs baseline, in each of the treatment arms, but was still considered poor and unsatisfactory according to the values of the KSS and OKS.
- There were no significant differences between the 2 study groups in any of the outcome measures (pain, function, QoL, or patient satisfaction). Lack of significant difference does not necessarily indicate that the two intervention have similar results as indicated by the authors). The power of the study may have been insufficient to detect statistically significant differences.

The use of Thermal Genicular Nerve Radiofrequency Ablation (GNRFA) for continued chronic knee pain post total knee replacement does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
64450	Injection(s), anesthetic agent(s) and/or steroid; other peripheral nerve or branch
64454	Injection(s), anesthetic agent(s) and/or steroid; genicular nerve branches, including imaging guidance, when performed
64624	Destruction by neurolytic agent, genicular nerve branches including imaging guidance, when performed
64640	Destruction by neurolytic agent; other peripheral nerve or branch
ICD-10 Codes	Description
M25.561	Pain in right knee
M25.562	Pain in left knee

Non-Medicare - Considered Not Medically Necessary:

CPT® Codes	Description
64450	Injection(s), anesthetic agent(s) and/or steroid; other peripheral nerve or branch

64454	Injection(s), anesthetic agent(s) and/or steroid; genicular nerve branches, including imaging guidance, when performed
64624	Destruction by neurolytic agent, genicular nerve branches including imaging guidance, when performed
64640	Destruction by neurolytic agent; other peripheral nerve or branch

Kaiser Permanente has elected to use the Mastectomy for Gynecomastia (KP-0273 v2 eff 04.01.2022) MCG* Care Guideline for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from primary care provider or specialist, addressing the indications described in the medical necessity criteria

***MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Gynecomastia is a unilateral or bilateral enlargement of the male breast due to benign proliferation of glandular elements. Pubertal gynecomastia resolves without intervention in the majority of cases. Gynecomastia in postpubertal males may be due to persistent pubertal gynecomastia, medications, liver disease, kidney disease, testicular tumors, or endocrine disorders. The cause remains undetermined in about 25% of cases. Male breast cancer is uncommon and usually presents as a discrete breast mass.

Heart Transplant

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. The following are current, generally accepted, guidelines for Heart transplantation¹. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral. As such, these should be applied together with careful clinical judgment.

1. GENERAL PRINCIPLES

- If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, then early referral should be made.
- Patients with a history of malignancy with a moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- Uncontrollable active infection is a contraindication to transplant.
- Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low^{2,3,4}. Exceptions may be made on a case-by-case basis.
- Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines and kidney) may require abstinence from tobacco products to be actively listed.
- Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
 - Patient must have a care giver or care givers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
 - Evidence of non-adherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- Patients must be willing and able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.

- h. The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.
- i. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

INDICATIONS FOR HEART TRANSPLANT

- a. End-stage heart disease as evidenced by one or more of the following:
 - i. Functional class III or IV
 - ii. Not correctable by medical or other surgical therapies
 - iii. A low VO₂ maximum: [5](#)
 - 1. ≤ 14 ml/kg/min in patients not on a beta blocker
 - 2. ≤ 12 ml/kg/min in patients on a beta blocker [6](#)
 - 3. < 19 ml/kg/min adjusted for lean body mass in patients with a BMI > 30 kg/m²
 - 4. Less than 50% of age predicted maximum.
 - iv. A VE/VCO₂ > 35 in a patient with a sub-maximal cardiopulmonary exercise test (RER < 1.05)²
 - v. Cardiac index < 2 L/min/m²
 - b. Unable to wean from mechanical or inotropic support.
 - c. Amyloid Cardiomyopathy
 - i. TTR Amyloid
 - ii. (AL) Amyloidosis without significant extra-cardiac involvement.
 - d. Refractory Life-Threatening Arrhythmias
3. The transplant should only be offered for conditions in which cardiac transplant has proven clinical benefits.
- ### CONTRAINDICATIONS FOR HEART TRANSPLANT
- (In conjunction with the General Principles listed above in Section 1 of these guidelines):
- a. Significant diseases such as:
 - i. Severe uncontrolled or poorly controlled hypertension.
 - ii. Clinically significant vascular disease not correctable by intervention.
 - iii. Pulmonary hypertension not reversible by drug manipulation despite maximum tolerated medical management. [7](#)
 - 1. Adults: PVR > 4 -6 Wood units or transpulmonary gradient > 15 mm Hg
 - 2. Children: PVR > 9 Wood units
 - iv. Severe pulmonary disease after optimal treatment of severe heart failure. [8](#)
 - v. Severe hepatic disease after optimal treatment of severe heart failure. [8](#)
 - vi. Kidney disease with creatinine clearance < 34 ml/kg/min or GFR < 30 ml/min after optimal treatment of heart failure. [8,9,10](#)
 - vii. Active and/or progressive central nervous system disease excluding patients with embolic stroke who have recovered completely.
 - viii. Evidence of cachexia or malnutrition (BMI < 19 kg/m² or $< 80\%$ ideal body weight). [10](#)
 - ix. Obesity (BMI > 35 kg/m² or $> 140\%$ ideal body weight) [11](#) has been associated with poor outcomes after cardiac transplant.
 - x. Diabetes with complications resulting in severe end-organ damage.
 - xi. Auto/acquired immune disease with multi-organ manifestation
 - xii. Acute pulmonary embolus
 - xiii. Active peptic ulcer disease
 - xiv. Severe symptomatic osteoporosis
 - xv. Age over 70 (Carefully selected patients over 70 years of age may be considered for cardiac transplantation)
 - xvi. AL Amyloidosis with significant extra-cardiac manifestations
 - xvii. Patients with viral hepatitis will require additional evaluation, including hepatology consultation.
 - xviii. Any other co-morbid condition that would limit life expectancy or quality of life.

Footnotes

- 1. Note: All patients must be continuously re-evaluated for indications and contraindications. Candidates considered for re-transplantation must be evaluated using the same indications.

6. Patients on Beta blockers should have a cut-off of ≤ 12 ml/kg/min, and patients intolerant to beta blockers a $VO_2 \leq 14$ ml/kg/min.
7. Circulation; 84 (3), 329 – 337. *Journal of Heart Transplantation* (1990): 526 – 537.
8. Selected patients for combined organ transplant will be evaluated on a case-by-case basis.
9. Must have 20mg per kilogram of creatinine in a 24-hour collection period. Creatinine clearance can also be calculated by the Cockcroft-Gault formula.
10. Mehra MR, Canter CE, Hannan MM, et al. The 2016 International Society for Heart Lung Transplantation listing criteria for heart transplantation: A 10-year update. *J Heart Lung Transplant* 2016; 35:1-23. 10.1016/j.healun.2015.10.023
11. Body Mass Index (BMI) = (weight [kg] / height² [m²]). Percent Ideal Body Weight (PIBW) was calculated as follows: Men IBW = 106 pounds for the first 5 feet of height, add 6 pounds for each additional inch. Women IBW = 100 pounds for the first 5 feet of height add 5 pounds for each additional inch. *Journal of Heart and Lung Transplantation*, Aug 1999, page 752.

LUNG TRANSPLANT:

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. The following are current, generally accepted, guidelines for lung & heart/lung transplantation. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral, rather should be applied together with careful clinical judgment.

1. GENERAL PRINCIPLES

- a. If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, early referral should be made.
- b. Patients with a history of malignancy with moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- c. Uncontrollable active infection is a contraindication to transplant.
- d. Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low. ^{4, 5, 6} Exceptions may be made on a case-by-case basis.
- e. Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products in order to be actively listed.
- f. Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
 - i. Patients must have a care giver or care givers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
 - ii. Evidence of non-adherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- g. Patients must be willing and able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.
- h. The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.
 - i. Evidence of such non-adherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- i. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

2. INDICATIONS FOR LUNG TRANSPLANT

- a. Must meet all prerequisites listed in the General Principles section
- b. Any disease state in which transplantation has become an accepted mode of treatment worldwide including

- i. Chronic obstructive pulmonary disease (COPD), which may include asthma, chronic bronchitis, emphysema and/or Alpha 1 antitrypsin deficiency
 - ii. Idiopathic pulmonary fibrosis
 - iii. Sarcoidosis
 - iv. Connective tissue disease-related pulmonary fibrosis
 - v. Eosinophilic granulomatosis
 - vi. Bronchiectasis
 - vii. Cystic fibrosis (CF)
 - viii. Pulmonary hypertension (both primary and secondary)
 - ix. Lymphangiomyomatosis (LAM)
 - x. Interstitial lung disease not otherwise defined.
- c. Patients should be referred for transplant evaluation by a pulmonologist or a cardiologist who has accumulated data defining both the disease as potentially treatable by transplantation and progression is occurring despite maximal medical therapy.
- d. Early referral is strongly encouraged for progressive lung disease with a poor prognosis⁷
- e. Ideally, the patient should be ambulatory with rehabilitation potential.

3. CONTRAINDICATIONS FOR LUNG TRANSPLANT

- a. Must meet all prerequisites listed in the General Principles section
- b. Invasive mechanical ventilator support⁸.
- c. Unresolved infection (except in cystic fibrosis and bronchiectasis).
- d. Uncontrolled chronic infection (i.e., HIV with detectable viral load)
- e. Other systemic diseases including but not limited to:
 - i. Diabetes with end organ effects; i.e., renal, cardiac or uncorrectable peripheral vascular disease. Insulin use itself is not a contraindication.
 - ii. Uncontrolled hypertension.
 - iii. Significant neurologic disease impairing cognitive function.
 - iv. Malnutrition⁹
 - v. Obesity >140% ideal body weight or BMI >32 kg/m² ^{10, 11}(with an understanding that a BMI <30 may be necessary for transplantation).
 1. May wish to consider initiating transplant workup if patient has pulmonary fibrosis and BMI >32 (but <34) if showing willingness to lose weight.
 - vi. Advanced hepatic dysfunction.
 - vii. Advanced renal dysfunction (creatinine clearance < 50 ml/min. after maximum therapy). However, patients with underlying cardiopulmonary causes of low creatinine clearance can be considered for transplant on a case-by-case basis.
 - viii. Evidence of clinically significant obstructive coronary artery disease and/or LVEF <40%. ¹²
 - ix. Active or unresolved peptic ulcer disease.
 - x. Chronic opiate use: Patients should be seen by a pain management specialist for alternative forms of therapy.
 - xi. Uncorrectable bleeding diathesis or clotting disorder

4. RELATIVE CONTRAINDICATIONS

- a. Patients with previous thoracotomy and/or sclerosing procedures should be considered on a case by case basis.
- b. Systemic corticosteroid therapy >10 mgs prednisone daily.
- c. Esophageal dysmotility and reflux. Surgical repair may be necessary.¹³
- d. Age >70 for lung transplant referral.
- e. Symptomatic osteoporosis.
- f. Major mechanical chest deformity (such as kyphoscoliosis).
- g. Short stature patients (in USA 4'11" for females and 5'4" for males) are significantly disadvantaged and early consideration of multiple listing is encouraged.

PATIENT PROFILE FOR COMMON DIAGNOSES LUNG TRANSPLANT REFERRAL GUIDELINES

Any or all of the listed guidelines for each disease entity should raise consideration for lung transplantation evaluation. Clinical correlation is always of primary importance.

1. GROUP A – Obstructive Lung Disease ^{14, 15} (See Table 1Below)

1.1. FEV1 < 25 %

1.2. DLCO < 40%

1.3. Hypoxemia; PO₂ < 55 Hypercapnia; PCO₂ > 51¹⁶

1.4. Bode Index > 5

2. GROUP B – Pulmonary Arterial Hypertension (See Table 1 Below)^{17, 18, 19}

2.1. Patients with clinically significant PAH should be evaluated by physicians experienced in treating pulmonary hypertension and have received maximum available pharmacological treatment.

2.2. Possible indications for referral include:

2.2.1. Pericardial Effusion²⁰

2.2.2. World Health Organization (WHO) (New York Heart Association) class 3 or 4

2.2.3. Lack of improvement in WHO Class 3 or 4 and/or lack of improvement in 6-minute walk test of < 350 meters, despite maximum pharmacological therapy.

2.3. Definite indications, after maximum pharmacologic treatment for referral include: ²¹

2.3.1. Mean RA > 15 mmHg

2.3.2. Cardiac Index < 2L per minute. Untreated, the mean survival for patients with these criteria is 10-11 months.

3. GROUP C – Cystic Fibrosis ²²(See table 1 Below)

3.1. FEV₁ < 40%

3.2. PO₂ < 55

3.3. Clinical deterioration, especially in young female patients, as characterized by increasing number of hospitalizations, including recurrent pneumothoraxes, rapid fall of FEV₁, recurrent major hemoptysis uncontrolled by embolization and/or increasing cachexia should prompt consideration for transplant referral.

3.4. PCO₂ > 51

3.5. Patients with *Burkholderia cepacia* have a relative contraindication.

4. GROUP D – Restrictive Lung Disease) ^{22, 23}(See Table 1 Below)

4.1. Force Vital Capacity < 80%²²

4.2. Decline in Forced Vital Capacity of ≥10% and/or decline in DLCO ≥ 15% during 6 months of follow-up²²

4.3. Diffusing Capacity (corrected for alveolar volume) < 60%

4.4. Evidence of interstitial lung disease on HRCT in conjunction with one or more of the above.

Referral to lung transplant program should be considered when a definitive diagnosis of usual interstitial pneumonitis (UIP) or idiopathic pulmonary fibrosis (IPF) is made and may be considered for the diagnosis of fibrotic nonspecific interstitial pneumonitis (NSIP).

OTHER CONDITIONS

Other conditions for which transplant may be appropriate include the Lung diseases described in Table 1 below.²⁴

Table 1: Lung allocation score (LAS) primary diagnostic groupings for lung transplant candidates

LAS lung disease diagnosis grouping	
Group A (obstructive lung disease)	<ul style="list-style-type: none"> Chronic obstructive pulmonary disease (COPD), with or without alpha-1-antitrypsin deficiency, due to chronic bronchitis and or emphysema Lymphangioleiomyomatosis (LAM) Bronchiectasis, including primary ciliary dyskinesia Sarcoidosis with a mean pulmonary artery (PA) pressure ≤ 30 mmHg
Group B (pulmonary vascular disease)	<ul style="list-style-type: none"> Idiopathic pulmonary arterial hypertension (iPAH, formerly known as primary pulmonary hypertension [PPH]) Eisenmenger's syndrome Other pulmonary vascular diseases
Group C (cystic fibrosis or immunodeficiency disorders)	<ul style="list-style-type: none"> Cystic fibrosis (CF) Immunodeficiency disorders such as hypogammaglobulinemia
Group D (restrictive lung disease)	<ul style="list-style-type: none"> Idiopathic pulmonary fibrosis (IPF) Pulmonary fibrosis due to other causes Sarcoidosis with mean PA pressure > 30 mmHg Obliterative bronchiolitis (nonretransplant)

ADDENDUM

GUIDANCE FOR LUNG TRANSPLANT FOR IRREVERSIBLE PULMONARY FAILURE FROM COVID-19

Background: Transplant has been successful for other conditions, including infections, that lead to irreversible pulmonary failure, so this disease has some familiar aspects within the lung transplant community. Because of the specific conditions surrounding the effects of SARS-CoV-2, and because much of the mechanism underlying the development of lung injury and recovery are still unclear, the following elements are recommended for any consideration for referral of and authorizations for potential candidates for lung transplant. The below represent elements, *IN ADDITION TO THE USUAL CRITERIA PROVIDED IN THE CMS LUNG PATIENT REFERRAL GUIDELINES*:

1. Age under 65 if ECMO has been used as bridge to transplant
2. Disease has progressed in spite of maximal non-invasive ventilatory support
3. No other significant organ dysfunction exists
4. Sufficient time for recovery must be allowed: once on invasive mechanical support or ECMO, referral should not be considered fewer than 4-6 weeks after ventilator-dependent or ECMO-supported pulmonary failure
5. Patients on prolonged O₂ therapy other than mechanical support or ECMO should be given sufficient time to determine irreversibility of the condition (usually three months) and should be ambulatory with good opportunity for rehabilitation.
6. Evidence of irreversible lung disease (bullae, fibrosis) must be present
7. The ability to gain patient, not surrogate, approval for transplant is an essential ethical concept in light of the relatively poor long-term outcomes from lung transplant
8. Ability to do adequate pulmonary rehabilitation while on support for respiratory failure
9. Have 2 negative SARS-CoV-2 PCR tests at least 24 hours apart with one of the samples being a deep respiratory specimen.
10. Transplants should be performed only at lung transplant programs experienced in the highest risk lung transplants including familiarity with transplanting patients with ECMO bridging to transplant. Furthermore, they should have:
 - a. Broad donor pool (represented by low time to transplant measures), and
 - b. Low wait-list mortality

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

This service is covered when it is medically necessary and identified as a benefit in the consumer's coverage contract. Kaiser Permanente adopted the MCG Guideline for medical necessity decision making.

Evidence and Source Documents

The scientific literature is periodically reviewed, and patient selection criteria are updated when new efficacy data becomes available.

Kaiser Permanente Committee on Medically Emerging Technology

Transplant, Lung, Double - 7/12/91 - Double lung transplantation is efficacious for appropriately selected patients.

Transplant, Lung, Single - 7/12/91 Single lung transplantation is efficacious for appropriately selected patients.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
33930	Donor cardiectomy-pneumonectomy (including cold preservation)
33933	Backbench standard preparation of cadaver donor heart/lung allograft prior to transplantation, including dissection of allograft from surrounding soft tissues to prepare aorta, superior vena cava, inferior vena cava, and trachea for implantation
33935	Heart-lung transplant with recipient cardiectomy-pneumonectomy
33940	Donor cardiectomy (including cold preservation)
33944	Backbench standard preparation of cadaver donor heart allograft prior to transplantation, including dissection of allograft from surrounding soft tissues to prepare aorta, superior vena cava, inferior vena cava, pulmonary artery, and left atrium for implantation
33945	Heart transplant, with or without recipient cardiectomy

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

^{MDCRPC} Medical Director Clinical Review and Policy Committee

^{MPC} Medical Policy Committee

Revision History	Description
03/05/2019	MPC approved to adopt KP National Criteria for Heart and Lung Transplant
09/03/2019	MPC approved to change General Principles 1.3 to <i>Uncontrollable infection is a contraindication to transplant</i> as recommended by KP National Transplant Services.
03/03/2020	MPC approved the proposed changes from KP National Transplant Services
04/06/2021	Per National Transplant Guidelines: 1.3 added "active" for Heart Transplant and changes to Lung Transplant. *Lung Transplant Guideline requires 60-day notice, effective date September 1, 2021.
01/10/2022	MPC approved the proposed changes from KP National Transplant Services. 60-day notice is not required.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

High-Frequency Chest Wall Oscillation Devices (HFCWO)

- ABI Vest® for Cystic Fibrosis
- Vest® Airway Clearance System

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	High Frequency Chest Wall Oscillation Devices (L33785)
Local Coverage Article (LCA)	High Frequency Chest Wall Oscillation Devices (A52494)

For Non-Medicare Members

A. The member must have **ONE** of the following:

1. A diagnosis of cystic fibrosis.
2. A diagnosis of bronchiectasis:
 - a) Characterized by daily productive cough for at least 6 continuous, months or, frequent (i.e. more than 2/year) exacerbations requiring antibiotic therapy, and
 - b) Confirmed by high resolution, spiral, or standard CT scan
3. Neuromuscular Disorder
 - a) Acid maltase deficiency
 - b) Anterior horn cell diseases, including amyotrophic lateral sclerosis
 - c) Hereditary muscular dystrophy
 - d) Multiple sclerosis
 - e) Myotonic disorders
 - f) Other myopathies
 - g) Paralysis of the diaphragm
 - h) Post-polio
 - i) Quadriplegia regardless of underlying etiology.

B. And meet **ALL** of the following criteria:

1. Well-documented failure of standard treatments to adequately mobilize retained secretions with all of the following:
 - a) Chest physical therapy and flutter device at least twice daily (when age appropriate)
 - b) A pattern of hospitalizations at least annually or more
 - c) Significantly deteriorating clinical condition
2. Be under the care of a pulmonologist
3. Had a rental trial to confirm compliance before purchase

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Conventional chest physical therapy (CPT), also known as percussion and postural drainage (P/PD) has traditionally been the standard of care of secretion clearance methods for patients with excessive or retained lung secretions. Depending on the severity of the disease or the presence of infection, CPT is performed in 1-3 sessions per day, each lasting between 23-30 minutes. These are administered by a physical therapist or a trained caregiver. CPT is labor intensive and time consuming, which could lead to poor compliance.

A number of airway clearing devices have thus been developed for independent use with little or no assistance by others. These include the high-frequency chest wall oscillation (HFCWO), which is an external non-invasive respiratory modality that mobilizes airway secretions from the small peripheral airways. The technique typically produces compression of the chest wall via an inflatable vest linked to an air pulse generator. The generator delivers an intermittent flow to the vest which rapidly compresses and releases the chest wall at a variety of frequencies. Consequently, an oscillation of airflow within the airways is achieved. The researchers believe that the underlying mechanisms include increased airflow-mucous interaction causing a reduction in viscoelasticity, production of airflow bias that promotes a cephalad movement of the mucous, as well as the enhancement and stimulation of ciliary activity (Osman 2010).

HFCWO is most commonly used for assisting mucous secretion in patients with disorders associated with abnormally thick mucous hypersecretion but preserved muscle function such as cystic fibrosis. It has also been advocated as an adjunctive therapy to assist cough clearance in patients with neuromuscular disorders who have relatively normal mucus but weak respiratory muscles (Chaisson 2006, Osman 2010, Finder 2010).

The FDA has cleared several airway clearing systems for delivering high-frequency chest wall oscillation to promote airway clearance and improve bronchial drainage in situations where physicians recommend external manipulation of the thorax. These systems include the Vest™ Airway Clearance System (also known as the ABI Vest or the ThAIRapy Vest, or the ThAIRapy Bronchial Drainage System), Medpulse Respiratory Vest System, and the FREQUENCER which produces sound wave stimulation to oscillate and loosen mucous secretion in the chest.

HFCWO is most commonly used with cystic fibrosis patients who have abnormally thick secretions. It has also been used for other conditions such as bronchiectasis. Another proposed application is treating patients with neuromuscular disorders, who may have impaired cough and may not be able to clear their airways. An inadequate cough in these patients can lead to atelectasis or pneumonia. Other possible treatments for airway clearance in patients with neuromuscular disorders include percussion and postural drainage (P&PD), the traditional procedure, autogenic drainage, positive expiratory pressure therapy, flutter valve and intrapulmonary percussive ventilation (IPV) (Panitch et al., 2006; Langenderfer, 1998).

Neuromuscular diseases are a heterogeneous group of inherited or acquired disorders characterized by progressive irreversible weakness of functional groups of skeletal muscles including the respiratory muscles necessary for ventilation and cough. Depending on the severity of the disorder, ineffective cough and clearing of respiratory secretions can present as frequent respiratory infections, pneumonias, and atelectasis. As the disorder progresses, the patients may develop spinal deformities, gas exchange abnormalities, sleep disorders, and cardiac dysfunction. These and any concomitant pulmonary disorder can severely compromise the existent muscle weakness and precipitate respiratory failure (Chaisson 2006, Yuan 2010).

The Vest™ Airway Clearance System (Hill-Rom, ST Paul, Minnesota), consists of a 1. Non-stretching inflatable cloth-like vest that covers the entire thorax and provides high frequency chest wall oscillation; 2. Large-bore tubing connects the vest to the air-pulse generator; and 3. An air pulse generator that creates pressure to inflate and deflate the vest against the thorax. The vest is inflated to a constant pressure to maximize the surface area over which high frequency (5-20 Hertz), small volume pressure impulses are transmitted externally to the entire chest area. Pressure pulses are controlled by the patient and applied during expiration. A typical treatment may last for 20-30 minutes and consists of periods of compression separated by huff coughs (Chatburn 2007).

Medical Technology Assessment Committee (MTAC)

ThAIRapy/ABI Vest®

12/13/2000: MTAC REVIEW

Evidence Conclusion: The scientific evidence does not permit conclusions about the effect of the ThAIRapy/ABI Vest® on health outcomes. The two randomized trials had small sample sizes and threats to validity that make their findings inconclusive. The Arens study did not find differences between patients (n=50) randomized to the ABI Vest® compared to chest physical therapy, but this may have been due to low statistical power (the authors did not discuss statistical power issues). The Kluft study included only 29 individuals, had a brief intervention (4 days total), no “wash-out” period between the ABI vest and chest physical therapy interventions (patients had a different intervention each day), gave nebulized saline to the ABI vest but not the physical therapy group, and examined sputum weight, an intermediate outcome measure. The Warwick and Hansen study, an interrupted time series design had the smallest sample size (n=16) and the validity was seriously threatened by possible selection bias. None of the available studies examined clinical outcomes such as pulmonary exacerbations or hospitalizations and no information was provided on short-term or long-term adverse health outcomes associated with the use of the ABI Vest®.

Articles: The search yielded 20 articles. 11 articles were not directly relevant or were review articles. Of the remaining 9 articles, 5 were randomized controlled trials (RCTs). The two RCTs with the largest sample sizes were selected for critical appraisal (the remaining three RCTs all had sample sizes of less than 20 patients). In addition, an interrupted time-series analysis with longer-term follow-up of patients was reviewed. Arens R, Gozal D, Omlin KJ, Vega J, Boyd KP, Keens TG, Woo MS. Comparison of high frequency chest compression and conventional chest physiotherapy in hospitalized patients with cystic fibrosis. *Am J Respir Crit Care Med* 1994; 150: 1154-7. See [Evidence Table](#). Kluft J, Beker L, Castaglini M, Gaiser J, Chaney H, Fink RJ. A comparison of bronchial drainage treatments in cystic fibrosis. *Pediatr Pulmonol* 1996; 22: 271-74. See [Evidence Table](#). Warwick WJ, Hansen LG. The long-term effect of high-frequency chest compression therapy on pulmonary complications of cystic fibrosis. *Pediatr Pulmonol* 1991; 11: 265-71. See [Evidence Table](#).

The use of ThAIRapy/ABI Vest® for treatment of cystic fibrosis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

ThAIRapy/ABV Vest®

10/08/2003: MTAC REVIEW

Evidence Conclusion: There is no published empirical evidence on the use of the Vest™ Airway Clearance System for bronchiectasis. There is no new published evidence on the use of the Vest™ Airway Clearance System for cystic fibrosis. The summary of the evidence on the ABI vest from December 2000 is: “The scientific evidence does not permit conclusions about the effect of the ThAIRapy/ABI vest on health outcomes. The two randomized trials had small sample sizes and threats to validity that make their findings inconclusive. The Arens study did not find differences between patients (n=50) randomized to the ABI vest compared to chest physical therapy, but this may have been due to low statistical power (the authors did not discuss statistical power issues). The Kluft study included only 29 individuals, had a brief intervention (4 days total), no “wash-out” period between the ABI vest and chest physical therapy interventions (patients had a different intervention each day), gave nebulized saline to the ABI vest but not the physical therapy group, and examined sputum weight, an intermediate outcome measure. The Warwick and Hansen study, an interrupted time series design had the smallest sample size (n=16) and the validity was seriously threatened by possible selection bias. None of the available studies examined clinical outcomes such as pulmonary exacerbations or hospitalizations and no information was provided on short-term or long-term adverse health outcomes associated with the use of the ABI vest.”

Articles: The search yielded 6 articles. There were no new empirical studies on the Vest™ Airway Clearance System for cystic fibrosis. There were no empirical studies on the Vest™ Airway Clearance System for bronchiectasis.

The use of ThAIRapy/ABI Vest® for treatment of cystic fibrosis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

High Frequency Chest Wall Oscillation

02/04/2008: MTAC REVIEW

Evidence Conclusion: There is no empirical evidence on the safety and effectiveness of the Vest™ Airway Clearance System for improving health outcomes in patients with neuromuscular disease.

Articles: The search yielded 11 articles. When limited to English language publications and human populations, there were 7 articles. Only 2 of the 7 articles, both of them reviews/opinion pieces, specifically addressed the topic of interest, airway clearance for patients with neuromuscular weakness. The remaining articles were on different,

related topics. No empirical studies were identified. One of the review articles (Panitch, 2006) stated that HFCWO has not been studied in patients with neuromuscular disease.

The use of High-frequency chest wall oscillation (HFCWO) for treatment of neuromuscular deficiency does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

10/18/2010: MTAC REVIEW

High Frequency Chest Wall Oscillation

Evidence Conclusion: The evidence on the use of high-frequency chest wall oscillation (HFCWO) therapy in patients with neuromuscular disorders is very limited and insufficient to determine the safety and effectiveness of the Vest™ Airway Clearance System for improving health outcomes in these patients. The published studies to date have very small sample sizes and short follow-up durations. Those with a control group have several threats to their internal validity. Among these are unblinding, including heterogeneous groups of population, potential selection bias, insufficient power to detect significant differences between therapies, relatively high dropout rates, and/or analyses were not based on intention to treat. Additionally, the studies were funded by the manufacturer of the airway clearance systems used.

Articles: The majority of published literature on high-frequency chest wall oscillation (HFCWO) was on its use for patients with cystic fibrosis and other obstructive airway diseases. The literature search for studies published after the last MTAC review of the technology for patients with neuromuscular disorders revealed only one small RCT that compared the use of HFCWO to the standard chest physiotherapy among a small group of pediatric population with cerebral palsy or neuromuscular disease. Yuan N, Kane P, Shelton K, et al. Safety, tolerability, and efficacy of high-frequency chest wall oscillation in pediatric patients with cerebral palsy and neuromuscular diseases: an exploratory randomized controlled trial. *J Child Neurol*. 2010; 25:815-821. See [Evidence Table](#)

The use of High-frequency chest wall oscillation (HFCWO) for treatment of neuromuscular deficiency does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

HPCP Codes	Description
A7025	High frequency chest wall oscillation system vest, replacement for use with patient-owned equipment, each
A7026	High frequency chest wall oscillation system hose, replacement for use with patient-owned equipment, each
E0480	Percussor, electric or pneumatic, home model
E0483	High frequency chest wall oscillation system, includes all accessories and supplies, each

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (oncologist, radiologist, primary care provider)
- Most recent imaging

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Prostate cancer is the second most frequently diagnosed cancer across the globe (Wolff et al., 2015). A 2008-2010 data estimated that 15% of men in the United States will be diagnosed with prostate cancer at some point in their lives (Wolff et al., 2015). However, the mortality rate is low because it is a slow growing cancer.

Treatment is based on a number of factors including tumor stage, prostate specific antigen (PSA) value, Gleason score (GS), patient's age, concomitant diseases, life expectancy and patient's preference (Warmuth, Johansson, & Mad, 2010). A wide range of options are available for prostate cancer and these include active surveillance, watchful waiting, radical prostatectomy, hormone therapy, radiotherapy, external beam radiotherapy (EBRT), brachytherapy and chemotherapy (Wolff et al., 2015). High Intensity Focused Ultrasound (HIFU) and cryotherapy are being considered as treatment options.

HIFU is a procedure in which beams target localized tissue without destroying the surrounding tissue and the high energy produced by HIFU leads to coagulative necrosis (Dogra, Zhang, & Bhatt, 2009). Two mechanisms including hyperthermia and acoustic cavitation cause the destruction of the tissue (Kennedy, Ter Haar, & Cranston, 2014). First, high energy is produced and converted to heat as the ultrasound wave disseminates through the tissue. This high energy leads to extreme temperatures surpassing the threshold level of protein denaturation (>43-degree C) resulting in coagulative necrosis. In the surrounding areas of the target zone, temperatures decrease suddenly keeping the outside tissues unaffected. Second, the interaction between ultrasound and micro-bubbles of water in the sonicated tissue result in cavitation. Cavitation may lead to diffusion of energy reinforcing tissue destruction (Stride & Coussios, 2010).

For this procedure, a transducer, covered by a condom through which cooled water is circulated to cool the rectal wall, is inserted into the rectum and several images are taken. The transducers generate very precise small lesions destroying the prostate partially or completely (Cordeiro et al., 2012).

HIFU is non-invasive and non-ionizing technique that is believed to have some advantages over other thermal therapy such as cryotherapy, laser ablation, and photothermal therapy and radiofrequency interstitial tumor ablation (Cordeiro et al., 2012). Two types of systems have been approved by the Food and Drug Administration (FDA). These include the Sonablate 450 (developed by SonaCare Medical) and the Ablatherm HIFU (EDAP TMS SA) both of which received FDA approval in October and November 2015 respectively. HIFU is indicated for primary treatment and salvage treatment for localized prostate cancer.

Medical Technology Assessment Committee (MTAC)

High Intensity Focused Ultrasound (HIFU) for the treatment of localized Prostate Cancer

MTAC REVIEW: 06/21/2016

Evidence Conclusion: INTC reviewed the technology in 2008 and concludes that there is insufficient evidence to determine whether the technology is medically appropriate for any patient and that the existing evidence regarding how HIFU treats prostate cancer is of insufficient quantity and quality. In April 2016, INTC conducted another review of the technology and concludes that: "the body of evidence that is available from which to assess the efficacy and safety of HIFU for localized prostate cancer (as primary and salvage therapy) is very low quality. The risk of bias in existing studies is high. Across studies, there is variation and/or lack of information regarding patient selection criteria, how HIFU was delivered, how outcomes were measured, and how long patients were followed"

INTC review can be adopted.

HIFU for Primary and Salvage therapy

Systematic Review of the Efficacy and Safety of High-Intensity Focused Ultrasound for the Primary and Salvage Treatment (Warmuth, Johansson, & Mad, 2010) (evidence table 1) The aim of this study was to assess the efficacy and safety of HIFU in the primary and salvage treatment for prostate cancer. The primary outcomes were the biochemical disease-free survival rate, the negative biopsy rate, overall survival rates, prostate cancer-specific survival rates, adverse events, and QOL. The literature search was performed from 200 to 2010 and included 20 case series (with more than 50 participants) in which 93% of patients were treated with primary therapy and 7% for salvage HIFU. For all HIFU procedures, the biochemical disease-free survival rate was between 78% and 84%, 45%- 84%, and 69% at 1, 5, and 7 years, respectively. The negative biopsy rate was 86% at 3 months and 80% at 15 months. Overall survival rate and prostate-cancer specific survival rate were reported in 1 study and were 90% and 100% at 5 years and 83% and 98% at 8 years, respectively. Adverse events were mainly related to the urinary tract (1-58%), potency (1-77%) and rectum (0-15%). The study has several limitations including the study design lacking control group, long term follow-up was not available and the quality of evidence of included studies was low, surrogate outcomes were used and the central question is whether surrogate outcomes corroborate with overall survival, QOL, and prostate cancer specific survival, and the possibility for publication bias. The evidence is of low quality; therefore, results should be interpreted with caution.

Ablative therapy for people with localized prostate cancer: a systematic review and economic evaluation (Ramsay et al., 2015) (evidence table 2) This systematic review indicates that the biochemical failure rate of HIFU was higher (statistically significant) than that of EBRT at 1 year but no statistically significant difference was observed at 5 years. The results also indicate statistically significant lower rate of disease free survival for HIFU compared to EBRT at 1 year. At 4 years, overall survival was better for HIFU compared to EBRT. Compared to RP, there was an increased risk of biochemical failure for HIFU at 1 and 5 years. But this difference was not significant. Also, in term of disease free survival, no statistical significant difference was noted when HIFU was compared to RP at 1 year. At 3 years, the difference was not statistically significant. For urinary incontinence, erectile dysfunction, or bowel problems (not in the table), data were insufficient to reach a conclusion. Results were not statistically significant for dysuria or urinary retention. Nonetheless, high proportion of urethral stricture was observed for HIFU. When comparing HIFU to active surveillance (AS) (not on the table), there was no difference in overall survival or erectile dysfunction. The results are mixed and due to the poor quality of case series included in the review, with the lack of long term findings, the result should be interpreted with caution.

HIFU for Salvage therapy

High intensity focused ultrasound (HIFU) for definitive treatment of prostate cancer (Cordeiro et al., 2012)

The purpose of this review was to update the available literature on HFU as definitive treatment of prostate cancer and to describe the techniques extensively and give an overview of historical background. Searched was conducted from 200 to December 2011. The search included case series with more than 50 participants assessing efficacy and safety of HIFU. No RCTs were identified and only 33 uncontrolled studies were identified. HIFU as salvage therapy after EBRT was assessed in two case series. The mean age was 68 years with mean preoperative PSA ranged from 6.89 to 7.73 ng/mL and Gleason score (GS) was ≥ 8 . Prostate volume preoperatively ranged from 18-21.4 mL; 34-56% received neoadjuvant androgen-deprivation therapy (NADT). Patients were followed for 15-18 months. The negative biopsy rate ranged from 73-80%; patients achieving $PSA \leq 5$ ng/ml was 61% in one study; the mean PSA Nadir ranged from 1.97-2.38 ng/ml and disease-free survival ranged from 38-53% (30 mos-36mos). In terms of complications, urinary retention represented 7.8%, urinary tract infections (1.4- 3.5%), urinary incontinence (7-31.5%), bladder stenosis (17%), rectal urethral fistula 3 weeks after HIFU (3-6%) and erectile dysfunction was not assessed. The authors concluded that HIFU seems to control cancer on the short to medium term with less adverse events compared to established therapies. There was heterogeneity among the studies; individual studies are case series resulting in low quality evidence. In addition, long term data was not available. Therefore, results should be interpreted with caution.

Additional studies

Subsequent studies (assessing HIFU as primary or salvage therapy) to the systematic reviews aforementioned were non-randomized controlled trial and did not compare HIFU to other treatment options. Accurate conclusions cannot be made from these studies. Summary of additional studies for HIFU as primary therapy: Nine non-RCTs (Aoun et al., 2015; Sebastien Crouzet et al., 2014; Dickinson et al., 2016; Feijoo et al., 2016; Ganzer et al., 2013; Liu & Chiang, 2016; Mearini et al., 2015; Uchida et al., 2015; van Velthoven et al., 2015) were examined and were for the most part observational studies. The sample size ranged from 50 to 1002; follow-up varied from 12 to 108 months. Of the nine studies, only two were comparative (Aoun et al., 2015; Liu & Chiang, 2016) and the findings from these two studies indicate: for Liu, 2016 (HIFU vs. cryoablation), no differences between biochemical recurrence rates were found; for Aoun, 2015 (HIFU vs. brachytherapy), similar survival outcomes were observed with greater biochemical recurrence free survival in the brachytherapy group. Summary of additional studies for HIFU as salvage therapy: Five observational studies (Baco et al., 2014; Sébastien Crouzet et al., 2012; Song et al., 2014; Uddin Ahmed et al., 2012; Yutkin et al., 2014) were examined; the sample size varied from 19 to 290; follow-up ranged from 19.8 months to 51.6 months and there was heterogeneity in the measures of outcomes. The survival rates varied as well.

Conclusion:

- No RCTs comparing HIFU to other treatment options were identified.
- The available evidence is of low quality since it is represented by non-comparative, case series/observational studies.
- The overall concerns are the lack of control group and long-term follow-up, the use of surrogate outcomes raising the question of consistency with overall survival and QOL, and the variations in patient populations and biochemical progression-free survival.
- Conclusion on efficacy and safety of HIFU for the treatment of localized prostate cancer or recurrent localized prostate cancer cannot be drawn at this time.

Articles: No RCTs were identified. The following articles are selected for critical appraisal: Systematic Review of the Efficacy and Safety of High-Intensity Focused Ultrasound for the Primary and Salvage Treatment (Warmuth et al., 2010) (evidence table 1) Ablative therapy for people with localized prostate cancer: a systematic review and economic evaluation (Ramsay et al., 2015) (evidence table 2) High intensity focused ultrasound (HIFU) for definitive treatment of prostate cancer (Cordeiro et al., 2012)

The use of High Intensity Focused Ultrasound (HIFU) for the treatment of localized Prostate Cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Not Medically Necessary:

CPT® or HCPC Codes	Description
55880	Ablation of malignant prostate tissue, transrectal, with high intensity-focused ultrasound (HIFU), including ultrasound guidance
C9734	Focused ultrasound ablation/therapeutic intervention, other than uterine leiomyomata, with magnetic resonance (MR) guidance

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria High-end imaging Site of Care Medical Policy

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

This policy does not apply to Medicare members.

For Non-Medicare Members

A high-tech imaging service (i.e., MRI/MRA/CT/CTA) must meet applicable medical necessity criteria for coverage. When coverage criteria are met for the requested imaging procedure, this coverage policy is used to help determine the medical necessity of the requested site of care for ambulatory, non-emergent imaging.

A high-tech imaging procedure in a *hospital-based* imaging department or facility is considered medically necessary for an individual with **ANY** of the following indications:

- Less than 13 years of age
- Requires obstetrical observation
- Requires perinatology services
- Imaging related to transplantation services at an approved transplantation facility
- Patient is enrolled in an approved clinical trial and trial protocol requires imaging to be done at this site
- Known contrast allergy and use of that contrast agent is planned
- There are no other appropriate alternative sites for the individual to undergo the imaging procedure for **ANY** of the following reasons:
 - Surgery or procedure will be performed at a specific hospital and pre-operative or pre-procedure imaging must be done at the same hospital, as it is an integral component of the procedure. This is not common. Examples would include epilepsy surgery where ablation of specific areas is planned or pre TAVR insertion in certain geographies. There must be documentation of a medically necessary reason the images cannot be performed at a freestanding facility and transmitted to the hospital and/or surgeon for pre op planning or in the OR.
 - Moderate or deep sedation or general anesthesia is required for the imaging procedure and freestanding facility providing such sedation is not available
 - Equipment for the size of the individual is only available at a hospital-based imaging facility
 - Individual has a documented diagnosis of claustrophobia requiring open magnetic resonance imaging which is not available in a freestanding facility; or
 - Imaging outside the hospital-based imaging department or facility is expected to adversely impact or delay care.
 - The patient has a pacemaker that requires coordination, monitoring, and a code team onsite during the MRI, which are not available at a nearby freestanding site*

*Kaiser Permanente can provide this at multiple sites

All other high-tech radiology (imaging) procedures at a hospital-based imaging department or facility are considered not medically necessary. In the absence of one of the above circumstances, it would be expected that non hospital-based locations would be used, such as a clinic or free-standing imaging centers. Hospital-based

imaging departments may be authorized if there is no appropriate geographically accessible free-standing imaging center.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Hospital-based advanced radiologic imaging procedures are generally more appropriate for individuals whose health status necessitates the availability of more supportive care for the minimization of the risks associated adverse health events.

Certain high-risk medical conditions can necessitate the need for an anesthesiologist to be present during the advanced radiologic imaging for individuals including neonates and children. Children can require specialized pediatric equipment including smaller anesthetic tools such as endotracheal tubes and monitoring equipment. Conversely, large individuals or those with claustrophobia may also require specialized equipment which could include an open magnetic resonance imaging (MRI) as opposed to a traditional MRI scanner.

Examples of advanced radiologic imaging include computed tomography, computed tomography angiography, magnetic resonance imaging, magnetic resonance angiography.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Computed Tomography (CT) and Computed Tomographic Angiography (CTA)

CPT® or HCPC Codes	Description
70450	Computed tomography, head or brain; without contrast material
70460	Computed tomography, head or brain; with contrast material(s)
70470	Computed tomography, head or brain; without contrast material, followed by contrast material(s) and further sections
70496	Computed tomographic angiography, head, with contrast material(s), including noncontrast images, if performed, and image postprocessing
70480	Computed tomography, orbit, sella, or posterior fossa or outer, middle, or inner ear; without contrast material
70481	Computed tomography, orbit, sella, or posterior fossa or outer, middle, or inner ear; with contrast material(s)
70482	Computed tomography, orbit, sella, or posterior fossa or outer, middle, or inner ear; without contrast material, followed by contrast material(s) and further sections
70486	Computed tomography, maxillofacial area; without contrast material
70487	Computed tomography, maxillofacial area; with contrast material(s)
70488	Computed tomography, maxillofacial area; without contrast material, followed by contrast material(s) and further sections
70490	Computed tomography, soft tissue neck; without contrast material
70491	Computed tomography, soft tissue neck; with contrast material(s)
70492	Computed tomography, soft tissue neck; without contrast material followed by contrast material(s) and further sections
70498	Computed tomographic angiography, neck, with contrast material(s), including noncontrast images, if performed, and image postprocessing
71250	Computed tomography, thorax, diagnostic; without contrast material
71260	Computed tomography, thorax, diagnostic; with contrast material(s)

71270	Computed tomography, thorax, diagnostic; without contrast material, followed by contrast material(s) and further sections
71271	Computed tomography, thorax, low dose for lung cancer screening, without contrast material(s)
71275	Computed tomographic angiography, chest (noncoronary), with contrast material(s), including noncontrast images, if performed, and image postprocessing
72125	Computed tomography, cervical spine; without contrast material
72126	Computed tomography, cervical spine; with contrast material
72127	Computed tomography, cervical spine; without contrast material, followed by contrast material(s) and further sections
72128	Computed tomography, thoracic spine; without contrast material
72129	Computed tomography, thoracic spine; with contrast material
72130	Computed tomography, thoracic spine; without contrast material, followed by contrast material(s) and further sections
72131	Computed tomography, lumbar spine; without contrast material
72132	Computed tomography, lumbar spine; with contrast material
72133	Computed tomography, lumbar spine; without contrast material, followed by contrast material(s) and further sections
72191	Computed tomographic angiography, pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
72192	Computed tomography, pelvis; without contrast material
72193	Computed tomography, pelvis; with contrast material(s)
72194	Computed tomography, pelvis; without contrast material, followed by contrast material(s) and further sections
73200	Computed tomography, upper extremity; without contrast material
73201	Computed tomography, upper extremity; with contrast material(s)
73202	Computed tomography, upper extremity; without contrast material, followed by contrast material(s) and further sections
73206	Computed tomographic angiography, upper extremity, with contrast material(s), including noncontrast images, if performed, and image postprocessing
73700	Computed tomography, lower extremity; without contrast material
73701	Computed tomography, lower extremity; with contrast material(s)
73702	Computed tomography, lower extremity; without contrast material, followed by contrast material(s) and further section
73706	Computed tomographic angiography, lower extremity, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74150	Computed tomography, abdomen; without contrast material
74160	Computed tomography, abdomen; with contrast material(s)
74170	Computed tomography, abdomen; without contrast material, followed by contrast material(s) and further sections
74174	Computed tomographic angiography, abdomen and pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74175	Computed tomographic angiography, abdomen, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74176	Computed tomography, abdomen and pelvis; without contrast material
74177	Computed tomography, abdomen and pelvis; with contrast material(s)
74178	Computed tomography, abdomen and pelvis; without contrast material in one or both body regions, followed by contrast material(s) and further sections in one or both body regions
75571	Computed tomography, heart, without contrast material, with quantitative evaluation of coronary calcium
75572	Computed tomography, heart, with contrast material, for evaluation of cardiac structure and morphology (including 3D image postprocessing, assessment of cardiac function, and evaluation of venous structures, if performed)
75573	Computed tomography, heart, with contrast material, for evaluation of cardiac structure and morphology in the setting of congenital heart disease (including 3D image postprocessing, assessment of LV cardiac function, RV structure and function and evaluation of venous structures, if performed)

75574	Computed tomographic angiography, heart, coronary arteries and bypass grafts (when present), with contrast material, including 3D image postprocessing (including evaluation of cardiac structure and morphology, assessment of cardiac function, and evaluation of venous structures, if performed)
75635	Computed tomographic angiography, abdominal aorta and bilateral iliofemoral lower extremity runoff, with contrast material(s), including noncontrast images, if performed, and image postprocessing
76380	Computed tomography, limited or localized follow-up study

Magnetic Resonance Angiography (MRA)

CPT® or HCPC Codes	Description
70544	Magnetic resonance angiography, head; without contrast material(s)
70545	Magnetic resonance angiography, head; with contrast material(s)
70546	Magnetic resonance angiography, head; without contrast material(s), followed by contrast material(s) and further sequences
70547	Magnetic resonance angiography, neck; without contrast material(s)
70548	Magnetic resonance angiography, neck; with contrast material(s)
70549	Magnetic resonance angiography, neck; without contrast material(s), followed by contrast material(s) and further sequences
72159	Magnetic resonance angiography, spinal canal and contents, with or without contrast material(s)
71555	Magnetic resonance angiography, chest (excluding myocardium), with or without contrast material(s)
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)
72198	Magnetic resonance angiography, pelvis, with or without contrast material(s)
73225	Magnetic resonance angiography, upper extremity, with or without contrast material(s)
73725	Magnetic resonance angiography, lower extremity, with or without contrast material(s)
C8900	Magnetic resonance angiography with contrast, abdomen
C8901	Magnetic resonance angiography without contrast, abdomen
C8902	Magnetic resonance angiography without contrast followed by with contrast, abdomen
C8909	Magnetic resonance angiography with contrast, chest (excluding myocardium)
C8910	Magnetic resonance angiography without contrast, chest (excluding myocardium)
C8911	Magnetic resonance angiography without contrast followed by with contrast, chest (excluding myocardium)
C8912	Magnetic resonance angiography with contrast, lower extremity
C8913	Magnetic resonance angiography without contrast, lower extremity
C8914	Magnetic resonance angiography without contrast followed by with contrast, lower extremity
C8918	Magnetic resonance angiography with contrast, pelvis
C8919	Magnetic resonance angiography without contrast, pelvis
C8920	Magnetic resonance angiography without contrast followed by with contrast, pelvis
C8931	Magnetic resonance angiography with contrast, spinal canal and contents
C8932	Magnetic resonance angiography without contrast, spinal canal and contents
C8933	Magnetic resonance angiography without contrast followed by with contrast, spinal canal and contents
C8934	Magnetic resonance angiography with contrast, upper extremity
C8935	Magnetic resonance angiography without contrast, upper extremity
C8936	Magnetic resonance angiography without contrast followed by with contrast, upper extremity

Magnetic Resonance Imaging (MRI)

CPT® or HCPC Codes	Description
70336	Magnetic resonance (eg, proton) imaging, temporomandibular joint(s)
70540	Magnetic resonance (eg, proton) imaging, orbit, face, and/or neck; without contrast material(s)
70542	Magnetic resonance (eg, proton) imaging, orbit, face, and/or neck; with contrast material(s)

70543	Magnetic resonance (eg, proton) imaging, orbit, face, and/or neck; without contrast material(s), followed by contrast material(s) and further sequences
70551	Magnetic resonance (eg, proton) imaging, brain (including brain stem); without contrast material
70552	Magnetic resonance (eg, proton) imaging, brain (including brain stem); with contrast material(s)
70553	Magnetic resonance (eg, proton) imaging, brain (including brain stem); without contrast material, followed by contrast material(s) and further sequences
70554	Magnetic resonance imaging, brain, functional MRI; including test selection and administration of repetitive body part movement and/or visual stimulation, not requiring physician or psychologist administration
70555	Magnetic resonance imaging, brain, functional MRI; requiring physician or psychologist administration of entire neurofunctional testing
71550	Magnetic resonance (eg, proton) imaging, chest (eg, for evaluation of hilar and mediastinal lymphadenopathy); without contrast material(s)
71551	Magnetic resonance (eg, proton) imaging, chest (eg, for evaluation of hilar and mediastinal lymphadenopathy); with contrast material(s)
71552	Magnetic resonance (eg, proton) imaging, chest (eg, for evaluation of hilar and mediastinal lymphadenopathy); without contrast material(s), followed by contrast material(s) and further sequences
72141	Magnetic resonance (eg, proton) imaging, spinal canal and contents, cervical; without contrast material
72142	Magnetic resonance (eg, proton) imaging, spinal canal and contents, cervical; with contrast material(s)
72146	Magnetic resonance (eg, proton) imaging, spinal canal and contents, thoracic; without contrast material
72147	Magnetic resonance (eg, proton) imaging, spinal canal and contents, thoracic; with contrast material(s)
72148	Magnetic resonance (eg, proton) imaging, spinal canal and contents, lumbar; without contrast material
72149	Magnetic resonance (eg, proton) imaging, spinal canal and contents, lumbar; with contrast material(s)
72156	Magnetic resonance (eg, proton) imaging, spinal canal and contents, without contrast material, followed by contrast material(s) and further sequences; cervical
72157	Magnetic resonance (eg, proton) imaging, spinal canal and contents, without contrast material, followed by contrast material(s) and further sequences; thoracic
72158	Magnetic resonance (eg, proton) imaging, spinal canal and contents, without contrast material, followed by contrast material(s) and further sequences; lumbar
72195	Magnetic resonance (eg, proton) imaging, pelvis; without contrast material(s)
72196	Magnetic resonance (eg, proton) imaging, pelvis; with contrast material(s)
72197	Magnetic resonance (eg, proton) imaging, pelvis; without contrast material(s), followed by contrast material(s) and further sequences
73218	Magnetic resonance (eg, proton) imaging, upper extremity, other than joint; without contrast material(s)
73219	Magnetic resonance (eg, proton) imaging, upper extremity, other than joint; with contrast material(s)
73220	Magnetic resonance (eg, proton) imaging, upper extremity, other than joint; without contrast material(s), followed by contrast material(s) and further sequences
73221	Magnetic resonance (eg, proton) imaging, any joint of upper extremity; without contrast material(s)
73222	Magnetic resonance (eg, proton) imaging, any joint of upper extremity; with contrast material(s)
73223	Magnetic resonance (eg, proton) imaging, any joint of upper extremity; without contrast material(s), followed by contrast material(s) and further sequences
73718	Magnetic resonance (eg, proton) imaging, lower extremity other than joint; without contrast material(s)
73719	Magnetic resonance (eg, proton) imaging, lower extremity other than joint; with contrast material(s)
73720	Magnetic resonance (eg, proton) imaging, lower extremity other than joint; without contrast material(s), followed by contrast material(s) and further sequences
73721	Magnetic resonance (eg, proton) imaging, any joint of lower extremity; without contrast material

73722	Magnetic resonance (eg, proton) imaging, any joint of lower extremity; with contrast material(s)
73723	Magnetic resonance (eg, proton) imaging, any joint of lower extremity; without contrast material(s), followed by contrast material(s) and further sequences
74181	Magnetic resonance (eg, proton) imaging, abdomen; without contrast material(s)
74182	Magnetic resonance (eg, proton) imaging, abdomen; with contrast material(s)
74183	Magnetic resonance (eg, proton) imaging, abdomen; without contrast material(s), followed by with contrast material(s) and further sequences
76391	Magnetic resonance (eg, vibration) elastography
77046	Magnetic resonance imaging, breast, without contrast material; unilateral
77047	Magnetic resonance imaging, breast, without contrast material; bilateral
77048	Magnetic resonance imaging, breast, without and with contrast material(s), including computer-aided detection (CAD real-time lesion detection, characterization and pharmacokinetic analysis), when performed; unilateral
77049	Magnetic resonance imaging, breast, without and with contrast material(s), including computer-aided detection (CAD real-time lesion detection, characterization and pharmacokinetic analysis), when performed; bilateral
77084	Magnetic resonance (eg, proton) imaging, bone marrow blood supply
C8900	MRA with contrast, abdomen
C8901	MRA without contrast, abdomen
C8902	MRA without contrast followed by with contrast, abdomen
C8903	Magnetic resonance imaging with contrast, breast; unilateral
C8905	Magnetic resonance imaging without contrast followed by with contrast, breast; unilateral
C8906	Magnetic resonance imaging with contrast, breast; bilateral
C8908	Magnetic resonance imaging without contrast followed by with contrast, breast; bilateral
C8909	MRA with contrast, chest (excluding myocardium)
C8910	MRA without contrast, chest (excluding myocardium)
C8911	MRA without contrast followed by with contrast, chest (excluding myocardium)
C8912	MRA with contrast, lower extremity
C8913	MRA without contrast, lower extremity
C8914	MRA without contrast followed by with contrast, lower extremity
C8918	MRA with contrast, pelvis
C8919	MRA without contrast, pelvis
C8920	MRA without contrast followed by with contrast, pelvis
C8931	MRA with contrast, spinal canal and contents
C8932	MRA without contrast, spinal canal and contents
C8933	MRA without contrast followed by with contrast, spinal canal and contents
C8934	MRA with contrast, upper extremity
C8935	MRA without contrast, upper extremity
C8936	MRA without contrast followed by with contrast, upper extremity

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To** verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).

^{MPC} Medical Policy Committee

Revision History	Description
------------------	-------------

03/26/2021	Clarifying language added to specify that the policy applies to non-emergent, ambulatory high-tech imaging requests.
05/20/2021	Updated policy effective date to 08/01/2021.
07/08/2021	Updated policy effective date to 09/01/2021.
04/25/2022	Updated applicable codes to include related HCPCS codes. Requires a 60-day notice, effective date 09/01/2022.
06/07/2022	MPC approved the updates to the alternative sites section of the criteria; updated MRI codes
07/14/2022	Added clarifying language for pre TAVR insertion in certain geographies

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Prometheus Lab Testing

- Anser™ ADA for Adalimumab (Humira) Antibodies
- Anser™ IFX test for Infliximab (Remicade) Antibodies
- Anser VDZ (Vedolizumab)
- IBD SGI Diagnostic Test

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	MoIDX: Prometheus IBD sgi Diagnostic Policy (L37313) This service is not covered per Noridian LCD.
Local Coverage Article	Billing and Coding: MoIDX: Prometheus IBD sgi Diagnostic Policy (A57517)
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance specific to Anser antibody levels for infliximab or adalimumab, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Prometheus Testing," for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

Anser antibody levels for infliximab or adalimumab can be approved under **ALL of the following** conditions:

1. Ordered by a gastroenterologist
2. Is being ordered as a consideration of changing to alternate therapy in the setting of a concern for loss of response

Service	Criteria
Homogenous Mobility Shift Assay (HMSA) Anser VDZ (Vedolizumab) Prometheus IBD sgi Diagnostic Test	There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage

Background

Many chronic inflammatory diseases are mediated by up-regulation of the pro-inflammatory cytokine tumor necrosis factor-alpha ((TNF)-α. Protein-based drugs that block TNF-α such as Infliximab (IFX), are effective in reducing the disease activity of these inflammatory disorders. IFX is a chimeric mouse-human monoclonal antibody approved by the FDA for the treatment of patients with Crohn's disease, ulcerative colitis, rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, and chronic severe plaque psoriasis. IFX is highly effective in

inducing and maintaining remission in a large proportion of these patients. However, more than 30% of cases fail to respond to anti-TNF- α therapy, and 20-60% of those who initially respond, lose their clinical response over time despite maintenance treatment. This loss of response (LOR) usually requires escalation of the dose, shortening the interval between doses, change in the anti-TNF agent to regain the clinical remission, or switching to a non-anti-TNF therapy (Wang 2012, Nanda 2013, Wang 2013, FDA web page accessed August 26, 2013).

The reason for loss of response to IFX is still debatable, but the anti-drug antibody formation is believed to play an important role. IFX is a chimeric mouse/human IgG1 molecule and thus the antibodies are primarily directed against the murine fragment. Antibodies to IFX (ATI), also frequently called human antichimeric antibodies (HACAs), are reported to develop in up to approximately 60% of patients depending on the dosing schedule, administration of concurrent steroids or immunomodulators, and the method of measuring the antibodies in the blood. The antibodies can appear as soon as after the first IFX dose and can persist in the blood for up to 4.5 years even after discontinuation of the therapy. ATI may increase the drug clearance in treated patients and/or neutralize its effect. Researchers found that a lower serum IFX levels is associated with a significantly higher risk of loss of clinical response to the drug. This loss of clinical response and remission due to immunogenicity is a potential major limitation to IFX leading to clinical relapse, impaired quality of life, and increased cost of care. Anti-drug antibodies may also cause serum sickness and hypersensitivity reactions. Despite these observed associations, some researchers dispute the clinical relevance of anti-infliximab antibodies and question whether the presence of antibodies to TNF agents is directly correlated to the decreased efficacy. To date, there is insufficient knowledge about the factors influencing the formation of the antibodies, and on whether the immune reaction to IFX can be transient. It is assumed however, that once the antibody is initiated, it cannot be overcome (Afif 2010, Kopylov 2012, Vande Casteele 2013, Nanda 2013, Wang 2013).

It is suggested that accurate monitoring of the serum drug and anti-drug antibody levels should be an important part of therapy in patients receiving anti TNF- α drugs. However, there is no gold standard technique or test for the detection and quantitative measurement of anti-infliximab antibodies (ATI). Anti-drug antibodies and drug levels in the serum are assessed by the bridging ELISA method, or less commonly by the radioimmunoassay (RIA) method. Each of these two methods has its limitations; the main limitation of the bridge ELISA method is its inability to accurately detect the antibodies in the presence of the drug in the circulation due to cross interference between the drug and the assay. This lowers the sensitivity of the test in detecting antibodies in the presence of IFX. Thus, ELISA can accurately measure the anti-drug antibodies only when there is no drug in the circulation, which limits its clinical utility. RIA method is limited by its complexity, safety concerns of handling radioactive material, and prolonged time needed to reach equilibrium for proper management (Wang 2012).

A novel Homogenous Mobility Shift Assay (HMSA) was recently developed and validated by group of researchers in San Diego (Wang and colleagues 2012) to quantitatively measure the induced ATI and IFX levels in serum samples of patients treated with infliximab. The AnserTMIFX test is not ELISA-based and is believed to be able to measure both the serum concentrations of infliximab and infliximab antibodies in the presence of serum infliximab. In the HMSA, serum samples are acidified during sample preparation to dissociate drug-anti-drug-antibody (IFX-ATI) complexes, thereby allowing the detection of ATI in the presence of IFX and overcoming the limitation of bridge ELISA (Casteele 2013).

Medical Technology Assessment Committee (MTAC)

Homogenous Mobility Shift Assay (HMSA)

10/21/2013: MTAC REVIEW

Evidence Conclusion: Analytic validity There is insufficient evidence to determine the analytic validity of the existing tests for measuring the antibodies to IFX. There is no gold standard technique for anti-infliximab antibodies (ATI) measurement and comparing the technical performance and accuracy of ATI assays in detecting ATI in the presence of IFX may be problematic. As indicated in the introduction the ELISA and RIA have their limitations, and there are no standards available for comparison. Several confounding factors can influence the measurement of these antibodies, and in turn the accuracy and reproducibility of the test. **Clinical validity** The results of studies that examined the association between ATI and clinical efficacy of IFX are inconsistent. While some studies showed that detectable levels of ATI using different ELISA methods or RIA were correlated with low concentrations or undetectable trough levels of IFX and higher rates of loss of response to IFX treatment, others showed no significant effect of ATI on loss of response. Two published meta-analyses (Lee et al, 2012 and Nanda et al, 2013) had conflicting results. Both had their limitations and pooled the results of randomized trials together with observational studies. In these studies, ATI was measured at one time point which may not capture its possible fluctuating, transient, or latent occurrence; different methods and assays, mainly ELISA, were used to measure ATI with no standardization; patients were on different IFX regimes (episodic or maintenance); and immunosuppressants were used among some, but not all patients. Lee et al' (2012), meta-analysis pooled the

results of 18 studies to determine the prevalence of ATI, its effect on perfusion reactions and on disease remission rates among IBD patients treated with infliximab. The analysis included 9 RCTs, 5 cohort studies, and 4 retrospective studies with a total of 3,326 patients. The pooled results showed that patients who tested positive for ATI (using ELISA) were at increased risk of infusion reactions (RR= 2.07 [95% CI, 1.61-2.67]), but with no significant difference in the rates of remission compared to those who tested negative for ATI (RR=0.90, 95% CI 0.79-1.02). On the other hand, the pooled results of the more recent meta-analysis (Nanda et al, 2013) of 13 studies involving 1,378 patients with IBD showed that the presence of ATI was associated with lower IFX serum levels and significantly higher risk of loss of clinical response (LOR) to IFX with a pooled risk ratio for LOR = 3.2 (2.0-4.9). The ATI was measured by different methods including double antigen ELISA, antihuman chain ELISA, immunochromatography-based ELISA, fluid-phase RIA, and western blot. The results of the meta-analysis, however, have to be interpreted with caution due to the high risk of bias in the studies included, significant heterogeneity between studies, publication bias, and combining the results of randomized studies together with of observational studies. In addition, there were differences between studies in the method of assessing ATI, IFX dosing regimens, immunosuppressants use, and assessment of clinical response. The Answer IFX (HMSA) Wang and colleagues (2012) developed and validated a homogenous mobility shift assay (HMSA) to measure the serum levels of infliximab (IFX) and antibodies to IFX (ATI). They compared the performance of the newly developed IFX-HMSA to bridge ELISA and measured the ATI levels with the new test in 100 patients with ELISA positive ATI and found a high correlation between the two methods. HMSA identified five false-positive samples from the bridging ELISA method. Intra-and inter-assay precision rates for ATI were <4% and <15% respectively which, are considered high. The cutoff point of the assay was determined using sera of 100 healthy subjects who were naïve to IFX. The mean values of ATI in patient serum samples were significantly higher than those in the drug naïve health controls (mean \pm SD=9.57 \pm 11.43, vs. 0.73 \pm 0.29, p<0.0001). The area under the curve (AUC) was 0.986, the sensitivity was 95% (95% CI, 88.72-98.36%) The authors concluded that the HMSA-IFX method showed a high assay sensitivity, precision and accuracy. However, validation was performed by using bridging ELISA methodology which can only accurately measure the anti-drug antibodies when there is no drug in the circulation.

Clinical utility- In a retrospective study, Afif and colleagues (2010) evaluated the clinical utility of measuring Human Anti-Chimeric Antibody (HACA) concentration in patients with IBD treated with infliximab. They used recorded data for 155 patients treated in one center (from 2003-2008) who had ATI and IFX concentrations measured. Testing for IFX and ATI levels was performed by ELISA at the discretion of the treating physician with no systematic strategy and was not done for all patients receiving IFX. 72% of the initial tests were ordered by a single physician, and the assay(s) used were not defined. Indications for testing were mainly due to loss of response (49%), partial response (22%) and autoimmune or delayed hypersensitivity reaction (10%). There was no control or comparison group and according to the authors, the study population represented only a subset of the total population receiving IFX at the clinic, and the clinical response was abstracted through review of patients' charts using predefined clinical criteria. The use of validated instruments as Crohn's disease Activity Index, Harvey-Bradshaw Index and endoscopic improvement could not be obtained retrospectively. 47% of the patients were on immunosuppressives, and 43 patients (29%) had the dose or frequency of IFX increased before testing. 35 patients had positive ATI based on which, the dose was increased in 6 patients, and 12 were put on a different anti-TNF. The overall results suggest that change to another anti-TNF in these ATI positive patients was associated with a significantly higher complete or partial response than those who received a dose escalation (92% vs. 17%). The authors concluded that measurement of ATI and IFX concentrations had an impact on management and was clinically useful. These results have to be interpreted with caution due to the study design and its limitations. In addition, there was no control group to determine whether any change in management in the absence of ATI measurement would have a similar or different clinical outcome. It also to be noted that 29% of the patients had the dose or frequency of IFX increased before testing. A more recent study (Vande Casteele and colleagues, 2013), used the new HMSA to retrospectively measure 1,232 consecutive frozen serum samples of 90 patients with IBD treated in one center from 1999-2011. The HMSA confirmed ATI in 59% of the patients, this was transient (disappeared by time) in 28% and was sustained in 72% of the patients. All treatment decisions to optimize and to stop therapy were based on clinical grounds and C-reactive protein level without knowledge of infliximab trough levels (TLI) or ATI status. The results of the analysis show that 68% of the patients with sustained ATI needed to discontinue IFX treatment vs. 13% with transient ATI (RR 5.1, 95% CI, 1.4-19.0). The overall results suggest, but do not provide good evidence that ATI may be transient, and that optimizing the IFX dose in patients with low-level ATI may be useful. It also indicates that sustained ATI increases the risk of loss of response to IFX. Based on these results, the authors recommended measuring IFX trough levels at week 14 and at time of loss of treatment response, and only measure ATI at consecutive time points when the trough levels of IFX are undetectable or low. These results have to be interpreted with caution due to the nature of the study and its limitations. In conclusion there is insufficient evidence to determine analytic and clinical validity of HMSA in detecting ATI to IFX. There is also inconclusive evidence to determine that ATI measurement has a significant impact on management of patients treated with infliximab or significant effect on clinical outcomes.

Articles: The published literature on the validity and clinical utility of measuring the antibodies to infliximab (ATI) levels among patients treated with IFX agent is limited. The therapeutic effect of IFX and measuring of the drug and antibody levels were mainly studied for patients with inflammatory bowel disease (IBD). The search revealed one study on the development and validation of a HMSA test, two meta-analyses on the impact of anti-IFX among IBD patients, two observational retrospective studies on clinical utility of measuring the anti-chimeric antibody concentration (ACAC), as well two studies that compared different ELISA methods in their ability to detect ATI. The meta-analysis with more valid methodology, the validation study on the new Anser IFX (HMSA) test, and the larger observational study on the clinical utility of detecting ATI were selected for critical appraisal, Afif W, Loftus EV, Faubion WA, et al. Clinical utility of measuring infliximab and human anti-chimeric antibody concentrations in patients with inflammatory bowel disease. *Am J Gastroenterol*. 2010; 105: 1133-1139. [See Evidence Table](#). Vande Castele N, Gils A, Singh S, et al. Antibody response to infliximab and its impact on pharmacokinetics can be transient. *Am J Gastroenterol*. 2013; 108:962-971. [See Evidence Table](#). Lee LY, Sanderson JD, Irving PM. Anti-infliximab antibodies in inflammatory bowel disease: prevalence, infusion reactions, immunosuppression and response, a meta-analysis. *Eur J Gastroenterol Hepatol*. 2012; 24:1078-1085. Nanda KS, Cheifetz AS, Moss AC. Impact of antibodies to infliximab on clinical outcomes and serum infliximab levels in patients with inflammatory bowel disease (IBD): a meta-analysis. *Am J Gastroenterol*. 2013; 108:40-47. Development and validation of a homogeneous mobility shift assay for the measurement of infliximab and antibodies-to-infliximab levels in patient serum. *J Immunol Methods*. 2012; 382:177-188.

The use of Homogenous Mobility Shift Assay (HMSA) (Anser TM IFX test) for Infliximab Antibodies does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Prometheus IBD sgi Diagnostic

10/17/2017: MTAC REVIEW

Evidence Conclusion: **Analytic validity:** No studies were identified **Clinical validity:** One study (Lawrence et al., 2015) with low evidence was reviewed. Fifty patients with symptoms of IBD and glycogen storage disease (GSD) type Ib were enrolled consecutively. Of 50 patients who were screened using Prometheus IBD, 11 (22%) tested positive for IBD. Of 11 patients who tested positive, 5 were Crohn's Disease, 5 were ulcerative colitis, and one was non-IBD. However, the major limitations included the sample size, lack of reference test (no test had been performed to confirm the diagnosis of IBD), non-randomized design of the study. **Clinical utility:** No studies were identified.

Conclusion:

- No studies assessing analytic validity or clinical utility were identified
- Only one study with non-randomized design and small sample size assessed clinical validity
- There is insufficient evidence to support for or against the use of Prometheus IBD sgi Diagnostic test for patients who present with symptoms of IBD

Articles: The search yielded 18 articles, none of which were relevant except one study (Lawrence, Chengsupanimit, Brown, & Weinstein, 2015) with low evidence.

The use of Prometheus IBD sgi Diagnostic does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met (Anser antibody levels for infliximab or adalimumab):

CPT® or HCPC Codes	Description
84999	Unlisted chemistry procedure

Considered Not Medically Necessary when requested/submitted as a panel (IBD sgi Diagnostic Test):

CPT® or HCPC Codes	Description
83520	Immunoassay for analyte other than infectious agent antibody or infectious agent antigen; quantitative, not otherwise specified
82397	Chemiluminescent assay

86140	C-reactive protein;
88346	Immunofluorescence, per specimen; initial single antibody stain procedure
88350	Immunofluorescence, per specimen; each additional single antibody stain procedure (List separately in addition to code for primary procedure)
81479	Unlisted molecular pathology procedure

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

For Non-Medicare Members

Kaiser Permanente has elected to use the Prothrombin Time (INR) Home Monitoring Device (A-0650) MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Documentation of initial start date for warfarin
- Last 6 months of clinical notes from requesting provider &/or specialist (orthopedics, cardiology)

Home testing is usually not recommended for a frequency of more than once a week.

Additional software or hardware required for downloading data from home prothrombin time testing systems to computers for the management of anticoagulation will not be covered because each is considered a convenience item and not medically necessary.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Oral anticoagulation (OAC) therapy is used for the prophylaxis and /or treatment of thromboembolic complications of deep vein thrombosis, embolic stroke, pulmonary embolism, cardiac valve replacement, and atrial fibrillation, as well as postmyocardial infarction. The aim of the therapy is to maintain a level of anticoagulation that will prevent thromboembolic events without increasing the risk of hemorrhagic complications. Warfarin is an oral anticoagulant that interferes with the cyclic interconversion of vitamin K which in turn leads to depletion its dependant coagulation factors including prothrombin. It is estimated that more than a million patients are treated annually with warfarin in the USA (Koerner 1998).

In the USA, almost 40,000 mechanical heart valves are implanted annually. Mechanical valves are associated with a risk of thrombus formation and emboli. This risk is reduced by lifetime treatment with oral anticoagulants. Biologic implants on the other hand, have a lower thrombogenicity and do not require long-term anticoagulation. Thromboembolism, together with anticoagulant-induced hemorrhage, account for three fourths of all complications after mechanical heart valve replacement. These events were found to be associated with the intensity of oral anticoagulation therapy and fluctuation of international normalized ratio (INR) values. (Edmunds 1987).

Atrial fibrillation (AF), a common arrhythmia, is a leading cause of thromboembolism. It is common among the elderly, and its prevalence increases with age (1% among 60-year-old population, 5% among those aged 70-75 and >10% for 80+ years patients. (Ezekowitz 1999). The incidence of ischemic stroke among these patients may be as much as six times higher than among others with no AF. Studies show that oral anticoagulants significantly reduce the rate of stroke among AF patients (Eldor 2002). However, older patients treated with OAC have a higher rate of bleeding mainly due to the slower metabolism of the drug, and its interaction with other underlying chronic health problems. These patients should thus have better monitoring, and more rigorous regulation of the OAC to optimize their therapy, and prevent intracerebral hemorrhages, and other bleeding complications.

The intensity of anticoagulation treatment also needs to be controlled closely due to the narrow therapeutic range of warfarin, the potentially life-threatening effects of both over, and under-dosing, and its interaction with other drugs or foods like leafy green vegetables. Several other factors may affect the patients' response to warfarin control including compliance to therapy, underlying liver or kidney diseases, infections, diet, and others.

Oral anticoagulation therapy has been monitored for almost 50 years with the prothrombin time (PT) test. The test is easy to perform but its results may widely vary between institutions, and even within the same institution. In 1983 the WHO proposed the international normalized ratio (INR) in attempt to standardize PT measurements. The proposal was supported by the International Committee for Standardization in Hematology in 1985, and INR is the current standard for monitoring anticoagulation therapy. It is calculated as: $INR = \frac{\text{patient PT}}{\text{mean normal PT}}$. The recommended therapeutic INR range for oral anticoagulant therapy is 2.0-3.0 for the majority of indications. A higher range of 2.5-3.5 is recommended for patients with mechanical heart valves, and when therapy is recommended to prevent recurrent MI (Koerner 1998). Monitoring patients on OAC requires frequent testing, which in turn requires frequent venous punctures, and regular visits to a physicians' office or lab, as well as lab standardization. Patients on a stable OAC are seen every 4-6 weeks. It was found that at this rate of testing, 40-60% of the PT measurements fall in the desired therapeutic range (Hortskotte, 1998).

Patients using long-term OAC usually worry about complications, regular visits to the physician or lab, frequent venous punctures that may be difficult at times, dietary limitations, freedom at traveling, and other concerns that may affect their quality of life. There has always been an interest in developing an accurate faster and easier way to measure PT. Currently several monitors for finger stick testing of PT are available. These include CoaguChek, CoaguChek plus, ProTime Microcoagulation System, and Harmony INR Monitoring System. These monitors require only a finger stick whole blood rather than the citrated venous blood, and the patients can perform it at home. Among the other advantages of these systems is the immediate INR results, and convenience. In theory patient self-testing at home increases the duration when the patient is within the therapeutic INR range, increases compliance, and patient interaction with his physician, and allows better control of OAC, which in turn reduces morbidity and mortality.

Self-management or personal-self testing however is not suitable for everyone. Patients need to operate the machine, and self-sample blood, they have to be free from any major visual problems, tactile dysfunction, or severe tremors to be able to mechanically handle self-testing, they also have to be reliable and complying with the dosage algorithm.

After Joint Replacement Patients undergoing major orthopedic surgery; hip or knee arthroplasty, or hip fracture repair are in the highest risk category for venous thromboembolism (VTE) solely on the basis of the orthopedic procedure itself. Without prophylaxis, the rate of deep vein thrombosis or pulmonary embolism in these patients range from 40% to 84% and is the most common cause of death. It is thus recommended to use some type of prophylaxis for total knee replacement (TKR), total hip replacement (THR), and hip fracture surgery. The currently available methods of thromboprophylaxis include intermittent pneumatic calf compression, elastic compression stockings, or the use of pharmacological agents.

Warfarin is the most commonly used pharmacological agent followed by low molecular weight heparin (LMWH). The American College of Chest Physicians (ACCP) recommends either adjusted-dose warfarin (INR range 2.0 to 3.0); started preoperatively or immediately after the hip or knee replacement, or SC LMWH therapy. The duration of thromboprophylaxis is controversial and varies widely between practices, ranging from 1-12 weeks postoperatively. Studies have shown a peak incidence of postoperative DVT two to three weeks after total hip arthroplasty. This, together with the shorter durations of hospitalization, extending the use of antithrombotic prophylaxis for up to 5 weeks is becoming more common (Schuringa 1999, Geerts 2001, Frederick 2003, He Xing 2008).

The intensity of anticoagulation treatment needs to be controlled closely due to the narrow therapeutic range of warfarin, its interaction with several other drugs and foods, and the potentially life-threatening effects of both over- and under-dosing of the drug. Monitoring patients on oral anticoagulation (OAC) therapy requires frequent testing, which in turn requires frequent venous punctures, laboratory standardization, and regular clinical visits.

There is an ongoing interest in developing a faster and easier way to accurately measure prothrombin time (PT). Currently several home testing systems have received FDA approval for use. These include CoaguChek, CoaguChek plus, ProTime Microcoagulation System, INRatio Prothrombin Time Monitoring System, Harmony INR Monitoring System, AcuSure, and Rubicon. These monitors may be used at home and only require a fingerstick whole blood rather than the citrated venous blood. They also give immediate INR results. In theory, patient self-testing at home increases the duration within the therapeutic INR range, increases compliance, patient interaction with his physician, and allows better control of OAC which reduces morbidity and mortality. Personal self-testing with or without self-management is however is not suitable for everyone. Patients have to be reliable and free from any major visual problems, tactile dysfunction, or severe tremors to be able to mechanically handle self-testing. They also have to comply with the dosage algorithm.

Medical Technology Assessment Committee (MTAC)

Home INR Monitoring

08/13/2003: MTAC REVIEW

Evidence Conclusion: Ideally the outcomes of randomized controlled studies for the effectiveness of a test should demonstrate its effect in altering treatment and improving the health outcomes. Two important health outcomes, bleeding and thromboembolism, were only studied in ESCAT (Kortke 2001), and time in the therapeutic range, an intermediate outcome, was used in all other studies. Kortke et al, in the ESCAT randomized controlled trial, followed 600 patients with mechanical heart valves for at least 2 years (25-51 months). They evaluated the event rates, as well as time in the therapeutic range. Less than 10% of the randomized sample took part in the 25-30-month follow-up. Patients in the self-management group had significantly less overall grade III complications (severe hemorrhage or thromboembolism) compared to those in the standard care group. The trial also showed that significantly more measurements were in the therapeutic range among patients in the self-management group. Sawicki's RCT in which 84% of the participants had heart valve replacement, also showed that a higher proportion of patients in the self-management group were within the INR target range compared to those in the routine care group. This difference was only statistically significant at three months of follow-up but not after six months. In Watzke's trial, 57% of the patients had mechanical heart replacement, and 24.5 % had atrial fibrillation. It also showed that a higher proportion of measurements among patients in the self-management group were in the therapeutic range vs. those in the standard care group, however the P value was not provided. Eldor's study on elderly patients with atrial fibrillation was too small, nonrandomized and had insufficient power to detect any difference between the groups. In conclusion there is some evidence that selected patients with mechanical heart valve replacement, who self-monitor their PT, and self manage their OAC therapy, have better control of their INR values, than those receiving a standard care. Only one trial with several limitations, showed some benefit in reducing the severe complications associated with OAC treatment. The other studies had insufficient sample sizes, and follow-up durations to study that outcome. It is worth noting that the studies were conducted among selected groups of patients and cannot be generalized to all patients with mechanical heart replacement. There is insufficient evidence to determine the effect of home INR monitoring on patients with atrial fibrillation.

Articles: The search yielded 28 articles. Many were reviews and tutorials. Abstracts, and studies conducted to evaluate the accuracy of the portable PT monitoring systems were not reviewed. The purpose of this review is assessing the home use of the monitors for patients with mechanical heart valves, or atrial fibrillation, and not for evaluating the portable systems that have been in use since 1987 (known as point of service). There were three randomized controlled trials, and three non-randomized controlled studies on self-testing/home INR monitoring. Trials conducted among patients with mechanical heart valves, or atrial fibrillation were selected. *The following articles was critically appraised:* Kortke H, and Korfer R. International Normalized Ratio self-management after mechanical heart valve replacement: is an early start advantageous? *Ann Thorac Surg* 2001; 72:44-48. See

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/01/2005: MTAC REVIEW

Home INR Monitoring

Evidence Conclusion: Ideally the outcomes of randomized controlled studies for the effectiveness of a test should demonstrate its effect in altering treatment and improving the health outcomes. Clinical endpoints for studies on self-management of anticoagulation therapy would be bleeding and thromboembolic complications. However, time within therapeutic INR range was used by some studies as a surrogate outcome to assess the quality of treatment based on self-management. In ESCAT I study (Koertke 2001) previously reviewed, 1,200 patients 6-11 days after a mechanical heart replacement were randomly divided into two groups: one monitored by family physicians, and the other controlling INR values at home. Patients were followed for at least 2 years (25-51 months) and the primary outcome was the rate of thromboembolic events and hemorrhage, and stability of INR values. Six hundred patients (50% of the randomized sample) were included in the analysis, dropouts and deaths were not included, and analysis was not based on intention to treat. The results of the trial showed that patients in the self-management group had significantly less overall grade III complications (severe hemorrhage or thromboembolism) compared to those in the standard care group. It also showed that significantly more measurements were in the therapeutic range among patients in the self-management group. ESCAT II study (Koertke 2003) was a large (N=3,300), multicenter RCT that randomized patients to two INR targets for self-management. The primary outcomes were the rate of thromboembolic events and hemorrhage, and the stability of INR values. It is an ongoing trial and the published articles only present the interim analysis with data on 55% of the total sample size. The investigators compared the results of the two INR targets for self-management in this trial and included data on thromboembolism and bleeding for the group controlled by general practitioner from ESCAT I study, which is not a valid comparison. ESCAT I was conducted years earlier, in a single center, and on a different group of patients. In this latter study, patients in the self-managed group had a higher mean INR value (3.0) compared ESCAT II study (2.8 for the conventional-dose INR, and 2.4 in the low-dose INR patients with aortic valve replacement). Overall, the interim results of ESCAT II study show that 72% to 74% of the patients in the low and conventional INR range, respectively, were within target range. The bleeding and thromboembolic rates were <1% in each of the two groups. There was no difference between them in the thromboembolic rates, and the difference in the bleeding rates did not reach statistical difference. There is no new evidence to determine the effect of home INR monitoring on patients with atrial fibrillation.

Articles: The search yielded 20 newer articles many of which were reviews and editorials. Studies conducted to evaluate the accuracy of the portable PT monitoring systems were excluded. The purpose of this review is to assess the home use of the monitors for patients with mechanical heart valves or atrial fibrillation, and not for evaluating the portable systems that have been in use since 1987 (known as point of service). There were two publications on one large randomized controlled trial (ESCAT II) that compared two INR targets for self-management of anticoagulants after mechanical valve replacement, a small RCT that included patients with different indications for anticoagulation, and small case series with intermediate outcomes. SMART, a large ongoing trial on self-management of anticoagulation was also identified but no results were published to date. The ESCAT II trial was critically appraised: Kortke H, Minami K, Boethig, et al. INR self-management permits lower anticoagulation levels after mechanical heart valve replacement. *Circulation* 2003;108 II:75-78. Kortke H, Zittermann A, Minami K, et al. Low-dose International normalized ratio self-management: A promising tool to achieve low complication rates after mechanical heart valve replacement. *Ann Thorac Surg* 2005; 79:1909-1914.

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/07/2006: MTAC REVIEW

Home INR Monitoring

Evidence Conclusion: The previous MTAC reviews of home INR monitoring showed some evidence that selected patients with mechanical heart valve replacement who self-monitor and manage their OAC therapy, may have better control of their INR values, than those receiving standard care. All studies were conducted among selected groups of patients and the results might not be generalized to all patients with mechanical heart

replacement. There was insufficient evidence to determine the safety and efficacy of home INR monitoring on clinically important outcomes as thromboembolic events, major hemorrhage, and death. There was also insufficient evidence to determine the benefit of home INR monitoring in patients with atrial fibrillation. Heneghan et al's recent meta-analysis (2006) assessed the effects of self-monitoring with/ or without or self-management of anticoagulation compared with standard monitoring. The meta-analysis had valid methodology, was well-conducted, and 10 out of the 14 studies it included were judged to be of good quality. The authors also performed a sensitivity analysis by excluding the studies with the lowest quality. However, the control groups in the trials received their routine care in different settings. The results of a recent meta-analysis (van Walraven, 2006) showed that the study setting has a major influence on anticoagulation control. Moreover, the majority of the trials included in Heneghan's meta-analysis, provided education and training sessions only to the patients randomized to self-testing, not to the entire study population. Education increases awareness, motivation, and may modify the patient's attitude and behavior. The education and training were given after randomization, and those who could not complete the training sessions or were incapable of self testing and/or self-management either left the study or were transferred to the routine care group. This resulted in a high dropout rate (20% to > 30%) in the intervention groups, and intention to treat analysis was not conducted in all the trials, which could overestimate the observed results. Ideally, training would be performed prior to randomization to eliminate those who are unable to complete it, and/or are incapable of self testing or self-management, from participating in the trial. The results of this meta-analysis indicate that the thromboembolic events, major bleeds, and death rates were significantly lower in the self-monitoring groups versus the controls who were managed by their personal physicians, anticoagulation management clinics, or managed service. Those who both self-tested and self-adjusted their therapy dose had significantly lower thromboembolic events and mortality rates but a non-significant reduction the rate of hemorrhage. The difference in thromboembolic event rates was not significant between the intervention and control groups in the pooled results of the 3 trials conducted among patients with mechanical heart valves. The authors did not report on the difference in major hemorrhage or death rate among these patients, and no subgroup analysis was provided for patients with atrial fibrillation. Kaiser Permanente INTC recalculated some of the results of Heneghan's meta-analysis using ITT analysis, and found no significant differences between the intervention and routine care group in the percent of subjects with a mean INR in the therapeutic range, and in the major hemorrhagic events in the self-management vs. those receiving care in AMS (anticoagulation management services). Fitzmaurice, et al's (2005) study was a relatively large, multicenter, randomized, and controlled trial. However, it had several limitations and potential biases. Less than 25% of the eligible patient agreed to participate in the trial and were actually randomized to the study groups. Training on self-testing was given after randomization and only to the intervention group not to the entire population, which resulted in a higher dropout rate (43%) in the self-management group compared to 11% of those in the routine care group. Those who were considered incapable of self managing withdrew from the trial or were returned to the routine care group. The study population who self-selected to enroll was younger and included more men than the eligible population. Moreover, participants in the intervention group tested their INR more frequently than those in the routine care group (mean every 12 days vs. 38 days) group, and apparently received more care, which is another potential source of bias. Patients in the routine care group were managed in a variety of models including anticoagulation clinics, hospital outpatient clinics, and primary care clinics which may have an influence on their anticoagulation control, and outcomes. Overall the results of this RCT show no significant differences between the intervention and routine care groups in the percent of time spent within therapeutic INR range (primary outcome) or in the rates of serious bleeding, or serious thrombosis. Patients in a target INR of 3.5 had poorer control before and during the study compared to those with target INR of 2.5. However, patients in the intervention group with a 3.5 target INR showed a significant improvement between the pre-study and study periods. No such improvement was observed for those with a 2.5 INR target in either group, or those with a 3.5, target in the routine care group. These results of the Heneghan's meta-analysis and Fitzmaurice's RCT may not be generalizable to all patients treated with long-term oral anticoagulants. The study participants were highly motivated, mainly younger, willing to take and complete a structured training course on self-management, and capable of performing self-testing correctly and reliably.

Articles: The search revealed 7 newer randomized trials that were published after the last review, as well as a meta-analysis of RCTs that assessed the effects of self-monitoring or self-management of anticoagulation compared with standard monitoring. Only three of the recent RCTs were relevant (Fitzmaurice 2005, Voler 2005, and Menedez-Jandula 2005). The latter two were included in the meta-analysis. Studies conducted to compare two home INR monitors, or to evaluate the accuracy of the portable PT monitoring systems were excluded. The purpose of this review is to assess the home use of the monitors for patients receiving long-term anticoagulation treatment, and not for evaluating the portable systems that have been in use since 1987 (known as point of service). Two ongoing trials were also identified: 1. Self-Management of Anticoagulation, a Randomized Trial (SMART) which is a large multicenter trial on self-management of anticoagulation and, 2. The Home INR Study (THINRS) with more than 400 patients from VA Medical Centers with atrial fibrillation and/or mechanical heart valve who are expected to be anticoagulated indefinitely. The trial compares anticoagulation (AC) management using home monitoring devices to high quality management implemented by an AC service. It will have a

minimum of 2 years of follow-up, and the primary outcome is event rates (stroke, bleeding or death). Heneghan's (2006) meta-analysis and the RCT that was not included in the meta-analysis were critically appraised. Heneghan C, Alanzo-Coello P, Garcia-Alamino JM et al. Self-monitoring of oral anticoagulation: a systematic review and meta-analysis. *Lancet* 2006; 367:404-11. See [Evidence Table](#) Fitzmaurice DA, Murray ET, McCahon D, et al. Self-management of oral anticoagulation: randomized trial. *BMJ* 2005;331:1057- See [Evidence Table](#)

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

12/01/2008: MTAC REVIEW

Home INR Monitoring

Evidence Conclusion: There is insufficient published evidence to determine the safety and efficacy of home INR monitoring for thromboprophylaxis warfarin therapy post knee or hip replacement surgery. An ideal study would be a randomized controlled trial that compares health outcomes of home INR monitoring of the warfarin dose to routine monitoring in hospital or anticoagulation management services. The trial should address the effect of INR home monitoring on altering treatment and preventing thromboembolism without increasing bleeding risks. The only published study on home thromboprophylaxis with warfarin anticoagulation therapy after hip and knee replacement surgery was a case series that studied the efficacy of a program designed to maintain the prophylactic anticoagulant oral therapy within the target range. The patients did not monitor their own INR or adjust their own therapy. Instead it was coordinated between Home Care and community laboratory, and dose adjustments were made by the patient's family physician. Yet the program failed to achieve the target INR in almost 60% of cases during the six weeks postoperatively. Conclusion There is insufficient evidence to determine that: Home INR monitoring after joint replacement surgery increases the percentage of time spent within the therapeutic INR range, compared to routine care. Home INR monitoring, vs. routine care, after joint replacement surgery is effective in reducing the deep vein thrombosis and pulmonary embolic events rates, without increasing hemorrhagic events.

Articles: The search did not reveal any RCT that compared outcomes of monitoring of INR post joint replacement at home vs. in the hospital or anticoagulation management centers. There was only one published empirical study on the home prophylaxis with warfarin after hip and knee arthroplasty. Schuringa P, Yen D. Home prophylactic warfarin anticoagulation program after hip and knee arthroplasty. *Can J Surg.* 1999; 42:360-362. See [Evidence Table](#).

The use of Home INR Monitoring in the treatment of anticoagulation for mechanical valves does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT or HCPC® Codes	Description
G0248	Demonstration, prior to initiation of home INR monitoring, for patient with either mechanical heart valve(s), chronic atrial fibrillation, or venous thromboembolism who meets Medicare coverage criteria, under the direction of a physician; includes: face-to-face demonstration of use and care of the INR monitor, obtaining at least one blood sample, provision of instructions for reporting home INR test results, and documentation of patient's ability to perform testing and report results
G0249	Provision of test materials and equipment for home INR monitoring of patient with either mechanical heart valve(s), chronic atrial fibrillation, or venous thromboembolism who meets Medicare coverage criteria; includes: provision of materials for use in the home and reporting of test results to physician; testing not occurring more frequently than once a week; testing materials, billing units of service include four tests
G0250	Physician review, interpretation, and patient management of home INR testing for patient with either mechanical heart valve(s), chronic atrial fibrillation, or venous thromboembolism who meets Medicare coverage criteria; testing not occurring more frequently than once a week; billing units of service include four tests

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Oxygen and Oxygen Equipment (L33797) "Oxygen reimbursement is a bundled payment. All options, supplies and accessories are considered included in the monthly rental payment for oxygen equipment."
Local Coverage Article	Oxygen and Oxygen Equipment – Policy Article (A52514) "Oximeters (E0445) and replacement probes (A4606) will be denied as non-covered because they are monitoring devices that provide information to physicians to assist in managing the beneficiary's treatment."

For Non-Medicare Members

Medical necessity review no longer required.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

The pulse oximeter is a completely noninvasive device that provides a means of continuous and quick real-time estimates of arterial oxygen saturation (SaO₂). It has been validated relative to transcutaneous oxygen tension, and arterial blood gas measurement. (Fanconi, 1985). The device estimates arterial hemoglobin saturation by measuring the light absorbance of pulsating vascular tissue at two wavelengths. It is easy to use and interpret and does not need any special training or new skills on the part of the user. It also requires a little setup time and adds no risk to the patient.

Pulse oximetry is becoming a standard of practice during general anesthesia in the United States (Eichhorn, 1986). It is also used as an independent monitor in emergency rooms and intensive care units. Other clinical applications of the device include monitoring patients during transport, respiratory monitoring during narcotic administration, and the evaluation of home-oxygen therapy.

The pulse oximeter, however, has some limitations; it does not provide an early warning of decreasing arterial oxygen tension (PaO₂) and may fail to detect an inadvertent endobronchial intubation in the operating room. It also cannot distinguish more than two hemoglobin species in the blood; thus methemoglobin and carboxyhemoglobin will cause errors in the pulse oximeter saturation (SpO₂) if present in large amounts. Artifactual signals created by patient motion or external light may also create a technical problem and interfere with the device in estimating the oxygen saturation. It was also reported that circumstances that reduce the amplitude of finger pulsation e.g. hypothermia, hypotension, or the administration of a vasoconstrictive drug would adversely affect the accuracy of the device (Yelderman, 1983).

The home pulse oximeter is being reviewed due to several requests received by Clinical Review for coverage for adult patients with progressive pulmonary disease, pediatric patients with RVS, or patients being discharged home but requiring continued monitoring to ensure stability in the home.

Medical Technology Assessment Committee (MTAC)

Home Pulse Oximetry

10/08/2003: MTAC REVIEW

Evidence Conclusion: There are insufficient published studies to provide evidence on the home use of pulse oximeters among adults or children with respiratory failure or chronic pulmonary disease.

Articles: The search yielded 46 articles. A large number was not related to home monitoring of oxygen saturation, and a few addressed the home use of pulse oximetry for the diagnosis of sleep apnea. The search did not reveal any empirical study conducted among adults with chronic obstructive lung disease using a home pulse oximeter to monitor their oxygen saturation. The search revealed three small case series conducted among either healthy infants to assess their oxygen saturation during the first six months or among infants with bronchopulmonary dysplasia receiving home oxygen therapy. None of the studies was critically appraised.

The use of home pulse oximetry in the management of oxygen levels for adults or children with respiratory failure or chronic pulmonary disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

For Non-Medicare Members

Kaiser Permanente has elected to use the Home Oxygen (KP-0343) MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider and/or specialist (palliative care, primary care, pulmonary care)
- Most recent Pulse Oximetry documentation and/or most recent at rest &/or activity log

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

In 1986, Kaiser Foundation Health Plan of Washington experienced an increased use of home oxygen and could find no clinical evidence in patient charts that would support the use of oxygen. In addition, once a patient was placed on home oxygen, they were never re-tested to verify continued need of the treatment. In 1989, a task force was initiated to review use and develop clinical indications for use at Kaiser Permanente. The task force reviewed the current literature and adopted the Medicare home oxygen criteria. In addition, they defined several situations where exceptions would be appropriate. The program was initiated for review of all home oxygen requests, and to set up testing and re-testing programs. The program was submitted to Medicare for approval. Medicare not only approved it, but also adopted several of its most critical features such as the re-testing program.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
E0424	Stationary compressed gaseous oxygen system, rental; includes container, contents, regulator, flowmeter, humidifier, nebulizer, cannula or mask, and tubing
E0425	Stationary compressed gas system, purchase; includes regulator, flowmeter, humidifier, nebulizer, cannula or mask, and tubing
E0430	Portable gaseous oxygen system, purchase; includes regulator, flowmeter, humidifier, cannula or mask, and tubing
E0431	Portable gaseous oxygen system, rental; includes portable container, regulator, flowmeter, humidifier, cannula or mask, and tubing
E0433	Portable liquid oxygen system, rental; home liquefier used to fill portable liquid oxygen containers, includes portable containers, regulator, flowmeter, humidifier, cannula or mask and tubing, with or without supply reservoir and contents gauge
E0434	Portable liquid oxygen system, rental; includes portable container, supply reservoir, humidifier, flowmeter, refill adaptor, contents gauge, cannula or mask, and tubing
E0435	Portable liquid oxygen system, purchase; includes portable container, supply reservoir, flowmeter, humidifier, contents gauge, cannula or mask, tubing and refill adaptor
E0439	Stationary liquid oxygen system, rental; includes container, contents, regulator, flowmeter, humidifier, nebulizer, cannula or mask, & tubing
E0440	Stationary liquid oxygen system, purchase; includes use of reservoir, contents indicator, regulator, flowmeter, humidifier, nebulizer, cannula or mask, and tubing
E0441	Stationary oxygen contents, gaseous, 1 month's supply = 1 unit
E0442	Stationary oxygen contents, liquid, 1 month's supply = 1 unit
E0443	Portable oxygen contents, gaseous, 1 month's supply = 1 unit
E0444	Portable oxygen contents, liquid, 1 month's supply = 1 unit
E0447	Portable oxygen contents, liquid, 1 month's supply = 1 unit, prescribed amount at rest or nighttime exceeds 4 liters per minute (LPM)
E1390	Oxygen concentrator, single delivery port, capable of delivering 85 percent or greater oxygen concentration at the prescribed flow rate
E1391	Oxygen concentrator, dual delivery port, capable of delivering 85 percent or greater oxygen concentration at the prescribed flow rate, each
E1392	Portable oxygen concentrator, rental
E1405	Oxygen and water vapor enriching system with heated delivery
E1406	Oxygen and water vapor enriching system without heated delivery
K0738	Portable gaseous oxygen system, rental; home compressor used to fill portable oxygen cylinders; includes portable containers, regulator, flowmeter, humidifier, cannula or mask, and tubing

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Criteria For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Hyperbaric Oxygen Therapy (20.29)
Local Coverage Determinations (LCD)	Oxygen and Oxygen Equipment (L33797)
Local Coverage Article	Oxygen and Oxygen Equipment (A52514)

*Note: It is clinically rare for a patient to require more than 40 hyperbaric treatments for any diagnosis. Requests for more than 40 treatments should be sent to the Medical Director for closer review.

For Non-Medicare Members

Hyperbaric oxygen may be indicated with a confirmed diagnosis of **ONE or more of the following:**

1. Chronic severe diabetic ulcer, and need for initial treatment, as indicated by **ALL of the following:**
 - a. Severe wound defined by Wagner grading system, as indicated by **one or more of the following:**
 - Grade 3 Wagner ulcers are deep and involve abscess(es), osteomyelitis (bone infection) and/or joint sepsis
 - Grade 4 Wagner ulcers include gangrene (decay of body tissues) in the forefoot (anterior third of the foot) or heel region(s)
 - Grade 5 Wagner ulcers involve extensive gangrene **AND**
 - b. There is a document plan for initial treatment, which includes **ALL of the following:**
 - Must have complete evaluation and treatment for any underlying peripheral vascular or neuropathic disease. To assess vascular status there must be a documented exam of femoral, popliteal, dorsalis pedis and posterior tibial pulses. If absent or reduced, must have documented ABI Scores. If questionable accuracy of ABI score, due to diabetes, a vascular surgeon consult is needed.
 - c. Minimal to no healing present despite conventional wound treatment for minimum of 30 days, including **ALL of the following:**
 - Documentation of adequate diabetic control and most recent HbA1C
 - Pressure reduction or offloading for at least 8 weeks. (Must have documentation at each visit of the use (or of noncompliance) of walker boot, knee, scooter, or wheelchair)
 - Topical wound treatment. Need documentation regarding what specific products have been used, duration, and effectiveness (i.e., Apligraf, dermagraph, saline, hydrogels, hydrocolloids, alginates, or wound vac)
 - Appropriate wound debridement (practitioner must have appropriate training to perform) and
 - d. Must have formal Infectious Disease consult and treatment for a minimum of 6 weeks for severe wound/bone infection
 - e. Transcutaneous tissue oxygenation (PtcO₂) levels of **one or more of the following:**
 1. PtcO₂ of 25 mm Hg (3.3 kPa) or greater on room air
 2. PtcO₂ value less than 25 mm Hg (3.3 kPa) on room air that meets **one or more of the following:**
 - a. PtcO₂ increase of more than 20 mm Hg (2.7 kPa) while breathing 100% oxygen via face mask at normal atmospheric pressure or

- b. PtcO₂ increase of greater than 200 mm Hg (26.6 kPa) in chamber during hyperbaric oxygen therapy
2. Chronic severe diabetic ulcer, and need for continued treatment, as indicated by **ALL of the following**:
 - a. Adherent to hyperbaric oxygen therapy
 - b. Documented evidence of improvement after 24 visits and need for continuing improvement after that point
 - c. Plan for no more than 40 total treatments
3. Decompression illness or suspected intravascular gas embolism
4. Anemia, as indicated by **ALL** of the following
 - a. Emergent anemia, as indicated by **1 or more** of the following
 - Active hemolysis with rapidly progressive anemia
 - Active massive hemorrhage
 - Severe signs or symptoms unresponsive to volume replacement (eg, tachycardia, hypotension, chest pain, cognitive impairment)
 - b. Patient unable or unwilling to receive red blood cell transfusions
5. Carbon monoxide (CO) poisoning is unconscious and has a carboxyhemoglobin level over 40%
6. Cyanide poisoning, acute
7. Intracranial abscess
8. Central retinal artery occlusion
9. Gas gangrene (inpatient only)
10. Idiopathic sudden sensorineural hearing loss (will need 20 visits maximum)

KP SSNHL GUIDELINES

A. Patients presenting with mild to moderate HL:

- Oral and IT steroid should be discussed with all patients.
- Treatment should be initiated, if possible, within 2 weeks of onset.
- Oral steroid alone should be recommended as initial therapy for mild to moderate HL within 2 weeks of onset but can be offered up to 6 weeks after onset.
- IT steroid should be strongly recommended for salvage for oral steroid failure within 6 weeks of onset
- Combo therapy (oral and IT steroid) should be recommended for those presenting more than 2 weeks after onset and within 6 weeks of onset.
- HBO should not be offered unless there are medical contraindications to oral or IT steroid therapy or special situations ie only hearing ear.
- Patients with > 25% drop in discrimination regardless of the severity of their pure tone loss should be treated as presenting with severe to profound HL patients

B. Patients presenting with severe to profound HL:

- HBO therapy combined with steroid treatment should be initiated within 2 weeks of onset if possible.
- Combo therapy (oral and IT steroid) should be “strongly” considered within 6 weeks of onset.
- IT steroid should be strongly recommended for salvage for oral steroid failure within 6 weeks of onset
- HBO should not be considered routinely as isolated adjuvant initial or salvage therapy without steroid therapy unless there are medical contraindications to oral or IT steroid therapy or special situations ie only has one hearing ear and that is the ear which is affected by sudden hearing loss.

C. Treatment:

- Oral Prednisone should be 60mg for at least 7 days.
- IT steroids should be Dexamethasone 10mg/ml up to 3 injections as needed. Treatment intervals – “weekly”
- HBO: 100% at 2-2.5 ATA 10-20 Dives lasting 90 or 60 minutes.

D. Audiogram:

- Initial, after treatment start consider audiograms prior to additional interventions or if patient reports significant improvement, 6 months after last intervention.

E. Ruling out Retro-cochlear Lesion:

- MRI (or CT with contrast if MRI contraindicated) required to rule out retro cochlear lesion

F. Routine Laboratory Testing:

Not recommended

11. Clostridial and non-clostridial myonecrosis: Plan of care indicates use will be in conjunction with other medical/surgical therapies and will not interfere with or delay surgical debridement. (Provided for hospital inpatient only)
12. Necrotizing soft tissue infections (provided for hospital inpatient only)
13. Osteoradionecrosis as indicated by **ONE or more of the following**:

- a. Mandibular/maxillary osteoradionecrosis (diagnosis is typically made by a clinical exam with exposed bone, and/or by imaging). History of previous radiation therapy to the mandible or maxilla of at least 5,000-7,000 rads
- b. Osteoradionecrosis in other sites, as an adjunct to conventional treatment. Osteoradionecrosis presents some months/years after radiation (sternum, long bones)
- c. 30 pre/10 post treatments
14. Open or closed crush injury, compartment syndrome, or acute traumatic ischemias (see <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6147240/>)
15. Femoral necrosis (see <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6147240/>)
16. Skin grafts and flaps (compromised) (see <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6147240/>)
17. Soft tissue radionecrosis as an adjunct to conventional treatment: Typically, bowel, bladder, larynx or wounds in area of prior radiation therapy. Must wait 6 months post completion of radiation therapy. Requires visualization of the damaged area with serial exams to monitor progress (e.g., cystoscopy, laryngoscopy, sigmoidoscopy). Additional health plan review if 30 treatments are exceeded. (40 max). Total radiation dose and field must be documented. Must have **ONE of the following**:
 - a. Radiation-induced proctitis diagnosed by sigmoidoscopy
 - b. Radiation-induced hemorrhagic cystitis diagnosed by cystoscopy
 - c. Radiation-induced head and neck soft tissue injury – soft tissue radionecrosis, typically of the larynx, or in a radiated field.
18. Dental extractions must meet **ALL of the following**:
 - a. Clinical plan on file from the dentist/oral surgeon detailing planned extractions timeline
 - b. History of at least 5,000-7,000 rads received to the teeth planned for the extraction
 - c. Initial Request is for 20 treatments prior and 10 after the extractions. If the initial treatment of 20/10 was delivered within prior 5 years, then only 10 more treatments post extractions are required for any additional extractions done within 5 years but not pre-extraction)
19. Chronic refractory osteomyelitis, unresponsive to both conventional medical and surgical treatment. Must have a prior infectious disease consultation and at least 6 weeks of medical management and a surgical consultation regarding debridement. Any hardware should be removed if feasible. Not indicated for acute osteomyelitis. If involves a distal toe, requires physician consultation prior to auth. Any treatments beyond 30 should have physician consultation. Pelvic bone osteomyelitis from decubiti requires debridement and flap surgery and does not respond well to hyperbaric. For osteomyelitis associated with a diabetic foot ulcer, see I. above.

Hyperbaric oxygen pressurization is considered investigational in all other situations.

***Note: Topical application of oxygen (CPT A4575) does not meet the definition of HBO therapy and is considered investigational/not medically necessary in all cases. Also, its clinical efficacy has not been established.**

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or consulting specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Hyperbaric oxygen therapy consists of placing a patient inside a pressurized chamber in which the patient breathes 100% oxygen under a pressure of greater than one atmosphere. Generally, there is a gradual increase to approximately two-and-a-half times the normal atmospheric pressure. Patients receive up to 40 treatment sessions lasting between 45 and 300 minutes. There are monoplace chambers for one person and multi-place chambers that can accommodate two or more patients. (Leach et al, 1998; Porter & Brian, 1999).

Hyperbaric oxygen therapy has both a mechanical (pressure) and physiological (oxygen) component. The increased pressure causes compression of gas bubbles in the body and is useful for conditions such as decompression illness. Breathing 100% oxygen at increased pressure allows more oxygen to reach non-healing tissue and helps to prevent tissue from dying to a lack of oxygen and blood (Porter & Brian, 1999).

Potential adverse events of hyperbaric oxygen therapy include myopia lasting for weeks or months, ruptured middle ear, seizures, lung damage and oxygen toxicity. The most common complication is a lack of pressure equalization on both sides of the eardrum which can cause pain and bleeding into the middle ear. The high concentration of oxygen also presents a fire hazard (Porter & Brian, 1999; oral cancer foundation).

Hyperbaric Oxygen for Treatment of Radiation Induced Cerebral Necrosis

BACKGROUND

Many types of cerebral cancer are treated with external beam, stereo tactically focused or implanted radiation. One of the most common and debilitating sequelae of high dose radiation is tissue destruction and necrosis. Radiation-induced necrosis (RIN) manifests itself as headache, ataxia, cranial nerve palsy, seizures, and visual loss. Necrotic tissue had historically been surgically re-sected when anatomically feasible or left untreated. One proposed method of treatment is the use of hyperbaric oxygen therapy (HBOT) which increases tissue oxygen concentration and may stimulate angiogenesis and establish a new blood supply to healthy cerebral tissue. Typically, hyperbaric oxygen is administered by placing patients into a whole-body hyperbaric chamber and exposing them to oxygen concentrations of 2 times normal atmospheric pressure for a period of 2-4 hours, once a day. Treatments are usually repeated usually 20-40 times with symptomatic improvement used as the measure of treatment success.

08/11/1999: MTAC REVIEW

Hyperbaric Oxygen for Treatment of Radiation Induced Cerebral Necrosis

Evidence Conclusion: Evidence identification was conducted by searching MEDLINE from 1996-1999 using terms radiation necrosis, radiation injuries, cerebral necrosis and hyperbaric oxygenation. Dr. Kindwall, the author of a recent review, identified 2 case series (n=10, n=2) as the only published data on hyperbaric oxygen for treating **cerebral** radiation-induced necrosis. The Kaiser Permanente New Technology hotline staff was also unable to identify any additional literature reporting original data. Data from the case series of 10 patients, 8 of whom had biopsy-proven RIN, demonstrated that, with a median follow up of 7 months post HBOT, symptoms completely resolved in 1 patient, improved in 4 patients, did not get worse in 1 patient, and ended up worse in 4 patients. One patient developed ear pain from HBOT and had ear tubes placed and one developed sinusitis and discontinued treatment. Because this study was a case series rather than a randomized trial, it is not possible to determine whether hyperbaric oxygen therapy improves the clinical outcome of patients with radiation-induced cerebral necrosis beyond what would be expected with corticosteroid therapy alone. The best published scientific evidence on treating radiation induced cerebral necrosis with hyperbaric consists of a case series of 10 patients, 8 of whom had biopsy-proven RIN, demonstrated that, with a median follow up of 7 months post HBOT, symptoms completely resolved in 1 patient, improved in 4 patients, did not get worse in 1 patient, and ended up worse in 4 patients. One patient developed ear pain from HBOT and had ear tubes placed and one developed sinusitis and discontinued treatment. Because this study was a case series rather than a randomized trial, it is not possible to determine whether hyperbaric oxygen therapy improves the clinical outcome of patients with radiation-induced cerebral necrosis beyond what would be expected with corticosteroid therapy alone.

The use of hyperbaric oxygen does not meet *Kaiser Permanente Medical Technology Assessment Criteria*.

Hyperbaric Oxygen Therapy for Prophylactic Treatment after Head and Neck Radiation to Prevent Osteoradionecrosis (ORN) of the Mandible

BACKGROUND

Hyperbaric oxygen therapy consists of placing a patient inside a pressurized chamber in which the patient breathes 100% oxygen under a pressure of greater than one atmosphere. Generally, there is a gradual increase to approximately two-and-a-half times the normal atmospheric pressure. Patients receive up to 40 treatment sessions lasting between 45 and 300 minutes. There are monoplace chambers for one person and multiplace chambers that can accommodate two or more patients. (Leach et al, 1998; Porter & Brian, 1999). Hyperbaric

[Back to Top](#)

oxygen therapy has both a mechanical (pressure) and physiological (oxygen) component. The increased pressure causes compression of gas bubbles in the body and is useful for conditions such as decompression illness. Breathing 100% oxygen at increased pressure allows more oxygen to reach non-healing tissue and helps to prevent tissue from dying to a lack of oxygen and blood (Porter & Brian, 1999). Potential adverse events of hyperbaric oxygen therapy include myopia lasting for weeks or months, ruptured middle ear, seizures, lung damage and oxygen toxicity. The most common complication is a lack of pressure equalization on both sides of the eardrum that can cause pain and bleeding into the middle ear. The high concentration of oxygen also presents a fire hazard (Porter & Brian, 1999; oral cancer foundation). Osteoradionecrosis (ORN) of the mandible is a potential complication of head and neck irradiation. It is defined as a nonhealing, nonseptic lesion of bone (Clayman, 1997). The underlying cause of ORN is believed to be progressive vascular occlusion and tissue hypoxia after radiation treatment (Porter & Brian, 1999). Three types of ORN have been described. Type 1 occurs when a patient receives radiation therapy within 21 days of tooth extraction or mandibulotomy. Type 2 is induced by trauma. It generally occurs 3-6 years after radiation therapy, usually following a tooth extraction. Type 3 occurs spontaneously 6 months to 2 years after radiation therapy and is associated with higher radiation doses, neutron beam therapy and brachytherapy (Cronje, 1998). Hyperbaric oxygen therapy is generally accepted as a treatment for patients who have ORN. The use of hyperbaric oxygen therapy is also proposed as a prophylactic treatment before dental work to prevent ORN in patients who have had irradiation of the head and neck.

04/09/2003: MTAC REVIEW

Hyperbaric Oxygen Therapy for Prophylactic Treatment after Head and Neck Radiation to Prevent Osteoradionecrosis (ORN) of the Mandible

Evidence Conclusion: There is weak evidence from one randomized controlled trial (Marx), published in 1985, that prophylactic hyperbaric oxygen treatment of patients with previous head and neck irradiation before tooth removal lowers the incidence of osteoradionecrosis of the mandible compared to patients treated prophylactically with penicillin. The Marx study had a small sample size (n=74) and the methodology was not well described, leaving open the possibility of threats to validity such as selection bias, inadequate randomization and biased assessment of outcomes. The results of the Marx study have not been replicated. Many factors may have changed since 1985 making the findings less relevant including different radiation protocols that alter the likelihood of developing ORN, better alternative prophylactic treatments and better treatments for patients with ORN. Recent authors have questioned the need for prophylactic hyperbaric oxygen treatment before dental surgery for all patients who have received head and neck radiation before dental surgery because the incidence of post-extraction ORN is relatively low and over half of the patients who do develop ORN heal after conservative treatment. The Marx study has also been criticized as including a particularly high-risk group of patients. The incidence of ORN in the Marx study was 30% in the penicillin-treated group compared to a 5.8% incidence in the general population of post-radiation tooth extraction patients and a lower incidence, 2.1% in studies conducted in the 1990s (Clayman, 1997).

Articles: The search yielded 35 articles. Many of the articles were reviews or opinion pieces, dealt with technical aspects of the intervention or addressed the treatment of osteoradionecrosis with hyperbaric oxygen rather than prophylaxis. No randomized controlled trials on prophylactic use of hyperbaric oxygen to prevent osteoradionecrosis were included in the search findings. However, an RCT published in 1985 was identified from the reference list of a review article. In addition to the RCT, there were several case reports and small case series (n<30 patients). The RCT was critically appraised: Marx RE, Johnson RP, Kline SN. Prevention of osteoradionecrosis: a randomized prospective clinical trial of hyperbaric oxygen versus penicillin. JADA 1985; 111: 49-54. See [Evidence Table](#).

The use of hyperbaric oxygen in the prevention of osteoradionecrosis of the mandible does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Hyperbaric Oxygen Therapy for Prophylaxis Before Breast Surgery

BACKGROUND

Breast cancer is the most common cancer in women, other than skin cancer, and the second leading cause of cancer death among them. According to the American cancer society, a woman has a 1 in 7 chance of having invasive breast cancer some time during her life. As of the 2004, there are slightly over 2 million women living in the USA who have been treated for breast cancer. Conservative therapy with lumpectomy, axillary dissection, and irradiation, is a frequently used option for treating early breast cancer. This allows the patient to keep her breast and reduce the physical and psychological trauma associated with the modified radical mastectomy. Radiation therapy is also indicated with mastectomy under certain conditions. In both cases, radiotherapy is given in a moderate to high dose and may be associated with mild to severe complications that might have negative influence on the health and quality of life. Among these complications are arm lymphedema, subcutaneous fibrosis, painful hardening of the breast, shoulder pain rib fracture, damage to the lungs and heart and others

© 1998 Kaiser Foundation Health Plan of Washington. All Rights Reserved.

[Back to Top](#)

(Gothard 2003, Feldmeier 1995). These complications may be due to early reactions to radiation, or late effects that occur after at least 90 days after the start of treatment (Pasquier, 2004). Late injuries are irreversible and progressive in the majority of cases. These may cause cellular depletion, reduction in vascular density, fibrosis and atrophy all of which may result in hypoxia, and in turn delayed healing of the wounds. Conservative measures may be adequate for managing moderate cases with minimal necrosis, but cases of extensive necrosis are more challenging. Hyperbaric oxygen (HBO) was first used for the treatment of radiotherapy patients in the 1950s (Pasquier, 2004). It is defined as the breathing of pure oxygen at pressure exceeding the normal atmospheric pressure of 100 kPa that increases the solubility of oxygen in the blood. HBO treatment is administered within hyperbaric chambers, which are compressed by air (Plafki, 1998) Researchers indicate that hyperbaric oxygen therapy stimulates angiogenesis, osteogenesis, fibroblast activity, and collagen formation in irradiated tissues, which would increase the cellular level of oxygen. It has been reported that HBO therapy is associated with a low complication rate, but that there is uncertainty about the best time to start the treatment, and the number of sessions needed (Plafki, 1998). There is also uncertainty on the efficacy of the treatment for the different complications, what are its side effects, who would respond to treatment, and for which symptoms.

12/08/2004: MTAC REVIEW

Hyperbaric Oxygen Therapy for Prophylaxis Before Breast Surgery

Evidence Conclusion: There is no evidence to date on the prophylactic use of hyperbaric oxygen therapy before breast surgery in patients with prior radiation therapy. There is also insufficient evidence on the efficacy of HBO therapy in the treatment of late sequelae in women receiving radiation after breast-conserving surgery. The study reviewed was a case series that provide the least grade of evidence. It was small nonrandomized, and with potential selection and observation bias. The results of the study show that patients who received a hyperbaric oxygen therapy had a significant reduction of pain, edema, and erythema compared to those who refused the therapy. There was no significant difference between the groups in the improvement of fibrosis or telangiectasia.

Articles: The search yielded 35 articles. Many were review articles, dealt with technical aspects of the therapy, or the use of hyperbaric oxygen for the treatment of radio-induced lesions in different tissues and organs other than the breast. The search did not reveal any study on the use of Hyperbaric Oxygen Therapy for prophylaxis in breast surgery in patients with prior radiation therapy. There was one prospective case series with a control group on the use of hyperbaric oxygen for the treatment of late sequelae of radiation therapy after breast surgery, a smaller series of 21 patients and control group, and a retrospective review of 23 cases.

The case series with a control group was selected for critical appraisal. Carl UM, Feldmeier JJ, Schmitt, et al. Hyperbaric oxygen therapy for late sequelae in women receiving radiation after breast-conserving surgery. *Int J Radiat Oncol Biol Phys.* 2001; 49:1029-31. See [Evidence Table](#).

The use of hyperbaric oxygen for prophylaxis before breast surgery does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Hyperbaric Oxygen Therapy for Treatment of Gastrointestinal Bleeding Related to Radiation Enteritis

BACKGROUND

Hyperbaric oxygen therapy consists of placing a patient inside a pressurized chamber in which the patient breathes 100% oxygen under a pressure of greater than one atmosphere. Generally, there is a gradual increase to approximately two-and-a-half times the normal atmospheric pressure. Patients receive up to 40 treatment sessions lasting between 45 and 300 minutes. There are monoplace chambers for one person and multiplace chambers that can accommodate two or more patients. (Leach et al, 1998; Porter & Brian, 1999). Hyperbaric oxygen therapy has both a mechanical (pressure) and physiological (oxygen) component. The increased pressure causes compression of gas bubbles in the body and is useful for conditions such as decompression illness. Breathing 100% oxygen at increased pressure allows more oxygen to reach non-healing tissue and helps to prevent tissue from dying to a lack of oxygen and blood (Porter & Brian, 1999). Potential adverse events of hyperbaric oxygen therapy include myopia lasting for weeks or months, ruptured middle ear, seizures, lung damage and oxygen toxicity. The most common complication is a lack of pressure equalization on both sides of the eardrum which can cause pain and bleeding into the middle ear. The high concentration of oxygen also presents a fire hazard (Porter & Brian, 1999; oral cancer foundation). The treatment of gastrointestinal bleeding related to radiation enteritis is one possible application of hyperbaric oxygen therapy.

04/09/2003: MTAC REVIEW

Hyperbaric Oxygen Therapy for Treatment of Gastrointestinal Bleeding Related to Radiation Enteritis

Evidence Conclusion: There is no published evidence on the effectiveness of hyperbaric oxygen therapy for the treatment of gastrointestinal bleeding related to radiation enteritis.

Articles: There were no published empirical studies. An abstract of a small case series (n=19) was identified in a review article. The abstract was presented at a professional meeting in 1998 and the study was not subsequently published.

The use of hyperbaric oxygen in the treatment of gastrointestinal bleeding related to radiation enteritis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
99183	Physician or other qualified health care professional attendance and supervision of hyperbaric oxygen therapy, per session
HCP Codes	Description
G0277	Hyperbaric oxygen under pressure, full body chamber, per 30-minute interval

Considered Not Medically Necessary - experimental, investigational or unproven:

HCP Codes	Description
A4575	Topical hyperbaric oxygen chamber, disposable

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

For Non-Medicare Members

Kaiser Permanente has elected to use the Thermal Intradiscal Procedures (A-0217) MCG* for medical necessity determinations. This is not covered per MCG. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (neurosurgeon, neurologist, physiatrist, pain specialists, orthopedic spine surgeon)

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Intradiscal Electrothermal Therapy (IDET) is a minimally invasive procedure that was developed as a treatment for lumbar discogenic pain. It aims to reduce the symptoms of the disrupted disc by thermocoagulating annular tissue and contracting collagen fibrils. The SpineCATH™ Intradiscal Catheter delivers thermal energy to the posterior annulus via a resistive heater coil. The annulus is comprised of Type I and II collagen fibers, which are held together by hydrogen bonds in a triple helix formation. It has been shown that these bonds break when heated to 60°C to 75°C is applied to the tissue. After being heated to the optimum temperature the collagen fibers contract and thicken. Following thermal contraction, collagen tissue undergoes a remodeling or regeneration process. Remodeling includes fibroblast in-growth and proliferation as well as new collagen formation in the treatment areas. The treatment is performed on an outpatient basis, under fluoroscopy.

IDET (SpineCath, Smith and Nephew) received FDA approval for the "coagulation and decompression of disc material to treat symptomatic patients with annular disruption of contained herniated discs" (DHHS, letter 8/17/2001). It does not appear to be approved for other types of low back pain.

[Back to Top](#)

Medical Technology Assessment Committee (MTAC)

Intradiscal Electrothermal Therapy (IDET)

10/11/2000: MTAC REVIEW

Evidence Conclusion: The study reviewed has a number of limitations including a small sample size, lack of a control group, potential selection bias, potential placebo effects, and the absence of significant improvements in outcomes after 6 months. Given the lack of peer-review studies and the limitation of this case series, the effectiveness of IDET for chronic back pain cannot be determined at this time.

Articles: Articles were selected based on study type. The only article found was a case series. A review article was reviewed, but no evidence table was created. *The articles selected for critical appraisal include:* Saal et al. Management of chronic discogenic low back pain with a thermal intradiscal catheter: A Preliminary Report. *Spine* 2000; 25:382-388. See [Evidence Table](#)

The use of Intradiscal Electrothermal Therapy (IDET) in the treatment of back pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria* (fails criteria 2 for effectiveness).

07/14/2004: MTAC REVIEW

Intradiscal Electrothermal Therapy (IDET)

Evidence Conclusion: The only published RCT on the effectiveness of IDET for discogenic low back pain (Pauza) does not provide strong evidence that IDET provides a clear clinical benefit to patients. In the *per protocol* analysis of 6-month follow-up data, the difference in the pain scores between the IDET and sham treatment groups just reached statistical significance ($p=.045$). Physical functioning measured by the SF-36 did not differ significantly between groups and the difference in the Oswestry disability scale did not attain statistical significance ($p=.050$). In the intention to treat analysis, there was a significant difference between groups in the proportion of patients who experienced >75% pain relief. The NNT=7 with a wide confidence interval, 95% CI=3 to 138 and there was no significant difference in the proportion of patients experiencing >50% pain relief. The sample size and length of follow-up were insufficient for quantifying any adverse effects of the treatment.

Articles: The search yielded 29 articles. There was one randomized controlled trial (Pauza) and this was critically appraised. There were also three case series with longer follow-up than the RCT and a cohort study. The other studies were not critically appraised because higher-grade evidence was available. The RCT reference was: Pauza KJ, Howell S, Dreyfuss P et al. A randomized placebo-controlled trial of intradiscal electrothermal therapy for the treatment of discogenic low back pain. *The Spine Journal* 2004; 4: 27-35. See [Evidence Table](#).

The use of Intradiscal Electrothermal Therapy (IDET) in the treatment of back pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria* (fails criteria 2 for effectiveness).

Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "IMIBG Imaging for Heart Failure" for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Heart failure (HF) is a complex clinical syndrome responsible for high morbidity and mortality in the world. The prognosis of HF remains poor and its burden on mortality, reduced quality of life, and healthcare cost is increasing across the world. The goals of HF treatment are to improve symptoms, slow the progression of the disease, and prolong survival (Martins da Silva 2013, Perrone-Filardi 2011, Nakou 2013, Jain 2014).

Treatment options for HF include medications, devices, and nonpharmacological interventions. Drug therapy for chronic heart failure including B-adrenergic blockade, vasodilators, angiotensin converting enzyme (ACE), inhibitors, mineralocorticoid receptor antagonists, and diuretics can relieve symptoms and/or improve survival. Devices as cardiac resynchronization therapy may improve outcomes in some patients with NYHA class II-IV heart failure, and implantable cardioverter defibrillators (ICDs) can reduce the risk of sudden cardiac death in patients with HF and reduced left ventricular ejection fraction (LVEF). However, these devices are not beneficial to all patients, are costly, and have potential significant complications. It is thus essential to identify the patients who are more likely to benefit from intensive therapies, and those among whom devices such as ICD are not indicated (Nakou 2013, Gupta 2014, Nakajima 2014).

Heart failure is characterized by sympathetic nerve hyperactivity (up to 50 times more active than normal), which serves as a compensatory mechanism for the cardiac dysfunction associated with HF. The increased sympathetic response is initially favorable to maintain the systemic hemodynamics and peripheral circulation. However, long-lasting and excess stimulation of sympathetic nerve function leads to deleterious consequences including

myocardial remodeling, reduced LVEF, and electrical instability which increase the likelihood of arrhythmia and sudden cardiac death (SCD) (Martins da Silva 2013, Jacobson 2010, Nakata 2013, Treglia 2013).

Researchers found that persistent stimulation of sympathetic nerve function in failing hearts impairs the efficiency of reuptake, turnover, and storage of norepinephrine (NE) at presynaptic nerve endings, resulting in spill-over and deficiency in NE stores leading to a decline in the myocardial sympathetic innervation. On this pathophysiological basis, it was suggested that the assessment of the degree of sympathetic activation of the heart can potentially be an indicator of the severity of the disease process and provide an insight to the prognosis of a patient with HF. This has led to the development of radiotracers for single-photon computed tomography (SPECT) and positron emission tomography (PET) (Martins da Silva 2013, Nakata 2013, Gupta 2014).

Guanethidine is a false neurotransmitter that is taken up by the uptake pathway for NE into presynaptic terminal. Chemical modification and labeling with radioactive iodine produce metaiodobenzylguanidine (123I-MIBG), an analog of NE that permits the visualization of adrenergic innervation in vivo. After depolarization MIBG is released into the synaptic cleft similar to NE, but unlike NE it is not metabolized by monoamine oxidase (MAO) or catechol-o-methyl-transferase (COMT), leading to higher cytoplasmic concentration that permits scintigraphic imaging in early and delayed phases (Treglia 2013, Gupta 2014).

The conventional protocol for scintigraphic myocardial imaging involves the injection of 123I-MIBG intravenously at rest after which early (from 10-30 minutes after administration) and delayed (3-4 hours after administration) images are obtained. The planar images with anterior view are adequate for evaluating cardiac sympathetic function. Tomographic images (SPECT) are often acquired to evaluate the regional myocardial uptake pattern. The most common semi-quantitative indices used for interpreting the images are the heart to mediastinum ratio (H/M) and washout rate (WR) obtained from the anterior planar images. Regions of interest are set in the heart (H: target region) and the mediastinum (M: background region) to obtain a mean count at each region. H/M ratio is calculated, and the degree of accumulation evaluated based on the resulting ratio. The WR is an index that indicates the rate at which MIBG is washed out between the early and delayed images through comparison with the cardiac count in the early image. This may reflect turnover of catecholamines attributable to the sympathetic drives and measures the ability of the myocardium to retain. MIBG normal values for these are derived from control patients and may differ between institutions (Treglia 2013).

Medical Technology Assessment Committee (MTAC)

I MIBG Imaging for Heart Failure

10/20/2014: MTAC REVIEW

Evidence Conclusion: AdreView Myocardial imaging for Risk Evaluation in Heart Failure (ADMIRE-HF., Evidence table 1), was the pivotal study that led to the recent FDA approval of 123I-MIBG use in HF patients) was a large, observational, multicenter study that evaluated the prognostic value of 123I-MIBG in HF patients. 961 participants with NYHA class II/III HF and LVEF <35% underwent 123I-MIBG myocardial perfusion imaging and were followed for a maximum of 2 years to assess the primary composite endpoint of HF progression necessitating hospital admission, life-threatening arrhythmic event, and cardiac death. During a median of 17 months of follow-up (range 2 days-30.4 months), 237 first cardiac events were observed. The analysis of the results suggests that H/M ratio <1.6 was most discriminative for identifying patients at higher risk of the composite endpoint and each of its components. Patients with H/M >1.60 had a significantly lower risk of cardiac events (HR 0.40; 95% CI, 0.25-0.64), lower rate of HF progression, lower rate of arrhythmic events, and higher 2-year survival rates. The incidence of cardiac death was <1% per year in patients with H/M >1.6 and 9.6% per year among those with H/M <1.6. The results also showed that late H/M ratio provided additional information to that of plasma BNP and LVEF for identifying patients at greater risk of cardiac events. The other parameters of the 123I-MIBG imaging (early H/M and washout rate (WR) were also associated with risk for cardiac events, but late H/M ratio was the only one with independent prognostic value. A subsequent retrospective analysis of the ADMIRE-HF (Shah 2012) suggests that 123I MIBG has prognostic value across the spectrum of LVEFs. Verschure D et al, 2014 (Evidence table 2) conducted a meta-analysis of individual patient data from 6 studies incorporating 636 chronic HF patients (599 from Europe and 37 from the USA) to determine the most appropriate prognostic endpoint for 123I-MIBG scintigraphy in patients with chronic heart failure. The primary outcomes were all-cause mortality, cardiac mortality, arrhythmic events, heart transplantation, and a composite outcome of all listed events. Overall, the results of the pooled analysis indicate that late H/M was an independent predictor for all outcomes studies except for arrhythmias. The lower late H/M is associated with higher risk. LVEF was also found to be an independent predictor for these events. The analysis did not examine whether MIBG has an incremental prognostic value over other independent variables. The etiology of HF i.e. ischemic vs. non-ischemic was not an independent predictor in the multivariate analysis for any of the outcome events. The meta-analysis had the advantage of including patient data from longitudinal studies, however, the authors did not evaluate the quality of

the studies included, did not test for homogeneity or publication bias, or do a sensitivity analysis. The analysis did not include the Japanese studies or the ADMIRE-HF study. In addition, there were variations between the studies included in the technical aspects of the procedure as regards the collimator selection, and method used to measure the myocardial uptake.

Nakata T, Nakajima K. and colleagues (2013, Evidence table 3) pooled data from six prospective cohort studies conducted in Japan from 1990 to 2009. The studies enrolled a total 1,322 patients with chronic HF, the mean follow-up duration was 78 months, and the five-year outcomes were available for 933 patients. The five-year cardiac deaths were determined by the original study investigators. Multivariate analysis was performed using the variables age, gender, early H/M, late H/M, MIBG washout rate, NYHA functional class, LVEF, history of diabetes, hypertension, dyslipidemia, atrial fibrillation, sustained ventricular tachycardia, and medications used. BNP data was available for only 512 patients. The results of the analysis indicate that survival rates decreased with decreasing H/M independent of other markers as NYHA class, BNP, and LVEF. All-cause mortality progressively decreased with increasing H/M ratio. Based on the ROC curve, a late H/M ratio threshold of 1.68 identified patients at a significantly higher mortality. This analysis only included data from studies conducted in Japan, and the H/M values as well as the results may not be generalized to other geographic areas using other methodologies or in populations with different characteristics. Pooled results of two earlier meta-analyses (Verberne H et al, 2008 et al and Kuwabara Y et al, 2011) also suggest that HF patients with reduced late H/M ratio or increased 123I-MIBG washout rate (WR) have a higher incidence of cardiac events compared to those with normal or relatively preserved uptake and washout rates. Incremental value of myocardial sympathetic innervation imaging with 123I-MIBG in heart failure patients Jain K and colleagues (2014) used data from ADMIRE-HF to assess the performance of four HF risk models (EFFECT, CARE-HF, MADIT-II and PACE) for predicting the composite clinical endpoint of cardiac death, progressive HF, or life-threatening arrhythmia. They then quantified the incremental prognostic utility of H/M ratio 123I-MBG imaging when added to each of the individual models. The results of the analysis suggest that H/M ratio >1.6 was consistent with the other models in identifying patient at lower risk of cardiac events, and that the addition of H/M to EFFECT, CARE-HF, MADIT-II and PACE models improved their discrimination by 33%, 59%, 49% and 37% respectively. These results, however, have to be interpreted with caution as it was derived from post-hoc evaluation of risk factors in ADMIRE-HF study. It may be limited to the characteristics of the participants included as well as the limitations in the observational study design.

Ketchum E, et al (2012) also used survival data from 961 NYHA II-III subjects in the ADMIRE-HF trial to investigate the incremental value of MIBG cardiac imaging when added to the Seattle Heart Failure Model (SHFM) for prediction of all-cause mortality. The results of the analysis showed that the addition of H/M to the SHFM in a Cox model significantly improved risk prediction ($P<0.0001$), with a greater utility in higher risk SHFM patients. The net reclassification improvement (NRI) was 22.7% ($P<0.001$), with 14.9% of subjects who died reclassified into a higher risk category than suggested by SHFM score alone ($P=0.01$) and 7.9% of subjects who survived reclassified into a lower risk category ($P<0.0001$). The 1-year area under the receiver-operator curve showed significant improvement for the combined model with H/M compared to the SHFM alone. Nakajima K, Nakata T, and colleagues (2014) used the same database (created By Nakata et al, 2013) to create a model for predicting fatal cardiac events by adding information from MIBG imaging. Nakata et al's pooled analysis included data for 1,322 chronic HF patients enrolled in cohort studies performed in Japan from 1990 to 2009. Prediction models were created with single and multiple variables to calculate cardiac mortality. Net reclassification improvement (NRI) analysis was based on prediction models with and without H/M ratio. The five-year risk levels were defined as low (<5%, corresponding to 1% mortality /year), intermediate (5-25%) and high (>25% corresponding to 5% mortality /year). For 5 years 205/933 patients (22%) died of a cardiac event. A multivariate analysis showed that age, gender, NYHA functional class (highest OR and X2 values), LVEF, and late MIBG H/M were significant predictors for 5-year cardiac mortality. The calculated ROC AUC (area under receiver operator curve) was 0.749 with the first 4 variables, and 0.780 after the addition of H/M ($p=0.0015$ for difference). The authors performed NRI analysis by the combination of age, gender, NYHA functional class and LVEF (model 1) and with the addition of late H/M (model 2). Patients who died with cardiac events were classified into the 3 risk levels according to the 2 models. The results indicate that classification was improved in 23 patients and made worse among 13 in model 2 vs. model 1. The net gain in classification was 4.9% ($p=0.096$). Of those who did not die of a cardiac event 38 were classified upwards and 103 downward with a net gain in classification of -9.0% ($p<0.0001$). This indicates that the addition of H/M is significantly improved the identification of patients at lower risk of cardiac death, i.e. it is more useful for reclassifying patients downwards to lower risk groups. This latter finding is contradictory to that observed in ADMIRE-HF study and the Ketchum and colleagues' analysis where MIBG was more effective in reclassifying patients upwards. The authors explained that this might be due to the differences between the Japanese trials and the ADMIRE-HF (USA and Europe) study. Participants in the Japanese trials were overall healthier as regards their NYHA functional class, LVEF level, higher prevalence of non-ischemic HF, and lower overall mortality. The mean H/M values were 1.71 in ADMIRE-HF, and 1.44 in the Japanese trials, which as the authors explained may be related to the technical differences between the imaging equipment in Japan vs. gamma cameras in the US and Europe. The study had its limitations as data were

compiled from a number of studies conducted as early as 1990, with some variations in the population included, medication used, and MIBG imaging techniques. Its results need to be validated in prospective large studies. Clinical Utility of myocardial sympathetic innervation imaging with 123I-MIBG in heart failure patients. There are no published randomized controlled trials to date that directly evaluated the benefit of 123I-MIBG imaging as an aid to clinical management of HF patients. A number of published studies evaluated the use of MIBG scintigraphy in monitoring improvement in sympathetic activity in HF patients treated with vasodilators and beta-blockers. Treatment decisions and selection therapy were not based on the results of MIBG imaging and thus may not be the right study design to evaluate the effect of the test on the management decisions and/or patient outcomes. Conclusion: There is fair evidence from a number of observational studies and pooled analyses that 123I imaging of patients with heart failure and low LVEF may have an independent predictive value for estimating their risk of fatal cardiac events. There is some evidence from three analyses that H/M may have an additive (incremental) value to other risk models used for predicting cardiac mortality in patients with HF and low LVEF. There is insufficient evidence, to date, to determine that 123I-MIBG imaging of patients with heart failure and low LVEF impacts the management plan and/or improves patient outcomes. The review of the technology conducted Blue Cross Blue Shield Association, Kaiser Permanente. TEC program in April 2014 came to similar conclusions that there is evidence that myocardial MIBG innervation imaging provides prognostic information for cardiac events, and that there is a lack of evidence that the prognostic information will lead to improved health outcomes.

Articles: The literature search revealed over 200 articles on 123I-MIBG sympathetic imaging, many of which were unrelated to the current review. There were a number of published studies that examined the prognostic value of 123I-MIBG imaging of patients with HF. The studies include the pivotal ADMIRE-HF study that led to the FDA approval of using 123I-MIBG sympathetic imaging for patients with HF. The results of many of these published studies were pooled in four systematic reviews (Verberne et al, 2008, Kuwabara et al, 2011 [Japanese studies only], Nakata et al. 2013, and Verschure et al 2014 [European and USA studies]). Two subanalyses from the ADMIRE-HF study examined the ability of 123I MIBG in predicting the arrhythmic events and hospitalization in subpopulations were recently published (Sood et al 2013, and Parker et al, 2014). The search also identified the recent assessment of 123I-MIBG sympathetic imaging by Blue Cross Blue Shield Association, Kaiser Permanente. Technology Evaluation Center (TEC) Assessment Program. The literature search did not identify any trial that evaluated the clinical utility of the 123I-MIBG sympathetic imaging in heart failure patients, i.e. the impact of the test results on the management of patients. Treglia and colleagues 2013, reviewed studies that used the 123I MIBG to evaluate the effectiveness of different pharmaceutical agents in patients with HF. These studies did not actually examine the clinical utility of the test as the title of the review implies, as the management of the patients or selection of pharmaceutical agents were not based on the test results. The most recent pooled analyses (published after the TEC review) as well as the ADMIRE-HF study were selected for critical appraisal. Jacobson AF, Senior R, Cerqueira MD, et al. Myocardial iodine-123 meta-iodobenzylguanidine imaging and cardiac events in heart failure. Results of the prospective ADMIRE-HF (AdreView Myocardial Imaging for Risk Evaluation in Heart Failure) study. J Am Coll Cardiol. 2010;55 (20): 2212-2221. See [Evidence Table 1](#). Verschure DO, Veltman CE, Manrique A, et al. For what endpoint does myocardial 123 I-MIBG scintigraphy have the greatest prognostic value in patients with chronic heart failure? Results of a pooled individual patient data meta-analysis. Eur Heart J Cardiovasc Imaging. 2014 Sep;15 (9): 996-1003. See [Evidence Table 2](#). Nakata T, Nakajima K, Yamashina S, et al. A pooled analysis of multicenter cohort studies of (123) I-mIBG imaging of sympathetic innervation for assessment of long-term prognosis in heart failure. JACC Cardiovasc Imaging. 2013;6 (7):772-784. See [Evidence Table 3](#).

The use of I MIBG Imaging for Heart Failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

National Coverage Determinations (NCD)	Infusion Pumps (280.14)
Local Coverage Determinations (LCD)	None
Local Coverage Article	Implanted Infusion Pump for Chronic Pain (A55323)

For Non-Medicare Members

The following criteria must be met for each specific type of treatment:

- Chemotherapy for Liver Cancer must meet **ALL of the following**:
 - Is receiving intra-arterial infusion of 5-FuR for the treatment of liver cancer.
 - Must meet **ONE of the following**:
 - Liver cancer for patients with primary hepatocellular carcinoma.
 - Duke's Class D colorectal cancer, in whom the metastases are limited to the liver, and where (1) the disease is unresectable or (2) the patient refuses surgical excision of the tumor.
- Anti-Spasmotic Drugs for Severe Spasticity must meet **ALL of the following**:
 - Use to administer anti-spasmodic drugs intrathecally (e.g., baclofen).
 - The patient has chronic intractable spasticity with a baseline average Ashworth Scale* score of at least 3 (or a Modified Ashworth Scale* score of 2), and a Spasm Frequency score** of at least 2.
 - The spasticity is unresponsive to less invasive medical therapy as determined by the following criteria:
 - A 6-week trial, the patient cannot be maintained on noninvasive methods of spasm control, such as oral anti-spasmodic drugs, either because these methods fail to control adequately the spasticity or produce intolerable side effects.
 - The patient has responded favorably to a trial intrathecal dose of the anti-spasmodic drug, e.g., demonstrates at least a 2-point reduction in the Ashworth Scale or Spasm Frequency score for 4 hours following an intrathecal bolus of baclofen.

*[Ashworth and Modified Ashworth Scale](#) (scale appears in middle of document)

**[Spasm Frequency Score](#)

- Opioid Drugs for Treatment of Chronic Intractable Pain must meet **ALL of the following**:
 - Used to administer opioid drugs intrathecally or epidurally.
 - Patient has severe chronic intractable pain of malignant or nonmalignant origin with a life expectancy of at least 3 months.
 - Patient agrees to a 50% reduction in systemic opiates prior to undergoing an intrathecal opiate trial.
 - Are proven unresponsive to one or more of the following less invasive medical therapies:

- Trial of neuropathic pain medication
 - Trial of nonsteroidal anti-inflammatory drugs (NSAIDs)
 - Trial of physical therapy
 - Trial of behavioral health treatments (e.g., CBT, ACT)
 - The patient's history indicates that he/she would not respond adequately to non-invasive methods of pain control, such as systemic opioids (documentation should include attempts to eliminate physical and behavioral abnormalities which may cause an exaggerated reaction to pain)
- e. No acute psychiatric instability or uncontrolled suicide risk
 - f. No diagnosed substance-related disorder (other than nicotine) or patient currently receiving active treatment for disorder
 - g. A preliminary trial of intraspinal opioid drug administration has been undertaken with a temporary intrathecal/epidural catheter to substantiate adequately acceptable pain relief and degree of side effects (i.e. patient has experienced > 50% reduction in pain and concomitant increase in function) and patient acceptance.

In addition to meeting the appropriate above criteria the patient does not have one of the following contraindications:

1. A known allergy or hypersensitivity to the drug being used (e.g., oral baclofen, morphine, etc.);
2. An infection;
3. Body size at the implant site is insufficient to support the weight and bulk of the device;
4. Other implanted programmable devices since crosstalk between devices may inadvertently change the prescription.

If requesting this service, please send the following documentation to support medical necessity:

- Last 3 months of clinical notes from requesting provider &/or consulting specialist.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Implantable pumps are designed to provide a continuous infusion of medication to a specific body site. The pumps are used with morphine for malignant pain management, and the drug 5-FuDR for liver cancer chemotherapy and Baclofen for intractable spasticity.

About two-thirds of metastatic cancer patients experience moderate-to-severe pain (Smith et al., 2002). Chronic non-malignant pain is also common. One type of non-malignant pain, chronic low back pain, is the second most frequent cause of hospital admissions in the United States (Deer et al., 2004).

Options for initial treatment of chronic pain include exercise, physical therapy, individual counseling, pain education classes, medications such as NSAIDs and complementary/alternative treatments such as massage or acupuncture. Opioids are an option as part of a comprehensive treatment plan if patients fail other therapies (GHC chronic non-malignant pain guideline). A meta-analysis of studies on oral morphine by the Cochrane Collaboration found it to be an effective analgesic for cancer pain (Wiffen et al., 2003). Another Cochrane review on chronic low-back pain found a lack of high-quality evidence and concluded that the benefits of opioids for this type of pain remain uncertain (Deshpande et al., 2007). Disadvantages of opioid analgesics include potential side effects such as nausea and vomiting, constipation, itching and respiratory depression. Moreover, during long-term opioid therapy patients may develop a tolerance leading to a need for higher doses, and patients may become physically dependent on opioids, and experience withdrawal symptoms if the medication is suddenly stopped (Wiffen et al., 2003).

The delivery of pain medication in directly into the fluid that surrounds the spinal cord (intrathecal analgesia) began in the 1970s following the discovery of opioid receptors in the central nervous system. Potential advantages of intrathecal analgesia include the ability to relieve pain in patients with previously intractable pain; the need for a lower milligram dose of opioids compared to systemic administration which may result in fewer side effects; and the ability to easily adjust the dose of opioids. Spinal analgesia was first used to treat chronic cancer-related pain. The use of intrathecal pain pumps for non-malignant pain is more controversial due to the limited

evidence on the ability of opioids to relieve non-malignant pain over the long-term. As with oral opioids, there are concerns about tolerance, dependence and addiction (Williams et al., 2000; Cohen & Dragovich, 2007). Side effects that have been associated with long-term intrathecal morphine therapy include nausea, vomiting, itching urinary retention, constipation, sexual dysfunction and edema (Ruan, 2007).

Chronic pain is a major public health problem in the United States and across the world. It has significant negative effects on patients' functional capacity and quality of life, as well as high direct and indirect costs for the health care system. In a Gallup Survey of "Pain in America" more than 4 out of 10 adults indicated that they experience pain on a daily basis. Chronic pain is a complex phenomenon that is difficult to define. The American Society of Interventional Pain Physicians (ASIPP) defined it as:

1. Pain that persists beyond the usual course of an acute disease or a reasonable time for any injury to heal that is associated with chronic pathologic processes that cause continuous pain or pain at intervals for months or years.
2. Persistent pain that is not amenable to routine pain control methods, and
3. Pain where healing may never occur (Boswell 2007).

Chronic non-cancer pain (CNCP) has also been defined as ongoing pain that lasts over six months, that is due to non-life-threatening causes, and does not respond to available treatment methods (Ghafoor 2007).

A key to successful management of chronic pain is a multidisciplinary approach that optimizes medication use in conjunction with other nonpharmacological therapies including exercise, physical therapy, individual counseling, pain education classes, and complementary/alternative treatments such as massage or acupuncture. When conservative treatments fail, surgery to correct underlying causes is considered. These conservative and surgical therapies provide adequate pain relief for most but not all CNCP patients (Ghafoor 2007).

Intrathecal (IT) analgesia was introduced in the 1970s following the discovery of opioid receptors in the central nervous system and was initially used for malignant pain in patients who have failed to obtain adequate pain relief, or those with adequate analgesia but with intolerable side effects to drug therapy. Currently, it is being used for other indications such as chronic back pain, neuropathy, mixed neuropathic-nociceptive pain, and radicular pain from failed back syndrome. IT analgesia involves the delivery of pain medication directly into the fluid that surrounds the spinal cord to target the pre- and post-synaptic receptors in the dorsal horn of the cord (Koulousakis 2007, Smith 2008, Patel 2009).

There are two types of implantable intrathecal drug delivery systems (IDDS) available in the US. The fixed rate pump allows continuous infusion and bolus dose administration but does not have the option of changing the flow rate. The other, and most common implantable pump is a programmable infusion system which is available in different reservoir sizes. The infusion pumps are typically implanted in the lower abdomen, just beneath the skin. A catheter is inserted into the intrathecal space of the spine, tunneled under the skin and connected to the implanted pump for medication delivery, and to an external programmer that controls infusion rate and records medication concentration, volume, and dosage. A drug is infused over an extended period and may be delivered at a constant or variable rate by calibrating the infusion pump according to the physicians' specification. The pump requires refilling regularly via subcutaneous port injections. A variety of analgesic/co-analgesic agents have been utilized to provide spinal analgesia however, morphine remains the gold standard and is the only opioid approved by the FDA for intrathecal delivery to treat chronic pain. The FDA approved the use of ziconotide, for patients unresponsive to intrathecally delivered morphine. It also approved the use baclofen with the use of implantable infusion pumps for patients with severe spasticity of spinal origin. However, off-label use of other drugs in IT pumps is common (Ghafoor 2007, Koulousakis 2007, Turner 2007).

The implantable infusion pump is an invasive alternative for medication delivery and requires ongoing maintenance and surgeries to periodically replace the pump. It has the potential benefit of providing more effective pain control by administering the analgesic drug directly to the target area, using lower doses of opioids compared to systemic administration, and the ability to adjust the dose of opioids. However, there are many risks and potential harms associated with IT drug therapy. These involve the problems related to the intrathecal drug delivery systems (IDDS), and the adverse events of the medications used. Serious complications that may occur after the intrathecal catheter placement include postoperative subarachnoid hemorrhage, meningitis, catheter tip inflammatory masses, infection, root irritation, reactive arachnoiditis, catheter dislocation, and pump failure. Drug-related side effects consist of dose-independent effects as urinary retention, pruritis, pain due to bolus injection, perspiration, and sedation; and dose-dependent side effects as nausea, constipation, dysphoria, euphoria, sedation, respiratory depression, hypotension, central depression, and tachyphylaxis. As with oral opioids, there are concerns about tolerance, dependence, and addiction. Drug overdose could take place if the pump is

inappropriately used or monitored; and drug withdrawal symptoms may occur with mechanical problems as pump failure or catheter blockage and kinking. There are also reports that patients with CNCP treated with intrathecal opioid therapy experience increased mortality compared to others with similar conditions treated with other therapies. It is thus recommended that pumps for chronic IT opioid application should only be implanted in specialized center. Before implantation the therapeutic effect of IT application should be assessed by a bolus trial or continuous injection via an external pump, connected to the intrathecal catheter through an implanted port (Cohen 2007, Koulousakis 2007, Smith 2008, Pasutharnchat 2009, Rathmell 2009, Coffey 2009).

In 1991, the Medtronic SynchroMed infusion system was approved by the FDA for the intrathecal delivery of morphine to treat malignant and non-malignant pain. The system consists of a pump that is generally implanted subcutaneously in the lower abdominal wall, a spinal catheter implanted into the lumbar intrathecal space between L1 and L4 and a programmer. The pump can be programmed via telemetry to control infusion modes and flow rates. SynchroMed is the only commercially available pump system that can be programmed outside the body. There are various models that differ in the size of the reservoir and the presence of a side catheter access port. Other implantable infusion pumps that have received FDA premarket approval include the Codman 3000 (Codman), Model 300 Constant Flow Implantable Infusion Pump (Arrow international) and the infused implantable Infusion Pump (Strato/infusaid).

Assessment objectives:

- To determine whether implanted infusion pumps for delivering intrathecal opioids are effective for the control of chronic noncancer pain (CNCP).
- To determine whether the use of implanted infusion pumps for delivering intrathecal opioids improves the quality of life and functioning in patients with CNCP.
- To determine whether the use of implanted infusion pumps for delivering intrathecal opioids are more effective than other non-invasive alternative therapies for pain control in patients with CNCP.
- To determine whether the technology is safe for use in patients with CNCP.

Medical Technology Assessment Committee (MTAC)

Implanted Pain Pumps for the Intrathecal Delivery of Opioids

08/06/2007: MTAC REVIEW

Evidence Conclusion: Cancer pain: The best evidence on the safety and effectiveness of implanted intrathecal pain pumps is an RCT with 200 patients. Of the 74% of patients with follow-up data at 4 weeks, there was a significantly greater reduction in toxicity, marginally significant reduction in pain and marginally significant increase in clinical success in the group assigned to receive a SynchroMed implantable pain pump in addition to comprehensive medical management (CMM) compared to CMM alone. Estimated survival at 6 months was higher in the group assigned to pain pumps, but the difference did not reach statistical significance. Limitations of the study include lack of blinding which could lead to biased estimates of self-report pain outcomes, funding by the device manufacturer and substantial cross-over (only 70% of the patients evaluated at 4 weeks in the pain pump group actually received implants and 5% of patients in the non-implant group received implants). Non-malignant pain: The evidence on safety and effectiveness is insufficient. There were case series and a cohort study that only compared pre- to post-implant changes, not between-group differences. The studies tended to find a reduction in self-reported pain after pump implantation and a reduction in oral morphine use (1 or 2 year follow-up). There were no comparison interventions and sample sizes were small. Device-related complications were relatively common.

Articles: The Medline search yielded one systematic review. This was published by the British Health Technology Assessment (HTA) group in 2000 and they did not identify any high-grade evidence. One randomized controlled trial was identified on malignant pain. Several articles were published based on this trial, the first on study outcomes in 2002. The article presenting the primary study outcomes (Smith et al., 2002) was critically appraised. No randomized controlled trials on non-malignant were identified. There was one non-randomized comparative trial which was critically appraised. (Thimineur et al., 2004). Two uncontrolled studies were also reviewed. Deer et al. (2004) reported data from the National Outcomes Registry for Low Back Pain. This registry was set up to prospectively collect data on patients with chronic low-back pain who underwent screening or a trial or an implanted pain pump. The other study was a prospective series using the Medtronic SynchroMed device (Anderson and Burchiel, 1999). There were other case series that had small sample sizes and/or did not mention whether a commercially available device was used. *Studies selected for critical appraisal were:*

back pain. Am Acad Pain Med 2004; 5: 6-13. See [Evidence Table](#). Anderson VC, Burchiel KJ. A prospective study of long-term intrathecal morphine in the management of chronic nonmalignant pain. Neurosurg 1999; 44: 289-300 See [Evidence Table](#).

The use of implanted pain pumps for the intrathecal delivery of opioids in the treatment of malignant pain meets the *Kaiser Permanente Medical Technology Assessment Criteria*.

The use of implanted pain pumps for the intrathecal delivery of opioids in the treatment of non-malignant pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

10/18/2010: MTAC REVIEW

Implanted Pain Pumps for the Intrathecal Delivery of Opioids

Evidence Conclusion: This re-review of the implantable infusion pumps for delivering intrathecal opioids did not identify any studies that would change the conclusion from the 2007 MTAC review of the technology for the control of chronic noncancer pain (CNCP). There is still insufficient published evidence on the safety and effectiveness of the infusion pump for the control of CNCP and/or improving the QoL of the patients. The published studies for this indication were small case series and observational studies with no control groups. Comparisons were made between pre- and post-implant changes, not between differences among groups receiving different therapies or interventions. The studies had multiple threats to validity and may only provide low quality evidence; they are subject to selection and observation bias and did not take into account the placebo effect of the treatment or assess outcome for patients who had not received the therapy. Moreover, the studies did not compare characteristics of patients who completed the study to those who dropped out, did not adjust for the use of additional therapies or other confounding factors, and were funded by the manufacturer. Overall, the results of the published studies indicate a reduction in self-reported pain, reduction in oral morphine use, and /or improvement in quality of life and psychological function. However, there was a significant proportion of side effects associated with the implanted pump, the catheter, and the IT opioid use.

The Washington State Health Technology Assessment (HTA) program reviewed the implantable infusion pump for drug administration to treat chronic non-cancer pain, in August 2008. After reviewing the evidence, the Health Technology Clinical Committee (HTCC) concluded, "The evidence on infusion pumps did not demonstrate net health benefit because weak or unproven evidence of some effectiveness for certain patients was undermined by significant evidence of serious harms and adverse events associated with the implantation of infusion pumps. The committee found that infusion pumps were not proven to be equally or more safe or effective, and the cost, while not a significant factor for this decision was likely equivalent. Based on these evidentiary findings, the committee voted 8 to 2 for non-coverage." Conclusion: There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids is effective for the control of chronic non-cancer pain (CNCP). There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids improves quality of life and functioning in patients with CNCP. There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids is more effective than other non-invasive alternative therapies for pain control in patients with CNCP. There is insufficient published evidence to determine that the use of implanted infusion pumps for delivering intrathecal opioids is safe for use in patients with CNCP.

Articles: The available published literature on intrathecal (IT) opioid therapy delivered through implanted pumps for chronic noncancer pain is limited and consists of systematic reviews that did not pool the results in meta-analyses, small case series, and observational cohort studies with no control or comparison groups. The literature search did not identify any meta-analyses or randomized controlled trials that compared IT opioid therapy with other non-invasive therapies published since the 2007 MTAC review. There was one retrospective cohort study (Atli 2010) reporting on 3-years outcome of chronic pain patients receiving IT treatment through implanted pumps, one case series (Shaladi 2007) of 24 patients with osteoporotic vertebral fractures treated with intrathecal morphine infusion, and another series (Duse 2009) reporting on psychological functionality of 30 patients with CNCP. The larger cohort study with a long-term follow-up was selected for critical appraisal: Atli A, Theodore BR, Turk DC, et al. Intrathecal opioid therapy for chronic nonmalignant pain: a retrospective cohort study with 3-year follow-up. *Pain Medicine* 2010; 11:1010-1016. See [Evidence Table](#).

The use of implanted pain pumps for the intrathecal delivery of opioids in the treatment of non-malignant pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
36260	Insertion of implantable intra-arterial infusion pump (eg, for chemotherapy of liver)
62360	Implantation or replacement of device for intrathecal or epidural drug infusion; subcutaneous reservoir
62361	Implantation or replacement of device for intrathecal or epidural drug infusion; nonprogrammable pump
62362	Implantation or replacement of device for intrathecal or epidural drug infusion; programmable pump, including preparation of pump, with or without programming
HCP Codes	Description
C1772	Infusion pump, programmable (implantable)
C1891	Infusion pump, nonprogrammable, permanent (implantable)
C2626	Infusion pump, nonprogrammable, temporary (implantable)
E0782	Infusion pump, implantable, nonprogrammable (includes all components, e.g., pump, catheter, connectors, etc.)
E0783	Infusion pump system, implantable, programmable (includes all components, e.g., pump, catheter, connectors, etc.)
E0785	Implantable intraspinal (epidural/intrathecal) catheter used with implantable infusion pump, replacement
E0786	Implantable programmable infusion pump, replacement (excludes implantable intraspinal catheter)

For Non-Medicare Members

Kaiser Permanente has elected to use the Intensity Modulated Radiation Therapy (IMRT) (KP-0455 v2) MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from oncologist and radiation oncologist

***MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Evidence and Source Documents

[Intensity-Modulated Radiation Therapy \(IMRT\) for Head and Neck Cancer](#)

[Intensity Modulated Radiation Therapy \(IMRT\) for Prostate Cancer](#)

Background

The aim of radical radiotherapy is to deliver a homogenous radiation dose to a tumor target with a minimal dose to surrounding normal tissue. Conventional external beam irradiation (EBRT) has been used to treat prostate cancer for more than thirty years. It partly achieves its goal but leads to irradiation of unnecessarily large volumes of normal tissue. The proximity to the rectum and the bladder has limited the ability to deliver doses > 70Gy to the prostate. This dose may be sufficient for many, but not all prostate cancer cases. The frequent persistence of local residual tumor after EBRT has been a matter of concern. The inability to eradicate some prostate cancers may be related to the lack of tumoricidal doses of radiotherapy on certain resistant clones of tumor cells.

Conformal radiotherapy (CRT) aims at minimizing the volume of normal tissue irradiated by shaping the dose distribution to conform tightly to the shape of the tumor, thus reducing the dose to the normal tissue surrounding it. The three-dimension conformal radiotherapy (3D-CRT) is a further advancement to the 2D dose planning system. It entails direction of multiple beams conformed to the shape of the target from each beam's eye view (BEV). It thus enables a higher degree of certainty of target localization and permits the use of narrow margins around it. Its ultimate goal is to escalate the radiation dose to the target, while maximally excluding the adjacent normal tissue. However, there are situations in which 3D-CRT cannot produce a satisfactory treatment plan because of complex target volume shapes, or close proximity of sensitive normal tissue.

Most recently, an advanced form of 3D-CRT, called intensity modulated radiation therapy (IMRT) was developed to overcome these limitations by adding modulation of beam intensity to beam shaping. In this method intensity modulators, such as multiple leaf collimators (MLC), or beam modifiers are used to divide the treatment beam into a set of small beamlets, the intensity of which vary from 0-100%, independent of all other beamlets. IMRT can achieve any dose distribution, notably an abrupt decrease in the dose at the limit between the tumor volume and the adjacent normal tissue.

The benefits of IMRT will be greatest for patients with tumor targets that are concave, and where normal tissues around it are clinically important. Examples of these are the larynx, pharynx, and thyroid. The main focus for IMRT in the United States has been the prostate, which forms the largest single tumor site treated with IMRT. It is hoped that it will reduce the rectal and bladder doses of irradiation, allow further dose escalation and increase the cure rates.

Special software and computer control systems are necessary to implement IMRT. The planner has to define the anatomical contour of the target volume, the desired dose and the degree of inhomogeneity in the tumor volume. Several target volumes can be distinguished e.g. primary tumor and lymph nodes. The total dose or the dose per session to each target volume can be modulated. IMRT could be used for the whole duration of a radiotherapy treatment, or simply as a boost after more conventional treatment.

Medical Technology Assessment Committee (MTAC)

Intensity-Modulated Radiation Therapy (IMRT) for Head and Neck Cancer

BACKGROUND

Intensity-modulated radiation therapy (IMRT) is a type of external beam radiation therapy that permits complex three-dimensional shaping of the radiation beams to precisely target the tumor. This allows for a larger dose of radiation to be applied to the tumor site, while minimizing exposure of the surrounding healthy tissue. Instead of a single, uniform beam as in traditional external beam radiation, IMRT involves the delivery of many small beams of varying intensity. Computer algorithms are used to coordinate the beams and plan the delivery of the radiation dose. Compared to other types of external beam radiation, IMRT is best able to generate concave dose distributions. Head and neck cancers may be particularly suited to treatment with IMRT because these tumors often have concave volumes and because head and neck tumors generally require relatively high doses (i.e. 60-70 Gy) of radiation and are in close proximity to critical tissues and organs that are radiation-sensitive (such as the salivary glands, inner and middle ears, temporomandibular joints, temporal brain and optic nerve). Head and neck cancers may also be good candidates for IMRT because of the relative lack of organ motion compared to other areas of the body. Due to the highly focused radiation dose, lack of motion is important. The most prevalent long-term adverse effect with radiation therapy for head and neck cancers is xerostomia (dry mouth) caused by damage to the salivary glands. This adverse effect may be reduced with IMRT. To date, several thousand patients worldwide have received IMRT treatment; so far, most of this has been for the treatment of prostate cancer. Several centers in the U.S. have been providing IMRT for head and neck cancer, most notably Washington University in St. Louis, the University of California, San Francisco (UCSF) and the University of Michigan (Cozzi & Fogliata, 2002). IMRT is a rapidly evolving technology that experienced clinicians believe will continue to evolve in the near future (Eisbruch, 2002).

04/09/2003: MTAC REVIEW**Intensity-Modulated Radiation Therapy (IMRT) for Head and Neck Cancer**

Evidence Conclusion: There is insufficient evidence to determine the effect of IMRT on health outcomes in patients with head and neck cancer compared to other types of radiation therapy. There is only one published comparative study with clinical outcomes, a retrospective cohort study. This study is limited because only 26 patients received IMRT (14 had post-operative IMRT and 12 had definitive IMRT). Although the findings suggest that there is a higher survival rate and lower rate toxicity rate with IMRT compared to other forms of radiation therapy, the statistics are unreliable due to the small number in the IMRT group. (Percentages are generally considered unstable when the sample size is less than 100). In the Lee case series, actuarial 4-year survival estimates were 98% for local-regional progression-free survival and 66% for distant metastasis-free survival. Two years after IMRT, 32% of patients had Grade I xerostomia and only 1 patient had Grade 2 xerostomia. In the Chao case series, the 2-year actuarial survival estimates was 85% for loco-regional control, (89% after salvage surgery). The case series were limited by lack of comparison groups, variable length of follow-up and inconsistent interventions (e.g. three different IMRT techniques were used over time in the Lee study, and in both case series, some patients had chemotherapy). In addition, each included a heterogeneous patient population in terms of cancer location and stage.

Articles: The search yielded 120 articles, many of which were reviews, opinion pieces, dealt with technical aspects of the procedure or addressed treatment planning only. There were no randomized controlled trials comparing clinical outcomes after IMRT versus other forms of radiation therapy. There was one non-randomized comparative clinical study, a retrospective cohort study. The other empirical studies were all case series. The most recent case series from the three major institutions performing IMRT for head and neck cancer (Washington University, UCSF and the University of Michigan) were identified. Two of these institutions had published series of over 50 patients with head and neck cancer who had received IMRT. The comparative study and the two largest case series were critically appraised: Chao KSC, Majhail N, Huang C et al. Intensity-modulated radiation therapy reduces late salivary toxicity without compromising tumor control in patients with oropharyngeal carcinoma: A comparison with conventional techniques. *Radiother Oncol* 2001; 61: 275-280. See [Evidence Table](#)

The use of IMRT in the treatment of head and neck cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

06/01/2004: MTAC REVIEW**Intensity-Modulated Radiation Therapy (IMRT) for Head and Neck Cancer**

Evidence Conclusion: No new randomized or non-randomized comparative studies were identified. There were updates of earlier case series from two of the major institutions performing IMRT for head and neck cancer, UCSF and Washington University. There were also several new small case series. The new literature does not substantially change the conclusions of the April 2003 MTAC review.

Articles: Medline was searched from 2003 to May 2004 using the terms, "intensity-modulated radiation therapy", "IMRT", and "head and neck cancer", with variations. The search was limited to English language publication and human populations. No new randomized or non-randomized comparative studies were identified. There were updates of earlier case series from two of the major institutions performing IMRT for head and neck cancer, UCSF and Washington University. There were also several new small case series. Lee N, Xia P, Quivey JM. Intensity-modulated radiotherapy in the treatment of nasopharyngeal carcinoma: An update of the UCSF experience. *Int J Radiation Oncology Biol Phys* 2002; 53: 12-22. See [Evidence Table](#) Chao KSC, Ozyigit G, Tran BN et al. Patterns of failure in patients receiving definitive and postoperative IMRT for head-and-neck cancer. *Int J Radiation Oncology Biol Phys* 2003; 55: 312-321. See [Evidence Table](#)

The use of IMRT in the treatment of head and neck cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Intensity Modulated Radiation Therapy (IMRT) for Prostate Cancer**BACKGROUND**

The aim of radical radiotherapy is to deliver a homogenous radiation dose to a tumor target with a minimal dose to surrounding normal tissue. Conventional external beam irradiation (EBRT) has been used to treat prostate cancer for more than thirty years. It partly achieves this goal but may lead to irradiation of unnecessarily large volumes of normal tissue. The proximity to the rectum and the bladder has limited the ability to deliver doses > 70 Gy to the prostate. This dose may be sufficient for many but not all prostate cancer cases. The frequent persistence of local residual tumor after EBRT has been a matter of concern. The inability to eradicate some prostate cancers may be related to the lack of tumoricidal doses of radiotherapy on certain resistant clones of tumor cells. Conformal radiotherapy (CRT) aims at minimizing the volume of normal tissue irradiated by shaping the dose distribution to conform tightly to the shape of the tumor, thus reducing the dose to the normal tissue surrounding it. The three-

dimension conformal radiotherapy (3D-CRT), is a further advancement to the 2D dose planning system. It entails direction of multiple beams conformed to the shape of the target from each beam's eye view (BEV). It thus enables a higher degree of certainty of target localization and permits the use of narrow margins around it. Its ultimate goal is to escalate the radiation dose to the target, while maximally excluding the adjacent normal tissue. However, there are situations in which 3D-CRT cannot produce a satisfactory treatment plan because of complex target volume shapes, or close proximity of sensitive normal tissue. Most recently, an advanced form of 3D-CRT, called intensity modulated radiation therapy (IMRT) was developed to overcome these limitations by adding modulation of beam intensity to beam shaping. In this method intensity modulators, such as multiple leaf collimators (MLC), or beam modifiers are used to divide the treatment beam into a set of small beamlets, the intensity of which vary from 0-100%, independent of all other beamlets. IMRT can achieve any dose distribution, notably an abrupt decrease in the dose at the limit between the tumor volume and the adjacent normal tissue. The benefits of IMRT will be greatest for patients with tumor targets that are concave, and where normal tissues around it are clinically important. Examples of these are the larynx, pharynx, and thyroid. The main focus for IMRT in the United States has been the prostate, which forms the largest single tumor site treated with IMRT. It is hoped that it will reduce the rectal and bladder doses of irradiation, allow further dose escalation and increase the cure rates. Special software and computer control systems are necessary to implement IMRT. The planner has to define the anatomical contour of the target volume, the desired dose and the degree of homogeneity in the tumor volume. Several target volumes can be distinguished e.g. primary tumor and lymph nodes. The total dose or the dose per session to each target volume can be modulated. IMRT could be used for the whole duration of a radiotherapy treatment, or simply as a boost after more conventional treatment. IMRT for prostate cancer was previously reviewed by MTAC in April, 2002. At that time, the evidence consisted of case series on the toxicity of IMRT and the item failed MTAC evaluation criteria.

4/10/02: MTAC REVIEW

Intensity Modulated Radiation Therapy (IMRT) for Prostate Cancer

Evidence Conclusion: The studies reviewed aimed at determining the toxicity of the high-dose radiation delivered by IMRT. In both studies IMRT was not compared to a low dose conventional treatment, instead it was compared to 3D-CRT, which also uses a high dose irradiation, yet not modulated. Compared to 3D-CRT, IMRT was found to cause significantly lower acute, and late rectal toxicity in Zelefsky's study, and significantly higher acute rectal toxicity in the Shu study. In the two studies reviewed, there was no significant difference between the two treatments in the acute or late bladder toxicity. Both studies were not randomized and non-blinded, there were some variations in the base-line characteristics in the treatment groups, and no adjustments were made for confounding factors. Randomized controlled studies with long-term follow-up are needed to study the effect of IMRT on the outcome of the cancer, as well as the morbidity from the radiation.

Articles: The search yielded 55 articles most of which were reviews, case reports, editorials, and letters. The literature did not reveal any randomized controlled studies or meta-analyses.

It also did not reveal any study on the effect of IMRT on the outcome of the prostate cancer. There were 2 articles on studies made to determine the toxicity of IMRT, and compare it to 3D-CRT. *The following articles were critically appraised:* Zelefsky MJ, et al. Clinical experience with intensity modulated radiation therapy (IMRT) in prostate cancer. *Radiotherapy and Oncology* 2000;55:241-9. See [Evidence Table](#) Shu H G, et al. Toxicity following high-dose three-dimensional conformal and intensity modulated radiation therapy for clinically localized prostate cancer. *Urology* 2001;57:102-7. See [Evidence Table](#)

The use of intensity modulated radiation in the treatment of prostate cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

2/11/04: MTAC REVIEW

Intensity Modulated Radiation Therapy (IMRT) for Prostate Cancer

Evidence Conclusion: The evidence is limited by the lack of randomized controlled trials, comparison only to 3D-CRT rather than lower-dose standard radiotherapy, inconsistent length of follow-up, lack of actual survival data and potential confounding by androgen deprivation therapy in a substantial proportion of patients. Both studies reported on biochemical survival rates. Three-year actuarial PSA relapse-free survival varied from 81-92% in the Zelefsky study and thirty-month actuarial PSA relapse-free survival was 94% for IMRT and 88% for 3D-CRT (non-significant difference) in the Kuplian study. Change in PSA level is an intermediate outcome and may not be an accurate measure of prognosis. There appeared to be relatively low rates of serious late toxicity, but many patients were not followed up long enough to contribute to this analysis. In the Zelefsky study, 9 of the patients followed for a sufficiently long time (1%) developed grade 3 late toxicity. In the Kuplian study, actuarial grade 3 late rectal toxicity at 30 months was 2% in the IMRT group and 8% in the 3D-CRT group. The evidence is limited by the lack of randomized controlled trials, comparison only to 3D-CRT rather than lower-dose standard radiotherapy, inconsistent length of follow-up, lack of actual survival data and potential confounding by androgen deprivation therapy in a substantial proportion of patients. Both studies reported on biochemical survival rates.

Three-year actuarial PSA relapse-free survival varied from 81-92% in the Zelefsky study and thirty-month actuarial PSA relapse-free survival was 94% for IMRT and 88% for 3D-CRT (non-significant difference) in the Kuplian study. Change in PSA level is an intermediate outcome and may not be an accurate measure of prognosis. There appeared to be relatively low rates of serious late toxicity, but many patients were not followed up long enough to contribute to this analysis. In the Zelefsky study, 9 of the patients followed for a sufficiently long time (1%) developed grade 3 late toxicity. In the Kuplian study, actuarial grade 3 late rectal toxicity at 30 months was 2% in the IMRT group and 8% in the 3D-CRT group.

Articles: The search yielded 102 articles, many of which were reviews, opinion pieces, dealt with technical aspects of the procedures or were on related procedures. There were no randomized controlled trials. There were three new case series publications by the Memorial Sloan-Kettering Cancer Center research group (led by Zelefsky). The patients included in the three publications overlapped. Two of the articles also included patients who were treated with 3D-CRT, but IMRT and 3D-CRT were not compared in analysis. The Zelefsky case series with the largest number of IMRT cases was critically appraised. In addition, there was a study conducted at the Cleveland Clinic which compared series of patients treated with short-course IMRT and 3D-CRT. There were no studies comparing IMRT to lower dose conventional radiotherapy. *The studies reviewed were:* Zelefsky MJ, Fuks Z, Hunt M et al. High-dose intensity modulated radiation therapy for prostate cancer: Early toxicity and biochemical outcome in 772 patients. *Int J Radiation Oncology Biol Phys* 2002; 53: 1111-1116. See [Evidence Table](#) Kuplian PA, Reddy CA, Carlson TP. et al. Preliminary observations on biochemical relapse-free survival rates after short-course intensity-modulated radiotherapy (70Gy at 2.5Gy/Fraction) for localized prostate cancer. *Int J Radiation Oncology Biol Phys* 2002; 53: 904-912. See [Evidence Table](#).

The use of intensity modulated radiation in the treatment of prostate cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
77301	Intensity modulated radiotherapy plan, including dose-volume histograms for target and critical structure partial tolerance specifications
77338	Multi-leaf collimator (MLC) device(s) for intensity modulated radiation therapy (IMRT), design and construction per IMRT plan
77385	Intensity modulated radiation treatment delivery (IMRT), includes guidance and tracking, when performed; simple
77386	Intensity modulated radiation treatment delivery (IMRT), includes guidance and tracking, when performed; complex
77387	Guidance for localization of target volume for delivery of radiation treatment, includes intrafraction tracking, when performed
HCPC Codes	Description
G6015	Intensity modulated treatment delivery, single or multiple fields/arcs, via narrow spatially and temporally modulated beams, binary, dynamic MLC, per treatment session
G6016	Compensator-based beam modulation treatment delivery of inverse planned treatment using three or more high resolution (milled or cast) compensator, convergent beam modulated fields, per treatment session
G6017	Intra-fraction localization and tracking of target or patient motion during delivery of radiation therapy (e.g., 3D positional tracking, gating, 3D surface tracking), each fraction of treatment

*Individual groups may provide additional benefits or exclusions – see current coverage agreement or contact member services for specific exceptions and limitations.

Based on Kaiser Permanente policy, a member is considered infertile if they are unable to conceive or produce conception:

- After 1 year of frequent, unprotected heterosexual sexual intercourse for members 35 and under
- After 6 months of frequent, unprotected heterosexual sexual intercourse if the female partner is over age 35 years.
- Alternately, a woman without a male partner may be considered infertile if she is unable to conceive or produce conception after at least 12 trials of medically supervised donor insemination (6 cycles for women aged 35 or older).
 - The initial 12 trials of medically supervised donor insemination (6 cycles for women aged 35 or older) to establish an infertility diagnosis, are not covered under the infertility benefit.
- A member is not considered "infertile" if they have had a voluntary sterilization (e.g. tubal ligation, vasectomy). Infertility treatment post-voluntary sterilization is not covered, even if the plan has an SI rider.

As of 1/1/2022, the following plans waived the requirement for a diagnosis of infertility but may still require prior authorization or clinical review based on individual benefits and plan riders.

Association of Washington Cities (AWC)

Boeing

City of Seattle

Meta (Facebook) – for cryopreservation only

SEIU

For *only* Kaiser Permanente Individual & Family (I&F) and Small Business Group (SBG) contracts

In addition to base infertility/sterility services listed in the Infertility and Sterility policy, member is eligible for:

- Tubal patency/uterine irregularities- HSG (radiology)
- TSH, prolactin (lab)
- Testing for Ovarian reserve –Day 3 FSH. (lab)
- Semen analysis (if member has Kaiser coverage) (lab)
- Member must use in-network lab

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Infertility is a common problem. According to the Centers for Disease Control and Prevention (CDC), about 10 percent of U.S. women ages 15 through 44 years have difficulty getting pregnant or staying pregnant.¹

Both women and men can have problems that cause infertility. About one-third of infertility cases can be connected to the woman. Another third of the cases of infertility can be connected to the man. In the remainder of instances, a cause can't be found.

Applicable Codes

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Infrared thermography is a non-invasive imaging procedure. It produces representations of variation in temperature on the surface of the human skin. Distribution of skin temperature depends on complex relationships between the skin tissue, inner tissue, local vasculature and metabolic and hormonal activity. Use of thermography as a diagnostic tool is based on the premise that the abnormal issue, such as a tumor, would raise the temperature on the skin surface due to increased metabolic activity. In the 1950s and 60s, researchers found that local skin temperatures over a breast tumor were about 2-3 degrees higher than normal skin temperature.

Although, over the past several decades, there has been experimentation with protocols for obtaining and interpreting thermograms, to date there no established procedures for using thermography to enhance diagnosis of breast cancer or other abnormalities (Mital & Scott, 2007; Ohashi & Uchida, 2000). Among the conditions for which thermography has been proposed are Raynaud's phenomenon, gastric cancer, headaches, deep vein thrombosis, and impaired spermatogenesis in infertile men.

Several thermography devices have been approved by the FDA, including the Mark I Thermal Imager (IX-DR; Howell, MI) in 2002 and EMD Thermography System in 2006. The EMD Thermography system includes an infrared sensor that is placed in contact with the skin to measure temperature. In addition, special software is used to analyze and display the temperature measurements.

Both recently approved devices were considered to be substantially equivalent to predicate devices. Approval was based on the technology's ability to measure skin temperature, rather than their proven ability to improve diagnosis of any disease. According to FDA documents, thermography is indicated for use as an adjunctive medical imaging modality in situations where a physician chooses to use it.

Medical Technology Assessment Committee (MTAC)

Infrared Thermography

06/04/2008: MTAC REVIEW

Evidence Conclusion: There is no empirical evidence that adjunctive infrared thermography improves the diagnosis of any disease or abnormality.

Articles: No technology assessments conducted by other organizations were identified. The Medline search did not yield any empirical studies that evaluated the diagnostic accuracy of thermography as an adjunctive diagnostic modality for any indication. Several articles were identified that proposed methods for analyzing thermograms or discussed technical aspects of using thermography.

The use of infrared thermography does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Background

Degenerative disc disease (DDD) resulting from wear and tear of the discs between vertebrae can lead to a painful condition that may require spinal fusion (arthrodesis) of the vertebrae on both sides of the degenerative disc. Spinal arthrodesis was introduced over a century ago for treating vertebral fractures, spinal tuberculosis, tumors and severe scoliosis. These indications were later expanded to include spondylolisthesis, spondylosis, intervertebral disc disorders, and discogenic low back pain. Spinal interbody fusion restricts the unstable spinal motion segment and may provide relief from the pain associated with DDD, when all other methods have failed. It involves the removal of the degenerated intervertebral disc and fusion of the adjacent vertebral bodies. This can be achieved through an anterior approach (anterior lumbar interbody fusion or ALIF), posterior fusion (PLIF), or transforaminal approach (TLIF) (Blumenthal 1988, Baskin 2003, Glassman 2005, Papakostidis 2008, Fu 2013, Skovrlj 2014, Noshchenko 2014, Bodalia 2016, Hofstetter 2016).

Vertebral fusions usually use graft material to stimulate the fusion. For decades autogenous iliac crest bone (ICB) has been, and is still considered, the gold standard bone grafting material for its superior osteoinductive and osteogenic properties. However, its harvest may be associated with postoperative complications including persistent pain from the donor site, deep infection, scarring, and other donor site morbidity. Another limitation of using iliac crest bone graft (ICBG) is the relative inadequate supply of graft tissue for multilevel fusions. Spine surgeons have thus been looking for alternative methods to promote spinal fusion. A variety of bone graft materials and substitutes such as local bone, bones from bone banks, demineralized bone matrix, synthetic grafts, platelet gels, and other materials have been introduced into clinical practice, but did not prove to be as effective as ICBG (Blumenthal 1988, Baskin 2003, Glassman 2005, papakostidis 2008, Fu 2013, Skovrlj 2014, Noshchenko 2014, Bodalia 2016, Hofstetter 2016).

Bone morphogenetic protein (BMP), a prototypical osteoinductive protein, was first described by Marshall Urist in 1965. BMPs are members of the superfamily of transforming growth factor-beta and play an important role in embryonic development including bone formation. In the late 1990s recombinant human bone morphogenetic protein type 2, a genetically engineered osteoinductive protein, was tested for use in lumbar fusion among humans in preclinical and clinical studies (Zhang 2014, Hofstetter 2016).

InFUSE® Bone Graft (Medtronic Sofamor Danek, Memphis, TN) is a recombinant human bone morphogenetic protein type-2 (rhBMP-2) applied to an absorbable collagen sponge (ACS) carrier that localizes the protein at the site of implantation and provides a scaffold for the formation of the new bone. The sponge is manufactured from bovine Type I collagen and is designed to resorb over time. InFUSE® Bone Graft is used in conjunction with a proprietary small thimble like titanium lordotic tapered cage (LT-Cage) implant, which is intended to restore the degenerated disc space to its original height. The LT-Cage Devices come in multiple sizes (from XX Small to Large II) to match various patient anatomies. The InFUSE® Bone Graft/LT-Cage® Lumbar Tapered Fusion Device is implanted through an open or laparoscopic anterior surgical approach. The bone graft is prepared immediately prior to its use during surgery*; the protein solution is soaked into the sponge, which is then inserted into the LT-Cage. After removing the contents of the disc space, two devices are implanted side by side in the prepared intervertebral disc space. The fusion cage maintains the spacing and temporarily stabilizes the diseased region of the spine while the InFUSE® Bone Graft induces new bone tissue at the site of implantation to fuse this portion of the spine. The fusion process requires several months to complete (Baskin 2003, Glassman 2005, Medtronic website accessed 2017)

*Once prepared, the INFUSE® Bone Graft contains rhBMP-2 at a concentration of 1.5 mg/mL

In 2002, the US Food and Drug Administration (FDA) approved the use of InFUSE® Bone Graft for anterior interbody fusion as an alternative to the iliac crest bone graft for use in conjunction with lordotic tapered cages (LT-CAGE) lumbar fusion device. According to the FDA, the device is indicated for spinal fusion procedures in skeletally mature patients with degenerative disc disease (DDD) at a single level from L4-S1. Patients should have had at least six months of nonoperative treatment prior to treatment with the InFuse Bone Graft. Later the FDA approved rhBMP-2 with other interbody fusion devices (INTER FIX™ Threaded Spinal Fusion Device and INTER FIX™ RP Threaded Fusion Device) also manufactured by Medtronic.

InFUSE® Bone Graft is contraindicated in patients who are pregnant, who may be allergic to any of the materials contained in the device, have an infection in the area of the incision, are skeletally immature, or with an existing or removed tumor in the area.

Medical Technology Assessment Committee (MTAC)

InFuse Bone Graft

10/08/2003: MTAC REVIEW

Evidence Conclusion: The trial reviewed does not provide sufficient evidence to conclude that InFUSE Bone Graft is equivalent or superior to the standard treatment. It was randomized and controlled; yet the authors compared improvements associated with the InFUSE Bone Graft with the preoperative condition, and not with the standard treatment. The trial shows that both treatments led to significant improvement in the back pain, leg pain, as well as pain associated with activity when compared to the preoperative scores. The two procedures were also associated with post-operative vs. baseline, high neurological success, patient satisfaction and bone fusion. The authors noted that the success rates and pain scores were similar between the two groups, based on the values observed and not on statistical tests of significance. It seems unlikely that there are any significant differences between the two groups, as the numbers, and scores are close. This may suggest that the effect of the two treatments may be similar, but the study isn't conclusive as it may have been underpowered to detect a difference and was not designed as an equivalence trial that requires a larger sample size, and a different method of analysis than superiority trials.

Articles: The search revealed 4 randomized controlled studies and one case series. Three of the RCTs were conducted by the same principle investigator and included patients from the same center: one large trial with 279 patients, and two smaller RCTs with 46, and 42 patients. The other trial revealed included only 14 patients. The search also revealed an article where the same principle investigator of the three RCTs pooled data from his trial as well as other 3 unpublished studies, two of which were non-randomized. It had a poor methodology and cannot be categorized as a meta-analysis. The largest of the three RCTs conducted by the same investigator group was selected for critical appraisal. *The following study was critically appraised:* Burkus JK, Gornet MF, Dickman CA, et al. Anterior lumbar interbody fusion using rhBMP-2 with tapered interbody cages. J Spinal Disord Tech. 2002; 15:337-49. See [Evidence Table](#).

The use of recombinant human bone morphogenetic protein (rhBMP-2) placed on an absorbable collagen sponge (ACS) in the treatment of degenerative disc disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

12/07/2009: MTAC REVIEW

InFuse Bone Graft

Evidence Conclusion: There is a lack published material on the use of InFUSE Bone Graft for anterior lumbar interbody fusion, the indication for which the technology received the FDA approval. Glassman and colleagues' trial (2008) had the advantage of comparing rhBMP-2 to iliac crest bone graft in a randomized controlled trial with 2-year follow-up duration. However, the technology was used off-label for a posterolateral lumbar fusion among patients older than 60 years of age. Moreover, the trial was not blinded, and the authors did not discuss the method of randomization, or clearly describe the inclusion/ exclusion criteria. Non-blinding may be a source of observation bias, especially with the subjective primary outcomes of the trial. The investigators tried to partially overcome this limitation by blinding the orthopedic surgeons who evaluated the radiological outcomes. The authors also did not discuss any power analysis for determining the sample size, and analysis was not based on intention to treat. Overall, the results of the trial show significant improvements in health-related

quality of life, as well as the leg, and back pains at one and two years of follow-up among the patients in the two treatment groups, when compared to the preoperative status. There were no significant differences in the primary outcomes between the two interventions. The outcomes may appear similar, but the lack of significant statistical significance does not necessarily imply equivalence. The study was relatively small and might have been unpowered to detect significant differences between the study groups. It was not designed as an equivalence trial that requires a larger sample size and different method of analysis than a superiority trial. Radiographic evaluations at two years showed higher fusion rate with rhBMP-2 vs. ICBG (86.3% and 70.8%, respectively). In conclusion there is insufficient published evidence to conclude that InFUSE Bone Graft is equivalent, noninferior, or superior to the standard iliac crest bone graft in improving functional ability and quality of life of patients with symptomatic degenerative disc disease.

Articles: The search revealed over 30 articles on rhBMP-2 /InFUSE Bone Graft. Many were unrelated to the current reviews; others used rhBMP-2 in different formulations or in combination with other elements e.g. ceramic granules. Two articles (Glassman, et al 2005 and 2008) reporting on one- and two-years results of a randomized controlled study comparing the use of rhBMP-2 versus iliac crest bone graft (ICBG) for lumbar spine fusion, were identified as well as a small nonrandomized trial and two case series studies on the use of InFUSE Bone Graft. The RCT with the 2-year follow-up was selected for critical appraisal. Glassman SD, Carreon LY, Djurasovic M, et al. RhBMP-2 versus iliac crest bone graft for lumbar spine fusion: A randomized, controlled trial in patients over sixty years of age. *Spine*. 2008; 33:2843-9. See [Evidence Table](#).

The use of recombinant human bone morphogenetic protein (rhBMP-2) placed on an absorbable collagen sponge (ACS) in the treatment of degenerative disc disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

06/21/2017: MTAC REVIEW

InFuse Bone Graft

Evidence Conclusion: As indicated in the previous section, the literature search did not identify any more recent RCTs evaluating InFUSE® Bone Graft for ALIF, but a number of qualitative reviews and quantitative meta-analyses of the published trials. All trials were open-label, the great majority was industry sponsored, and the principal authors had financial ties with the industry.

Efficacy and safety of InFUSE® Bone Graft compared to the gold standard autogenous iliac crest bone graft (ICBG) Carragee and colleagues (2011) conducted a systematic review and critical analysis of the original peer reviewed industry-sponsored publications and compared their results and conclusions versus the available FDA summaries, follow-up publications, and administrative and organizational database analyses. According to the authors, the systematic review was prompted by complaints to the editorial board of the *Spine Journal* including allegations of research bias, failure to report adverse event recorded by the study surgeons, and discrepancies between FDA summaries and published data. The authors reviewed the results of 13 original industry-sponsored rhBMP-2 publications regarding safety and efficacy, including reports and analyses of 780 patients receiving rhBMP-2 within prospective controlled study protocols. These included studies using anterior, posterior and posterolateral interbody fusion. The estimated rate of adverse events associated with rhBMP-2 use in spinal interbody fusion ranged from 10% to 50% depending on the approach and spinal level of fusion.

- Anterior interbody lumbar with rhBMP-2 was associated with higher rates of implant displacement, subsidence, infection, urogenital events, and retrograde ejaculation versus the controls.
- Posterior lumbar interbody fusion was associated with radiculitis, ectopic bone formation, osteolysis, and poorer global outcomes.
- In posterolateral fusions, the risk of adverse effects associated with rhBMP-2 use was equivalent to or greater than that of iliac crest bone graft harvesting, and 15% to 20% of subjects reported early back pain and leg pain adverse events. Higher doses of rhBMP-2 were associated with a greater apparent risk of new malignancy.
- Anterior cervical fusion with rhBMP-2 had an estimated 40% greater risk of adverse events in the early postoperative period including life-threatening events.

The authors provided evidence showing discrepancy between the FDA documents and the published results of industry-sponsored trials on rhBMP-2. He noted that while the authors of the industry sponsored trials on ALIF, reported no adverse events, the FDA concluded that the original data from the trials indicate that "The incidence of adverse events that were considered device related, including implant displacement/loosening, implant malposition and subsidence were all greater in the investigational [rhBMP-2] groups compared to the control

group” (Carragee 2011). Carragee and colleagues summarized the areas of concern regarding the safety and efficacy reported by the industry sponsored trials as follows:

1. Underestimation of adverse events and serious harms associated with rhBMP-2.
2. Presence and magnitude of conflict of interest and potential for reporting bias.
3. Invalid assumption and methodology used for estimating adverse events associated with iliac crest bone grafts, which led to exaggeration of the benefits underestimating the morbidity of rhBMP-2.
4. Significant bias against the selection of the control and techniques used in the PLIF and PLF.

The reviewers concluded that Level I and Level II evidence from original FDA summaries, original published data, and subsequent studies suggest possible study design bias in the original trials, as well as a clear increased risk of complications and adverse events to patients receiving rhBMP-2 in spinal fusion. This risk of adverse events associated with rhBMP-2 is 10 to 50 times the original estimates reported in the industry-sponsored peer-reviewed publications. Fu and colleagues, 2013 ([Evidence Table 1](#)) performed a meta-analysis to evaluate the effectiveness and harms of rhBMP-2 in spinal fusion and to assess the reporting bias in industry sponsored journal publications. The authors used data from the literature and individual patient level data of the rhBMP-2 trials (including unpublished data from the trials) provided by the manufacturer through the Yale Open Data Aces (YODA) Project. The latter project was sponsored by the manufacturer for an independent review of all published and unpublished data. The analysis included=13 RCTs (12 sponsored by Medtronic) and 31 cohort studies, 47 intervention series, and 35 case series or reports. The primary outcome was the overall success and fusion. The meta-analysis had generally valid methodology, and the studies included were rated by the authors to be of moderate quality. However, all were unblinded; industry sponsored, and according to the authors, had poor ascertainment of harm. The authors analyzed anterior and posterior fusion separately as well as cervical and lumbar fusion. The pooled results of studies comparing rhBMP-2 versus ICBG for ALIF, showed no significant differences in overall success except for very slight improvement in leg pain at 6 weeks with rhBMP-2. There were higher rates to urogenital complications and retrograde ejaculation with rhBMP-2, the difference was not significant but could be due to insufficient power. The cancer risk was significantly higher with rh-BMP-2. The authors of the meta-analysis noted that early journal publications misrepresented the effectiveness and harms through selective reporting, under-reporting, and duplicate publications. They concluded that their technology had no proven advantage over bone graft and may be associated with important harms. Simmonds et al, 2013 meta-analysis ([Evidence Table 2](#)) also used data from the YODA project to evaluate the safety and effectiveness of rhBMP-2 compared to ICBG. The analysis included 12 RCTs (11 Medtronic sponsored) for effectiveness plus 35 additional controlled adverse events studies for safety analysis. The primary outcomes were patient centered pain and function, fusion and adverse events. The results of the analysis showed that from 6 months after surgery up to 2-years, rhBMP-2 led to greater pain reduction compared to ICBG. The authors noted however; the difference may not be clinically significant as patients in both treatment groups experienced considerable reduction in pain. Successful fusion rates were found to be higher with rhBMP-2 but there was significant heterogeneity between studies in the relative risk of fusion, and the authors noted that Medtronic definitions of fusion may have been stringent as only 69% of ICBG recipients achieved fusion in 24 months. The authors found no correlation between successful fusion with rhBMP-2 and pain reduction. As regards safety, the analysis showed that pain (which was reported as an outcome and as an adverse effect) was significantly higher with rhBMP-2 shortly after surgery and lower at 24 months, compared to ICBG. Other adverse events including Implant-related events, neurologic events, retrograde ejaculation, vascular events, wound complications, and cancer, all occurred at a higher rate with rh-BMP-2, but the difference did not reach a significant level, which could be attributed to the small number of events. Zhang and colleagues, 2014 ([Evidence table 3](#)) conducted a meta-analysis of randomized controlled trials to compare the effectiveness and safety of fusion with BMPs (-2 or -7) versus ICBG for the treatment of degenerative lumbar conditions. The analysis included 19 RCTs involving 1,852 patients. The studies recruited patients with a variety of spinal disorders and different approaches were used for the fusion. In 14 of the 19 trials rhBMP was used off-label. The co-primary outcomes of the analysis were solid fusion rate, clinical outcomes, complications, and reoperation rate. The pooled results showed that the rate of fusion was significantly higher among patients in BMPs group; however, this difference was no longer significant with the sensitivity analysis that excluded 7 studies with high risk of bias. There were statistically significant differences in the overall success of clinical outcomes, complication rate, blood loss, hospital stay, patient satisfaction, or work status. Significant reductions in the operating time and reoperation rate were found in BMPs. This was a high-quality meta-analysis as regards its methodology, analysis and grading the evidence for each outcome. However, the quality of the results of a meta-analysis relies heavily on the quality of the studies it includes. Due

to the nature of the intervention, all published trials evaluating rh-BMP-2 were unblinded, which is a source of bias, especially with subjective outcomes. In addition, there were other limitations to the published studies regarding methods of randomization and allocation procedures. There were variations between the trials in BMP used and the approach for fusion as well the methods and standards used for assessing the bone fusion which. The studies included in the meta-analysis used plain radiography, CT scan, or surgical exploration for evaluating the fusion rate. The authors explained that imaging was used to assess the status of spinal fusion, and that it provides less accurate data compared to direct operative exploration. In addition, the majority of the studies were industry sponsored and some of the authors reported conflict of interest. Overall, the authors concluded that the limited evidence does not show that BMP is superior to ICBG for the treatment of lumbar DDD and that more high-quality trials with long-term outcomes are needed. Other published meta-analyses (Chen, 2012 and Noshchenko, 2014) included the same industry sponsored RCTs, and had similar results showing that rhBMP-2 may lead to slightly higher fusion rates compared to ICBG, but with possible harm and no significant clinical improvement. **Impact of patient characteristics on the effectiveness and harms of rhBMP-2 compared with ICBG.** Laurie and colleagues' (2016) meta-analysis used the data from the YODA project to examine the impact of patient characteristics on the effectiveness and harms of rhBMP-2 as compared with ICBG. The analysis included 10 industry sponsored RCTs involving 1,255 participants. 5 trials used the anterior lumbar approach, 4 used the posterior lumbar, and one used the posterolateral lumbar approach for the interbody fusion with rhBMP-2. The population sizes of the individual trials varied from 10 to 463 participants. The results of the analysis suggest that there may be a differential treatment effect between rhBMP-2 and ICBG according to some patient characteristics. Fusion success was found to be higher with rhBMP-2 vs. ICBG in patients under the age of 60 at 6 months after the surgery and among smokers and normal weight individuals at 24 months postoperatively. No significant differences were observed between the two procedures for overweight or obese patients. The analysis also showed that the rate of device-related adverse events with rhBMP-2 was lower in individuals with no previous back surgery. **Impact of rh-BMP-2 dosing on outcomes** The BMP dose varied widely among the published studies which may indicate that is uncertainty regarding the optimal dose for the spinal fusion procedures. Hofstetter and colleagues' meta-analysis (2016) examined the effect of BMP dosing on successful fusion and morbidity with the common fusion procedures. The analysis included 48 articles involving 5,890 patients. 9 trials were on ALIF, 17 on transforaminal or posterior lumbar interbody fusion (TLIF/PLIF), 7 on anterior cervical discectomy and fusion (ACDF), and 9 trials on posterior lumbar fusion (PLF) supplemented with BMP. The authors performed separate meta-analyses for each procedure. The results of the analyses suggest that there is a wide range in the BMP dosing used for specific spinal fusion procedures (from 2.5mg/level for posterior cervical fusion [PCF] to 10.5mg/level in ACDF). The meta-analysis of studies on ALIF showed a trend toward an association between the likelihood of complications and the dose of BMP. In reports of ALIF supplemented with high doses of BMP (4.3-12.0 mg/level) the rates of endplate resorption and graft subsidence were high. More studies are needed to determine the safe and effective BMP dosing for the different applications.

Conclusion:

- The published literature does not provide sufficient evidence to determine that rh-BMP-2 has superior or equivalent effectiveness and safety compared standard iliac crest bone graft for adult patients with symptomatic lumbar degenerative disc disease referred to anterior interbody lumbar fusion.
- A number of meta-analyses and systematic reviews, including those using data from the Yale University Open Database Project, suggest that spinal interbody fusion using InFUSE® Bone Graft had a small or no advantage when compared to the standard use of iliac crest bone graft (ICBG), and may be associated with more serious adverse events.

Articles: The updated literature search did not reveal any recent trials that examined the efficacy and safety of using InFUSE® Bone Graft for anterior lumbar interbody fusion (ALIF) in patients with symptomatic single level degenerative disc disease from L1-L4. There was a number of systematic reviews with or without meta-analyses as well as several retrospective analyses on the effectiveness and safety of rhBMP-2 for spinal fusion. There were more publications and studies on the use of InFUSE® Bone Graft for cervical interbody fusion, or using the posterior, lateral, or posterolateral approaches for lumbar interbody fusion, all of which are off-label use of InFUSE® and out of scope for the current review. Two meta-analyses that included individual patient data of the rhBMP-2 trials provided by the manufacturer through the Yale Open Data Access (YODA) project, as well as another meta-analysis of published trials were selected for critical appraisal. Fu R, Selph S, McDonagh M, et al. Effectiveness and harms of recombinant human bone morphogenetic protein-2 in spine fusion: a systematic review and meta-analysis. *Ann Intern Med.* 2013 Jun 18; 158(12):890-902. Simmonds MC, Brown JV, Heirs MK,

et al. Safety and effectiveness of recombinant human bone morphogenetic protein-2 for spinal fusion: a meta-analysis of individual-participant data. *Ann Intern Med*. 2013 Jun 18; 158(12):877-889. Zhang H, Wang F, Ding L, Zhang Z, et al. A meta-analysis of lumbar spinal fusion surgery using bone morphogenetic proteins and autologous iliac crest bone graft. *PLoS One*. 2014 Jun 2; 9(6): e97049.

The use of the InFUSE® Bone Graft/LT-Cage® Lumbar Tapered Fusion Device for Anterior Lumbar Interbody Fusion (Recombinant Bone Morphogenetic Protein Type 2 [rhBMP-2]) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Inhaled Nitric Oxide (iNO) Therapy

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Non-Medicare Members

- A. Treatment of pulmonary hypertension (PHN) to reduce risk of chronic lung disease, and respiratory failure in infants born or at near term (>34 weeks)
 1. Neonate does not have congenital diaphragmatic hernia, and
 2. Conventional therapies such as administration of high concentrations of oxygen, hyperventilation, high-frequency ventilation, the induction of alkalosis, neuromuscular blockade, and sedation have failed or are expected to fail.
 3. Treatment of Congenital Diaphragmatic Hernia (CDH)
 - a. iNO is required to stabilize a patient during transition to ECMO (Usually required for a few hours before)
 - b. iNO is required during transition off of ECMO when pulmonary arterial pressures are high (this can be a period of time ranging from hours to several days)
- B. Treatment of pulmonary hypertension in pre-term newborns (≤34 weeks)

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.
- C. Treatment of acute respiratory distress syndrome (ARDS) in adults and children

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.
- D. Treatment of Cyanotic Congenital Heart Disease with pulmonary hypertensive crisis (all pediatric patients)
 1. The patient is being managed for acute pulmonary hypertension crisis and acute right heart failure with a predisposition to unrestricted over-circulation. OR
 2. The patient requires a surgical intervention with increased risk of pulmonary hypertension crisis and is receiving pulmonary vascular therapy AND
 - a. Typical course of treatment 3 days (this may be longer on a case by case basis) to transition to oral medications and wean-off iNO OR
 - b. The patient needs transplant for right heart failure and requires iNO for 1 week to several months.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Treatment of persistent pulmonary hypertension (PPHN) and respiratory failure in infants born or at near term.

Persistent pulmonary hypertension of the newborn (PPHN) is an important cause of cardiorespiratory failure in the near-term neonate (>34 weeks). It occurs when normal cardiopulmonary transition fails to take place after birth; the newborn's arteries to the lungs remain constricted limiting the amount of blood flow to the lungs and therefore

the amount of oxygen into the blood stream. PPHN can occur either as a primary condition of neonatal maladaptation or secondary to other conditions such as pneumonia, sepsis, hyaline membrane disease, meconium aspiration, congenital diaphragmatic hernia, or pulmonary hyperplasia. Causes of PPHN may be variable, but all lead to same physiologic changes; a persistently raised pulmonary vascular resistance that leads to severe hypoxemia due to extra pulmonary shunting. Even with appropriate therapy, the mortality for PPHN remains between 5 and 10% (Gonzales 2009, Finer 2009, Steinhorn 2010).

The goal of therapy of PPHN is to maximize the amount of oxygen transported to the lungs and in turn to the systemic circulation. Conventional therapies include supplemental oxygen with often requires intubation and mechanical ventilation, induction of alkalosis, paralysis, sedation, as well as maintenance of temperature, electrolytes, glucose, and intravascular volume. Infants who fail conventional therapies may require treatment with extracorporeal membrane oxygenation (ECMO). During ECMO, the jugular vein and/or carotid artery is surgically bisected and connected to a heart-lung machine with a cannula to oxygenate the infant's blood. ECMO therapy can be lifesaving, but is highly invasive, labor intensive, and has potential side-effects such as intracranial hemorrhage and ligation of the right common carotid artery (Steinhorn 2010).

Inhaled nitric oxide (iNO) has been investigated for the treatment of PPHN to improve oxidation, reduce the need for ECMO, and decrease mortality. Nitric oxide is a colorless, almost odorless gas that is naturally produced by various human tissues and is involved in several physiologic functions. It is a rapid and potent vasodilator, and because of its small gas molecule, it can be delivered as inhalation therapy to airspaces in close proximity to the pulmonary vascular bed. Once in the blood stream NO binds to hemoglobin and is rapidly inactivated with an estimated half-life of 3-5 seconds. The effect of iNO is limited to the lungs making it a selective pulmonary vasodilator without adverse systemic hemodynamic effect (DiBlasi 2010, Steinhorn 2010).

iNO therapy is not without harmful side effects. When oxygen and nitric oxide mix together, they chemically react to form nitrogen dioxide (NO₂), which is toxic to the lungs. Nitrogen dioxide concentrations greater than 10 parts per million (ppm) have been known to induce pulmonary edema, alveolar hemorrhage, changes in the surface tension properties of surfactant, and death. NO₂ is dose- dependent and its concentrations should be maintained below 3 ppm by decreasing the iNO concentration if its level increases. Methemoglobinemia (MetHb), which impairs the ability of the hemoglobin molecule to bind with oxygen, is another harmful side effect of iNO therapy. MetHb is dose-dependent and its levels must be carefully monitored. Significant methemoglobinemia has been reported after accidental overdose of iNO, and a level >10% may cause cyanosis, headaches, muscle weakness, and tissue hypoxia. Laboratory and clinical studies have suggested that high doses of inhaled nitric oxide may increase the risk of bleeding, which is a serious concern because of the predisposition of premature newborns to intracranial hemorrhage (Kinsella 2006, Finer 2009, Henry 2012).

The recommended initial dose of iNO is 20 ppm, and the duration of its use is normally less than 5 days but may be maintained for up to 14 days, or until the underlying oxygen desaturation has been resolved. Abrupt discontinuation of the therapy can lead to worsening of PaO₂ and increasing pulmonary artery pressure. The use of iNO was approved by the Food and Drug Administration (FDA) in 1999 for the treatment of term and near-term neonates (>34 weeks) with hypoxic respiratory failure with clinical or echocardiographic evidence of pulmonary hypertension. Using iNO for other medical conditions is considered "off label" usage.

iNO therapy is provided through a delivery system used in conjunction with a ventilator or other breathing gas administration system. Nitric oxide delivery system consists of a nitric oxide administration apparatus, a nitric oxide gas analyzer, and a nitrogen dioxide gas analyzer. INOmax® (INO Therapeutics Inc., Clinton NJ) is a commercially available brand of iNO that received initial Food and Drug Administration approval in 1999 to be used as a vasodilator in conjunction with ventilatory support and other appropriate agents. In 2009, the FDA updated the INOmax safety labeling indicating that in patients with pre-existing left ventricular dysfunction, iNO may increase pulmonary capillary wedge pressure leading to pulmonary edema, even when used for a short time (FDA webpage accessed July 20, 2012).

Treatment of pulmonary hypertension in pre-term newborns

Approximately 8-13% of all babies are born preterm (<37 weeks of gestation) across developed countries. Although survival rates have improved markedly in recent decades, preterm delivery still accounts for more than 75% of all perinatal complications and death. It is estimated that three fourths of preterm infants with birth weight <1000g develop respiratory distress syndrome (RDS), and 30- 40% are still oxygen dependent at a postmenstrual age (gestational age plus chronological age) of 36 weeks. Breathing failure in premature newborns may be complicated by raised pressure within the vessels that carry blood to the lungs (pulmonary hypertension). Those who require assisted ventilation are at high risk of developing long-term medical and neurocognitive impairment including bronchopulmonary dysplasia (BPD), which is characterized by arrested lung growth, reduced

alveolarisation, and dysmorphic vasculature (i.e. the infants' lungs are not fully formed or are not able to make enough surfactant, which is a liquid that coats the inside of the lungs and helps keep them open so an infant can breathe in air once he or she is born). Without surfactant, the lungs collapse, and the infant may not be able to breathe in enough oxygen to support the body's organs. This may lead to neurodevelopmental impairment and damage to other organs (Barrington 2006, Askie 2010, 2011).

Conventional therapy of respiratory failure complicated by pulmonary hypertension in preterm newborn involves respiratory support, which includes assisted ventilation and continued distending pressure, the administration of surfactant, and sedation or muscle relaxation if needed.

iNO has been investigated as a treatment to prevent lung injury in preterm infants based on the findings from experimental studies performed on a variety of fetal animals and/ or premature animal models with hyaline membrane disease and elevated pulmonary artery pressure. These experiments showed that iNO therapy may enhance pulmonary angiogenesis and lung alveolarisation, reduce the pulmonary vascular resistance and improve oxygenation. Studies in full-term infants also showed that iNO may cause selective pulmonary vasodilatation to reduce pulmonary artery pressure and improve ventilation /perfusion mismatch. However, the results of studies conducted among term or near-term infants cannot be extrapolated to the preterm babies because of the difference in pathophysiology of respiratory failure, and the difference in the potential risks of iNO in preterm infants. If iNO therapy leads to a decrease in required ventilation support, it may also lead to a reduction in lung injury and bronchopulmonary dysplasia. However, it is still uncertain which subpopulation of premature infants may profit most from iNO. There is also opposing data on whether exogenous NO is protective or destructive in the presence of hyperoxia. Inhaled nitric oxide has pro-oxidation and antioxidants activities and can potentially worsen lung injury. Preterm infants are also at higher risk of developing intracranial hemorrhage, and there is a concern about the effect of iNO in increasing the bleeding time (Barrington 2006, Love 2012).

Inhaled nitric oxide is provided through a delivery system used in conjunction with a ventilator or other breathing gas administration system. iNO delivery system consists of a nitric oxide administration apparatus, a nitric oxide gas analyzer, and a nitrogen dioxide gas analyzer. INOmax® (INO Therapeutics Inc., Clinton NJ) is a commercially available brand of iNO that received initial Food and Drug Administration approval in 1999 to be used as a vasodilator in conjunction with ventilatory support and other appropriate agents for the treatment of term and near-term (>34 weeks gestation) neonates with hypoxic respiratory failure associated with clinical or echocardiographic evidence of pulmonary hypertension. The use of iNO for other neonatal medical conditions is considered "off label" use.

Treatment of acute respiratory distress syndrome (ARDS) in adults and children

Acute respiratory distress syndrome (ARDS) is a major source of morbidity and mortality, with a case fatality rate exceeding 30%. ARDS is defined by acute non-cardiogenic pulmonary edema, acute severe hypoxemia irrespective of positive end expiratory pressure, bilateral infiltrates on chest radiography, and a pulmonary artery occlusion pressure ≤ 18 in any adult or child more than one month old. Acute lung injury (ALI) is a milder form of the syndrome and both conditions are often referred to as acute hypoxemic respiratory failure (AHRF). They are characterized by an inflammatory process of the alveolar-capillary membrane that may result from a primary lung disease or is secondary to a number of systemic diseases. AHRF results in intrapulmonary shunting with hypoxemia and pulmonary hypertension. Hypoxemia in ARDS is mainly caused by ventilation perfusion mismatch leading to increased pulmonary shunting due to pulmonary vasodilatation in non-ventilated lung regions and vasoconstriction in ventilated areas (Milberg 1995, Afshari 2011, 2012).

Treatment of ARDS/ALI is mainly supportive and aims at improving gas exchange, control of infection, and preventing complications. The optimal therapy involves judicious fluid management, protective mechanical lung ventilation with low tidal volumes and moderate positive end expiratory pressure, multi-organ support, and treatment of the underlying cause, when possible. Pharmacotherapies have a very limited role in the management of ARDS, and to-date there is no effective medical treatment that improves survival for adult patients with the syndrome, although exogenous surfactant is beneficial in the pediatric population (Dushianthan 2011).

In 1991, inhaled nitric oxide (iNO) was shown to be a selective pulmonary vasodilator in patients with pulmonary hypertension, as well as in animals with pulmonary hypertension induced by drugs or hypoxia. Two years later, inhaled nitric oxide was introduced as a potential therapy for ARDS. Nitric oxide is a colorless, odorless gas that rapidly diffuses from alveoli through epithelial cells to gain direct access to the vasculature. Once in the blood stream it binds to hemoglobin and is rapidly inactivated with an estimated half-life of 3-5 seconds. The effect of iNO is limited to the lungs making it a selective pulmonary vasodilator without adverse systemic hemodynamic effects. iNO causes vasodilatation of ventilated lung units and redistribution of pulmonary blood flow away from non-ventilated lung areas. It decreases pulmonary vascular resistance, improves the ventilation perfusion

mismatch, and subsequently reduces the elevated vascular resistance and pulmonary hypertension. It is also believed that iNO may also regulate both the immune and inflammatory responses (oxygenation by redistributing pulmonary blood flow toward ventilated lung units in patients with this condition (Griffiths 2005, DiBlasi 2010, Dushianthan 2011, Pierrakos 2011).

iNO therapy is also associated with harmful side effects. Nitric oxide is unstable in air and when inhaled with high concentrations of oxygen, the gaseous NO slowly forms nitrogen dioxide which is potentially cytotoxic. A NO₂ concentrations higher than 10 parts per million (ppm) has been known to induce pulmonary edema, alveolar hemorrhage, changes in the surface tension properties of surfactant, and death. NO₂ is dose-dependent and its concentration should be maintained at a level below 3 ppm by decreasing the iNO concentration if it goes any higher. Methemoglobinemia (MetHb), which impairs the ability of the hemoglobin molecule to bind with oxygen, is another harmful side effect of iNO therapy. MetHb is dose-dependent and must be carefully monitored as significant methemoglobinemia has been reported after accidental overdose of iNO. A MetHb level >10% may cause cyanosis, headaches, muscle weakness, and tissue. Renal failure has also been reported with iNO use (Kinsella 2006, Finer 2009, Dushianthan 2011, Henry 2012).

Inhaled nitric oxide is provided through a delivery system used in conjunction with a ventilator or other breathing gas administration system. The delivery system consists of a nitric oxide administration apparatus, a nitric oxide gas analyzer, and a nitrogen dioxide gas analyzer. INOmax® (INO Therapeutics Inc., Clinton NJ) is a commercially available brand of iNO that received initial Food and Drug Administration approval in 1999. It was approved for use as a vasodilator, in conjunction with ventilatory support and other appropriate agents for the treatment of term and near-term (>34 weeks gestation) neonates with hypoxic respiratory failure associated with clinical or echocardiographic evidence of pulmonary hypertension. The use of iNO for other neonatal medical conditions and for treatment in the adult patient population is considered "off label" usage.

Medical Technology Assessment Committee (MTAC)

iNO for Treatment of Persistent Pulmonary Hypertension

08/20/2012: MTAC REVIEW

Evidence Conclusion:

There is fair evidence that inhaled nitric oxide therapy for adult patients with acute respiratory distress syndrome or acute lung injury does not improve survival or other clinical outcomes and may increase the risk of renal impairment. There are insufficient published pediatric trials to determine any benefit or harm of iNO therapy in children with ARDS or ALI.

Articles: Treatment of persistent pulmonary hypertension (PPHN) and respiratory failure in infants born or at near term: The literature search revealed a number of randomized controlled studies and a Cochrane review with a meta-analysis that pooled the results of 12 RCTs. Clinical Review Criteria Dermal Fillers for Facial Lipoatrophy

- Sculptra
- Radiesse

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Dermal Injections for the Treatment of Facial Lipodystrophy Syndrome (LDS) (250.5)
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

For Non-Medicare Members

Dermal filler injections are covered when **ALL** of the following criteria are met:

- 1) The member has **ALL** of the following:
 - a) a diagnosis of human immunodeficiency virus (HIV), and
 - b) a diagnosis of facial lipodystrophy/lipoatrophy, grades 3-4*, related to HIV or highly active antiretroviral therapy (HAART), and

AND

- 2) The dermal filler is approved by the Food and Drug Administration for Facial Lipodystrophy Syndrome (LDS), e.g. Sculptra® and Radiesse®.

Multiple sessions may be necessary to complete the therapy, depending upon the severity of the lipodystrophy. The following link provides examples of the Carruthers grading system*: www.facialwasting.org.

If the patient has:

- 1) Grade 3 lipodystrophy, up to 4 sessions may be required
- 2) Grade 4 lipodystrophy, up to 8 sessions may be required

*If additional treatments are desired, the treating provider will need to reevaluate the patient or repeat photos of the patient's face will be required to determine if further treatments are warranted.

Repeat treatment is typically necessary one to two years after the initial therapy, when the patient has regressed to Grade 2 or greater lipoatrophy.

CONTRAINDICATIONS

Coagulopathy, active infection (whether or not related to HIV disease), inadequate immune function as determined by HIV provider.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

HIV-associated lipodystrophy has been reported in the literature starting in the late 1990s. This condition involves loss of subcutaneous fat or fat accumulations in particular regions of the body. It can include fat accumulation around the abdomen, dorsocervical area (buffalo hump) and breast hypertrophy. Regions affected by fat loss (lipoatrophy) include the limbs, buttocks and face, especially the nasolabial regions, the temples and the eye sockets. The condition is different from HIV wasting syndrome that is mainly due to loss of muscle mass. HIV-associated lipodystrophy is also associated with insulin resistance, hyperglycemia and low levels of high-density lipoprotein (HDL) (James et al., 2002).

Although the cause of HIV-associated lipodystrophy is not well understood, some investigators believe there is a link with HIV protease inhibitors (PI). The condition started being reported in the literature around the time that protease inhibitors were introduced and prescribed to HIV-infected patients. In addition, the prevalence of lipodystrophy is higher in HIV-infected patients who received PIs compared to PI-naïve patients (James et al., 2002). Lipoatrophy may be associated with the use of specific nucleosides such as stavudine and didanosine in treatment while lipoaccumulation may be associated with protease inhibitors, especially ritonavir (Dr. Wayne Dodge, personal communication).

The treatment of facial lipoatrophy is the subject of the current MTAC review. There is little published literature on this topic, but anecdotal information suggests that facial lipoatrophy negatively affects HIV-infected individuals' body image and self-esteem and can lead to social and sexual problems. The long-term natural history of lipoatrophy is also not well known. Lipoatrophy does not appear to resolve on its own, or after discontinuation of PIs and other medication (James et al., 2002; Huff, 2004).

Sculptra, an injectable form of poly-L-lactic acid (PLA) is the first FDA-approved treatment for HIV-associated facial lipoatrophy. PLA is a biocompatible, biodegradable substance that is synthetically derived from natural components. It was been used in surgical products such as dissolvable stitches and bone screws. PLA was approved in Europe in 1999 for cosmetic treatment of scars and wrinkles, under the brand name New-Fill. The FDA did not approve Sculptra for the treatment of wrinkles. FDA approval of Sculptra for facial lipoatrophy was based on unpublished data submitted by the manufacturer Dermik Laboratories. A condition of FDA approval was that Dermik agreed to conduct a registry study for five years to evaluate Sculptra's long-term safety (FDA press release; James et al., 2002). Potential limitations of injectable PLA for severe cases of facial lipoatrophy are that large quantities of material are needed to fill the defects and there may be high maintenance costs (Binder & Bloom, 2004).

Medical Technology Assessment Committee (MTAC)

Injectable Poly-L-Lactic Acid (PLA)

12/08/2004: MTAC REVIEW

Evidence Conclusion: There was one randomized controlled trial with 30 patients (Moyle, 2004) and this compared immediate treatment with PLA to delayed treatment after 12 weeks. The 12-week follow-up is the appropriate point in the study to compare treatment with no treatment. At 12 weeks, there were no significant differences between groups in depression or anxiety scores. A significantly greater proportion of patients in the immediate treatment group perceived "less thinness" in the face. The study was limited by the short follow-up period, small sample size with no statistical power analysis and lack of clear primary outcomes. The other empirical study reviewed was a case series with 50 patients (Valentin, 2003). Although there was no comparison group, advantages of the Valentin study were that there was objective measurement of changes in facial thickness and follow-up was longer, 96 weeks. There was a significant increase in total cutaneous thickness (TCT) of the face after a series of treatments with PLA and the increase in TCT persisted until the 96-week follow-up. There was a significant increase in the quality of life score compared to baseline at the 24- and 48 weeks follow-ups, but not at the 72- or 96-week follow-ups. No serious adverse effects were reported in either study. Safety and efficacy beyond 96 weeks is not known. The generalizability of Valentin study has been criticized because one dermatologist performed all of the injections; it is not known whether there would be similar results

with other dermatologists. In summary, there is some evidence from an uncontrolled case series that treatment with Sculptra can reduce facial lipoatrophy for up to 96 weeks and has no serious adverse effects, when used by a trained dermatologist. There are no good data from controlled studies. The impact on quality of life is less clear. There are no published data on safety and efficacy of Sculptra beyond 96 weeks.

Articles: The search yielded 10 articles. Several were reviews or opinion pieces. Three empirical studies were identified. The ideal study would have the following characteristics: Randomized controlled trial, Comparison of Sculptra to alternative treatment, or placebo, Long-term follow-up, sufficiently large sample size, Important outcomes include whether treatment with Sculptra is effective at increasing facial fat and reduces any adverse psychosocial effects. In this case, there is no standard alternate treatment and no other FDA-approved new treatments for HIV-associated facial lipoatrophy. No placebo-controlled studies were identified. There was one randomized controlled trial that compared immediate treatment with PLA to delayed treatment. There was also a case series with 96 weeks' follow-up. Case series can provide important long-term safety data. The RCT and case series were critically appraised. Both used New-Fill, the European version of PLA. The third empirical study was a case report presenting data on 4 patients and was excluded from review. The following studies were critically appraised: Valantin M-A Aubron-Olivier C, Ghosn J et al. Poly lactic acid implants (New-Fill) to correct facial lipoatrophy in HIV-infected patients: results of the open-label study VEGA. *AIDS* 2003; 17: 2471-2477. See [Evidence Table](#). Moyle GJ, Lysakova L, Brown S et al. A randomized open-label study of immediate versus delayed poly lactic acid injections for the cosmetic management of facial lipoatrophy in persons with HIV infection. *HIV Medicine* 2004; 5: 82-87. See [Evidence Table](#).

The use of injectable poly-L-lactic acid (PLA) in the treatment of facial lipoatrophy does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
G0429	Dermal filler injection(s) for the treatment of facial lipodystrophy syndrome (LDS) (e.g., as a result of highly active antiretroviral therapy)
Q2026	Injection, Radiesse, 0.1 ml
Q2028	Injection, Sculptra, 0.5 mg

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Injectable Bulking Agents for Fecal Incontinence

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	Injectable Bulking Agents for the Treatment of Fecal Incontinence (A52923) Noridian retired Local Coverage Article (LCA A52923). These services still need to meet medical necessity as outlined in the LCA and will require review. LCAs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an LCD. Most LCAs are not retired because they are incorrect. The criteria should be still referenced when making an initial decision. However, if the decision is appealed, the retired LCD cannot be specifically referenced. Maximus instead looks for "medical judgment" which could be based on Kaiser Permanente commercial criteria or literature search.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Fecal incontinence occurs when a person loses the ability to control his/her bowel movements and is unable to retain feces in the rectum. It can be caused by a wide variety of conditions that affect either the anatomy or function of the anal sphincter. Perineal injury during childbirth is a common cause of fecal incontinence in women. It can also be caused by neurological disorders such as spinal injury and multiple sclerosis, or it can result from anorectal surgery. In any case, fecal incontinence is common and, due to its association with considerable physical and social disability, is often under-reported (Tjandra, Chan et al. 2009).

First line treatment for fecal incontinence is usually conservative and includes antidiarrheal medication and pelvic floor muscle training. In patients for whom conservative treatment fails, alternative treatments include surgery to tighten the anal sphincter, sacral nerve stimulation, creation of a new sphincter from other suitable muscles,

implantation of an artificial sphincter or a permanent colostomy. Injectable bulking agents offer an additional, less invasive, second line treatment for fecal incontinence. The concept is to inject a biocompatible material to close the anal canal to avoid fecal incontinence (Siproudhis, Morcet et al. 2007; Maeda, Vaizey et al. 2008; Graf, Mellgren et al. 2011).

At least ten different materials have been used as bulking agents for fecal incontinence including autologous fat, Teflon, bovine glutaraldehyde, cross-linked collagen, carbon coated zirconium beads, polydimethylsiloxane elastomer, dextranomer in nonanimal stabilized hyaluronic acid, hydrogel cross-linked with polyacrylamide, porcine dermal collagen, synthetic calcium hydroxylapatite ceramic microspheres and polyacrylonitrile in cylinder form (Maeda, Laurberg et al. 2013). The material can be injected either via the perianal skin or via the anal mucosa. The procedure may be performed under local, regional or general anesthesia and the injection may be guided by the surgeon's finger in the anal canal or by ultrasound. This treatment is potentially attractive in its simplicity and minimal invasiveness and can be performed in an outpatient setting.

Several injectable bulking agents have been approved by the U.S. Food and Drug Administration (FDA) in recent years for the treatment of fecal incontinence in patients 18 years and older who have failed conservative therapy.

The Medical Technology Assessment Committee (MTAC) previously reviewed and failed bulking agents for the treatment of GERD in 2003. Currently, the committee has been asked to review the literature on the safety and efficacy of injectable bulking agents for the treatment of fecal incontinence compared to standard treatment for fecal incontinence. This is the first time that bulking agents have been reviewed for this indication. The topic is being reviewed for decision making guidance.

Medical Technology Assessment Committee (MTAC)

Injectable Bulking Agents for Fecal Incontinence

10/21/2013: MTAC REVIEW

Evidence Conclusion: **EFFICACY** The Cochrane Collaboration identified five randomized trials for inclusion in their review to determine if the injection of bulking agents is better than currently available treatments or no treatments for fecal incontinence in adults. Only two of the trials compared a bulking agent to sham treatment and none of the studies made a comparison of bulking agents versus other therapies. On the whole, the studies were of poor quality with only two providing adequate information to reliably assess bias. In addition, most of the studies were small and limited to short-term follow up. Two of the trials reported on the short-term benefit from injections as outcome measures improved with time but neither trial had follow up beyond 12 months (Siproudhis, Morcet et al. 2007; Graf, Mellgren et al. 2011). In addition, there appeared to be some short-term benefits from injections given with ultrasound guidance compared with digital guidance (Tjandra, Han et al. 2004). Two of the studies compared different types of bulking agents with the larger trial reporting that silicone material was better than the carbon coated beads in terms of fecal incontinence at six and 12 months (Tjandra, Chan et al. 2009). The smaller trial, which was not included in this critical appraisal, compared the injection of Bulkamid™ with Permacol™ and showed some improvement in outcomes in both groups but ultimately was too small to detect differences between groups (Maeda, Vaizey et al. 2008). Currently the literature addressing the efficacy of injectable bulking agents is limited for a variety of reasons. First and foremost, outcome measures and the definition of response to treatment are varied, and as a result, problematic for this indication. Furthermore, it is unclear how severity of incontinence at baseline affects outcomes data. Finally, there is a lack of information regarding the volume, the precise location where the agent should be placed, and the choice of guidance of the needle track. Several different techniques were employed with various bulking agents used across all studies making comparisons complicated. **SAFETY** Four of the five studies reported on adverse effects (Tjandra, Han et al. 2004; Siproudhis, Morcet et al. 2007; Tjandra, Chan et al. 2009; Graf, Mellgren et al. 2011). Overall, the observed adverse events were similar across all the studies with few complications reported and the most commonly reported complication being pain at injection site. Safety data collected from these trials is limited as it is not clear if complications were recorded systematically. The severity and duration were not always mentioned, and in many cases, adverse events were recorded with no information on the number of patients reporting these events. (For example, Graf and colleagues reported 128 adverse events in patients treated with NASHA Dx and 29 events in the sham treatment group but do not detail the number of patients reporting these adverse events.) Furthermore, the safety of injectable bulking agents has not been studied past 12 months. Other studies not included in this review also reported experiencing pain or minor ulceration at the injection site or in the anal canal for up to 10 weeks after the procedure (Malouf, Vaizey et al. 2001). Further complications included leakage of the bulking agent in 1 of 10 patients and, in a different study, passing of the bulking agent in 2 of 18 patients (Davis, Kumar et al. 2003). Conclusion: There is evidence from one large randomized trial to suggest that injectable bulking agents are effective up to 12 months. There is evidence to suggest that injectable bulking agents are reasonably safe in the short term. There is no evidence to permit conclusions about long term safety or efficacy of injectable bulking agents for fecal incontinence.

Articles: A literature search was conducted revealing a variety of publications including multiple case-series reports as well as case-control and cohort studies. One recent Cochrane review was also revealed which included five randomized trials measuring the effects of bulking agents versus placebo, bulking agents versus other types of bulking agents and bulking agents versus other minimally invasive interventions. No studies that compared the injection of bulking agent versus conservative treatment were revealed. Four of the studies included reporting of adverse events up to 12 months post treatment. The Cochrane review did not pool the results of the trials due to their heterogeneity. Four of the five trials included in the Cochrane Review were selected for appraisal:

Graf W, Mellgren A, Matzel KE, Hull T et al. Efficacy of dextranomer in stabilized hyaluronic acid for treatment of faecal incontinence: a randomized, sham-controlled trial. *Lancet* 2011; **377**(9770):997-1003.

[See Evidence Table 1.](#) Siproudhis, L., J. Morcet, et al. Elastomer implants in faecal incontinence: a blind, randomized placebo-controlled study. *Alimentary Pharmacology & Therapeutics* 2007;**25**(9):1125-1132.

[See Evidence Table 2.](#) Tjandra, J., W. Han, et al. (2004). "Injectable silicone biomaterial for faecal incontinence due to internal sphincter dysfunction is effective." *Diseases of the Colon & Rectum* **47**(12): 2138-2146. [See Evidence](#)

[Table 3.](#) Tjandra, J, Chan M, et al. Injectable silicone biomaterial (PTQTM) is more effective than carbon-coated beads (Durasphere®) in treating passive faecal incontinence – a randomized trial." *Colorectal Disease* 2009;**11**(4):382-389. [See Evidence Table 4.](#)

The use of Injectable Bulking Agents for Fecal Incontinence does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	See the Medicare Benefit Policy Manual Chapter 1 - Inpatient Hospital Services Covered Under Part A 110 - Inpatient Rehabilitation Facility (IRF) Services
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

For Non-Medicare Members

Inpatient Rehabilitation Facility (IRF - acute rehabilitation) admission is indicated by **ALL of the following**:

- 1) No acute hospital care needs.
The inpatient rehabilitation benefit is not to be used as an alternative to completion of the full course of treatment in the referring hospital. (e.g. for completion of antibiotics or to observe renal failure)
- 2) A preadmission screening assessment must be completed. A preadmission screening assessment is an evaluation of the patient's condition and need for rehabilitation therapy and medical treatment that must be conducted by licensed or certified clinician(s) (Registered Nurse, Physical or Occupational Therapist, Nurse Practitioner, or Medical Doctor) within the 48 hours immediately preceding the IRF admission. A preadmission screening that includes all of the required elements, but that is conducted more than 48 hours immediately preceding the IRF admission, will be accepted as long as an update is conducted in person or by telephone to document the patient's medical and functional status within the 48 hours immediately preceding the IRF admission in the patient's medical record at the IRF.
- 3) There must be documentation in the preadmission screening assessment (a copy of the assessment must be available for review) that includes **ALL of the following**:
 - a) Must indicate the patient's prior level of function (prior to the event or condition that led to the patient's need for intensive rehabilitation therapy),
 - b) Expected level of improvement and
 - c) Expected length of time necessary to achieve that level of improvement.
 - d) Nature and degree of improvement identified with practical goals established for patient's condition
 - e) Conditions that caused the need for rehabilitation,
 - f) Treatments needed (i.e., physical therapy, occupational therapy, speech-language pathology, or prosthetics/orthotics),
 - g) Expected frequency and duration of treatment in the IRF,
 - h) Discharge plan that includes **ALL of the following**:
 - Anticipated discharge destination including documentation that patient will be appropriate for discharge to home or to a community-based environment. (not to a SNF or LTC facility)
 - i) Any anticipated post-discharge treatments and any other information relevant to the care needs of the patient.

- 4) In order for IRF care to be considered reasonable and necessary, the documentation must demonstrate a reasonable expectation that **ALL of the following** criteria will be met at the time of admission to the IRF:
- a) The patient must require the active and ongoing therapeutic intervention of more than two therapy disciplines (physical therapy, occupational therapy, speech-language pathology, or prosthetics/orthotics), one of which must be physical or occupational therapy.
 - b) Need for an intensive rehabilitation therapy program that includes **ONE or more** of the following:
 - Therapy at least 3 hours per day for 5 days per week OR
 - Therapy at least 15 hours per week consecutive days
 - c) Therapy must not exceed the patient's need or tolerance or compromise the patient safety.
 - d) The patient must reasonably be expected to actively participate in, and benefit significantly from, the intensive rehabilitation therapy program. Also, there should be a reasonable expectation that a measurable, practical improvement in the patient's functional condition can be accomplished within a predetermined and reasonable period of time.
 - e) Close physician involvement with need for treating rehabilitation physician face-to-face assessment at least 3 days per week (e.g. monitoring of uncontrolled pain, bowel and bladder issues, and complex rehabilitation needs such as adapting mobility devices.)
 - f) The patient must require an intensive and coordinated interdisciplinary approach to providing rehabilitation
- 5) Document must state why an equivalent outcome will not be achieved in a Skilled Nursing Facility.

The following indications are not covered:

- Coma stimulation
- Custodial care
- Routine services for maintenance of medication administration, routine enteral feedings, routine colostomy care, ongoing straight catheterization for chronic conditions.
- Single joint replacement unless the individual has significant comorbidity(ies) resulting in functional deficits which would necessitate an acute inpatient level of rehabilitation in order to achieve a satisfactory outcome within a reasonable time period.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Last 6 months of radiology if applicable

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Inpatient rehabilitation hospital admissions provide intensive rehabilitation to patients with various neurological, musculo-skeletal, orthopedic and other medical conditions following stabilization of their acute medical issues. The inpatient rehabilitation bed is specifically licensed for the rehabilitation services and is sometimes part of an acute hospital or a separate facility.

Rehabilitation hospitals were created to meet a perceived need for facilities which were less costly on a per diem basis than general hospitals, but which provided a higher level of professional therapies such as speech therapy, occupational therapy, and physical therapy than can be obtained in a "skilled nursing care" facility. Prior to admission to an inpatient rehabilitation facility an evaluation is conducted by a psychiatrist to determine appropriateness for this level of admission.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Clinical Review Criteria

Insulin Pump

• InPen System

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Infusion Pumps (280.14)
Local Coverage Determinations (LCD)	External Infusion Pumps (L33794)
Local Coverage Article	External Infusion Pumps – Policy Article (A52507)
Kaiser Permanente Medical Policy	For InPen System Requests Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, “ InPen System ” for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

Initial Insulin Pump:

- I. To qualify for an insulin pump the member must meet **ALL of the following**:
 - A. Patient has Type 1 diabetes of at least six months' duration or Type 2 diabetes requiring a basal/bolus insulin regimen of multiple daily injections using long-acting basal insulin and a rapid-acting analogue
 - B. Referral initiated by a Diabetes specialist* that will manage therapy with an insulin pump.
 - C. Documentation from the Diabetes specialist* that includes **ALL of the following**:
 1. Assessment for clinical therapeutic value of an insulin pump.
 2. Assessment of patient pump education and skill training preparation prior to pump start (either one-on-one or within a group).
 3. Assessment of the patient's (or caregiver's) ability to safely and appropriately participate in an insulin-pump self-management plan.
 - D. Has been on a treatment regimen of multiple daily injections (MDI) of insulin that includes a trial of both a long-acting insulin analog and a short-acting insulin analog with a plan for pre-meal short acting insulin dose adjustment for at least 3 – 6 months prior to initiation of the insulin pump.
 - E. Require less than 200 units of total insulin per day prior to pump therapy.
 - F. Has documented logs of glucose self-testing or CGM results - at least 4 times per day during the 1 month prior to consideration of an insulin pump.
 - G. Meets **ONE or more of the following** while on an MDI regimen:
 1. Recent history (within last six months) of significant, recurring hypoglycemia (blood glucose < 70 mg/dl).
 2. Wide fluctuations (well below and above the set glycemic targets) in blood glucose before and after mealtimes, despite appropriate MDI using up to date insulins (analogs) and dose adjustments to affect control.
 - H. Patient has advanced carbohydrate counting skills and actively uses this information for insulin dosing

- I. Patient demonstrates ability to recognize their glucose patterns and safely problem-solve these
- J. Has no other illness that could impede use of the pump (i.e., alcohol/chemical abuse, psychological instability, difficulty with digital dexterity, visual impairment).
- K. Pediatric Patients
 - 1. On a case-by-case basis, upon review by a clinical review medical director, pediatric patients under the age of 13 may waive the 6-month time period, if patient monitoring is occurring per the diabetes management plan outlined by an Endocrinologist.

*Note – Requests for an insulin infusion pump used with continuous glucose sensing (HCPCS code E0787 or E0784 + K0554 for Medicare) will only be authorized if the patient meets both criteria for initial or replacement insulin pump as outlined in this criteria and all criteria outlined in the [Continuous Glucose Monitoring](#) clinical review criteria including that current device is no longer under warranty.

Ongoing Coverage of Pump and Supplies:

To qualify for ongoing coverage of an insulin pump the member must meet **ALL of the following**:

- A. There is documentation that patient monitors glucose at least four times daily, or appropriately uses a continuous glucose monitor.
- B. Patient maintains advanced carbohydrate counting skills and actively uses this information for insulin dosing
- C. Patient maintains ability to recognize their glucose patterns and safely and appropriately problem-solve these, including troubleshooting pump malfunction
- D. Patient does not have other conditions or psychosocial stressors which might impede safe use of an insulin pump
- E. Patient has at least one visit per year with diabetes specialist* (face-to-face, secure message, or telephone encounter)

InPen System

To qualify for an InPen System the member must meet **ALL of the following**:

- A. Patient has Type 1 diabetes of at least six months' duration or Type 2 diabetes requiring a basal/bolus insulin regimen of multiple daily injections using long-acting basal insulin and a rapid-acting analogue
- B. Referral initiated by a Diabetes specialist* that will manage therapy with an InPen System.
- C. Documentation from the Diabetes specialist* that includes **ALL of the following**:
 - 1. Assessment for clinical therapeutic value of an InPen System.
 - 2. Assessment of patient InPen education and skill training preparation prior to InPen start (either one-on-one or within a group).
 - 3. Assessment of the patient's (or caregiver's) ability to safely and appropriately participate in an InPen System self-management plan.
- D. Has been on a treatment regimen of multiple daily injections (MDI) of insulin that includes a trial of both a long-acting insulin analog and a short-acting insulin analog with a plan for pre-meal short acting insulin dose adjustment for at least 3 – 6 months prior to initiation of the InPen System.
- E. Has documented logs of glucose self-testing or CGM results - at least 4 times per day during the 1 month prior to consideration of an InPen System.
- F. Meets **ONE or more of the following** while on an MDI regimen:
 - 1. Recent history (within last six months) of significant, recurring hypoglycemia (blood glucose < 70 mg/dl).
 - 2. Wide fluctuations (well below and above the set glycemic targets) in blood glucose before and after mealtimes, despite appropriate MDI using up to date insulins (analogs) and dose adjustments to affect control.
- G. Patient has advanced carbohydrate counting skills and actively uses this information for insulin dosing
- H. Patient demonstrates ability to recognize their glucose patterns and safely problem-solve these
- I. Prescriber has documented a need for detailed electronic monitoring the patient's blood glucose levels and insulin dose administered

Ongoing Coverage of InPen System:

To qualify for ongoing coverage of an InPen System the member must meet **ALL of the following**:

- A. There is documentation that patient monitors glucose at least four times daily, or appropriately uses a continuous glucose monitor.
- B. Patient maintains advanced carbohydrate counting skills and actively uses this information for insulin dosing
- C. Patient maintains ability to recognize their glucose patterns and safely and appropriately problem-solve these, including troubleshooting InPen malfunction
- D. Patient has at least one visit per year with diabetes specialist* (face-to-face, secure message, or telephone encounter)

Replacement When Insulin Pump is No Longer under Warranty

The following considerations apply for replacement of an insulin pump that is no longer under warranty:

- A. The warranty for the current device has expired (requests for replacement are not covered when the device is still under warranty). Currently, Medtronic and Tandem have 4-year warranty periods, OmniPod Dash does not have a warranty period. It is recommended to check the manufacturer's website for current information.
A prior-authorization request from the treating diabetes specialist* managing the insulin pump to the Kaiser Permanente Pre-Service department is always required when an insulin pump is being replaced.
- B. A face-to-face visit with the treating diabetes specialist* managing the insulin pump is documented within the past year.
- C. The reason for the replacement request is fully documented in the member's medical treatment plan.
- D. The current pump was previously approved by Kaiser Permanente or the current pump was approved by another non-Medicare plan, and the member meets the medical necessity and coverage criteria for Kaiser Permanente.
- E. Suitability for continuance of pump therapy has been reviewed and confirmed by the Diabetes specialist*.
- F. The item is not lost or damaged as a result of abuse.

A treating provider may order ongoing pump supplies in the interval between annual visits with the Diabetes specialist*

*Diabetes Specialist= Adult or Pediatric Endocrinologist or a provider under his or her direct supervision (eg. PA or ARNP with CDE or BC-ADM certification or Diabetes Team RN-CDE) or a Perinatologist managing a patient with diabetes during pregnancy.

Documentation requirements to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist (endocrinology, primary care)
- Last 6 months of lab work
- Last 1-2 months of legible home monitoring logs or a printout of CGM results

[Insulin Pump Replacement Request Form](#)

The following information was used in the development of this document and is provided as background only. It is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

In January 1998, the state of Washington passed the Diabetes Cost Reduction Act that requires that major health carriers provide coverage (all, or in part) for diabetes supplies (insulin, syringes, and delivery devices) and education. This new law includes insulin pumps.

Insulin pumps are high technology infusion devices, about the size of a small tape cassette. Flexible tubing connects to the pump that contains the insulin, and then to the patient via a needle that is put in place and changed every 2 to 3 days. The pump itself can then be programmed to deliver 'background' insulin on a continuous basis, and also allow pre-meal "boluses" to accommodate meals. The pump is NOT a system that a patient can just plug into and forget diabetes.

In fact, patients who use the pump have to learn how to program and trouble-shoot the technology, and also learn how to do complex decision-making. This intensive management approach requires multiple daily blood testing, learning how to recognize and use types of food in a very sophisticated way, keeping records, and learning to use the information for complex problem solving. This education is an absolute prerequisite to being on the insulin pump, so special education classes and supervised care are required.

Medical Technology Assessment Committee (MTAC)

Insulin Pump Type II Diabetes

04/20/2015: MTAC REVIEW

Evidence Conclusion: *Effectiveness* At baseline, the mean HbA1c was 9.0% (75 mmol/mol) in both groups. At six months, both groups saw a decrease in HbA1c (7.9% in the pump group vs. 8.6% in the MDI group) with a -0.7% (95% CI -0.9 to -0.4; -8 mmol/mol, 95% CI -10 to -4 mmol/mol, adjusted $p < 0.0001$) difference between groups favoring pump treatment. Reduction in HbA1c in the pump group was also associated with a 20% lower daily dose of insulin compared with the MDI group, and was not accompanied by an increase in hypoglycemia or weight gain. Ultimately, the investigators concluded that patients with poorly controlled T2DM who received CSII over six months achieved significantly greater reductions in HbA1c. In a separate analysis, the investigators retrospectively stratified the study population according to concentrations of two different biomarkers determined from plasma collected at baseline. The first biomarker, anti-glutamic acid decarboxylase (anti-GAD) antibody (Ab), was present in 18% of the population at baseline indicating that the study population may include patients with T1DM. The investigators attribute this high rate to false-positives, relatively low cutoff values or a combination of both. The second biomarker, C-peptide, a measure of insulin production, did not appear to be associated with A1C level. Ultimately, the analysis demonstrated that HbA1c values were independent of both biomarkers (Reznik and Huang 2014). *Safety* The investigators reported five episodes of hyperglycemia related to the device or study procedure in the pump group and two diabetes related serious adverse events (SAE) resulting in hospital admission. Comparison with the MDI group is not possible as the collection of safety data appears to be incomplete. The investigators noted that data on self-reported mild hypoglycemia and hyperglycemia were not collected, nor were data for hyperglycemia in the MDI group. The studies strengths include randomization, sufficient sample size and the utilization of an intent-to-treat (ITT) analysis. To add to this, the study was conducted across 36 hospitals in five different countries. Methodological limitations of the study can be attributed to the nature of the treatments preventing blinding of patients and assessors. In addition, the investigators acknowledge that the average number of daily glucose self-monitoring tests in both groups was below the generally recommended standard of care, however, this may be consistent with real-life experiences. Finally, the investigators note that due to the inclusion/exclusion criteria and run-in phase, the results of the study may not be generalizable. As a final note, the study was designed and sponsored by Medtronic, the manufacturer of the device. Although they had no role in data collection, the analysis was carried out by statisticians employed by Medtronic. **Conclusions:** There is evidence to support the efficacy of CSII in achieving glycated hemoglobin targets in highly motivated patients with T2DM with have poor glycemic control, who are taking a total daily dose of insulin less than 220 units. There is limited evidence to support the safety of CSII patients with T2DM.

Articles: The literature was searched for studies assessing the effectiveness of CSII for glycemic control in patients with T2DM. A variety of publications were revealed including several observational studies and four small randomized controlled trials (RCT) with conflicting results. The best available evidence was a recent RCT comparing CSII with multiple daily injections (MDI). The following articles were selected for critical appraisal: Reznik Y, Cohen O, Aranson R, et al. Insulin pump treatment compared with multiple daily injections for treatment of type 2 diabetes (opT2mise): a randomized open-label controlled trial. *The Lancet*. 2014;384(9950):1265-1272. See [Evidence Table 1](#)

The use of Insulin Pump for Type II diabetes does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Artificial Pancreas

BACKGROUND

Diabetes mellitus is a metabolic disorder resulting from a defect in insulin secretion, insulin action or both. More specifically, in type 1 diabetes, the pancreas is unable to produce insulin which results in increased blood glucose levels, and ultimately, leads to complications which may affect the eyes, kidneys, nerves, heart and blood vessels. As a result, an essential part of diabetes management is to maintain blood glucose levels to as near normal as possible over all hours of the day. Implementation of this approach requires the individual to be capable of and committed to a day-to-day medical program. It requires ongoing compliance with multiple daily glucose measurements accompanied by appropriate adjustments in insulin dose and insulin injection. Additionally, successful intensive diabetic management requires response to a variety of external factors including changes in diet, exercise, and presence of infection.

Typically, patients self-monitor their blood glucose via fingerprick in an effort to optimize glycemic control, however, this technique is tedious and uncomfortable for the patient. In addition, this technique only provides information about a single point in time making it difficult to recognize trends. In any case, intensive glucose monitoring and insulin therapy can be challenging as they require obtaining, retaining, processing and applying vast amounts of information in the course of everyday life (Watkins, Connell et al. 2000; Boland, Monsod et al. 2001; Brauker 2009).

Evolving technologies such as continuous subcutaneous insulin infusion (CSII), and continuous glucose monitoring (CGM) have allowed patients to safely maintain glycemic goals and prevent other related complications. While there is evidence to support the efficacy of CSII (Misso, Egberts et al. 2010), the reliability and robustness of CGMs leaves much to be desired. Even with the aid of these devices, maintaining blood glucose concentrations within a suggested optimal range is a constant struggle.

Most recent technologic advancements have integrated these components into an Artificial Pancreas Device System (APDS). In addition to CSII and CGM, the APDS incorporates a control algorithm designed to facilitate communication between the different components thus automating the process of maintaining blood glucose concentrations at or near a specified target or range and, ultimately, improving glucose control, preventing complications, and decreasing disease burden. With a wide range of current products available on the market, there is potential for a large variety of different types and designs of ADPSs.

In an effort to help advance the development of the diabetes technologies, the U.S. Food and Drug Administration (FDA), in 2011, established three new product classifications for APDSs including threshold suspend, single hormonal control, and bihormonal control, all of which are regulated as class III device systems (general controls and premarket approval). In September of 2013, Medtronic's MiniMed® 530G was the first system approved under this new product classification. ADPSs have not previously been reviewed by the Medical Technology Assessment Committee (MTAC) and are currently being reviewed due to provider request.

The development of an "artificial pancreas" has been the "holy grail" for management of Type 1 diabetes for several decades. To understand why this is such a difficult task it helps to understand what the normal non-diabetic person's body actually does in response to changes in blood glucose. Within the pancreas we all have 1-2 million groups of cells called the Islets of Langerhans which function together to help maintain the blood glucose levels within a quite narrow range (of around 70-160mg/dl). The islets make two main hormones (insulin from the beta-cells and glucagon from the alpha cells) which work together in concert. These islet cells monitor the blood glucose flowing through them constantly. Whenever the blood goes up (after a meal, for example) the islets increase the amount of insulin that they are secreting from the beta-cells and decrease the amount of glucagon that they are secreting from the alpha cells. Whenever the blood glucose drops below normal the beta-cells turn off completely (so that no insulin is secreted) and the alpha cells crank out lots of glucagon. Glucagon (as well as other hormones like epinephrine, growth hormone and cortisol) stimulate the liver to release glucose into the blood stream (the liver stores about 300 grams of glucose in the form of a kind of starch called glycogen). The insulin and glucagon are released directly into the portal circulation of blood flowing from the pancreas to the liver. In other words, a non-diabetic person is functioning with millions of blood glucose measurements being done every day with the results connected to a continuously variable secretion of both insulin and glucagon released directly into the blood flowing to the liver. Even though the commercially made components of an "artificial pancreas" may seem very sophisticated they are a very crude and imprecise way of trying to do what the real non-diabetic person's pancreas can do.

First consider the delivery of insulin. Rather than having both insulin and glucagon being released directly into the blood flowing to the liver we have a continuous subcutaneous infusion of insulin alone. The insulin is absorbed out of the subcutaneous fat into the peripheral systemic circulation and only then gets to the liver. This can give a fairly accurate and stable basal delivery of insulin but when larger amounts of insulin are delivered immediately before meals (bolus insulin delivery) the rate of rise and fall of insulin in the bloodstream is a lot slower than in a healthy non-diabetic person's body.

Second, consider the measurement of blood glucose. Typically, diabetic patients test the capillary glucose level in their fingertips 2-8 times per day. This can give useful information but does not show the constant rising and falling of blood glucose excursions throughout the day. If needle sensors are placed in the subcutaneous tissue this can give a reading of interstitial fluid glucose (similar to plasma glucose) every 10-20 minutes throughout the day and so can show the trends as the blood glucose rises and falls. Several companies now make these continuous glucose monitoring systems (CGMS). There are two practical issues with CGMS, however: a) the interstitial fluid glucose lags behind the actual plasma glucose by 15-20 minutes and so can give a falsely low or high value if it is measured at times when the blood glucose is rising rapidly (after a meal) or is falling rapidly (after exercise or after injecting a bolus of insulin), and b) the glucose oxidase enzyme system for measuring blood glucose can drift over time and so the readings from a CGMS will be inaccurate unless they are calibrated several times a day by doing a capillary blood glucose test at a time when the blood glucose is expected to be stable (not rising or falling rapidly).

The concept of an "artificial pancreas" is that a person could wear both an insulin pump and a CGMS device and that the insulin pump uses the information from the CGMS to automatically make adjustments to the rate of insulin

infusion. The person would not need to worry about testing their blood glucose or of thinking about what they eat and when they exercise but could go about their day-to-day life safe in the knowledge that their blood glucose would stay within normal limits. It is because of the practical limitations of the technology (outlined above) that we are still a long way away from that idealized situation.

02/14/2014: MTAC REVIEW

Artificial Pancreas

Evidence Conclusion: In this review, the results of four RCTs were included. One of these studies compared sensor-augmented insulin pumps to multiple daily insulin injections while two of them compared threshold suspend systems with standard insulin pumps. The last study compared two closed-loop algorithms to patient self-control with CSII. *Effectiveness:* Comparison of the effectiveness of sensor augmented pump therapy versus multiple daily injections (MDI) was examined in a one year multicenter, randomized and controlled phase of the sensor-augmented pump therapy for hemoglobin A_{1c} reduction (STAR-3) study. Compared with 241 subjects on MDI, those on pump therapy (n=244) experienced greater reductions in A_{1c} levels by three months, with the trend continuing throughout the remainder of the study. By the end of the study, the baseline A_{1c} level (8.3% in the two study groups) had decreased to 8.1% in the MDI group compared with 7.5% in the pump therapy group ($P<0.001$). Participants were offered an optional six-month continuation phase which allowed subjects in the pump therapy group to continue therapy and allowed subjects in the MDI group to cross over to pump therapy. The continuation phase resulted in a sustained lower mean A_{1c} value for patients in the pump therapy group and decreased the mean A_{1c} values to 7.6% ($P<0.001$) among MDI subjects who crossed over to pump therapy for the continuation phase. (Bergenstal, Tamborlane et al. 2010; Bergenstal, Tamborlane et al. 2011). See [Evidence Table](#). In the three-month automation to simulate pancreatic insulin response trial (ASPIRE), 247 patients with type 1 diabetes and nocturnal hypoglycemia were randomized to sensor augmented insulin pump therapy with the threshold suspend feature (Paradigm group) or to the standard sensor-augmented insulin pump therapy (control group). The primary efficacy outcome was the area under the curve (AUC) for nocturnal hypoglycemic events. At the end of three months, the mean AUC for nocturnal hypoglycemic events was found to be significant through supportive analysis at 37.5% lower in the Paradigm group than in the control group ($P<0.001$) (Bergenstal, Klonoff et al. 2013). See [Evidence Table](#). In another trial, 95 adults and children with type 1 diabetes were randomized to use of a sensor-augmented insulin pump with threshold suspension or a standard insulin pump. After six months, the combined incidence of moderate and severe hypoglycemic events was significantly lower in patients using the pump with the threshold suspension compared with the standard insulin pump (9.5 vs. 34.2 per 100 patient-months) (Ly, Nicholas et al. 2013). See [Evidence Table](#). Most recently, Luijf and colleagues compared two validated closed-loop algorithms versus patient self-control with CSII in terms of glycemic control. The investigators concluded that both the algorithm developed by the University of Cambridge (CAM) and the algorithm developed by the University of Pavia, Padova, University of Virginia and University of California Santa Barbara (international artificial pancreas [iAP]) provide safe glycemic control. This study, however, occurred in a highly controlled environment for short periods of time. While the algorithms may have the benefit of less time in hypoglycemia, this came at the expense of higher mean glucose values when compared to self-management (open loop) and thus, more time spent in hyperglycemia (Luijf, DeVries et al. 2013). See [Evidence Table](#).

Safety and Adverse Events: Safety and adverse events were included as endpoints in two of the four selected studies. In the STAR 3 study, data on adverse events were collected at each follow up clinic visit. Severe hypoglycemia was defined as an episode requiring assistance and was confirmed by documentation of a blood glucose value of less than 50 mg per deciliter (Bergenstal, Tamborlane et al. 2010). In the ASPIRE study, the primary safety endpoint was the change in glycated hemoglobin level. The change in the glycated hemoglobin level from randomization to study end was not significant in both groups, and the difference in hemoglobin level between groups was only 0.05 percentage points. Beyond that, no episodes of diabetic ketoacidosis occurred in either group or no severe hypoglycemic events occurred in the Paradigm group. During the study phase there were seven adverse events thought to be related to the study device which included skin irritation and device malfunction resulting in severe hyperglycemia (Bergenstal, Klonoff et al. 2013). Generally speaking, the studies had the advantage of randomization and control, however, the lack of blinding makes the evidence vulnerable to bias. In addition, the Ly et al. study relied on patient recall for their results and some of the experimental subjects may have had more contact with physicians opening up the results to recall and observation bias. Sample size ranged anywhere from 48 to 495 participants and most of the studies, with the exception of the STAR 3 Trail, did not report on the racial and ethnic composition of the study samples, and for those that did, participants were predominantly white. Furthermore, inclusion criteria were extremely selective with few studies including children younger than 12 years. In the same way, the data lack generalizability because management was limited to expert settings and among highly motivated patients. Further limitations include heterogeneity in definitions of hypoglycemia and short duration of follow-up ranging anywhere from 24 hours to 18 months. With many complications of diabetes developing over many years it would be ideal to see results allowing for multiple periods of sensor wear and to evaluate changes in subject needs over time. With that said, at the current point in time, APDSs are a rapidly evolving technology that should only be considered in select patients.

Conclusion:

- The results of the published studies suggest that APDS may be effective in reducing hypoglycemia in highly selected, motivated and compliant groups of individuals.
- There is some evidence to support the safety of APDS in highly compliant adult patients.

Articles: The search revealed over 500 articles many of which were commentary, discussion, or systematic review articles. Articles were screened for randomized, comparison studies of outcomes between patients using APDS and a control group of patients using currently available technology. The following articles were selected for critical appraisal: Bergenstal RM, Tamborlane WV, Ahmann A, et al. Effectiveness of sensor-augmented insulin-pump therapy for type 1 diabetes. *New England Journal of Medicine*. 2010;**363**(4):311-320. See [Evidence Table](#). Bergenstal RM, Klonoff DC, Garg SK, et al. Threshold-based insulin-pump interruption for reduction of hypoglycemia. *New England Journal of Medicine*. 2013;**369**(3):224-232. See [Evidence Table](#). Ly TT, Nicholas JA, Retterath A, et al. Effect of sensor-augmented insulin pump therapy and automated insulin suspensions vs standard insulin pump therapy on hypoglycemia in patients with type 1 diabetes a randomized clinical trial. *JAMA*. 2013; **310**:1240-1247. See [Evidence Table](#). Luijck YM, DeVries JH, Zwinderman K, et al. Day and night closed-loop control in adults with type 1 diabetes. *Diabetes Care*. 2013;**36**: 3882-3887. See [Evidence Table](#).

The use of Artificial Pancreas does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Insulin Pump and supplies – Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
E0784	External ambulatory infusion pump, insulin
A4230	Infusion set for external insulin pump, nonneedle cannula type
A4231	Infusion set for external insulin pump, needle type
A4232	Syringe with needle for external insulin pump, sterile, 3 cc
K0552	Supplies for external noninsulin drug infusion pump, syringe type cartridge, sterile, each

Insulin Pump used with continuous glucose monitor

Medicare - Considered not medically necessary

Non-Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
E0787	External ambulatory infusion pump, insulin, dosage rate adjustment using therapeutic continuous glucose sensing
A4226	Supplies for maintenance of insulin infusion pump with dosage rate adjustment using therapeutic continuous glucose sensing, per week

Artificial Pancreas -

Medicare - Considered not medically necessary

Non-Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met

CPT® or HCPC Codes	Description
S1034	Artificial pancreas device system (e.g., low glucose suspend [LGS] feature) including continuous glucose monitor, blood glucose device, insulin pump and computer algorithm that communicates with all of the devices
S1035	Sensor; invasive (e.g., subcutaneous), disposable, for use with artificial pancreas device system
S1036	Transmitter; external, for use with artificial pancreas device system
S1037	Receiver (monitor); external, for use with artificial pancreas device system

InPen Smart Insulin Pen –

Considered medically necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
No specific codes – often submitted as <i>E1399 Durable medical equipment, miscellaneous</i> or <i>A4211 Supplies for self-administered injections</i>	

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

^{MPC} Medical Policy Committee

Revision History	Description of Change
04/07/2015	Revised C-peptide testing requirement.
04/27/2015	Added MTAC review on Insulin Pump for Type II Diabetes
07/07/2015	Revised criteria to include indications for Type II Diabetes
09/03/2015	Added criteria for Pediatrics – 18 years and under
11/09/2015	Merged Artificial Pancreas criteria with Insulin Pump
02/17/2016	Added HCPCS codes
01/03/2017	Revisions made to insulin pump criteria; combined adult and pediatric into one policy
02/07/2017	MPC approved criteria to manage insulin pumps for pregnant patients
10/08/2018	Updated request form links
11/03/2020	Added note about combined insulin pump/CGM device and documentation requirements to support medical necessity; removed insulin brand names
07/20/2021	Added note about InPen Smart Insulin Pen not currently considered medically necessary pending MTAC review.
11/02/2021	MPC approved to waive the 6-month period typically used to learn how to monitor diet and other factors that impact blood sugar results prior to being eligible for an insulin pump for patients under the age of 13. This will be on a case-by-case basis as approved by a medical director. Requires 60-day notice, effective 04/01/2022.
01/04/2022	Updated required length of time to provide self-testing/CGM logs from 2 months to 1 month for initial insulin pump. MPC approved clinical criteria for the InPen System. 60-day notice is required; effective June 1, 2022.
02/24/2022	Updated applicable codes
07/05/2022	MPC approved to cover the Omnipod 5 system and will apply to the Insulin Pump criteria.
12/02/2022	Updated Medicare Policy to defer to KP Non-Medicare criteria for InPen system requests. Updated Medicare LCD L33794 and LCA A52507 links.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Intrastromal Corneal Ring Segments (INTACS Inserts)

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Intrastromal Corneal Ring Segments (INTACS Inserts)," for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

- 1) Implantation of intrastromal corneal ring segments may be considered medically necessary for the treatment of keratoconus when **ALL of the following** criteria are met:
 - Functional vision cannot be achieved with contact lenses or spectacles
 - Age 21 years or older
 - Clear central cornea
 - Corneal transplantation is the only other remaining option to improve functional vision
- 2) Implantation of intrastromal corneal ring segments is considered not medically necessary for the treatment of myopia.
- 3) Implantation of intrastromal corneal ring segments is considered investigational for all other conditions including, but not limited to, pellucid marginal degeneration.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Keratoconus is a progressive noninflammatory corneal disorder characterized by corneal thinning and protrusion of the central cornea. Signs and symptoms of keratoconus vary and depend on disease severity. In the early stages of keratoconus, individuals may be asymptomatic; however, as the disease progresses, there is considerable distortion of vision in the form of myopia and irregular astigmatism. For patients with mild to moderate keratoconus, vision may be corrected with spectacles or contact lenses. However, as the disorder progresses, or when the patients can no longer tolerate contact lenses, they are referred for corneal transplant (penetrating keratoplasty). The outcomes of this surgery are generally favorable; however, the surgery is not

without complications. Complications of penetrating keratoplasty include graft rejection, intraocular damage, postoperative astigmatism, recurrence of keratoconus, and side effects from the long-term use of topical corticosteroids (Ambekar 2011, Ertan 2007, Romero-Jiménez 2010).

Intrastromal corneal ring segments (Intacs®) inserts are an alternative treatment strategy for patients with mild to moderate keratoconus who are no longer able to achieve adequate vision using contact lenses or glasses and for whom corneal transplant is the only remaining option. Intacs® inserts are small rings of synthetic material that are implanted in the deep corneal stroma with the aim of generating modifications of corneal curvature in an attempt to improve visual acuity, contact lens tolerance, and prevent or delay corneal transplant. The procedure is performed outside the corneal visual axis and the inserts may be removed or replaced if the desired outcome is not achieved. Intacs® inserts should not be used in patients who can achieve functional vision on a daily basis using contact lenses, are younger than 21 years of age, do not have clear corneas, or have corneal thickness less than 450 microns at the proposed incision site. Complications associated with Intacs® inserts include patient dissatisfaction with visual quality, discomfort, and ring segment extrusion or migration (Ambekar 2011, Bromley 2010, Ertan 2007, Romero-Jiménez 2010).

Intacs® inserts received FDA approval in 2004.

Medical Technology Assessment Committee (MTAC)

INTACS Inserts in the Treatment of Keratoconus

10/03/2005: MTAC REVIEW

Evidence Conclusion: The studies reviewed, as well as others revealed by the literature search, were all case series comparing the postoperative results to the preoperative values among the same groups of patients. Case series have potential selection and observation biases as well as other threats to internal validity. The results of these series may indicate some improvement in visual acuity after the implantation of Intacs in patients with keratoconus with a clear central cornea and intolerance to contact lenses. However, the technology was not compared to penetrating keratoplasty or other alternative therapies, and the follow-up duration was insufficient to determine the stability of the observed outcomes and the long-term harms that could be associated with Intacs inserts. Moreover, these studies do not provide evidence to determine if this technology would prevent the progression of keratoconus and eliminate the need for penetrating keratoplasty (PK). In conclusion, larger studies with longer follow up and that compare the outcomes of the technology with those achieved with PK are needed to determine the efficacy and long-term stability, benefits, and harms of the technology.

Articles: The search revealed 18 articles. There were no meta-analyses or randomized controlled trials. All published studies identified were prospective or retrospective case series and had no control groups. Two prospective series on the use of Intacs for the management of keratoconus were selected for critical appraisal. Selection was based on the sample size, duration of follow-up, and quality of study. *Evidence tables were created for the following studies:* Hellstedt T, Makela J, Uusitalo R, et al. Treating keratoconus with Intacs corneal ring segments. *J Refract Surg.* 2005; 21:236-246. See [Evidence Table](#). Siganos CS, Kymionis GD, Kartakis N, et al. Management of keratoconus with Intacs. *AM J Ophthalmol* 2003; 135:64-70. See [Evidence Table](#).

The use of INTACS Inserts in the treatment of keratoconus does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

12/19/2011: MTAC REVIEW

INTACS Inserts in the Treatment of Keratoconus

Evidence Conclusion: The study reviewed for the 2011 update, as well as those reviewed in the original 2005 MTAC review, were all case series comparing postoperative results to the preoperative values among the same groups of patients. Results from case series should be interpreted with caution as this type of study design is prone to bias. The results of these studies may indicate some improvement in visual acuity after the implantation of Intacs® inserts in patients with keratoconus with a clear central cornea and intolerance to contact lenses. However, the technology was not compared to other alternative therapies, and the follow-up duration was insufficient to determine the stability of the observed outcomes and the long-term harms that could be associated with Intacs inserts. Moreover, these studies do not provide evidence to determine if this technology would prevent the progression of keratoconus and eliminate the need for penetrating keratoplasty (Colin 2007, Hellstedt 2005, Siganos 2003). Conclusion: There is insufficient evidence to determine the safety and efficacy of Intacs® inserts for the treatment of keratoconus.

Articles: The literature search did not reveal any meta-analyses or randomized controlled trials. The published studies identified were prospective or retrospective case series. The largest prospective case series with the longest duration of follow-up was selected for review.

The following study was critically appraised: Colin J and Malet F. Intacs for the correction of keratoconus: two-year follow-up. *J Cataract Refract Surg.* 2007; 33:69-74. See [Evidence Table](#).

The use of INTACS Inserts in the treatment of keratoconus does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Peripheral arterial disease (PAD) is a common condition that affects approximately 8-12 million people in the US. The prevalence of the disease increases rapidly with age and is associated with significant morbidity and mortality. PAD commonly affects the arteries supplying the leg and is mostly caused by atherosclerosis. Restriction of blood flow due to arterial stenosis or occlusion is commonly clinically presented as intermittent claudication which is pain in the calf muscles that occurs on walking or exercising and is rapidly relieved by resting.

The clinical course of patients with intermittent claudication is variable. Most patients either improve or have a stable condition, but over one fourth will experience deterioration in symptoms. These patients may eventually develop critical leg ischemia or gangrene which can lead to amputation. Fontaine classified chronic leg ischemia into four stages: Stage I: asymptomatic, stage II: intermittent claudication, stage III: ischemic rest pain, and stage IV: ulceration, gangrene, or both (Hirsch 2001, Leng 1993, Delis 2000, 2005, Beard 2000).

The treatment of PAD aims at increasing blood flow to alleviate symptoms and prevent arterial leg ulcers, critical leg ischemia, and major complications. Management options for claudication include a structured program of regular exercise, smoking cessation, control of risk factors or associated medical diseases, percutaneous

transluminal angioplasty, and surgical revascularization. Drug therapy, even with the most effective agents, was found to result in only a modest improvement. Surgical bypass reconstruction is indicated for severe cases and after failure of other forms of conservative therapy. Patients with non-healing ulcers may not be suitable for revascularization for technical reasons, frail condition, or rejection of surgical intervention. Due to the limited non-operative treatment options, long-term graft failure, perioperative deaths, and imitations or contraindications to intervention, researchers have focused their attention on mechanical methods as potential means for augmenting arterial volume flow in lower limbs (Delis 2000, Montori 2002, 2005).

The concept of using mechanical means to increase blood flow to an ischemic limb dates back to 1930s when a group of investigators applied alternating external pressure to ischemic legs with advanced atherosclerotic peripheral vascular disease. They were however unable to measure blood flow or optimize pneumatic compression. The interest in using intermittent pneumatic compression was renewed in the late 1970s when researchers observed that intermittent pneumatic compression can temporarily increase the arterial blood flow to the limbs. The devices developed apply high pressures by compression cuffs placed on the thigh, calf, and/or foot, intermittently inflate and deflate with cycle times and pressures that vary between devices.

The ArtAssist® Device (ACI Medical Inc., San Marcos, California), is a mechanical pneumatic pump consisting of an impulse generator and two plastic inflatable cuffs. It applies high pressure in a synchronized manner to the foot and calf. This outpatient treatment usually performed for three 1-hour sessions per day while the patient is sitting upright. According to the manufacturer, when the device compresses tissue below the knee, venous blood is emptied, and the venous pressure drops to near zero. The resultant increase in the arteriovenous pressure gradient increases arterial blood inflow. Another potential mechanism also described by the manufacturer involves the release of vasodilating substances as endothelial nitric oxide due to the decreased local vascular resistance. Stimulation of collateral blood vessel formation may also occur (ACI medical Inc. web site).

The ArtAssist device as well as the Flow Medic™ system, and ArterialFlow™ system are all FDA approved for use to improve blood circulation in the lower extremities to help prevent and reduce complications of poor circulation.

Medical Technology Assessment Committee (MTAC)

Intermittent Pneumatic Compression

02/04/2008: MTAC Review

Evidence Conclusion: The trials on intermittent pneumatic compression (IPC) studied the efficacy of the therapy, mainly using the ArtAssist device, for patients with stable intermittent claudication. There were no RCTs with clinical outcomes that evaluated the IPC for use among patients with more severe condition or those who failed revascularization. All published trials were small, single centered, conducted among highly selected groups of patients, were not blinded, short-term, and none compared IPC to a sham therapy. Kakkos and colleagues (2005), randomized 34 highly selected patients with stable intermittent claudication to receive IPC (n=13), supervised exercise (n=12), or unsupervised exercise (n=9). The study was too small, was unblinded, and had a high dropout rate. Its results show that compared to the unsupervised exercise, both IPC and supervised exercise increased the initial claudication distance (ICD) and the absolute claudication distance (ACD). The difference in improvement observed was statistically significant at the end of the six-month treatment and after six additional months of follow-up. There was no significant difference however between the IPC and supervised exercise groups.

In their pilot study, Ramaswami and colleagues (2005) evaluated the efficacy of IPC among 34 patients with stable intermittent claudication who were randomized to receive IPC with daily unsupervised exercise or to just perform daily unsupervised exercise. IPC was not compared to sham treatment or to a supervised exercise program. The results showed an increase in the initial and absolute claudication distances with IPC at 4 and 6 months of treatment and the improvement was sustained at 1 year. Delis and Nicolaides (2005) also evaluated the effectiveness of IPC in 41 highly selected patients with stable intermittent claudications. These were randomly assigned to receive IPC and salicylic acid (75 mg/dL), or salicylic acid (75 mg/dL) alone. All participants in the two groups were encouraged to exercise daily and were followed up for 12 months after the treatment period. The results of the trial show that the ICD, ACD, increased significantly in the IPC group starting at the first month of treatment and was sustained for one year after completing the therapy. Only a small insignificant change was observed in the control group, and the difference between the two study groups was significant. The quality of life also improved significantly in the IPC group, but not in the control group. **Conclusion:** The available evidence from these trials as well as other earlier studies and case series suggest that intermittent pneumatic compression therapy of the foot and calf with ArtAssist device might be associated with improvement in the arterial blood flow and in the walking distance over a short term among patients with stable intermittent claudication. However, the studies included highly selected groups patients with stable claudications who had superficial femoral artery

occlusion, and patent iliac arteries (also patent popliteal artery as indicated by some studies). Those with a history of a lower extremity revascularization history were excluded, as well as those with several other comorbidities. Moreover, the studies had control groups not placebo groups undergoing a sham IPC treatment. There were no long-term outcomes beyond one year of follow-up, and the studies did not determine the effectiveness of treatment in improving rest pain, ulcer healing, or reducing amputation rate, all of which may limit generalization of the results. In conclusion there is insufficient evidence to determine the efficacy of pneumatic compression devices for the treatment intermittent claudication, or more severe symptoms among patients with peripheral artery occlusive disease.

Articles: There were five small RCTs, one nonrandomized controlled study, and several prospective and retrospective small case series with no control or comparison groups. The majority of trials were conducted among patients with stable claudication. There was a small trial, with intermediate outcomes that compared three modes of IPC in healthy limbs as well as those with successful grafts. The literature search did not reveal RCT that evaluated the IPC use for patients with more severe condition or those who failed revascularization. *Studies with an appropriate comparison group and/or longer follow-up duration were selected for critical appraisal:* Kakkos SK, Geroulakos G, Nicolaides AN. Improvement of the walking ability in intermittent claudication due to superficial femoral artery occlusion with supervised exercise and pneumatic foot and calf compression: A randomized controlled trial. Eur J Vasc Endovasc Surg. 2005; 30:164-175. See [Evidence Table](#) Ramaswami G, D'ayala M, Hollier LH, et al., rapid foot and calf compression increases walking distance in patients with intermittent claudication: Results of a randomized study. J Vasc Surg. 2005; 41:794-801. See [Evidence Table](#) Delis KT, Nicolaides AN. Effect of intermittent pneumatic compression on foot and calf on walking distance, hemodynamics, and quality of life in patients with arterial claudication. A prospective randomized controlled study with 1-year follow-up. Ann Surg 2005;241:431-441 See [Evidence Table](#)

The use of Intermittent pneumatic compression in the treatment of peripheral arterial occlusive disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

For Non-Medicare Members

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral.

Intestinal Transplantation alone may be considered for selected pediatric and adult patients with Short Bowel Syndrome and/or intestinal failure who require chronic Total Parenteral Nutrition (TPN) and have severe complications that lead to serious morbidity and could lead to mortality.

Combined Intestinal/Liver Transplantation may be considered in selected pediatric and adult patients with Short Bowel syndrome and irreversible progressive chronic liver disease when there is no prospect for prolonged survival with conventional therapy.

The following are current, generally accepted, guidelines for Intestinal Transplantation.

1. GENERAL PRINCIPLES

- 1.1. If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, then early referral should be made.
- 1.2. Patients with a history of malignancy with a moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- 1.3. Uncontrollable active infection is a contraindication to transplant.
- 1.4. Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low^{1,2,3}. Exceptions may be made on a case-by-case basis.
- 1.5. Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products in order to be actively listed.
- 1.6. Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.

- 1.7. Patients must be willing and able to travel within short notice to a KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.
- 1.8. Patient must have a caregiver or caregivers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
- 1.9. The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.
- 1.10. Evidence of such nonadherence may be: failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required.
- 1.11. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

2. INDICATIONS FOR INTESTINAL TRANSPLANT

- 2.1. Intestinal Transplant
 - 2.1.1. Pediatric or adult patients with irreversible Short Bowel Syndrome or intestinal failure⁴, who have severe complications of TPN, including, but not limited to the following:
 - 2.1.1.1. Lack of vascular access
 - 2.1.1.2. Recurrent central venous catheter-related infections
 - 2.1.1.3. Metallic bone disease
 - 2.1.1.4. Evidence of severe or progressive hepatic dysfunction
- 2.2. Combined intestinal-liver transplant.
 - 2.2.1. Adult and pediatric patients with Short Bowel Syndrome and/or intestinal failure and irreversible progressive chronic liver disease.

3. CONTRAINDICATIONS FOR INTESTINAL TRANSPLANT

- 3.1. Advanced cardiopulmonary disease or any other life limiting disorders, excluding hepatopulmonary syndrome.
- 3.2. Inability to accept the procedure, understand its nature, or cooperate with the treatment protocol.
- 3.3. Patients with HCC, who exceed Region 5⁵/UCSF⁴ criteria, should not be sent for intestinal transplant evaluation at this time because they are not medically appropriate. Exceptions may be made on a case by case basis for hepatoblastoma.⁵
- 3.4. Irreversible brain damage or significant neurologic dysfunction.

4. RELATIVE CONTRAINDICATIONS FOR INTESTINAL TRANSPLANT

- 4.1. Relative contraindications include, but not necessarily limited to:
 - 4.1.1. Renal Failure (excluding hepatorenal syndrome)
 - 4.1.2. Portal Vein thrombosis
 - 4.1.3. Active infection outside the hepatobiliary system
 - 4.1.4. Advanced malnutrition
 - 4.1.5. Severe diabetic complications
 - 4.1.6. Multiple abdominal surgeries

1. Liver Transplantation 2006, .12:813-820. Alcohol consumption patterns and predictors of use following liver transplantation for alcoholic liver disease.
2. Liver Transplant Surg, 1997, Vol 3, 304 – 310. The natural history of alcoholism and its relationship to liver transplantation.
3. Alcohol abstinence prior to liver transplantation for Alcoholic Liver Disease (G110807), TPMG New Medical Technology

4. May be due, but not necessarily limited, to the following examples:

- a. Volvulus
- b. Atresia
- c. Necrotizing Enterocolitis
- d. Crohn's Disease
- e. Gastroschisis
- f. Superior Mesenteric Artery Thrombosis
- g. Trauma

5. The Region 5 criteria for intestinal patients with HCC is 1 tumor: S5 cm or 2 – 3 lesions, none >3 cm and no vascular invasion. NEJM 1996, 334: 633-699. Pediatr Surg Int. 2016 Oct 11., J Pediatr Surg. 2007 Jan;42(1):184-7., Pediatr Transplant. 2016 Jun;20(4):515-22. doi: 10.1111/petr.12699. Epub 2016 Mar 27.

REVISED BY CLINICAL MANAGEMENT SUBCOMMITTEE: SEPTEMBER 23, 2020
ADVISORY COUNCIL APPROVED AND EFFECTIVE DATE: OCTOBER 22, 2020

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Intestinal transplantation is an evolving procedure that was experimentally developed more than 30 years ago. It involves transplantation of a cadaveric intestinal allograft for the purpose of restoring bowel function for patients with irreversible failure. The intestine's massive lymphocyte content and heavy bacterial load provided barriers for nearly three decades. Intestines are more susceptible to rejection and carry higher risk of graft versus host disease (GVHD). The procedure proved to be clinically feasible for humans in the late 1980s but had considerable morbidity and mortality. The initial recipients of the intestinal grafts did poorly because of technical complications, graft rejection and sepsis. Recently better results were reported due to improved surgical techniques, more potent immunosuppressive drugs, and standard prophylaxis for infections and lymphoproliferative disease. Although the purpose of intestinal transplantation is to restore bowel function, patient survival should be considered the primary outcome of interest.

The first long-term success was reported in 1988 when cyclosporin-based immunosuppression was used, yet there were many failures due to rejection. The introduction of FK 506 or Tacrolimus have led to an explosion of the intestinal transplantation activity in the 1990s. It is 100 times more potent than cyclosporin and is somewhat less toxic. Steroids are administered during the early postoperative period and discontinued completely within a month. Since 1990 surgeons at the University of Pittsburgh Medical Center (UPMC) and Children's Hospital of Pittsburgh have performed more than 115 transplants involving the small intestine. This is close to half the total number performed worldwide.

There are three types for intestinal transplantation: small bowel transplantation (SBT), Small bowel/liver transplantation (SB/LT), and multivisceral transplantation (MVT) which is defined as en-bloc transplantation of 3 or more abdominal organs that include liver, stomach, pancreatic-duodenal complexes as well as the intestine with or without the right hemi-colon. Intestinal transplantation is not an alternative to total parenteral nutrition (TPN) but is only intended for selected patients who are predicted to have poor survival on TPN. It should be considered as a life-saving procedure. Patients who can be maintained on long term TPN are not considered for transplantation at the present time.

An isolated intestinal graft is recommended for patients who have fluid and electrolyte loss that cannot be managed by TPN, those with severely limited venous access and/or moderate liver dysfunction secondary to TPN. Combined SB/LT is offered to patients with irreversible liver failure due to TPN, or intestinal/liver failure associated with a hyper-coagulable state that is corrected by a simultaneous liver graft. Multivisceral

transplantation is offered to patients with locally aggressive tumors that can only be removed by a massive evisceration of the abdominal organs. Intestinal transplantation is contraindicated in old age, cardiopulmonary deficiency, AIDS, systemic malignancy and life-threatening infections.

The FDA does not regulate surgical procedures such as intestinal and multivisceral transplantation. However, immunosuppressive drugs are FDA regulated. Tacrolimus, the primary immuno-suppressant used with these transplants was approved by the FDA in April 1994 for rejection prophylaxis in allogenic liver transplantation.

Medical Technology Assessment Committee (MTAC)

Intestinal Transplantation

04/10/2002: MTAC REVIEW

Evidence Conclusion: The literature reviewed did not reveal any study that compared intestinal transplantation to the long term TPN therapy, and the evidence available does not allow for definitive conclusions. The studies reviewed show that the one- year survival rate of intestinal transplantation varied among studies from 54% to 75%. This dropped to around 42-50% at 5 years. Infection was responsible for more than 40% of the deaths. All studies were case series with limitations including potential selection bias, and lack of control or comparison group. However, it is unlikely that controlled trials, in which outcomes from intestinal/multivisceral transplantation are compared to TPN and medical management, would be conducted. The current use of intestinal transplantation as a rescue therapy for TPN-dependent patients invalidates any comparison with TPN.

Articles: Articles were selected based on study type. The search yielded 175 articles most of which were reviews, opinion pieces, editorials, and letters. The literature did not reveal any randomized controlled trials, or meta-analyses, only clinical reports and case series. The articles with the largest size, longest follow-up duration, and with patient survival as the primary outcome of interest were selected for critical appraisal. *Evidence tables were created for the following case series:* Abu-Elmagd K, et al. Clinical intestinal transplantation. *Annals of Surgery* 2001;234(3):404-17. See [Evidence Table](#) Jamieson NV. Adult small intestine transplantation in Europe. *Acta Gastro- Enterologica Belgica* 1999;62(2):239-43. See [Evidence Table](#) Madariaga JR, et al. The long-term efficacy of multivisceral transplantation. *Transplantation proceedings* 2000; 32:1219-20. See [Evidence Table](#).

The use of Intestinal Transplantation in the treatment of irreversible intestinal failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Intraocular Lens Following Cataract Extraction

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Non-Medicare Members

Accommodative Intraocular Lenses

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

Multifocal Intraocular Lenses

Multifocal intraocular lenses will not be covered. Standard monofocal intraocular lenses are covered following cataract surgery. The patient may elect to pay for the multifocal lens.

Toric Intraocular Lenses

Toric intraocular lenses to correct astigmatism are not covered. The purposes of these lenses are to reduce dependence on glasses. Improved vision with glasses is the purpose of standard cataract surgery, the additional benefit of improved vision without glasses is not a covered service.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

It is estimated that over 20 million Americans older than 40 years have cataract in at least one eye. It is predicted that this number will increase to 30 million by 2020. The current approach of treating cataracts is to replace the natural crystalline lens of the eye with an artificial intraocular lens (IOL). Traditionally intraocular lenses are monofocal lenses, which can provide excellent distance vision and optical quality, but they do not deliver functional vision at other ranges of distance. After their implantation most patients need spectacles at least for near vision. Bifocal and multifocal IOLs were developed to overcome the lack of accommodation in these pseudophakic patients (i.e. patients with an artificial IOL). They provide good functional distance, near, and intermediate vision without the use of corrective lenses. However, multifocal and bifocal IOLs may have optical side effects such as decreased contrast sensitivity, glare disability, and halos, which can reduce the retinal image quality and affect the patient's visual performance (Harman 2008, Alio 2010, Alio 2011, Cochener 2011).

Accommodative Intraocular Lens

Positional accommodating IOLs were developed to avoid the optical side effects of the multifocal IOLs and provide some accommodative capability and functional near vision. The basic mechanism of these lenses is the transmission, by haptics (plastic plates or struts), of the contracting forces of the ciliary body to the flexible lens. The design of these IOLs is based on the optic-shift concept i.e. on the axial (backward and forward) movement of the optic resulting from the contraction and relaxation of the ciliary muscle. A hinge between the optic and haptics allows the lens to move forward as the eye focuses on near objects and backward as the eye focuses on distant objects, thereby increasing the dioptric power of the pseudophakic eye. The first developed accommodative IOLs were positional single optic lenses used for both cataract and surgical correction of presbyopia. Among these are the Crystalens™ (Eyeonics, Inc., 1CU [Human Optics Erlangen, Germany], and Tetraflex [KH3500, Lenstec, St Petersburg Florida]) (Marchini 2007).

The Crystalens™ AT-45 IOL is the seventh design of the Crystalens™. It consists of a single biconvex lens with a 4.5 mm optic with two plate haptics each terminating in two polyamide loops that anchor it to the capsular bag. Adjacent to the optic are grooved flexible hinges in the plates that allow forward movement of the optic during accommodative effort to provide near and intermediate vision in pseudophakic patients. The optic is square-edged and is made of silicone to maximize biocompatibility and flexibility and allow easy insertion of the lens through a 3 mm corneal incision. A newer Crystalens™ model (Crystalens HD) has a mechanism of action based on the transitional movement of the lens in anterior and posterior direction due to ciliary muscle contraction and vitreous mass displacement (Macsaï 2006, Cumming 2006).

The Tetraflex (Lenstec) lens is an anteriorly vaulted, single-piece, foldable, accommodating IOL that is implanted using a custom-designed injector system through an incision as small as 3 mm. The lens' optic is 5.75 mm and is made of a highly biocompatible and extremely flexible hydrophilic acrylic material (HEMA). The IOL's two haptics, each with two footplates, sit posteriorly in the peripheral capsular bag (Sheppard 2010).

The 1CU is a foldable single-piece lens with an optic diameter of 5.5 mm and an overall length of 9.8 mm. It is made of a hydrophilic acrylic material and has a biconvex square-edged optic and 4 modified flexible haptics that are designed to bend when constricted by the capsular bag after ciliary muscle contraction. This allows anterior displacement of the optic resulting in an increase in the refractory power (Pallikaris 2011).

The single-optic passive shift IOLs are considered pseudoaccommodative and have limited accommodative ability as their anterior movement is insufficient to provide functionally significant amplitudes of accommodation. The limited optic power of the single optic lenses led to the development of dual-optic devices as the Synchrony (Visiogen, Irvine, California, USA), and the Sarfarazi IOL (developed by FM Sarfarazi of Shenasa Medical LLC, Carlsbad, CA, USA). The configuration of these devices with a high positively-powered mobile anterior optic, connected to a stationary negatively-powered posterior optic, is designed to increase the potential accommodative amplitude (Alio 2009, Sheppard 2010).

Investigators indicate that the way of measuring the range of accommodation in pseudophakic eyes is still unclear. In a recent review article, Pallikaris and colleagues state "Objective measurement of the accommodative capability offered by the accommodative IOLs is extremely difficult to obtain, and different methods such as autorefractometers, retinoscopy, and ultrasound imaging during accommodative effort, ray tracing, or pharmacological stimulation have been developed but the results are sometimes inconsistent... Pseudophakic accommodation, that is, the dynamic component of ocular refractive variation during near vision, and pseudophakic pseudoaccommodation, that is, the depth of focus and the subjective adaption to defocus during near vision, are the two core parts of pseudoaccommodation. Currently there is no consensus in the literature on the percentage of the participation of each part in the phenomenon of pseudoaccommodation. Several different methods are utilized by investigators for the study of the phenomenon thus resulting in different results." (Pallikaris 2011).

Multifocal Intraocular Lens

Bifocal and multifocal intraocular lenses have optical side effects such as glare, halos, and decreased contrast sensitivity, which can reduce the retinal image quality and affect the patient's visual performance. The Array IOL (Advanced Medical Optics [AMO], Santa Ana, CA), one of the first IOLs approved by the FDA (1997) is a typical refractive multifocal IOL. Earlier trials demonstrated that Array IOL improved distance and near visual acuity and reduced spectacle dependency after cataract extraction, but it was also associated with problems as decreased contrast sensitivity, glare, and halos. Newer generations of multifocal IOLs have been developed with the aim of providing better visual acuities at various distances with less glare and halos and without need for any spectacles. Currently in the United States, multifocal lens options include the ReZoom™ lens (Abbott Medical Optics [AMO])

Inc, Santa Ana, CA), ReSTOR® lens (Alcon Laboratories Inc, Fort Worth, TX), and the Tecnis® lens (Abbott Medical Optics Inc, Santa Ana, CA) (Kawamorita 2009).

The ReZoom™ (AMO) is a second-generation multifocal refractive lens that improved on the design of the Array with the aim of decreasing the symptoms of glare and halos. It is a three-piece multifocal lens made of hydrophobic acrylic material and has five refractive optical zones; each zone designed for different light and focal distances: zones 1, 3, and 5 are adjusted for far vision, while zones 2 and 4 are adjusted for near vision. The design of ReZoom is different from the Array in that the second and third zones have been enlarged, and the fourth and fifth zones have been reduced in size. An aspheric transition between zones provides balanced intermediate vision. These changes potentially reduce in night-time glare and improves uncorrected near visual acuity (Forte 2009, Kawamorita 2009, Alio 2011, Kubal 2011, Lichtinger 2012).

The ReSTOR® (Alcon Laboratories Inc) is a diffractive one-piece posterior chamber IOL. It is the first diffractive IOL to be approved by the FDA. ReSTOR® is a biconvex lens made of a soft plastic that can be folded prior to insertion, allowing placement through an incision smaller than the optic diameter of the lens. After surgical insertion into the eye, the lens gently unfolds to restore vision. The supporting arms (haptics) provide for proper positioning of the IOL within the eye. ReSTOR® lens has 12 concentric diffractive rings that cover the central 3.6 mm of the lens. The diffractive portion of the lens is apodized i.e. the height of each diffractive step decreases with increasing distance from the lens center in order to create a smoother transition between focal points. The ReSTOR® is considered a hybrid of diffractive and refractive IOLs with the lens periphery functioning as a refractive zone focusing for distance vision. In 2007, the FDA approved the aspheric version of the ReSTOR® (AcrySof IO, ReSTOR), which has a 10 µm of negative asphericity, while maintaining its apodization and diffractive and refractive components. Recently, a new +3.0 diopter (D) was introduced to improve intermediate vision, which was suboptimal with the +4 D models (Alio 2011, Sood 2011, Zhang 2011, Kubal 2011, Lichtinger 2012).

The Tecnis® Multifocal Intraocular Lens (AMO) is an ultraviolet light-absorbing posterior chamber lens. It was first available as a 3-piece silicone lens (ZM900), then later it became available as a 3-piece acrylic (ZMA00), or a single piece acrylic (ZMB00) lens. The lens is foldable so that it can be inserted into the eye through a very small incision that is actually smaller than the diameter of the lens itself. It has an optical design based on a principle of diffraction similar to the AcrySof ReSTOR® IOL, but with the diffractive rings covering the entire posterior surface of the lens. The rings start very close to the center of the lens and then continue out toward the periphery, usually with an increasing distance between the rings. As a result, the lens achieves its multifocal effects with minimal dependence on the size of the pupil (Sood 2011, Lichtinger 2012).

The ReZoom™, AcrySof ReSTOR 3.0 and 4.0 D, and Tecnis® multifocal intraocular lenses have all received FDA clearance for the visual correction after cataract extraction in adult patients with and without presbyopia.

Medical Technology Assessment Committee (MTAC)

Multifocal Intraocular Lens

04/11/2001: MTAC REVIEW

Evidence Conclusion: A single well-done RCT provides evidence that multifocal IOL are as effective as monofocal IOL for distance acuity. Patients with multifocal IOL had better uncorrected near VA and distance-corrected near VA than monofocal IOL patients, but similar best-corrected near VA add power. A case series with long-term follow-up showed a high rate of efficacy on visual acuity with multifocal IOL. All studies reviewed indicated that a limitation of multifocal IOL is decreased contrast sensitivity. The cohort study, which had compromised validity, found less contract sensitivity with multifocal compared to monofocal IOL in daylight and twilight with no glare and twilight with central glare. The benefits of multifocal IOL should be weighed against possible decreases in contrast sensitivity and the efficacy of monofocal IOLs with glasses for near focus.

Articles: The search yielded 30 articles. There were 2 RCT articles; these were based on data from the same study. The majority of the articles were case series with small numbers of patients. Evidence tables were created for three studies: The most recent report of RCT data: Javitt JC, Steinert RF. Cataract extraction with multifocal intraocular lens implantation: A multinational clinical trial evaluating clinical, functional and quality-of-life outcomes. *Am Acad Ophthalmol* 2000; 107: 2040-2048. See [Evidence Table](#). A cohort study examining possible adverse effects of multifocal IOL: Winther-Nielsen A, Corydon L, Olsen T. Contrast sensitivity and glare in patients with a diffractive multifocal intraocular lens. *J Cataract Refract Surg* 1993; 19: 254-257. See [Evidence Table](#). A case series with long-term follow-up data: Slagsvold JE. 3M diffractive multifocal intraocular lens: Eight year follow-up. *J Cataract Refract Surg* 2000; 26: 402-407. See [Evidence Table](#).

The use of multifocal Intraocular Lens in the treatment of visual correction following cataract surgery does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

07/2005: MTAC REVIEW

Intraocular Lens

Evidence Conclusion: *Accommodative Intraocular Lens* The evidence on Crystalens™ is insufficient to draw conclusions about its efficacy and safety compared to standard intraocular lenses. The single published comparative study (Alio et al., 2004) had threats to validity. It was a non-randomized comparison of three case series, one on Crystalens, one on the Array multifocal lens and one on the Twinset bifocal IOL. The study is subject to selection bias because patients were not randomized, and the authors did not control statistically for confounding factors. The study was also non-blinded and thus subject to observation bias. The study had four primary outcomes. Between-group differences were statistically significant for one out of the four outcomes, mean best corrected near acuity, but not for mean uncorrected distance acuity, mean best corrected distance acuity or mean uncorrected near acuity. There were two studies on the 1CU IOL by HumanOptics, a non-FDA approved accommodative IOL. This evidence is also weak. One of the studies (Kuchle et al., 2004) was non-randomized and did not control for confounding factors and is therefore subject to selection bias. The other study (Dogru et al., 2005) was randomized, but the study methodology was not well described, making it impossible to assess validity. There were also validity issues with the statistical analysis in the Dogru study.

Articles: *Accommodative Intraocular Lens* There was one study comparing the FDA approved accommodative IOL, Crystalens, to other types of IOLs. There were two studies comparing the non-FDA approved 1CU accommodative IOL (HumanOptics: Erlangen, Germany) to other IOLs. Like Crystalens, the 1CU IOL has a hinge-like design which allows for forward and backward movement. These three empirical studies were critically appraised. In addition, there was a small case series (n=14) reporting on the initial phase of the Crystalens FDA clinical trial. This study was excluded from further review. Evidence tables were created for the following studies: Crystalens™ Alio JL, Tavalato M, De la Hoz F et al. Near vision restoration with refractive lens exchange and pseudoaccommodating and multifocal refractive and diffractive intraocular lens. J cataract Refract Surg 2004; 30: 2494-2503. See [Evidence Table](#). Human Optics 1CU. Dogru M, Honda R, Omoto M. Early visual results with the 1CU accommodating intraocular lens. J Cataract Refract Surg 2005; 31: 895-902. See [Evidence Table](#). Kuchle M, Seitz B, Langenbucher A et al. Comparison of 6-month results of implantation of the 1CU accommodative intraocular lens with conventional intraocular lens. Ophthalmology 2004; 111: 318-324. See [Evidence Table](#).

The use of Accommodative Intraocular Lens in the treatment of visual correction following cataract surgery does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

04/16/2012: MTAC REVIEW

Intraocular Lens

Evidence Conclusion: *Accommodative Intraocular Lens* Crystalens™: AT-45 The literature search did not reveal any published large good quality RCTs that compared the implantation of the accommodative Crystalens™ with multifocal or monofocal intraocular lenses after cataract extraction. The best published evidence on Crystalens™ comes from the FDA multicenter clinical trial with 12 months follow-up (Evidence table 1). The initial study was a phase II trial that evaluated the efficacy and safety of the Crystalens™ AT-45. It was a prospective cohort study with no control or comparison group. The results of 12 months follow-up of 263 patients receiving the implant in the primary eye showed that the accommodating Crystalens™ AT-45 provided good uncorrected near and distance visual acuity with minimal adverse effects. In a substudy the authors compared contrast sensitivity under mesopic conditions with and without glare in a subgroup of patients who received the Crystalens versus a matched population of 64 patients who received standard IOL. The results of this substudy showed that the difference in contrast sensitivity between the two groups of patients was clinically irrelevant.

ICU (Human Optics) Several randomized and nonrandomized trials compared the performance of 1CU with monofocal and multifocal intraocular lenses (IOLs) (Evidence tables 2-4). The results of the studies showed that distance corrected near vision was significantly better in the 1CU group versus other groups receiving non-accommodating IOLs. Two small studies showed that the accommodative ability of the lens may decrease by time (8 months in Sauder and colleagues' trial and 12 months in Dogru and colleagues' study) leading to a reduction in the near vision acuity. The studies had some limitations and long-term follow-up is needed to determine the long-term safety and efficacy of the lens. In a large prospective, controlled, but non-randomized trial with potential biases (Evidence table 3), Uthoff and colleagues found that 1CU had a minor statistical advantage of half a reading step towards monofocal IOLs measured with subjective methods in near point, defocusing curve, and near visual acuity with BSCVA. They explained that this could be due to the pseudophakic accommodation by the optic shift or as a result of the additional pseudophakic pseudoaccommodation. The accommodative effect differed between patients and was unpredictable. *Tetraflex*: The prospective nonrandomized US Food and Drug Administration trial (Sanders 2010) on Tetraflex accommodative IOL is ongoing. In this study 255 patients

received Tetraflex IOLs and 101 received monofocal IOLs. Interim results of 12 months follow-up of 239 patients in the Tetraflex arm and 96 controls show that the Tetraflex patients read better than the controls at print sizes of 20/80 ($P=.04$), 20/63 ($P=.01$), 20/50 ($P<.001$), 20/40 ($P=.001$), 20/32 ($P<.001$), and 20/25 ($P=.001$). The proportion of patients reading at a speed of ≥ 80 words per minute was significantly higher with the Tetraflex IOL ($P=.003$). Ninety-six percent of Tetraflex patients reported never wearing glasses for distance compared with 80% of control patients ($P<.001$). Seventy-five percent of the Tetraflex patients reported that they did not or occasionally needed to wear glasses for near reading small print and/or dim light compared with 46% of control patients ($P<.001$). The trial had its limitations and the study groups were not randomly assigned to type the IOL implanted which is a source of selection bias. They were also not blinded to the IOL received, which is another source of bias especially with subjective outcomes as self-reporting of use of spectacles. Moreover, the reading ability and speed is dependent on many factors in addition to visual acuity. In conclusion, large randomized, controlled, and blinded trials with long-term follow-up are needed to determine the long-term efficacy, durability of benefit, and safety of the accommodative intraocular lenses.

Multifocal Intraocular Lens: A Cochrane meta-analysis with valid methodology (Leyland et al, 2008, evidence table 1) pooled the results of ten randomized controlled trials that compared visual outcomes of multifocal IOLs versus monofocal IOL implantation after cataract surgery. There were variations between the studies in population sizes, measures and outcomes reported, as well as follow-up durations. The main pooled results of the analysis showed no significant differences between multifocal and monofocal IOLs in uncorrected distance visual acuity or the proportion of patients achieving distance 6/6 best-corrected distance visual acuity. The uncorrected near vision was improved with the multifocal IOLs, and the rate of freedom from use of glasses was also higher with the multifocal IOLs. Contrast sensitivity was lower among participants receiving multifocal IOL implants who also experienced significantly higher rates of glare and halos. The results of another meta-analysis (Cochener et al 2011, Evidence table 2) that had the limitation of pooling results of observational studies together with randomized controlled trials, also showed that multifocal IOLs provided better uncorrected near visual acuity and less need for spectacles compared to monofocal IOLs. The results of the analysis also showed that diffractive multifocal lenses led to better results than the refractive IOLs, and that ReSTOR® had better uncorrected near visual acuity, uncorrected distance visual acuity, and higher spectacle independence rates compared with other multifocal IOLs. The incidence of halos was higher with multifocal lenses versus monofocal IOLs, but there was no significant difference between the different multifocal IOLs. No sensitivity analysis including only RCTs was made, and the results of the meta-analysis should be interpreted with caution. A more recent randomized controlled trial by Alió and colleagues (2011, Evidence table 3) compared the visual performance of 4 different IOLs: monofocal Acri. Smart, multifocal AcrySof ReSTOR® SN6AD3, multifocal Acri.Lisa 366D, and multifocal ReZoom refractive IOL. The same type of lens was implanted bilaterally in each of the 152 participants (304 eyes). After six months of follow up, the results showed that all patients had postoperative significant improvement in uncorrected and corrected visual acuities. Patients with the ReSTOR® and Acri.Lisa multifocal lens implants had significantly better uncorrected reading acuity than those in the monofocal or the refractive ReZoomTM groups. The monofocal group had the greatest uncorrected reading distance at 1 and 6 months postoperatively. The authors did not evaluate patient satisfaction with the different types of IOLs, nor did they assess the contrast sensitivity, or presence of glare and halos. Studies comparing ReSTOR® +3.0 D versus ReSTOR® +4.0 D were not critically appraised in this report, but their overall results showed better intermediate visual acuity, but more glares with the +3.0 D vs.+4.0 D IOLs. Conclusion: There is good evidence from the published literature that multifocal intraocular lenses improve near visual acuity when compared to monofocal lenses, without compromising distance visual acuity.

There is good evidence that patients undergoing multifocal IOLs implantation have higher rates of spectacle independence compared to those with monofocal lens implants. There is evidence that patients with multifocal IOL implants experience more halos and glare and have lower contrast sensitivity than those with monofocal implants. There is fair evidence that optical outcomes are better with diffractive versus refractive multifocal IOLs, and that improvement in near vision without use of glasses and patient satisfaction are more evident with ReSTOR® compared to other multifocal IOLs. There is insufficient evidence to determine any significant difference in contrast sensitivity, glare, or halos between multifocal IOLs.

Articles: *Accommodative Intraocular Lens* Single optic IOLs - The majority of studies published on the accommodative intraocular lenses evaluated single optic accommodative IOL, mainly the ICU (Humans Optics), and to a lesser extent the CrystalensTM AT-45. The search identified one meta-analysis of RCTs, a small number of controlled randomized and nonrandomized trials, and case series. The larger trials with more valid methodology and longer-term follow-up were selected for critical appraisal. The meta-analysis was not critically appraised as it had a low methodological quality and only included only 5 RCTs with very small sample sizes, along with other nonrandomized, and non-controlled studies published from 1996-2006. Dual optic IOLs - The literature search revealed a small pilot prospective case series with a retrospective control on the Synchrony dual-optic IOL. Phase III FDA clinical trials are still ongoing. The following studies were critically appraised: Harman FE, Maling S, Kampougeris G, et al. Comparing the 1CU accommodative, multifocal, and monofocal intraocular lenses: a randomized trial. *Ophthalmology*. 2008; 115:993-1001. See [Evidence Table](#). Cumming JS, Colvard DM,

Dell SJ, et al. Clinical evaluation of the Crystalens AT-45 accommodating intraocular lens: results of the U.S. Food and Drug Administration clinical trial. *J Cataract Refract Surg.* 2006;32:812-825 See [Evidence Table](#). Mesci C, Erbil HH, Olgun A, et al. Visual performances with monofocal, accommodating, and multifocal intraocular lenses in patients with unilateral cataract. *Am J Ophthalmol.* 2010; 150:609-618. See [Evidence Table](#). Uthoff D, Gulati A, Hepper D, Potentially accommodating 1CU intraocular lens: 1-year results in 553 eyes and literature review. *J Refract Surg.* 2007; 23:159-171. See [Evidence Table](#).

Multifocal Intraocular Lens The literature search revealed a large number of studies on multifocal intraocular lenses. The majority were prospective or retrospective observational studies and case series with different population sizes and follow-up durations and no comparison or control groups. There were also a number of published randomized or nonrandomized controlled trials that evaluated the visual function, and /or quality of life after the implantation of monofocal versus multifocal lenses. The search also identified three meta-analyses that pooled the results of trials comparing multifocal versus monofocal intraocular lenses, one meta-analysis of studies compared different IOLs, as well as a pooled analysis of two non-randomized trials that compared outcomes of ReSTOR vs. monofocal IOLs lenses. The most recent meta-analysis comparing outcomes of monofocal versus multifocal lenses, and the meta-analysis that compared different multifocal lenses were selected for critical appraisal. A recent RCT that compared outcomes of one monofocal and three different multifocal IOLs was also critically appraised. Alió JL, Grabner G, Plaza-Puche AB., et al. Postoperative bilateral reading performance with 4 intraocular lens models: six-month results. *Cataract Refract Surg.* 2011; 37:842-852. See [Evidence Table](#). Cochener B, Lafuma A, Khoshnood B, et al. Comparison of outcomes with multifocal intraocular lenses: a meta-analysis. *Clin Ophthalmol.* 2011; 7:45-56. See [Evidence Table](#). Leyland M, Pringle E. Multifocal versus monofocal intraocular lenses after cataract extraction. *Cochrane Database of Systematic Reviews* 2008, issue 4. See [Evidence Table](#).

The use of Accommodative Intraocular Lens in the treatment of visual correction following cataract surgery does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered not medically necessary:

HPCP Codes	Description
V2787	Astigmatism correcting function of intraocular lens
V2788	Presbyopia correcting function of intraocular lens

CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Noridian retired LCD Sensory Evoked Potentials & Intraoperative Neurophysiology Monitoring (L34072) . These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an LCD. Most LCDs are not retired because they are incorrect. The criteria should be still referenced when making an initial decision. However, if the decision is appealed, the retired LCD cannot be specifically referenced. Maximus instead looks for "medical judgment" which could be based on our commercial criteria or literature search.
Local Coverage Article	None

For Non-Medicare Members

GENERAL CRITERIA

- Intraoperative neurophysiologic monitoring must be performed by either a licensed physician trained in clinical neurophysiology or a trained technologist who is practicing within the scope of his/her license/certification as defined by state law or appropriate authorities and is working under direct supervision of a physician trained in neurophysiology; AND
- Intraoperative neurophysiologic monitoring must be interpreted by a licensed physician trained in clinical neurophysiology, other than the operating surgeon, who is either in attendance in the operating suite or present by means of a real-time remote mechanism for neurophysiologic monitoring situations and is immediately available; AND
- Monitoring is conducted and interpreted real-time (either on-site or at a remote location) and continuously communicated to the surgical team; AND
- The physician performing, or supervising monitoring must be monitoring no more than three cases simultaneously; AND
- Charges related to intraoperative monitoring will only be reimbursed when billed on a HCFA 1500 claim form for professional charges; AND
- Any charges related to intraoperative monitoring billed on a UB form are not reimbursable.

INDICATIONS

Intraoperative neuromonitoring may be indicated for a variety of spinal, intracranial, and vascular procedures. The specific type of monitoring indicated for each procedure varies, as outlined in the below criteria and summarized in the following tables. Pre-procedural baseline testing may be separately reported, but only once per operative session.

Somatosensory-evoked potentials with or without motor-evoked potentials

Intraoperative neuromonitoring using somatosensory-evoked potentials (SSEP), with or without motor-evoked potentials (using electrical stimulation), may be medically necessary during the following procedures:

- Spinal procedures
 - Dorsal rhizotomy
 - Correction of scoliosis
 - Correction of deformity involving traction on the spinal cord
 - Spinal cord tumor removal
 - Surgery due to traumatic injury to spinal cord
 - Surgery for arteriovenous (AV) malformation of spinal cord
- Intracranial procedures
 - Microvascular decompression of cranial nerves
 - Removal of acoustic neuroma, congenital auricular lesions, or cranial base lesions
 - Cholesteatoma, including mastoidotomy or mastoidectomy
 - Vestibular neurectomy for Meniere's
 - Removal of cranial nerve neuromas affecting any of the following nerves:
 - Abducens
 - Facial
 - Glossopharyngeal
 - Hypoglossal
 - Oculomotor
 - Recurrent laryngeal
 - Spinal accessory
 - Superior laryngeal
 - Trochlear
 - Deep brain stimulation
 - Endolymphatic shunting for Meniere's disease
 - Oval or round window graft
 - Removal of cavernous sinus tumors
 - Resection of brain tissue near primary motor cortex and requiring brain mapping
 - Resection of epileptogenic brain tissue or tumor
 - Other intracranial procedures (e.g., aneurysm repair, intracranial AVM)
- Non-cranial vascular procedures
 - Carotid artery surgery
 - Arteriography with test occlusion of carotid artery
 - Deep hypothermic circulatory arrest
 - Distal aortic procedures
 - Surgery of the aortic arch, its branch vessels, or thoracic aorta

Electroencephalographic monitoring

Intraoperative electroencephalographic (EEG) monitoring may be considered medically necessary for any of the following procedures

- Intracranial procedures
 - Microvascular decompression of cranial nerves
 - Removal of acoustic neuroma, congenital auricular lesions, or cranial base lesions

- Cholesteatoma, including mastoidotomy or mastoidectomy
- Vestibular neurectomy for Meniere's
- Removal of cranial nerve neuromas affecting any of the following nerves:
 - Abducens
 - Facial
 - Glossopharyngeal
 - Hypoglossal
 - Oculomotor
 - Recurrent laryngeal
 - Spinal accessory
 - Superior laryngeal
 - Trochlear
- Deep brain stimulation
- Endolymphatic shunting for Meniere's disease
- Oval or round window graft
- Removal of cavernous sinus tumors
- Resection of brain tissue near primary motor cortex and requiring brain mapping
- Resection of epileptogenic brain tissue or tumor
- Other intracranial procedures (e.g., aneurysm repair, intracranial AVM)
- Non-cranial vascular procedures
 - Carotid artery surgery
 - Arteriography with test occlusion of carotid artery

Electromyographic monitoring

Intraoperative electromyographic (EMG) monitoring may be considered medically necessary when monitoring is during any of the following procedures:

- Dorsal rhizotomy
- Microvascular decompression of cranial nerves
- Removal of acoustic neuroma, congenital auricular lesions, or cranial base lesions
- Cholesteatoma, including mastoidotomy or mastoidectomy
- Vestibular neurectomy for Meniere's
- Removal of cranial nerve neuromas affecting any of the following nerves:
 - Abducens
 - Facial
 - Glossopharyngeal
 - Hypoglossal
 - Oculomotor
 - Recurrent laryngeal
 - Spinal accessory
 - Superior laryngeal
 - Trochlear

SPINAL PROCEDURES	SSEP (with or without MEP) 95925,95926, 95927,95938 With MEP – 95928, 95929, 95939	EEG 95822 95955	EMG 95860 95861 95867 95868 95870

Resection of epileptogenic brain tissue or tumor	☑	☑	
Other intracranial vascular procedures (e.g. aneurysm repair, intracranial AV malformation)	☑	☑	

*Intraoperative brainstem auditory evoked response monitoring may also be appropriate for intracranial procedures in which auditory function is at risk, such as acoustic neuroma resection or brainstem tumor resection.

EXPERIMENTAL AND INVESTIGATIONAL

IONM is considered experimental/investigational for all indications not meeting the above criteria. Examples of procedures for which there is insufficient evidence to establish net benefit of IONM include, but are not limited to, the following:

© 2015 Kaiser Foundation Health Plan of Washington. All Rights Reserved.

Date Sent: 6/28/23

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage.

Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

[Back to Top](#)

- Routine lumbar or cervical laminectomies and fusions
- Spinal cord stimulator implantation
- Thyroid or parathyroid surgery
- Cochlear implantation
- Vagal nerve stimulator implantation
- Spinal injections
- Hip replacement
- Parotid gland surgery

Intraoperative monitoring of visual evoked potentials is experimental and investigational for all indications.

Intraoperative monitoring of motor evoked potentials using transcranial magnetic stimulation is experimental and investigational for all indications.

Nerve conduction studies for intraoperative monitoring purposes are considered experimental and investigational for all indications.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Last 6 months of radiology if applicable

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

EVIDENCE BASIS

There is moderate strength of evidence that IONM may identify patients at greater risk of adverse outcomes due to neurological injury among individuals undergoing certain spinal procedures. For surgeries that risk damaging the spinal cord (e.g., scoliosis correction, spinal cord tumor removal), the effectiveness of IONM has been assumed. As such, the evidence base for comparative studies is minimal. However, multiple retrospective and prospective cohort studies indicate that IONM may accurately identify those with postoperative neurological deficits. Less clear is whether knowledge of injury, intraoperatively, can lead to intervention which prevents or reverses said neurological deficits.

A systematic review (Fehlings 2010) concluded that IONM is sensitive and specific for detecting neurological complications during spinal surgery. That review included 14 prospective cohort studies addressing a variety of spinal indications. Across all included studies, IONM was not associated with any serious harms. Authors concluded that IONM can be a valuable tool during spinal surgery when the spinal cord or nerve roots are at risk.

IONM has also been proposed as potentially valuable during thyroid surgery as a means to prevent injury to the recurrent laryngeal nerve. A systematic review (Malik 2016) evaluated 17 studies comparing thyroid surgery with and without IONM. Using pooled data from those studies, authors found no statistically significant difference in recurrent laryngeal nerve palsy (RLNP) between those who had undergone thyroid surgery with or without IONM. Another systematic review (Yang 2017) reported a slightly lower incidence of RLNP among those who had thyroid surgery with IONM, but this difference was not statistically significant.

The American Association of Neurological Surgeons (AANS) and the Congress of Neurological Surgeons (CNS) released a position statement on IONM in April 2014. The AANS/CNS concluded that there is insufficient evidence to show that the use of IONM mitigates the severity of neurological injury or reduces its incidence. However, the position statement did note that use of IONM may help to diagnose neurological injury during surgery. Later that year, an analysis of all spine surgeries performed from 2007-2011 that were included in the Nationwide Inpatient Sample database was published by James WS, et al. This study included 443,194 spine procedures in which 31,680 cases utilized IONM. Iatrogenic neurological injury was rare, occurring in less than 1% with no difference in cases where IONM was used. In 2015, Hawksworth et al, from the University of Texas Health Sciences Center, published an analysis of their department's spine surgeries completed from 2011-2013, before and after adopting a departmental policy limiting IONM use to intradural procedures and those for spinal deformity correction. While utilization of IONM dropped from 38% of spinal cases to 7%, there was no change in

incidence of neurological injury. In fact, the only observed cases of injury occurred in cases utilizing IONM where the monitoring did not alert the surgeon to the injury.

In 2017, Hadley, et al published, "Guidelines for the Use of Electrophysiological Monitoring for Surgery of the Human Spinal Column and Spinal Cord" which was approved by both the American Association for Neurological Surgeons and the Congress of Neurological Surgeons. This Guideline was based on review of relevant published literature from 1966-2017. Similar to the aforementioned 2014 position statement, this new Guideline found that IONM "has not been shown to be successful in reducing the rate or perioperative neurological deterioration or to improve neurological outcome during spinal surgery procedures." The authors later conclude that because use of IONM during spinal surgery has not been correlated with improvements in neurological outcome that its expense does not appear justified.

In a systematic review on IONM for cervical degenerative myelopathy and radiculopathy, authors concluded that altering of the surgical plan or intraoperative steroid administration based upon IONM monitoring was not shown to decrease the incidence of neurological injury. However, the review concluded that IONM may be sensitive for assessing neurological injury for diagnostic information.

The American Association of Neuromuscular and Electrodiagnostic Medicine (AANEM) released a position statement in 2014 supporting the use of intraoperative SSEP for certain spinal surgeries, particularly those with increased risk for nerve root or spinal cord injury (including complex, extensive, or lengthy procedures). Authors also stated that intraoperative SSEP was not indicated for routine lumbar or cervical root decompression.

In 2012, the American Academy of Neurology (AAN) and the American Clinical Neurophysiology Society (ACNS) identified 11 studies as part of their evidence-based guidelines process, from which they concluded the IONM is safe and effective for identifying increased risk of adverse outcomes, including paraparesis, paraplegia, and quadriplegia during spinal surgery (Nuwer 2012).

Medical Technology Assessment Committee (MTAC)

Intraoperative Neurophysiologic Monitoring (IONM)

08/17/2015: MTAC REVIEW

Evidence Conclusion: The selected studies offer a small sample of the extensive literature currently available relating to IONM. For the most part, the available evidence is descriptive and details the experience of IONM in various surgical settings. In the selected studies, IONM is used to support surgeries in various specialties including neurosurgery (brain and spine), cardiac, and vascular. Population sizes range from 62 to 119 and assessed pre- and post- surgical outcomes such as neurophysiologic alerts during surgery and post-operative neurological deficits. Conclusions from the selected studies conflict with some asserting the utility of IONM technology and others finding minimal utility due to the inability to predict post-operative complications (Schramm, Koht et al. 1990; Linstedt, Maier et al. 1998; Gharani, Liard et al. 1999; Bose, Sestokas et al. 2004). Surgical procedures and interventions are not always based on scientific evidence and instead, tend to evolve over time. Today, IONM is considered to be a standard of care limiting the ability to carry out methodologically sound comparative studies due to equipoise. Beyond that, the existing literature base is extremely heterogeneous addressing various surgical procedures in different populations with varying and conflicting conclusions. As a result, the evidence is insufficient to be able to determine if IONM is truly effective at detecting and preventing neurologic complications.

Conclusions: There is insufficient evidence to establish that IONM, either on-site or remote, reduces the risk of neurologic injuries during surgical procedures. There is insufficient evidence to support the safety of IONM.

Articles: The literature search revealed a large number of publications relating to IONM. There were no randomized controlled trials (RCTs) comparing the outcomes of surgeries that employed the use of IONM (either remote or on-site) with those not utilizing the monitoring technique nor were there any studies making a comparison between remote and onsite monitoring. The search yielded a wide variety of observational studies the majority of which had no comparison group. Due to the extensive amount of literature identified, the following studies are a small sample of the available evidence: Bose B, Sestokas AK, Schwartz DM. Neurophysiological monitoring of spinal cord function during instrumented anterior cervical fusion. *The Spine Journal*. 2004;4(2):202-207. [See Evidence Table 1](#). Schramm J, Koht A, Schmidt G, et al. Surgical and electrophysiological observations during clipping of 134 aneurysms with evoked potential monitoring. *Neurosurgery*. 1990;26(1):61-70. [See Evidence Table 1](#). Gharani S, Liard L, Spaey J, et al. Retrospective study of somatosensory evoked potential monitoring in deep hypothermic circulatory arrest. *The Society of Thoracic Surgeons*. 1999; 67:1915-1918. [See Evidence Table 1](#). Linstedt

U, Maier C, Petry A. Intraoperative monitoring with somatosensory evoked potentials in carotid artery surgery – less reliable in patients with preoperative neurologic deficiency? *Acta Anaesthesiol Scand*. 1998;42(1):13-16. [See Evidence Table 1](#).

The use of Intraoperative Neurophysiologic Monitoring (IONM) does not meet *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

General Neuromonitoring:

CPT® or HCPC Codes	Description
95940	Continuous intraoperative neurophysiology monitoring in the operating room, one on one monitoring requiring personal attendance, each 15 minutes (List separately in addition to code for primary procedure)
95941	Continuous intraoperative neurophysiology monitoring, from outside the operating room (remote or nearby) or for monitoring of more than one case while in the operating room, per hour (List separately in addition to code for primary procedure)
G0453	Continuous intraoperative neurophysiology monitoring, from outside the operating room (remote or nearby), per patient, (attention directed exclusively to one patient) each 15 minutes (list in addition to primary procedure)

Somatosensory-evoked potentials (SSEP):

NOTE: CPTs 95925 and 95926 should not be billed during the same procedure if both upper and lower limbs are monitored; instead, CPT 95938 should be used. CPT 95938 should not be coded in conjunction with either 95925 or 95926. Similarly, 95928 and 95929 should not be billed together; instead 95939 should be used if both upper and lower limbs are monitored.

CPT® or HCPC Codes	Description
95925	Short-latency somatosensory evoked potential study, stimulation of any/all peripheral nerves or skin sites, recording from the central nervous system; in upper limbs
95926	Short-latency somatosensory evoked potential study, stimulation of any/all peripheral nerves or skin sites, recording from the central nervous system; in lower limbs
95927	Short-latency somatosensory evoked potential study, stimulation of any/all peripheral nerves or skin sites, recording from the central nervous system; in the trunk or head
95938	Short-latency somatosensory evoked potential study, stimulation of any/all peripheral nerves or skin sites, recording from the central nervous system; in upper and lower limbs

Motor evoked potentials (MEP):

CPT® or HCPC Codes	Description
95928	Central motor evoked potential study (transcranial motor stimulation); upper limbs
95929	Central motor evoked potential study (transcranial motor stimulation); lower limbs
95939	Central motor evoked potential study (transcranial motor stimulation); in upper and lower limbs

Electroencephalography:

CPT® or HCPC Codes	Description
95822	Electroencephalogram (EEG); recording in coma or sleep only
95955	Electroencephalogram (EEG) during nonintracranial surgery (eg, carotid surgery)

Electromyography:

CPT® or HCPC	Description
--------------	-------------

Codes	
95860	Needle electromyography; 1 extremity with or without related paraspinal areas
95861	Needle electromyography; 2 extremities with or without related paraspinal areas
95867	Needle electromyography; cranial nerve supplied muscle(s), unilateral
95868	Needle electromyography; cranial nerve supplied muscles, bilateral
95870	Needle electromyography; limited study of muscles in 1 extremity or non-limb (axial) muscles (unilateral or bilateral), other than thoracic paraspinal, cranial nerve supplied muscles, or sphincters

Considered not medically necessary:

CPT® or HCPC Codes	Description
95907	Nerve conduction studies; 1-2 studies
95908	Nerve conduction studies; 3-4 studies
95909	Nerve conduction studies; 5-6 studies
95910	Nerve conduction studies; 7-8 studies
95911	Nerve conduction studies; 9-10 studies
95912	Nerve conduction studies; 11-12 studies
95913	Nerve conduction studies; 13 or more studies
95930	Visual evoked potential (VEP) checkerboard or flash testing, central nervous system except glaucoma, with interpretation and report
95937	Neuromuscular junction testing (repetitive stimulation, paired stimuli), each nerve, any 1 method

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

Revision History	Description
05/07/2019	MPC approved to adopt KP National criteria for IONM.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Iontophoresis Phonophoresis

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Iontophoresis" for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

Treatment	Criteria Used
Iontophoresis	Kaiser Permanente has elected to use the Iontophoresis (KP-0617) MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.
Phonophoresis	Kaiser Permanente has elected to use the MCG Phonophoresis guideline (A-0616): this is not covered per MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.
For Medication Delivery with Iontophoresis for Temporomandibular Joint (TMJ) Dysfunction and Joint Pain or Devices for use in the member's home	There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

*MCG are proprietary and cannot be published and/or distributed. However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Evidence and Source Documents

[Iontophoresis for Hyperhidrosis using Drionic or Idrostar Devices](#)

[Iontophoresis for Joint Pain](#)

[Medication Delivery with Iontophoresis for Temporomandibular Joint \(TMJ\) Dysfunction](#)

Background

Iontophoresis is the use of electricity to enhance the percutaneous absorption of a drug or chemical ions. Ions in solution are transferred through the skin by passing DC electrical current between two electrodes. Iontophoresis uses a low current and patients have little or no sensation during the procedure. Drugs used in iontophoresis should be those that ionize. Drugs used for iontophoresis may include lidocaine hydrochloride (a positive ion forming drug) and dexamethasone sodium phosphate (a negative ion forming drug). Possible advantages include greater convenience and less discomfort compared to injection, less variation in absorption, and fewer side effects compared to oral administration of medication.

Medical Technology Assessment Committee (MTAC)

[Iontophoresis for Hyperhidrosis using Drionic or Idrostar Devices](#)

BACKGROUND

Hyperhidrosis or excessive sweating may be classified into primary or essential hyperhidrosis with an unknown cause, and secondary hyperhidrosis which is due to an underlying condition as hyperthyroidism, menopause, obesity, psychiatric disorder, and others. It may be localized in one or several locations of the body, most often in the hands (palmer hyperhidrosis) but may also be planter, axillary, facial, or general. Several methods are used to treat patients with primary hyperhidrosis, or secondary cases with heavy sweating or untreatable conditions. These include the use of antiperspirants, drugs, psychotherapy, surgery, iontophoresis, use of botulinum toxin, alternative medicine, and others. Iontophoresis can be defined as a means of delivering medication to a localized tissue area by applying electrical current to a solution of the medication. It consists of applying low intensity current (15-18 mA) supplied by a D/C generator to the palms and/or soles immersed in an electrolyte solution. The procedure has to be repeated regularly, and the results may vary among patients. The Drionic and Idrostar devices are battery-operated methods of inducing tap water iontophoresis.

06/12/2002: MTAC REVIEW

[Iontophoresis for Hyperhidrosis using Drionic or Idrostar Devices](#)

Evidence Conclusion: There is not enough evidence to permit conclusions on the use of either the Drionic or Idrostar device for treating hyperhidrosis.

Articles: The search yielded three articles, two of which were reviews, and the third was a small case series with 22 patients with hyperhidrosis treated with the Drionic unit.

The use of Idrostar in the treatment of hyperhidrosis via iontophoresis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/03/2009: MTAC REVIEW

[Iontophoresis in the Treatment of Hyperhidrosis](#)

Evidence Conclusion: There is insufficient evidence to draw conclusions on the safety and efficacy of iontophoresis for treating hyperhidrosis. No published comparative studies were identified. The literature base consists of case series, mostly with fewer than 25 patients and one case series with 112 patients. The larger series reported that about 81% of participants responded to treatment. The criteria provided for response was not clearly defined and there was no long-term follow-up.

Articles: Four empirical studies specifically evaluating iontophoresis for hyperhidrosis were identified. There were no randomized or non-randomized controlled studies. All of the empirical studies were case series. Three had

fewer than 25 patients and were excluded from further review. The fourth (Karakoc et al., 2002) included 112 patients and was critically appraised. See [Evidence Table](#).

The use of iontophoresis in the treatment of hyperhidrosis does not meet the Kaiser Permanente *Medical Technology Assessment Criteria*.

Iontophoresis for Joint Pain

BACKGROUND

Iontophoresis is proposed as a treatment for joint pain. It has been used for various types of tendonitis including epicondylitis, patellar tendonitis, biceps tendonitis, rotator cuff tendonitis and Achilles tendonitis (Winn, unpublished manuscript). Iontophoresis is the use of electricity to enhance the percutaneous absorption of a drug or chemical ions. Ions in solution are transferred through the skin by passing DC electrical current between two electrodes. Iontophoresis uses a low current and patients have little or no sensation during the procedure. Drugs used in iontophoresis should be those that ionize. Dexamethasone sodium phosphate, a negative ion, is a commonly used drug used for iontophoresis treatment of joint pain. Possible advantages include greater convenience and less discomfort compared to injection, less variation in absorption, and fewer side effects compared to oral administration of medication. Common treatments for joint pain include rest, ice after exercise, stretching, bracing and immobilization; medications such as analgesics and non-steroidal anti-inflammatory drugs (NSAIDs) and injection of corticosteroids. A well-done randomized controlled trial (Hay et al., 1999) found that local injection of corticosteroid was more effective for treating lateral epicondylitis than NSAID treatment, but that more than 80% of patients were improved at 12 months regardless of treatment.

10/08/2003: MTAC REVIEW

Iontophoresis for Joint Pain

Evidence Conclusion: There is insufficient evidence to conclude that iontophoresis for joint pain is effective compared to the accepted alternatives, corticosteroid injection and NSAID treatment. No studies compared iontophoresis with one of these established treatments. There is some evidence that iontophoresis is not more effective than placebo treatment, although the data are limited. The highest quality study identified was an RCT comparing active iontophoresis with placebo iontophoresis in patients with epicondylitis (Nirschl). This study found a greater effect with active iontophoresis two-days after treatment, but no difference in efficacy after one-month. The study was powered to detect a 20% difference between groups. Another RCT conducted with patients with epicondylitis (Runeson) found no difference in the efficacy of active or placebo iontophoresis 3- and 6-months after treatment. Neither RCT had an intention to treat analysis, but follow-up was much higher in the Nirschl study (90% compared to 64% in the Runeson study). Statistical power was not discussed in the Runeson study. The quality of evidence for conditions other than epicondylitis was low.

Articles: The search yielded 12 articles. None of the studies compared iontophoresis to corticosteroid injection or oral medication treatment. There were four RCTs conducted with patients who had epicondylitis. Two studies compared active iontophoresis treatment to placebo treatment and were critically appraised. The two other studies had irrelevant comparison groups and were not reviewed: one compared iontophoresis with two types of active substances and one compared iontophoresis to an experimental treatment, phonophoresis. In addition, there were three controlled studies conducted among patients with other types of tendonitis. All three had weaker methodology than the placebo-controlled epicondylitis studies and were not reviewed. Two did not compare the different treatment groups in analysis and one had a sample size of only 22 patients. *The following studies were critically appraised:*

Nirschl RP, Rodin DM, Ochiai et al. Iontophoretic administration of dexamethasone sodium phosphate for acute epicondylitis. *Am J Sports Med* 2003; 31: 189-195. See [Evidence Table](#). Runeson L, Haker E. Iontophoresis with cortisone in the treatment of lateral epicondylalgia (tennis elbow)- a double blind study. *Scand J Med Sci Sports* 2002; 12: 136-142. See [Evidence Table](#).

The use of iontophoresis in the treatment of joint pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Medication Delivery with Iontophoresis for Temporomandibular Joint (TMJ) Dysfunction

BACKGROUND

Temporomandibular joint (TMJ) dysfunction is a common condition and involves pain, particularly in the chewing muscles and jaw joint, radiating pain in the face, neck or shoulders, painful clicking sounds in the jaw joint, and restricted jaw movement. Drug therapies for TMJ dysfunction include analgesics, minor tranquilizers or muscle relaxants at bedtime, antidepressants, injections of a local anesthetic and cortisone injections.

Iontophoresis is the use of electricity to enhance the percutaneous absorption of a drug or chemical ions. Ions in solution are transferred through the skin by passing DC electrical current between two electrodes. Iontophoresis

uses a low current and patients' have little or no sensation during the procedure. Drugs used in iontophoresis should be those that ionize. Drugs used for iontophoresis to treat TMJ include lidocaine hydrochloride (a positive ion forming drug) and dexamethasone sodium phosphate (a negative ion forming drug) (Lark & Gangarosa). Iontophoresis is proposed as an alternative to local anesthetic injections for the treatment of TMJ dysfunction. Possible advantages are less discomfort than interarterial injection and fewer side effects than systemic medications.

02/13/2002: MTAC REVIEW

Iontophoresis in the Treatment of Temporomandibular Joint Syndrome

Evidence Conclusion: There is insufficient published scientific evidence on which to base conclusions about the effect of medication delivery with iontophoresis on health outcomes in patients with temporomandibular joint syndrome. Two small RCTs were reviewed, both of which may have had insufficient statistical power to detect clinically important differences between groups; neither of the study discussed statistical power calculations. Shiffman did not compare the randomized groups in analysis. Reid did not find that iontophoresis was more effective than placebo.

Articles: The search yielded eight articles. The majority were review articles/opinion pieces. There were two small randomized controlled trials (RCTs) with clinical outcomes. These two articles were critically appraised: Shiffman EL, Braun BL, Lindgren BR. Temporomandibular joint iontophoresis: A double-blind randomized clinical trial. *J Orofacial Pain* 1996; 10: 157-65. See [Evidence Table](#). Reid KJ, Dionne RA, Sicard-Rosenbaum L, Lord D, Dubner RA. Evaluation of iontophoretically applied dexamethasone for painful pathologic temporomandibular joints. *Oral Surg Oral Med Oral Pathol* 1994; 77: 605-9. See [Evidence Table](#).

The use of Iontophoresis in the treatment of temporomandibular joint syndrome does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Iontophoresis -

Considered Medically Necessary when criteria in the applicable policy statements listed above are met

CPT® Codes	Description
97033	Application of a modality to 1 or more areas; iontophoresis, each 15 minutes

Phonophoresis - Considered Not Medically Necessary:

CPT® or HCPC Codes	Description
No specific codes	

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

MPC Medical Policy Committee

Revision History	Description
09/08/2015	Revised LCD L35008
12/13/2017	Added home unit language
09/03/2019	MPC approved to add clinical indication for Palmar/Plantar Hyperhidrosis
11/05/2019	MPC approved to adopt non coverage criteria for Phonophoresis; adopting MCG A-0616
06/15/2020	60-day notice required for non-coverage of phonophoresis, updated effective date to 10/1/2020
08/04/2020	Added Medicare LCA A57642
08/03/2021	Removed LCD L35008 and LCA A57642; added KPWA medical policy statement under Medicare section.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Intraoperative Radiation Therapy (IORT)

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	4/01/2016 Noridian retired LCD Brachytherapy: Non-Intracoronary (L34065) . These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an LCD. Most LCDs are not retired because they are incorrect. The criteria should be still referenced when making an initial decision. However, if the decision is appealed, the retired LCD cannot be specifically referenced. Maximus instead looks for "medical judgment" which could be based on our commercial criteria or literature search.
Local Coverage Article	None

For Non-Medicare Members

Intraoperative radiation therapy (IORT) may be considered medically necessary in the following situation:

- Rectal cancer with positive or close margins with T4 lesions or recurrent disease.

IORT is considered investigational when used for all other oncologic applications, including but not limited to:

- Breast cancer
- Fibromatosis
- Gastric cancer
- Glioma
- Gynecologic cancers
- Head and neck cancers
- Neuroblastoma
- Pancreatic cancer
- Renal cell cancer
- Soft tissue sarcoma

Some requests may be approved on a case-by-case basis by the Medical Director.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage

Background

The usual method for delivering radiation is external beam with high-energy photons. However, the external beam doses required to achieve local tumor control can exceed the radiation tolerance of some normal organs and other structures of the body.

Intra-operative radiation therapy (IORT) is being investigated as a technique to deliver a high dose of radiation to a locally advanced tumor while attempting to protect adjacent normal tissues at the time of surgery. It is delivered with applicators and cones attached to the treatment head of high-energy medical linear accelerators. After all or most of the cancer is surgically removed, a large, single-dose of high-energy radiation is aimed directly at the tumor site. Nearby healthy tissue is protected with special shields.

The goal of IORT is to enhance local tumor control. Most patients receiving IORT are concurrently treated with high-dose external beam photon irradiation. The term “intraoperative radiation therapy” may also refer to intra-operative brachytherapy, the temporary or permanent implantation of radioactive seeds. Intra-operative radiation therapy is usually a component of a multi-disciplinary treatment approach for localized cancers that cannot be completely removed or that have a high risk of recurring in nearby tissues.

Medical Technology Assessment Committee (MTAC)

Intraoperative Radiation Therapy (IORT) for Breast Cancer

BACKGROUND

Breast cancer is the most common cancer in women of all races and ethnicities (not counting skin cancer), and the second most common cause of death from cancer among white, black, Asian/Pacific Islander, and American Indian/Alaska Native women. The American Cancer Society (ACS) estimated that in 2015, 231,840 new cases of invasive breast cancer and 62,570 breast carcinoma in-situ, will be diagnosed among women in the U.S. and that 40,290 will die from breast cancer. The reported five-year relative survival rate is 98.5% for women diagnosed with localized breast cancer. This drops to 84% among women with cancer that has spread to nearby lymph nodes (regional stage) and to 24% in those with metastases in distant lymph nodes and/or other organs (CDC and ACS web pages accessed October 27, 2015). The widespread screening programs and new developments in early detection of cancer have led to an increase in the incidence of early stage breast cancer. Surgical treatment has thus shifted from radical mastectomy to personalized local treatment that preserves the breast and axillary lymph nodes, together with adjuvant therapy. Breast conserving surgery (BCS) followed by postoperative whole breast external beam radiotherapy (EBRT or WBRT) is currently considered the standard treatment for patients with early-stage breast cancer. This approach has been shown to reduce local recurrence (LR) and improve the overall survival. Traditional whole breast EBRT is administered in the postoperative setting as 45-50 Gy in daily fractions for 5 consecutive weeks. An additional external beam boost of 10-16 Gy is often delivered to the tumor bed to improve local control and reduce local recurrence. It is reported that almost one third of the patients undergoing BCS in North America do not receive post-BCS breast radiation therapy and many others choose mastectomy instead, for several reasons including the long course of treatment, comorbidities, advanced age, distance from the radiation therapy facility, inconvenience, and cost (Vaidya, 2010, Esposito 2014, Abbott 2015, Zhang 2015). Accelerated partial breast irradiation (APBI), is a radiation technique that targets partial breast tissue around the tumor cavity with fewer fractions. APBI has emerged in the last 2 decades and is increasingly being accepted as an alternative to whole breast EBRT. It is based on the observation that more than 90% of local recurrences occur at /or near the tumor bed after BCS. There are several techniques for delivering APBI, including multi-catheter interstitial brachytherapy, balloon catheter brachytherapy, 3D- conformal radiation therapy, and intraoperative radiation therapy (IORT). These techniques differ widely in regard to the degree of invasiveness, radiation delivery, operator proficiency, acceptance between radiation oncologists, and length of treatment (Njeh 2010, Vaidya 2010, Abbott 2015, Esposito 2015, Zhang 2015). IORT is an APBI approach that delivers a single dose of irradiation directly to the tumor bed at the time of surgery. Unlike other APBI techniques that target the index quadrant, IORT specifically targets the tumor cavity. The index quadrant is not demarcated anatomically, whereas the tumor cavity is easily located by the operating surgeon. IORT can be delivered by

using low-energy X-rays, electron beam radiation therapy, brachytherapy, high-dose-rate (HDR) after loaders, and other hybrid devices (Esposito 2015). The intrabeam® device (Carl Zeiss, Oberkochen, Germany) is a device used to deliver IORT during surgery after removal of the tumor. It comprises a miniature low-energy X-ray source (50 kVp) that delivers a dose of 20 Gy at the surface of the applicator and 5-5 Gy at 1 cm deep, in 20-40 minutes treatment time. Tungsten-impregnated sheets are used to shield the wound before treatment. Access to the operating room should be controlled and the medical personnel shielded during treatment. The intraoperative electron radiation therapy (IOERT) is another method for delivering IORT that involves the application of electron radiation directly to the tumor bed at the time of surgery. Compared to the X-ray beams, the electron beams have limited penetration into the tissue and faster delivery of the required radiation dose. The IOERT systems are designed to deliver radiation in non-shielded operating theaters. Currently there are three mobile linear accelerators that can be moved easily into an operating room and deliver IOERT (Novac 7®, Liac®, and the Mobetron®). The radiation procedure is completed in 2 minutes delivering a dose of 21 Gy with the depth of 90% isodose ranging from 13-24 mm (Esposito 2015). The advantages of IORT include the reduced treatment visits by delivering a single radiotherapy fraction during surgery, immediate visualization of the operative bed before delivering the radiotherapy, minimizing the possibility of missing the target, shielding the surrounding organs, avoiding treatment delay for patients who may also need to undergo chemotherapy, and reducing healthcare costs. Disadvantages of IORT on the other hand, include longer operating time, reported increased local recurrence compared to EBRT, and lack of final pathological results before delivering the IORT. In patients with positive margins that require re-excision, an IORT boost may be ineffective and may cause complications in re-excision of the margins and difficulty in interpreting the pathology. In addition, IORT requires training of staff, operating room equipment efforts, and expensive devices (Hanna 2014, Esposito 2015).

12/21/2015: MTAC REVIEW

IORT for breast cancer

Evidence Conclusion: There are two large published intraoperative radiation therapy (IORT) trials that investigated whether IORT is equivalent (ELIOT) or noninferior (TARGIT-A) to standard EBRT for the treatment of women with early stage breast cancer undergoing breast conservative surgery. The ELIOT trial used electron IORT (using 2 linear accelerators; NOVAC 7 and Liac) and the TARGIT-A trial used a point source low-energy x-rays (50kV maximum) using the Intrabeam device. TARGIT-A trial (Vaidya et al, 2010, 2014), Evidence Table 1 This was a large multicenter trial that examined the noninferiority of IORT to EBRT (within a specified margin of 2.5%) after breast conserving surgery (BCS). 2,232 women 48-75 years of age, with invasive ductal breast cancer undergoing BCS were randomly assigned to receive either a standard regimen of 25-25 fractions (40-56 Gy) EBRT or a single fraction low energy IORT. Randomization was performed either before surgery (pre-pathology entry) or after surgery (post-pathology entry). In the latter group IORT was given after surgery by reopening the wound. 15% of the patients in the IORT group received additional EBRT (the trial protocol allowed recipients of IORT to receive additional EBRT based on unfavorable features found in the pathology [risk adapted policy]). The primary outcome of the trial was pathologically confirmed ipsilateral breast tumor recurrence (IBTR). The initial results of the trial were published in 2010 when only less than one fifth of the participants were followed-up for at least 4 years (median 25 months for all subjects). These results showed that the IBTR rate was 1.2% in the IORT arm and 0.95% the EBRT arm ($p=0.41$). More recent results were published in 2014 after the addition of 1,219 participants, and longer follow-up for the initial cohort. The estimated 5-year risk of local recurrence was 3.3% in the IORT group and 1.3% in the EBRT group ($p=0.042$) (median follow-up was 29 months due to the short follow-up of the additional patients; only 18% of the patients had 5 years of follow-up). The results published in the first report indicate that rate of ipsilateral local recurrence in the IORT group IORT met the noninferiority margin of 2.5% (prespecified by the investigators) for the overall patient population, and for the pre-pathology subgroup, but not for the post-pathology group. However, the incidence of the local recurrence was significantly higher with IORT vs. EBRT. This higher rate was observed at a median follow-up of 29 months which is below the median time when local recurrences are expected, especially when 90% of the women had estrogen receptor positive tumors that tend to recur later. In addition, almost two thirds of the women received adjuvant hormonal therapy which delays recurrence in estrogen receptor positive cases (Silverstein 2014). The results also show that the women who received IORT alone had 3 times the recurrence rate vs. those who received IORT+EBRT (2.7 vs. 0.9%). The authors indicated that the difference was not statistically significant, but no p value was provided. The trial was multicenter, randomized, and controlled. However, it had several methodological limitations, mainly the inadequacy of follow-up duration needed to provide conclusive evidence on the noninferiority of IORT to EBRT. The prespecified non-inferiority margin of 2.5% required a 5-year follow-up for all patients, which was only fulfilled by 20% of the study cohort. Other limitations of the trial include the open-label design (due to the nature of the intervention), and the multiple amendments made to the protocol along the course of the study such as the addition of more participating countries, increasing the population size, changing the start and ending date of the trial, and changing the funding source. In addition, each center participating in the trial managed the EBRT group according to its institutional guidelines and determined its own criteria for treating patients with IORT given alone or as a boost therapy. ELIOT trial (Veronesi, et al 2013), Evidence Table 2 This was a prospective single-center

trial that randomized 1,305 women 48-75 year of age with clinically invasive T1-T2, ≤ 2.5 cm breast cancer suitable for breast conservative surgery (BCS), to undergo whole breast EBRT delivered over 6 weeks, or receive a single dose of electron beam IORT. The primary outcome of the trial was ipsilateral breast tumor recurrence (IBTR). The results of the analysis show that after a median follow-up of 5.8 years the IBTR fell within the pre-defined equivalence margin of 4.5%, but the rate was significantly higher in the IORT group (4.4% vs. 0.4% in the EBRT group, $p < 0.0001$, NNH of 25). The significantly higher rates of IBTR in the IORT group were observed for both the true local recurrence in the index quadrant, and for new ipsilateral breast tumors in other quadrants. The author indicated that the difference may be attributable to the very low recurrence rates in the EBRT group because of the high experience and quality of management. Some investigators raised the question on whether the 4-cm applicator size used in the trial might have been too small to adequately treat microscopic disease that extended beyond the existed tumor. Axillary or other regional lymph node metastasis and locoregional tumor recurrence were also significantly higher in the IORT group (NNH=143 and 22 and respectively). There were no significant differences between the two study arms in the development of contralateral breast metastasis, distant metastasis, or in the 5-year overall survival rate. Subgroup analysis according to patients' risk based on tumor size, grade, receptor status, and nodal positivity, showed that low risk women (69.4% of the study participants) had a 5-year IBTR rate of only 1.5% compared to 11.3% of those with one or more high-risk factors. A multivariate analysis showed that tumors size > 2 cm, ≥ 4 positive lymph nodes, poorly differentiated tumors, and tumors with triple negative subtypes doubled the risk of IBTR. The rate of adverse skin effects (erythema, dryness and hyperpigmentation) was significantly higher in the EBRT group, and the rate of fat necrosis was significantly higher in the IORT group. There were no significant differences between the groups in mammary retraction, pain, or burning. Conclusion: The results of the two large published RCTs show that the rate of local recurrence with IORT was non-inferior (TARGIT-A trial) or equivalent (ELIOT trial) to EBRT. However, these results were based on margins prespecified by the investigators of the trials. The results of both TARGIT-A and ELIOT trials show that the risk of ipsilateral tumor recurrence was significantly higher with the IORT compared to EBRT. The published trials had relatively short follow-up duration and do not provide sufficient evidence to determine the long-term risk of delayed cancer recurrence inside or outside the index quadrant, as well as the long-term efficacy and safety of the therapy. There was significant heterogeneity between the published studies as regards to the study design, patients' ages, tumor size, threshold values, radiation sources and techniques used for delivering the IORT, as well as the follow-up duration. Multivariate analysis of the ELIOT trial results showed that the risk of ipsilateral local recurrence in women receiving IORT was almost double in patients with tumors size > 2 cm, ≥ 4 positive lymph nodes, poorly differentiated tumors, or with triple negative subtypes.

Articles: The literature search revealed two large RCTs on IORT (TARGIT-A trial and ELIOT trial) as well a systematic review and meta-analysis of published studies, and a large number of single institution cohort studies. The two large RCTs and the meta-analysis were selected for critical appraisal. Vaidya JS, Joseph DJ, Tobias JS, et al. Targeted intraoperative radiotherapy versus whole breast radiotherapy for breast cancer (TARGIT-A trial): an international, prospective, randomised, non-inferiority phase 3 trial. *Lancet*. 2010 Jul 10; 376 (9735):91-102. See [Evidence Table 1](#). Vaidya JS, Wenz F, Bulsara M, et al. Risk-adapted targeted intraoperative radiotherapy versus whole-breast radiotherapy for breast cancer: 5-year results for local control and overall survival from the TARGIT-A randomised trial. *Lancet*. 2014 Feb 15; 383 (9917):603-613. See [Evidence Table 1](#). Veronesi U, Orecchia R, Maisonneuve P, et al. Intraoperative radiotherapy versus external radiotherapy for early breast cancer (ELIOT): A randomized controlled equivalence trial. *Lancet Oncol*. 2013 Dec; 14 (13):1269-1277. See [Evidence Table 2](#). Zhang L, Zhou Z, Mei X, et al. Intraoperative Radiotherapy versus Whole-Breast External Beam Radiotherapy in Early-Stage Breast Cancer: A Systematic Review and Meta-Analysis. *Medicine (Baltimore)*. 2015 Jul; 94(27):e1143. See [Evidence Table 3](#).

The use of IORT for breast cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
19294	Preparation of tumor cavity, with placement of a radiation therapy applicator for intraoperative radiation therapy (IORT) concurrent with partial mastectomy (List separately in addition to code for primary procedure)
77424	Intraoperative radiation treatment delivery, x-ray, single treatment session
77425	Intraoperative radiation treatment delivery, electrons, single treatment session
77469	Intraoperative radiation treatment management

HPCPC Codes	Description
C9726	Placement and removal (if performed) of applicator into breast for intraoperative radiation therapy, add-on to primary breast procedure

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

For Non-Medicare Members

Effective October 1, 2022

ADD SOC for IP requests also

**This criteria does not apply to revision or replacement of a previous knee arthroplasty.*

Total knee and unicompartmental arthroplasty may be considered medically necessary for degenerative joint disease when **ALL** of the following are met:

1. Treatment is needed because of functional disabling pain of at least 3 months duration which interferes with the ability to carry out activities of daily living

AND

2. Radiographic imaging or arthroscopic evidence of moderate or severe osteoarthritis as evidenced by **ONE of the following:**

- Moderate multiple osteophytes, definite narrowing of joint space, some sclerosis and possible deformity of bone contour (Kellgren-Lawrence Grade 3)
- Large osteophytes, marked narrowing of joint space, severe sclerosis, and definite deformity of bone contour (Kellgren-Lawrence Grade 4)
- Exposed subchondral bone (full thickness cartilage loss with underlying bone reactive changes) noted on arthroscopy or MRI (Outerbridge Grade IV)

AND

3. Patients must have three months of non-operative, conservative treatment as demonstrated by a trial of one or more of the following medications:

- Non-steroidal anti-inflammatory drugs (oral or topical)
- Acetaminophen

C. Intra-articular injection of corticosteroids as appropriate

AND

4. A trial of **All** of the following physical measures:

- i. Supervised Physical therapy, attends >75% of sessions
 - At least half of PT must be in person (not virtual)
- ii. Flexibility and muscle strengthening exercises
- iii. Reasonable restriction of activities
- iv. If conservative therapy is not appropriate, the medical record must clearly document why such an approach is not reasonable.

AND

5. All patients who meet the above criteria to undergo standard elective surgery must also meet **ALL of the following**:

- A. BMI < 35: if BMI is > 35, optimization efforts must be documented, demonstrating active attempts towards weight loss as shown by sustained weight loss over 3-6 months OR stagnant weights despite documented active participation in a weight loss or exercise program. Formal nutritional counseling must be documented. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. However, BMI > 40 is a relative contraindication. Despite not achieving this BMI, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
- B. No diabetes, or diabetes with HbA1c < 7.5 (with the presence of heart disease, no lower than 7.5). Members who have an A1C >7.5 must actively be involved with medical management and demonstrate a reduction in A1c over 3-6 months. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. A1c > 8.0 is a relative contraindication. Despite not achieving this A1c, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
- C. Members who use nicotine/tobacco must be actively involved in a nicotine cessation program and must be nicotine/tobacco-free for a minimum of 30 days prior to surgery or have a 90% reduction in nicotine/tobacco use. If nicotine/tobacco reduction attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. No changes in nicotine/tobacco use is a relative contraindication.

Knee arthroplasty may ALSO be considered medically necessary, after failure of nonoperative interventions, for the following diagnoses:

- Distal femur fracture repair in a patient with osteoporosis
- Failure of a previous proximal tibial or distal femoral osteotomy
- Hemophilic arthroplasty
- Limb salvage for malignancy
- Posttraumatic knee joint destruction
- Avascular necrosis (osteonecrosis) of tibial or femoral condyle
- Inflammatory Arthritis

***Kellgren-Lawrence Classification of Osteoarthritis**

Grade	Description
grade 0 (none)	definite absence of x-ray changes of osteoarthritis
grade 1 (doubtful)	doubtful joint space narrowing and possible osteophytic lipping
grade 2 (minimal)	definite osteophytes and possible joint space narrowing
grade 3 (moderate)	moderate multiple osteophytes, definite narrowing of joint space and some sclerosis and possible deformity of bone ends
grade 4 (severe)	large osteophytes, marked narrowing of joint space, severe sclerosis and definite deformity of bone ends

Osteoarthritis is deemed present at grade 2 although of minimal severity.

Outerbridge

Outerbridge 0: Cartilage is normal

Outerbridge 1: Cartilage shows chondromalacia,

Outerbridge 2: Cartilage shows partial thickness fibrillation

Outerbridge 3: Cartilage shows deep fibrillation

Outerbridge 4: Full thickness cartilage loss

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist, including a history & physical

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Joint replacement surgery has been performed on millions of people over the past several decades and has proved to be an important medical advancement in the field of orthopedic surgery. The hip and knee are the two most commonly replaced joints. The knee is the largest joint in the body and includes the lower end of the femur, the upper end of the tibia and the patella. The knee joint has three compartments, the medial, the lateral and the patellofemoral. The surfaces of these compartments are covered with articular cartilage and are bathed in synovial fluid. The bones of the knee joint work together, allowing the knee to function smoothly.

The most common reason for total knee replacement surgery is arthritis of the knee joint. Types of arthritis include:

- osteoarthritis,
- rheumatoid arthritis and
- traumatic arthritis (arthritis which occurs as a result of injury).

Arthritis causes a severe limitation in the activities of daily living (ADLs), including difficulty with walking, squatting, and climbing stairs. Pain is typically most severe with activity and patients often have difficulty getting mobilized when seated for a long time. Other findings include chronic knee inflammation or swelling not relieved by rest, knee stiffness, lack of pain relief after taking non-steroidal anti-inflammatory medications and failure to achieve symptom improvement with other conservative therapies such as steroid injections and physical therapy.

Osteonecrosis and malignancy are additional reasons to proceed with total knee replacement surgery. The use of TKR in patients with malignancy must be weighed against considerations of life expectancy and possible alternative procedures to relieve pain. The goal of total knee replacement surgery is to relieve pain and improve or increase patient function.

Occasionally, there may be a need to perform a reoperation on a previous total knee replacement. This is often referred to as a revision total knee.

Circumstances that lead to the need for a revision Total Knee Arthroplasty continued disabling pain, continued decline in function which can be attributed to failure of the primary joint replacement. Failure can be due to infection involving the joint, substantial bone loss in the structures supporting the prosthesis, fracture, aseptic loosening of the components and wear of the prosthetic components.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Total Knee:

Revision History	Description

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Total Hip Arthroplasty

- Inpatient Hip Arthroplasty Indications (SOC)
- Hip Arthroplasty Medical Necessity Criteria

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Total Hip Arthroplasty (L36573)
Local Coverage Article (LCA)	Billing and Coding: Total Hip Arthroplasty (A57684)
MLN Matters Article	Jan 2020 MLN Article: Update of the Hospital Outpatient Prospective Payment System (OPPS) - Topic 5. Changes to the Inpatient-Only list (IPO) for CY 2020

****The following codes are listed in the Medicare inpatient list and should not be reviewed for ambulatory or outpatient status for Medicare members: 27132, 27134, 27137, and 27138. These codes are applicable for ambulatory or outpatient status for all other plans.**

Effective until June 1, 2023

For Non-Medicare Members

I. Site of Care (SOC) - Inpatient Total Hip Arthroplasty

For total hip replacement (27130) or revision of total hip arthroplasty (27132**, 27134**, 27137**, or 27138**) to be approved as *inpatient*, **ONE of the following** criteria must be met:

- Bilateral total hip
- Coexisting neurologic condition (such as multiple sclerosis, history of stroke, or other neurologic conditions) where the expected length of stay is planned to be longer than 2 midnights

Effective June 1, 2023

For Non-Medicare Members

I. Site of Care (SOC) - Inpatient Total Hip Arthroplasty (for ambulatory SOC, proceed to II.)

For total hip replacement (27130) or revision of total hip arthroplasty (27132**, 27134**, 27137**, or 27138**) to be approved as *inpatient*, **ONE of the following** criteria must be met:

- Bilateral total hip
- Coexisting neurologic condition (such as multiple sclerosis, history of stroke, or other neurologic conditions) where the expected length of stay is planned to be longer than 2 midnights

AND

II. Request for ALL Total Hip Arthroplasty (includes ambulatory & inpatient) must meet the Medical Necessity Criteria:

**Preauthorization is not required for acute fractures admitted through the emergency department.*

1. Member has advanced joint disease demonstrated by:

- Pain and functional disability that interferes with activities of daily living (ADLs) from injury due to osteoarthritis, rheumatoid arthritis, avascular necrosis, or post-traumatic arthritis of the hip joint; *and*
- Limited range of motion (ROM), antalgic gait, and pain in hip joint with passive ROM on physical examination; **AND meet ONE of the following categories:**

2. Arthritis, Degenerative Hip Disease: Meets criteria above **AND**

- A. Radiographic or imaging evidence (performed within the prior 12 months) of moderate/severe osteoarthritis; Xray findings should include **ONE of the following:**
- Subchondral cysts
 - Subchondral sclerosis
 - Periarticular osteophytes
 - Joint subluxation
 - Bone on bone articulation
 - Moderate/Severe joint space narrowing
 - Tönnis Grade 2 or 3 Osteoarthritis

Tonis Grading Scale of Hip Osteoarthritis	
Grade	Radiographic Features
0	-No signs of osteoarthritis
1	-Slight narrowing of joint space -Slight lipping at joint margin -Slight sclerosis of the femoral head or acetabulum
2	-Small cysts in the femoral head or acetabulum -Increasing narrowing of joint space -Moderate loss of sphericity of the femoral head
3	-Large cysts -Severe narrowing or obliteration of joint space -Severe deformity of the femoral head -Avascular necrosis

AND

B. Documentation of failure of non-surgical conservative management of **ALL of the following:**

- i. Anti-inflammatory medication ≥ 3 weeks, one or more of the following:
 - Non-steroidal anti-inflammatory drugs (oral or topical), unless contraindicated
 - Acetaminophen
 - Intra-articular injection of corticosteroids as appropriate
- ii. A trial of Physical Therapy in the last 12 months, which should include some of the following features:
 - Supervised Physical therapy, attendance at $>75\%$ of sessions, minimum of 3 visits
 - Flexibility and muscle strengthening exercises

- Reasonable restriction of activities (activity or weightbearing modification or use of an assistive device)
 *If conservative therapy is not appropriate, the medical record must clearly document why such approach is not reasonable. Appropriate exemptions may include:
 - Rapid progression or advancement of radiographic arthritic severity
 - Rapid or progressive flexion contraction
 - Medical or social confounding factors precluding the safety or feasibility of conservative treatment

AND

3. All patients who meet the above criteria to undergo standard elective surgery must also meet **ALL of the following**:

- i. BMI < 35: if BMI is > 35, optimization efforts must be documented, demonstrating active attempts towards weight loss as shown by sustained weight loss over 3-6 months OR stagnant weights despite documented active participation in a weight loss or exercise program. Formal nutritional counseling must be documented. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. However, BMI > 40 is a relative contraindication. Despite not achieving this BMI, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
- ii. No diabetes, or diabetes with HbA1c < 7.5 (with the presence of heart disease, no lower than 7.5). Members who have an A1C > 7.5 must actively be involved with medical management and demonstrate a reduction in A1c over 3-6 months. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. A1c > 8.0 is a relative contraindication. Despite not achieving this A1c, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
- iii. Members who use nicotine/tobacco must be actively involved in a nicotine cessation program and must be nicotine/tobacco-free for a minimum of 30 days prior to surgery or have a 90% reduction in nicotine/tobacco use. If nicotine/tobacco reduction attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. No changes in nicotine/tobacco use is a relative contraindication.

4. **Avascular Necrosis**

Radiographic or imaging evidence by plain film or MRI shows Avascular Vascular Necrosis/ bone infarct:

- Can proceed directly with surgery

5. **Inflammatory Arthritis** (may include but not limited to: Rheumatoid Arthritis, Psoriatic Arthritis, Spondyloarthropathy, pseudogout/Gout, Lupus, Non-DJD arthritis, Hemophilia related arthritis, among others) must meet **ALL of the following**:

- A. Patient actively being followed by Rheumatology and has been judged to have exhausted all nonsurgical options including DMARDs
- B. Radiographic or imaging evidence (performed within the prior 12 months) of moderate/severe osteoarthritis; Xray findings should include one of the following:
 - Subchondral cysts
 - Subchondral sclerosis
 - Periarticular osteophytes
 - Joint subluxation
 - Bone on bone articulation
 - Moderate/Severe joint space narrowing
- C. Documentation of failure of non-surgical conservative management of **ALL of the following**:

- i. A trial of Physical Therapy in the last 12 months, which should include some of the following features:
 - Supervised Physical therapy, attendance at >75% of sessions, minimum of 3 visits
 - Flexibility and muscle strengthening exercises
 - Reasonable restriction of activities (activity or weightbearing modification or use of an assistive device)

**If conservative therapy is not appropriate, the medical record must clearly document why such approach is not reasonable. Appropriate exemptions may include:*

- Rapid progression or advancement of radiographic arthritic severity
- Rapid or progressive flexion contraction
- Medical or social confounding factors precluding the safety or feasibility of conservative treatment

- D. All patients who meet the above criteria to undergo standard elective surgery must also meet **ALL** of the following:
 - i. BMI < 35: if BMI is > 35, optimization efforts must be documented, demonstrating active attempts towards weight loss as shown by sustained weight loss over 3-6 months OR stagnant weights despite documented active participation in a weight loss or exercise program. Formal nutritional counseling must be documented. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. However, BMI > 40 is a relative contraindication. Despite not achieving this BMI, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
 - ii. No diabetes, or diabetes with HbA1c < 7.5 (with the presence of heart disease, no lower than 7.5). Members who have an A1C > 7.5 must actively be involved with medical management and demonstrate a reduction in A1c over 3-6 months. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. A1c > 8.0 is a relative contraindication. Despite not achieving this A1c, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
 - iii. Members who use nicotine/tobacco must be actively involved in a nicotine cessation program and must be nicotine/tobacco-free for a minimum of 30 days prior to surgery or have a 90% reduction in nicotine/tobacco use. If nicotine/tobacco reduction attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. No changes in nicotine/tobacco use is a relative contraindication.

6. Replacement/Revision of previous Arthroplasty must meet **ALL** of the following:

- A. Hip arthroplasty may be considered medically necessary for a replacement/revision of a previous arthroplasty as indicated by **ANY** of the following:
 - Aseptic loosening of one or more prosthetic components confirmed by imaging
 - Bearing surface wear leading to symptomatic synovitis or local bone or soft tissue reaction
 - Component instability
 - Periprosthetic fracture
 - Fracture, mechanical failure, or recall of a prosthetic component
 - Periprosthetic infection
 - Progressive or substantial periprosthetic bone loss
 - Recurrent or irreducible dislocation
 - Recurrent, disabling pain associated with clinically significant leg length inequality or audible noise
- B. Conservative therapy not indicated
- C. All patients who meet the above criteria to undergo standard elective surgery must also meet **ALL** of the following (**if the replacement is deemed urgent or time sensitive i-iii can be waived*):
 - i. BMI < 35: if BMI is > 35, optimization efforts must be documented, demonstrating active attempts towards weight loss as shown by sustained weight loss over 3-6 months OR stagnant weights despite documented active participation in a weight loss or exercise program. Formal nutritional counseling must be documented. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared

- decision making. However, BMI > 40 is a relative contraindication. Despite not achieving this BMI, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
- ii. No diabetes, or diabetes with HbA1c < 7.5 (with the presence of heart disease, no lower than 7.5). Members who have an A1C > 7.5 must actively be involved with medical management and demonstrate a reduction in A1c over 3-6 months. If optimization attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. A1c > 8.0 is a relative contraindication. Despite not achieving this A1c, if the provider has documented adequate efforts to improve these parameters, the case will be reviewed on a case-by-case basis by a medical director.
 - iii. Members who use nicotine/tobacco must be actively involved in a nicotine cessation program and must be nicotine/tobacco-free for a minimum of 30 days prior to surgery or have a 90% reduction in nicotine/tobacco use. If nicotine/tobacco reduction attempts are unsuccessful, the surgeon and patient may proceed if there is documentation of understanding of the risks through shared decision making. No changes in nicotine/tobacco use is a relative contraindication.

7. Other Conditions

A. Hip arthroplasty may be considered medically necessary for **ANY of the following** clinical situations:

- Acute hip fracture by imaging
- Conversion of previous surgeries of the hip due to progression of disease or failure.
Scenarios include:
 - previous closed- or open-reduction and internal fixation of the femur or acetabulum (includes hip pinning)
 - intramedullary nail
 - hemiarthroplasty
 - hip resurfacing
 - hip fusion and resection arthroplasty ("Girdlestone")

AND

B. Conservative therapy not indicated

8. Situations where hip replacement is contraindicated:

- A. Total hip arthroplasty is considered not appropriate when **ANY of the following** are present:
- Active infection of the hip joint or active systemic bacteremia
 - Active skin infection (except for recurrent cutaneous staph infections) or open within the planned surgical site of the hip
 - Underlying medical/social issues such as:
 - Unstable angina
 - Dementia that interferes with successful rehabilitation
 - Lack of caregiver/unstable home situation for rehabilitation
 - Non-ambulatory patients

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- If the orthopedist has a patient who does not meet one of the criteria above but has determined that the procedure should be performed in an inpatient setting, the orthopedist can submit a separate explanation with the request that will be reviewed by clinical staff on a case-by-case basis.
- If a patient is approved for ambulatory status under the prior authorization request but ends up staying longer than expected, the inpatient claim could be adjusted to inpatient if deemed appropriate.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

A total hip arthroplasty (aka total hip replacement, THA, THR) is one of the most common orthopedic surgeries currently performed. The surgical procedure involves removing damaged bone and cartilage of the hip joint and replacing it with a prosthetic implant. The hip joint consists of two main components: a ball (femoral head) which is the upper end of the femur (thighbone) and socket (acetabulum) which is part of the large pelvis bone. Total hip replacement surgery is most often performed due to severe pain caused by osteoarthritis (degenerative arthritis) of the hip joint that persists despite conservative treatment with non-steroidal anti-inflammatory medications, activity modification, or physical therapy. Pain from a damaged joint also limits a person's ability to carry out their everyday activities of living such as walking, bending, climbing stairs, bathing, and cooking. Other conditions that cause hip pain and loss of function that may result in the need of a total hip arthroplasty include rheumatoid arthritis, posttraumatic arthritis, avascular necrosis, and malignant tumors of the affected bones. The goal of a total hip arthroplasty is to provide pain relief and restore functional mobility and range of motion. KPWA will use commercial criteria and Medicare criteria to assure that this invasive procedure is being done appropriately to help assure both safety and efficacy.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Total Hip:

CPT® or HCPC Codes	Description
27130	Arthroplasty, acetabular and proximal femoral prosthetic replacement (total hip arthroplasty), with or without autograft or allograft
27132	Conversion of previous hip surgery to total hip arthroplasty, with or without autograft or allograft
27134	Revision of total hip arthroplasty; both components, with or without autograft or allograft
27137	Revision of total hip arthroplasty; acetabular component only, with or without autograft or allograft
27138	Revision of total hip arthroplasty; femoral component only, with or without allograft

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

Kaiser Permanente Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " Shoulder Arthroplasty - Inpatient " for medical necessity determinations. Use the Non-Medicare criteria below.

****The following codes are listed in the Medicare inpatient list and should not be reviewed for ambulatory or outpatient status for Medicare members: 23335, 23474, 27132, 27134, 27137, 27138, 27486, 27487, or 27488. These codes are applicable for ambulatory or outpatient status for all other plans.**

For Non-Medicare Members

Total hip or shoulder replacement/revision requested for ambulatory or outpatient status do not require review.

Service	Criteria
---------	----------

Total Hip Arthroplasty	<p>Effective until June 1, 2023</p> <p>For total hip replacement (27130) or revision of total hip arthroplasty (27132**, 27134**, 27137**, or 27138**) to be approved as <i>inpatient</i>, ONE of the following criteria must be met:</p> <ul style="list-style-type: none"> • Bilateral total hip • Coexisting neurologic condition (such as multiple sclerosis, history of stroke, or other neurologic conditions) where the expected length of stay is planned to be longer than 2 midnights <p>Effective June 1, 2023</p> <p>Please see link to <i>Inpatient and Clinical Review Criteria for Total Hip Arthroplasty</i> here</p>
Total Shoulder Arthroplasty	<p>For elective shoulder arthroplasty/hemi-arthroplasty (23470, 23472) or revision/replacement (23335**, 23473, 23474**) of a shoulder arthroplasty to be approved as <i>inpatient</i>, ONE of the following criteria must be met:</p> <ul style="list-style-type: none"> • Bilateral shoulder arthroplasty or hemi-arthroplasty procedures • Coexisting neurological condition (such as multiple sclerosis, history of stroke, or other neurologic conditions)
Total Knee Arthroplasty	<p>Please see link to <i>Inpatient and Clinical Review Criteria for Total Knee Arthroplasty</i> here</p>

If the orthopedist has a patient who does not meet one of the criteria above but has determined that the procedure should be performed in an inpatient setting, the orthopedist can submit a separate explanation with the request that will be reviewed by clinical staff on a case-by-case basis.

If a patient is approved for ambulatory status under the prior authorization request but ends up staying longer than expected, the inpatient claim could be adjusted to inpatient if deemed appropriate.

The above policy is pertinent only to elective shoulder arthroplasty/revision and does not apply to unplanned or urgent/emergent procedures.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist, including a history & physical

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

The Centers for Medicare & Medicaid Services (CMS) removed the Current Procedural Terminology (CPT) codes describing shoulder arthroplasty and hemi-arthroplasty procedures from Medicare's Inpatient-Only List (IPO) effective January 1, 2021. This allows shoulder arthroplasty and hemi-arthroplasty procedures to be performed on an inpatient or outpatient basis. In other words, it allows Medicare payment to be made to the hospital for shoulder arthroplasty and hemi-arthroplasty procedures regardless of whether a beneficiary is admitted to the hospital as an inpatient or as an outpatient, assuming all other criteria are met. This does not have any impact on CMS' 2-midnight policy.

CMS policy does not dictate a patient's hospital admission status and has no default determination on whether a shoulder arthroplasty or hemi-arthroplasty procedure should be done on an inpatient or outpatient basis. Rather, CMS continues its long-standing recognition that the decision to admit a patient as an inpatient is a complex

medical decision, based on the physician's clinical expectation of how long hospital care is anticipated to be necessary, and should consider the individual beneficiary's unique clinical circumstances.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Total Hip Arthroplasty:

CPT® or HCPC Codes	Description
27130	Arthroplasty, acetabular and proximal femoral prosthetic replacement (total hip arthroplasty), with or without autograft or allograft
27132	Conversion of previous hip surgery to total hip arthroplasty, with or without autograft or allograft
27134	Revision of total hip arthroplasty; both components, with or without autograft or allograft
27137	Revision of total hip arthroplasty; acetabular component only, with or without autograft or allograft
27138	Revision of total hip arthroplasty; femoral component only, with or without allograft

Total Shoulder:

CPT® or HCPC Codes	Description
23335	Removal of prosthesis, includes debridement and synovectomy when performed; humeral and glenoid components (eg, total shoulder)
23470	Arthroplasty, glenohumeral joint; hemiarthroplasty
23472	Arthroplasty, glenohumeral joint; total shoulder (glenoid and proximal humeral replacement (eg, total shoulder))
23473	Revision of total shoulder arthroplasty, including allograft when performed; humeral or glenoid component
23474	Revision of total shoulder arthroplasty, including allograft when performed; humeral and glenoid component

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

^{MPC} Medical Policy Committee

Revision History	Description
03/02/2021	MPC approved the additional codes for revision/replacement of a knee arthroplasty; Codes include 27486, 27487, or 27488. MPC approved the additional codes for revision/replacement of a hip arthroplasty; Codes include 27132, 27134, 27137, and 27138. Archived- Merged Total Knee, Total Hip and Total Shoulder criteria. Requires 60-day notice, effective date 08/01/2021.
07/27/2021	Updated policy effective date to September 1, 2021
05/03/2022	Removed Total Knee Arthroplasty from criteria page to its own separate criteria
06/21/2022	Added clarification around Medicare inpatient only list
10/13/2022	Revised effective date for updated Total Knee Arthroplasty criteria to 10/25/2022
10/18/2022	Moved Medicare IPO applicable codes up under Medicare Criteria for more clarity

12/19/2022	Removed Total Knee Codes from this criteria page as they are listed on its own separate criteria page.
01/10/2023	MPC approved to adopt coverage for Total Hip Arthroplasty. 60-day notice required; effective June 1, 2023.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Intraperitoneal Hyperthermic Chemotherapy (IPHC)

- Hyperthermic Intraperitoneal Chemotherapy (HIPEC)
- Intraoperative Chemo Hyperthermic Peritoneal Perfusion (CHPP)
- Intraperitoneal Hyperthermic Chemoperfusion (IHCP)

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Hyperthermia for Treatment of Cancer (110.1) <i>*Per NCD: Covered in connection with radiation therapy for certain types of malignancies, <u>not covered</u> in connection with chemotherapy</i>
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

Service	Criteria Used
Cytoreductive Surgery	Cytoreductive surgery and perioperative hyperthermic intraperitoneal chemotherapy may be considered medically necessary for the treatment of: <ul style="list-style-type: none"> • pseudomyxoma peritonei • diffuse malignant peritoneal mesothelioma • ovarian cancer
Perioperative Hyperthermic Intraperitoneal Chemotherapy	Cytoreductive surgery and perioperative hyperthermic intraperitoneal chemotherapy is considered investigational for: <ul style="list-style-type: none"> • peritoneal carcinomatosis from colorectal cancer, gastric cancer, or endometrial cancer; • all other indications, including goblet cell tumors of the appendix.
Intraperitoneal chemotherapy without hyperthermic methodology	Intraperitoneal chemotherapy without hyperthermic methodology is considered standard therapy and is not subject for review and is covered.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Colon Cancer

In the United States, approximately 108,070 patients are diagnosed with colon cancer (CRC) per year, and between 10-30% of these patients will develop peritoneal carcinomatosis (PC) at some point after their initial diagnosis. PC is characterized by intraperitoneal spread of tumor nodules in the peritoneum which may occur as a result of growth of the tumor and its invasion through the serosal lining of the bowel lumen, or as result of iatrogenic manipulation during surgical procedures. PC of colorectal origin has poor survival and is the second most frequent cause of death in patients with colorectal cancer (CRC), after metastatic liver disease. It has always been regarded as a terminal condition and was commonly treated only with palliative therapies (Franko 2012, Macri 2010, Ripley 2010, Chua 2012).

Over the last two decades, significant advances made in the field of cytotoxic chemotherapy and biological agents have changed the treatment of PC from a palliative to a potentially curative approach. Modern chemotherapeutic regimens have increased the response rate and median survival of patients with PC. However, few patients experience long-term survival with chemotherapy alone. In the 1980s a multimodal technique was developed to manage PC based on cytoreduction of the primary tumor, peritonectomy, and hyperthermic antitubercular peritoneal perfusion (HIPEC). Theoretically cytoreductive surgery (CRS) treats the macroscopic residual disease and intraperitoneal (IP) chemotherapy treats the microscopic residual disease. IP chemotherapy is based on the principle that a high concentration of chemotherapy within the abdominal cavity will kill the tumor cells on the surface with less diffusion into the tissues and thus are less toxicity. Hyperthermia with IP chemotherapy optimizes the process as heat has direct cytotoxic effects on cancer cells and increases the cytoactivity and penetration of certain cytotoxic drugs (Verwaal 2008, Macri 2010, Ripley 2010, Vaira 2010, Glehen 2010, Mizumato 2012, Chua 2012, Miceli 2012).

HIPEC is achieved by the intraperitoneal administration of a large volume of chemotherapeutic agents in a carrier solution through an open or closed technique. It involves the placement of one inflow and three outflow catheters in the abdominal cavity after the cytoreduction surgery. The cytotoxic agent is applied through the inflow drainage using a roller pump and heat exchanger in a closed system that allows perfusion circulation. The intraperitoneal temperature should reach 41-42°C and is monitored by two sensors placed in the inflow catheter and in the Douglas pouch. At the end of the procedure the solution is drained, and the abdominal wall is closed. There is no standardized procedure for HIPEC and there are variations between the centers in the combinations and/or concentrations for the cytotoxic agents used, as well as the intraabdominal temperature and duration of the treatment which ranges from 30 minutes to 2 hours depending on the protocol of the drug used. The combination therapy of cytoreductive surgery and HIPEC is complex, has a steep learning curve, and is associated with significant morbidity and mortality. Preoperative selection of patients to achieve complete cytoreduction plays a crucial role for the success of therapy regarding the clinical and ontological outcomes as well as the patient quality of life (Glockzin 2009, Mizumato 2012).

There is controversy around the use of cytoreduction therapy and HIPEC for peritoneal surface disease from CRC, and the procedure is not widely accepted despite the Consensus Statement (issued by representatives from the major Peritoneal Surface Malignancy Centers from around the world) on the role of cytoreductive surgery and HIPEC in the management of peritoneal surface malignancies of colonic origin (Esquivel 2007).

Ovarian Cancer

Ovarian cancer is the fifth leading cause of death in women in the US and the most common cause of death from gynecological cancer in the Western World. It was estimated that around 22,280 women will be diagnosed with ovarian cancer and that 15,500 women will die of the disease in the US in 2012. Approximately two thirds of the women are diagnosed at an advanced stage due to the nonspecific nature of the presenting symptoms of ovarian cancer and its high tendency for early peritoneal spread. Peritoneal carcinomatosis occurs through exfoliation of malignant cells into the peritoneal fluid and their dissemination along the abdominal and pelvic peritoneum. Traditionally these patients with extensive peritoneal carcinomatosis were often labeled as having terminal disease and were only given palliative therapy with no curative intent (Chua 2009, Spiliotis 2011, Chan 2012, de Bree E 2012, Mulier 2012, Siegal 2012, Tentes 2012).

The standard therapy for patients with ovarian cancer is maximal cytoreductive surgery (CRS) followed by systemic chemotherapy with a platinum-based agent and a taxane combination. Ovarian cancer is one of the most chemosensitive tumors, and its response to this initial therapy is high, but the disease often recurs, mostly locoregionally, involving the peritoneum and adjacent intra-abdominal organs. The sensitivity of epithelial ovarian

cancer to chemotherapy and its tendency to remain confined to the peritoneal cavity through much of its natural history, have led the researchers to investigate regional treatment such as intraperitoneal (IP) administration of chemotherapy (IPC). The theoretical benefits include the achievement of a high drug concentration in the peritoneal cavity without the toxic effects of the systemic chemotherapy. IP chemotherapy has been investigated in clinical trials including the Gynecologic Oncology Group (GOG-172) phase III trial that showed approximately 16 months improvement in the median survival of women treated with a combination intravenous (IV) and IP chemotherapy compared to those treated with IV chemotherapy alone, but on the expense of the increased risk of toxicity and catheter-related complications. Based on the results of this as well as other trials, the National Cancer Institute (NCI) issued a clinical announcement in 2006 recommending that women with optimally debulked stage III ovarian cancer and their physicians consider a combination of intravenous (IV) and intraperitoneal chemotherapy (IPC). IPC has limited tissue penetration and may be indicated only following optimal resection of peritoneal disease when there is either no or very small macroscopic disease remaining (<1.0 cm). The use of IPC however, is controversial and is not widely accepted by the medical community as a standard treatment in the management of advanced epithelial ovarian cancer, due to its high toxicity, catheter-related complications, and negative impact on the patients' quality of life (Almadrones 2007, Trimble 2008, Runowicz 2008, Lim 2009, Spiliotis 2011, Tentes 2012, Chan 2012, de Bree 2012).

In the last two decades researchers investigated the synergistic effect of combining regional hyperthermia and intraperitoneal chemotherapy (hyperthermic IPC, or HIPEC) together with the CRS. Theoretically, in addition its tumoricidal effect, hyperthermia increases the permeability of the drug to the tumor cells (up to 5-6 mm compared to 2-3 mm of the conventional IPC). Hyperthermia may also alter the cellular metabolism, and cellular drug pharmacogenetics. A potential advantage of administering HIPEC intraoperatively is providing superior and homogenous exposure of the seroperitoneal surface to the drug and heat before the development of adhesions. The disadvantage of HIPEC compared to IPC is the shorter tumor exposure time and its administration only once during the surgery or at the most twice when a secondary surgery is performed (de Bree 2012).

Other primary peritoneal malignancies or secondary dissemination from gastrointestinal tract or other pelvic organs.

Primary peritoneal malignancies such as peritoneal mesothelioma or papillary serous carcinoma are rare, but peritoneal dissemination from gastrointestinal tract and ovarian carcinomas are common. In the past these carcinomas were regarded as terminal and the patients were only treated with palliative measures. Over the last 30 years however, novel more aggressive treatment strategies that combine cytoreductive surgery with intraperitoneal (IP) chemotherapy were explored. Hyperthermic intraperitoneal chemotherapy (HIPEC) and early postoperative IP chemotherapy emerged as the most commonly used IP adjuvant therapies. Theoretically cytoreductive therapy treats the macroscopic disease, and intraperitoneal chemotherapy (IP) treats the microscopic disease and the residual or free tumor cells left in the peritoneal cavity after surgery, in order to prevent and control peritoneal dissemination. IP chemotherapy is based on the principle that a high concentration of chemotherapy within the abdominal cavity will kill the tumor cells on the surface with less diffusion into the tissues and less toxicity. Hyperthermia with IP chemotherapy optimizes the process as heat has direct cytotoxic effects on cancer cells and increases the cytotoxicity and penetration of certain cytotoxic drugs. Hyperthermia is also believed to modulate the cells of the innate and adaptive immune system, thereby improving effectiveness (Shen 2009, Glehen 2010, Mizumoto 2012, Sun 2012, MI 2013).

Medical Technology Assessment Committee (MTAC)

Intraperitoneal Hyperthermic Chemotherapy (IPHC)

04/02/2007: MTAC REVIEW

Evidence Conclusion: *Prevention of peritoneal carcinomatosis* Two randomized controlled trials from Japan, conducted among patients who underwent surgery for T2-T4 gastric carcinoma with serosal involvement, found a significant benefit from including HIPEC treatment. The study with the stronger methodology (Yonemura et al., 2001) found a higher estimated 5-year survival in the group receiving cytoreduction and HIPEC (61%), compared to two other groups (cytoreduction and normothermic intraperitoneal chemotherapy, 44%; and surgery alone 42%). The other RCT (Fujimoto et al., 1999) had poorly described methodology, and also found a significantly higher estimated survival rate in a group receiving cytoreduction plus HIPEC compared to surgery alone. The first study had a minimum of 2.4 years of follow-up; length of follow-up was not reported in the Fujimoto study. Findings from studies on Japanese gastric cancer may not be generalizable to the United States. *Treatment of peritoneal carcinomatosis* There is evidence from one reasonably valid randomized controlled trial that HIPEC is beneficial as a treatment for peritoneal carcinomatosis (Verwaal et al., 2003). The study, which included 105 patients with histologically proven peritoneal metastases of colorectal adenocarcinoma, compared an experimental treatment (cytoreduction and HIPEC, plus adjuvant chemotherapy) to standard treatment (outpatient chemotherapy, surgery only if necessary). After a median follow-up of 22 months, the survival rate was

significantly higher in the experimental treatment group (56% vs. 39%). Sub-group analyses suggest that survival was lower in patients with extensive residual disease or involvement of more than 5 regions of the abdominal cavity. A case series by the same research group found an estimated one-year survival of 75% and three-year survival of 28% with the experimental treatment. There were no long-term survival data for the standard treatment group. The evidence base would be strengthened with additional comparative studies.

Articles: *Prevention of peritoneal carcinomatosis* Three RCTs were identified: all were conducted by Japanese investigators. The two trials with the larger sample sizes (n=139 and n=141) were critically appraised. The third study was smaller (n=82) and had limitations including a non-significant finding with no discussion of statistical power. *Citations for the reviewed studies are as follows:* Yonemura Y, deAretxabala X, Fukimura T et al. Intraoperative chemohyperthermic peritoneal perfusion as an adjuvant to gastric cancer: Final results of a randomized controlled study. *Hepato-Gastroenterology* 2001; 48: 1776-1782. See [Evidence Table](#). Fujimoto S, Takahashi M, Mutou T et al. Successful intraperitoneal hyperthermic chemoperfusion for the prevention of postoperative peritoneal recurrence in patients with advanced gastric carcinoma. *Cancer* 1999; 85: 529-534. See [Evidence Table](#). *Treatment of peritoneal carcinomatosis:*

One RCT from the Netherlands was identified and critically appraised (Verwaal et al., 2003). There have also been a number of case series, most had sample sizes under 100. The largest case series was a multicenter study by Glehen et al., 2004 and included 506 patients. This study was limited in that it combined data from different centers that had different protocols and patient populations. All of the centers used perioperative intraperitoneal chemotherapy, but it appears that not all used hyperthermic treatment. As a result, the Glehen article was excluded from further review. The next largest case series available in English was by Verwaal et al., 2005. This article reported long-term follow-up on 117 patients, 48 of whom were included in the 2003 RCT, and was critically appraised. *The two studies reviewed were as follows:* Verwaal VJ, van Ruth S, de Bree E et al. Randomized trial of cytoreduction and hyperthermic intraperitoneal chemotherapy versus systemic chemotherapy and palliative surgery in patients with peritoneal carcinomatosis of colorectal cancer. *J Clin Oncol* 2003; 21: 3737-3743. The use of intraperitoneal hyperthermic chemotherapy (IPHC) in the treatment of peritoneal carcinomatosis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Intraperitoneal Hyperthermic Chemotherapy (IPHC)

10/16/2012: MTAC REVIEW

Evidence Conclusion: Verwaal and colleagues (2003, 2008) conducted a randomized controlled trial in one center in the Netherlands to compare the efficacy of cytoreductive surgery (CRS) and HIPEC versus systemic chemotherapy and surgery in the management of peritoneal carcinomatosis of colorectal origin. The study randomized 105 patients younger than 71 years of age, with peritoneal metastases of CRC to undergo CRS in combination with hyperthermic intraperitoneal therapy (HIPEC) or systemic chemotherapy and surgery. The authors published the results after a median of 21.6 months, and later after an extended follow-up of 91 month. The initial results of the trial showed a significantly higher median survival of the patients treated with CRS and HIPEC vs. standard therapy (22.3 months and 12.6 months respectively). After 8-years of follow-up, 9 patients were still alive. This long-term follow-up showed a median progression-free survival of 12.6 months in the CRS and HIPEC group and 7.7 months in the standard therapy group. Subgroup analyses of the results showed that patients with 6-7 regions had a very poor survival (median 5.4 months) compared to those with 0-5 regions (median >29 months), and that survival was significantly higher with success of surgical procedure i.e. complete cytoreduction. The trial had generally valid methodology; it was randomized and controlled. However, it was conducted over a decade ago and significant progress in chemotherapy has been accomplished since then. The systemic therapy with 5-FU and leucovorin used in the control group is outdated, and mitomycin-C, the HIPEC drug used in the experimental group is not the most effective drug for used for CRC. In addition, the experimental group underwent both cytoreduction and HIPEC and it is difficult to determine whether the survival benefit was due to one of the two treatment modalities or their combination, and whether heating of the chemotherapy had an additive effect to the IP therapy.

Articles: The search revealed one meta-analysis, one randomized controlled trial with long-term follow-up, and a number of observational studies with or without comparison groups. The randomized trial was selected for critical appraisal. The meta-analysis pooled the results of that RCT together with a retrospective study and was not critically reviewed. Verwaal VJ, van Ruth S, de Bree E, et al Randomized trial of cytoreduction and hyperthermic intraperitoneal chemotherapy versus systemic chemotherapy and palliative surgery in patients with peritoneal carcinomatosis of colorectal cancer. *J Clin Oncol* 2003;21:3737-3743 See [Evidence Table](#). Verwaal VJ, Bruin S, Boot H, et al 8-year follow-up of randomized trial: cytoreduction and hyperthermic intraperitoneal chemotherapy versus systemic chemotherapy in patients with peritoneal carcinomatosis of colorectal cancer. *Ann Surg Oncol*.2008; 15:2426-2432 See [Evidence Table](#).

The use of intraperitoneal hyperthermic chemotherapy (IPHC) in the treatment of peritoneal carcinomatosis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Intraperitoneal Hyperthermic Chemotherapy (IPHC)

02/11/2013: MTAC REVIEW

Evidence Conclusion: There is insufficient published evidence to determine the efficacy and safety of hyperthermic intraperitoneal chemotherapy for the treatment of patients with ovarian cancer whether as an initial therapy, consolidation therapy, or for the treatment of a persistent or recurrent disease. The published studies on HIPEC for ovarian cancer are all prospective or retrospective case series. The studies included heterogeneous groups of women of different ages, different disease characteristics, stages, and tumor load, previous use of systemic chemotherapy regimens, chemo resistance, and with different indications for HIPEC therapy (primary, consolidation, persistent, or recurrent disease after initial therapy). In addition, the published studies recruited patients over long periods of time and used different HIPEC protocols and chemotherapeutic regimens some of which were outdated by the time the studies were completed and their results published. In a small observational study, Spiliotis and colleagues (2011, evidence table 1) compared survival benefit of HIPEC for ovarian cancer among two case series: one with 24 patients treated with CRS followed by HIPEC and systemic chemotherapy, and the other with 24 were treated with CRS and systemic chemotherapy alone without HIPEC for various reasons not explained by the authors. The results of the study show that the median survival was significantly higher for those who received HIPEC vs. those who did not (19.4 months vs. 11.2 months). The 1-year and 3-year survival rates were also significantly higher among patients treated with HIPEC. Within each of the two groups survival outcomes were better among patients with less extensive peritoneal disease and more complete cytoreduction. Due to the study design, the potential selection bias and confounding, it is difficult to determine whether improved survival was due to HIPEC, successful cytoreduction, or other confounding factors. An earlier observational study (Gori et al, 2005) compared the outcomes of a second look surgery and HIPEC (4-8 weeks after standard CRS and systemic chemotherapy) in 29 patients, to the outcomes for 19 patients who refused the second look and HIPEC. All patients had stage III ovarian cancer and had undergone a primary complete or optimal cytoreductive surgery (residual lesion <2cm) and 6 cycles of systemic chemotherapy. After a median follow-up of 73 months (range 24-134 months) the results showed a higher but statistically insignificant median survival patients treated with HIPEC vs. those who refused to undergo the treatment. The results of a larger retrospective case series with a historical comparison group (Ryu et al 2004, evidence table 2) show that HIPEC may be associated with better disease response and survival in patients with ovarian cancer. However, these results must be interpreted cautiously due to the limitations of the study including but not limited to potential selection bias, confounding, and other inherent limitations of case series and the use of retrospective data. Conclusion: Overall the results of the published observational studies suggest, but do not provide sufficient evidence to conclude, that HIPEC is feasible and may improve survival in women with advanced ovarian cancer. Due to the inherent limitations of the observational studies, it is hard to ascertain the extent at which the reported survival benefit resulted from selection bias, and whether it was due to the intraoperative intraperitoneal therapy, the hyperthermia, the aggressive cytoreduction therapy, the systemic chemotherapy regimens used, or other confounding factors. It is also difficult to determine whether complications occurring after major cytoreduction surgery and HIPEC were due to the surgery itself or the HIPEC. Only well conducted, adequately powered, randomized controlled trials with long-term follow-up may determine the net clinical benefit of incorporating HIPEC in the management of patients with ovarian cancer. Currently, at least three randomized controlled trials are ongoing to investigate the efficacy and safety of adding HIPEC to primary or secondary cytoreductive surgery in women with stage III or relapsing ovarian cancer. Among these trials are the OVIHIPEC trial in the Netherlands, the CHIPOR trial in France, and the HORSE trial in Italy. Their results may answer many questions about the role of HIPEC in treating ovarian cancers, its indications, efficacy, morbidity, and net clinical benefits.

Articles: The literature search did not reveal any randomized controlled trial that compared the efficacy of HIPEC to standard therapy for treatment of women with ovarian cancer. The published studies were mainly prospective or retrospective observational studies. The search identified one retrospective review and three case series that compared the outcomes of patients undergoing HIPEC to those who refused to undergo the procedure or did not receive the HIPEC therapy for various other reasons.

Two case series that compared the outcomes of patients who received HIPEC to those of patients who did not were selected for critical appraisal. Spiliotis J, Vaxevanidou A, Sergouniotis F et al. The role of cytoreductive surgery and hyperthermic intraperitoneal chemotherapy in the management of recurrent advanced ovarian cancer: a prospective study. J Buon 2011; 16:74-75. See [Evidence Table](#). Ryu KS, Kim JH, et al. Effects of intraperitoneal hyperthermic chemotherapy in ovarian cancer. Gynecol Oncol. 2004; 94:325-332. See [Evidence Table](#).

The use of intraperitoneal hyperthermic chemotherapy (IPHC) in the treatment of ovarian cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Intraperitoneal Hyperthermic Chemotherapy (IPEC)**08/19/2013: MTAC REVIEW**

Evidence Conclusion: The current review focuses on the safety and efficacy of HIPEC therapy for non-ovarian, non-colorectal cancers with serosal invasion or peritoneal carcinomatosis. Perioperative HIPEC in combination with cytoreductive surgery was evaluated in small, randomized controlled trials and a number of meta-analyses for patients with gastric cancer. The search did not identify any RCTs or large prospective studies that evaluated HIPEC for the treatment of peritoneal mesothelioma, pseudomyxoma peritonei, or for peritoneal carcinomatosis secondary to urinary bladder cancer, or uterine leiomyosarcoma. *HIPEC for Gastric cancer:* Mi DH and colleagues' meta-analysis (2013) pooled the results of 16 trials that examined the effectiveness and safety of radical surgery (RS) combined with HIPEC vs. RS without HIPEC in 1,906 patients with histologically diagnosed, primary, locally advanced gastric cancer with macroscopic serosal invasion, but with no peritoneal or distant metastases. The primary outcome of the analysis was overall survival. The pooled results indicate that compared with surgery alone, the combination of surgery with HIPEC was associated with a significant improvement in survival rate at 1,2,3,5 and 9 years. It was also associated with a significant reduction in recurrence rates at 2, 3, and 5 years. There was however, a significantly higher incidence of abdominal pain with HIPEC. The rates of other adverse events were too small to show a significant difference. Sun and colleagues' meta-analysis (2012) also examined the effectiveness and safety of gastrectomy combined with HIPEC versus gastrectomy alone in patients with advanced gastric cancer with serosal invasion but without distant metastases or peritoneal carcinomatosis. The analysis included 10 trials with a total of 1,062 patients. The primary outcome was overall survival defined as the time from treatment to the last follow-up or death. Similar to Mi et al's analysis, the pooled results indicate that surgery combined with HIPEC may improve the overall survival for patients and prevent peritoneal local recurrence. There pooled results do not show a significantly higher risk of complications associated with HIPEC, but again the numbers were too small to provide sufficient statistical power. The two meta-analyses had had generally valid methodology and analysis. However, they had only 5 trials in common despite almost similar literature search dates. The trials included were small, all were conducted in Asia, and many were performed in the late 1980s and early 1990s and the procedures used may be currently outdated. In addition, there was no standardized agent or dose used for HIPEC; different chemotherapeutic agents were used among the trials and at different doses. The most commonly used agents in the trials were mitomycin C and cisplatin given alone, in combination together, or in combination with other agents. A small phase III RCT (Yang et al, 2011) conducted in Japan, evaluated the efficacy and safety of cytoreductive surgery (CRS) in combination with hyperthermic intraperitoneal therapy (HIPEC using mitomycin C and cisplatin) for the treatment peritoneal carcinomatosis (PC) from gastric cancer. The study randomized 68 participants to receive CRS combined with open HIPEC or CRS alone. The primary outcome was overall survival. After a median follow-up of 32 months (range 7.5-83.5 months), the results showed that patients in the CRS and HIPEC had significantly better overall survival compared to those who underwent CRS with no HIPEC. The numbers of serious adverse events were higher in the HIPEC group but were too small to allow any conclusion. *HIPEC for diffuse malignant peritoneal mesothelioma (DMPM):* Baratti and colleagues (2009) analyzed data from a prospective database for 70 patients with DMPM who were treated with cytoreduction surgery and HIPEC by the same surgical team from 1996 to 2008 at a cancer institute in Italy. Disease progression was the primary outcome of the study. This occurred among 38 (54.28%) of the participants after a median follow-up of 43 months. The median time to disease progression (TTP) among these patients was 9 months and the median survival from progression was 8 months. Failure pattern was categorized as peritoneal progression, which occurred among 31 (81.58%) patients, liver metastasis in one patient, abdominal lymph node involvement in 2, and pleural seeding in 4 patients. Residual tumor ≤ 2.2 mm was the only independent risk factor for disease progression. Progressive disease was treated with second HIPEC in 3 patients, debulking in 4, systemic chemotherapy in 16, and supportive care in 15. A multivariate analysis showed that time to progression < 9 months, poor performance status, and supportive care correlated to reduced survival from progression. These results should be interpreted with caution as the study was small, observational, conducted in a single center, and had no comparison or control group. *HIPEC for Pseudomyxoma peritonei (PMP)* In a retrospective study, Chua and colleagues (2012) reported on the outcome of nearly 2,300 patients from 16 institutions worldwide that were treated with cytoreductive surgery (CRS) and HIPEC over an 18-years period for pseudomyxoma peritonei (PMP) that arose from the appendix. The study was based on data from the Peritoneal Surface Oncology Group International registry. The median survival was 16.3 years, and the median progression-free survival was 8.2 years, with 10-year survival rate of 63% and a 15-year survival rate of 59%. The postoperative mortality rate after cytoreductive surgery and HIPEC was low (2%), but 24% of patients experienced major complications and 10% of patients required surgery for their complications. Data on quality of life were not provided. A multivariate analysis indicated that prior chemotherapy treatment, peritoneal mucinous carcinomatosis (PMCA) histopathological subtype, major postoperative complications, high peritoneal cancer index, and debulking surgery were independent predictors for a poorer progression-free survival. Use of HIPEC was associated with a favorable progression-free survival. Older age, major postoperative complications, debulking surgery, prior chemotherapy treatment, and PMCA histopathological subtype were independent predictors of a poorer overall survival. Elias and colleagues (2010) also conducted a retrospective

analysis of data from a registry with 301 patients with PMP treated with CRS and HIPEC between 1993 and 2007 in 18 French speaking centers in Europe and Canada. The mean follow-up was 88 months, the 5-year and 10-year overall survival rates were 73% and 54.8% respectively. The 5-year disease-free survival was 56%. 4.4 % of the patients died postoperatively, 40% had a grade 3-4 complication. 17.5% of all patients required a re-operation due to complications. These results of these retrospective analyses should be interpreted with caution due to the methodological limitations of retrospective studies, and lack of control groups. Conclusion: There is some evidence from small RCTs conducted in Asia, and meta-analyses pooling their results that cytoreductive surgery combined with intraperitoneal hyperthermic chemotherapy may improve the overall survival in patients with advanced gastric cancer without macroscopic peritoneal carcinomatosis or distant metastases. There is insufficient evidence to determine the subgroup of patients with gastric cancer who would benefit most from HIPEC as the effectiveness of HIPEC may depend on size and depth of micrometastases. There is insufficient evidence to determine the optimal regimen for HIPEC. There is insufficient evidence to determine the efficacy of HIPEC in patients with peritoneal carcinomatosis from gastric cancer. There is insufficient evidence to determine the safety of HIPEC or its effect on the quality of life in patients with gastric cancer with or without dissemination to the peritoneum. There is insufficient evidence to determine the safety and efficacy of HIPEC for the treatment of other peritoneal malignancies, whether of a primary origin or peritoneal carcinomatosis secondary to cancer in other organs within the peritoneal cavity.

Articles: The literature search for studies on the efficacy and safety of HIPEC in patients with pseudomyxoma peritonei, GI cancers (other than colorectal cancer) identified two recent meta-analyses of RCTs, two older ones, and a phase III RCT on HIPEC for patients with gastric cancer. The search did not reveal any RCTs that evaluated HIPEC for primary peritoneal malignancies, or other peritoneal disseminations from other cancers evaluated in this review. The published studies were mainly small prospective or retrospective case series with no comparison or control groups. The two more recent meta-analyses and the RCT that evaluated the efficacy and safety of HIPEC for gastric carcinoma were selected for critical appraisal.

The use of intraperitoneal hyperthermic chemotherapy (IPHC) in the treatment of Gastric, DMPM, and PMP cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Medicare – Considered not medically necessary for use of hyperthermia with chemotherapy

Non-Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
77600	Hyperthermia, externally generated; superficial (ie, heating to a depth of 4 cm or less)
77605	Hyperthermia, externally generated; deep (ie, heating to depths greater than 4 cm)
77610	Hyperthermia generated by interstitial probe(s); 5 or fewer interstitial applicators
77615	Hyperthermia generated by interstitial probe(s); more than 5 interstitial applicators
77620	Hyperthermia generated by intracavitary probe(s)

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

08/02/2016	Removed the diagnosis, Pseudomyxoma Peritonei (PMP), from the non-covered list
05/22/2020	Added CPT codes 77600, 77610, 77615, 77620 and removed 96446.
03/01/2022	Added ovarian cancer to the list of medically necessary diagnoses.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Intense Pulsed Light (IPL) for Meibomian Gland Dysfunction

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, Intense Pulsed Light (IPL) for Meibomian Gland Dysfunction , for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Meibomian glands are located in the eyelids and secrete lipids into the surface of the eye. These lipids prevent the tears from evaporating rapidly. Meibomian gland dysfunction (MGD) is an abnormality or obstruction of meibomian glands leading to evaporation of the tears which in turn results in dry eye. Increased evaporative loss results in tear film instability, hyperosmolarity and lacrimal system inflammation (<https://www.uptodate.com/contents/dry-eye-disease>).

Meibomian gland dysfunction affects 70% of the population in some parts of the world (Craig, Chen, & Turnbull, 2015). Risk factors include age (the risk of MGD increases with age), ethnicity (Asians have high risk of MGD), eye makeup, contact lenses. The pathophysiology of MGD is multifactorial; it includes inflammation, bacterial overgrowth, abnormal blood vessel growth around the meibomian gland, and abnormal meibum production (Sabeti, Kheirkhah, Yin, & Dana, 2019).

Clinical symptoms include dryness, red eyes, general irritation, gritty sensation, burning, paradoxical excessive tearing, and decreased visual acuity (<https://www.uptodate.com/contents/dry-eye-disease>).

Treatment of MGD includes artificial tears, heat application, manual gland expression, warm compresses, lubricants with fatty acids, omega-3 supplementation, topical antibiotics, oral antibiotics, corticosteroids, or topical cyclosporine (Craig et al., 2015; Dell, Gaster, Barbarino, & Cunningham, 2017). However, these therapies come with adverse events, are temporarily effective and both physicians and patients are unsatisfied (Craig et al., 2015). IPL has garnered interest due to its concomitant effectiveness on ocular and dermatological manifestations in patients with rosacea. However, the mechanism by which this occurs is not well understood (Rennick & Adcock, 2018).

The most common indication for IPL has been skin disorders such as rosacea and acne. Regarding this treatment, the skin is exposed to the light with wavelengths from 500 to 1200 nm. The targeted tissue absorbed the light. This generates heat which destroys the lesions (Craig et al., 2015). In addition, the wavelengths stimulate melanin and hemoglobin in the skin causing coagulation and ablation of blood vessels ((Gao et al., 2019); Rennick & Adcock, 2018) and suppressing inflammation. IPL can also eliminate bacteria on treated zones of the skin. The theory is that IPL should improve MGD. There are several mechanisms by which IPL enhances MGD: heating, occlusion of abnormal blood vessels, liquefaction of meibum improving secretion and excretion, reduction in epithelial turnover, local photomodulation, activation of fibroblasts, enhancement of collagen synthesis, and destruction of Demodex mites (Sabeti et al., 2019).

The procedure starts with placement of shields over the eyes. This serves as protection from the light. A cooling gel is then applied to the area followed by administration of pulsed light around the eyelids. Manual gland expression is then performed, and normal oil flow is restored in the tear film. The procedure lasts approximately 20 minutes and is performed once a month for four months (<https://www.theeyeinstitute.com/dry-eye/intense-pulsed-light-ipl-treatment/>). Gao et al., 2019 (Gao et al., 2019) applied lidocaine cream for anesthesia for 30 minutes before placing the protective shield and administering IPL. Indications include rosacea, acne, MGD. Other indications include hypertrichosis, benign cavernous hemangiomas, benign venous malformations, telangiectasia, and pigmented lesions. It is also used in the cosmetic industry (Craig et al., 2015). IPL can only be used for patients whose skin is Fitzgerald type four or below (<https://www.reviewofophthalmology.com/article/intense-pulsed-light-for-treating-dry-eye>).

Medical Technology Assessment Committee (MTAC)

Intense Pulsed Light (IPL) for the treatment of meibomian gland dysfunction (MGD)

01/13/2020: MTAC REVIEW

Evidence Conclusion:

The evidence consists of six small randomized controlled trials. One RCT compared intense pulsed light (IPL) to tobramycin/dexamethasone, three RCTs compared IPL plus meibomian gland expression to meibomian gland expression alone, and two other RCTs compared IPL vs sham. Statistically significant reduction of symptoms was found in each study. In addition, IPL appears to be safe as no serious adverse events were reported. However, the studies have small sample size, short follow-up, the risk of bias is not low, power calculations were not consistently provided. High-quality studies with large sample size and long-term follow-up are warranted. The findings are promising.

Overall, the evidence is not sufficient to draw overarching conclusions on the effectiveness and safety of intense pulsed light for the treatment of meibomian gland dysfunction.

Articles: PubMed search was conducted up to December 2, 2019 with the search terms (intense pulsed light OR intense-pulsed-light OR intense pulse light OR intense-pulse-light OR IPL) AND (dry eye OR DED OR meibomian OR MGD OR meibomian gland dysfunction). The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. Non-randomized controlled trials were excluded. Only randomized controlled trials were included in the review. The search yielded several articles. However, seven RCTs were retained and reviewed. See [Evidence Table](#).

The use of Intense Pulsed Light (IPL) for the treatment of meibomian gland dysfunction (MGD) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Not Medically Necessary:

CPT® Codes	Description
0207T	Evacuation of meibomian glands, automated, using heat and intermittent pressure, unilateral

0507T	Near-infrared dual imaging (ie, simultaneous reflective and trans-illuminated light) of meibomian glands, unilateral or bilateral, with interpretation and report
0563T	Evacuation of meibomian glands, using heat delivered through wearable, open-eye eyelid treatment devices and manual gland expression, bilateral
<i>May be submitted with unlisted code 17999 and ICD-10 codes H02.88-H02.88B</i>	Unlisted procedure, skin, mucous membrane and subcutaneous tissue
	Meibomian gland dysfunction of eyelid

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Islet Cell Transplantation in the Context of a Clinical Trial (260.3.1)
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Some patients with Type I diabetes fail to obtain adequate glucose control despite insulin treatment. Pancreas allo-transplantation can restore metabolic control, but this procedure is limited by a shortage of donor organs and a complex surgical procedure with associated morbidity and mortality. Transplantation of pancreatic islet cells is a possible alternative treatment. The islet of Langerhans cells contains insulin-secreting *b* cells and make up only about 1% of the whole pancreas.

In the early 1970s, researchers found that islet cell transplantation could be used to treat diabetes in rats. Since that time, there have been attempts to apply this treatment to humans. Most of the applications of this procedure were unsuccessful; the Islet Transplant Registry estimated in 1996 that only 6 percent of islet transplantations done between 1990-1996 were successful (success defined as not needing insulin treatment for a year after transplantation).

Medical Technology Assessment Committee (MTAC)

Islet Cell Transplantation

10/11/2001: MTAC REVIEW

Evidence Conclusion: To date, there has been one report of some success with islet cell transplantation in 7 patients; only 3 of these were followed-up for at least a year. The effectiveness of islet cell transplantation for type 1 diabetes cannot be determined based on the current published scientific evidence. A randomized controlled trial, which will provide higher-quality data, was recently initiated by the Juvenile Diabetes Foundation and the National Institutes of Health to study the effectiveness of islet cell transplantation.

Articles: The searches yielded 60 articles. These were predominantly review articles and articles on technical aspects of the procedure. There were no randomized controlled trials or meta-analyses. There were 3 empirical articles with clinical outcomes; all were case series studies with sample sizes less than n=10. An evidence table was done for the case series that used the most up-to-date techniques: Shapiro AMJ, Lakey JRT, Ryan EA, Korbitt GS, Toth E, Warnock GL, Kneteman NM, Rajotte RV. Islet cell transplantation in seven patients with type 1 diabetes mellitus using a glucocorticoid-free immunosuppressive regimen. NEJM 2000; 343: 230-8. See [Evidence Table](#).

The use of Islet Cell Transplantation in the treatment of diabetes does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered not medically necessary

CPT® Codes	Description

CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article (LCA)	None
Kaiser Permanente Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " Jaw Motion Rehabilitation Device ," for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

Jaw motion rehabilitation system is medically necessary to treat mandibular hypomobility when caused by radiation therapy in persons with head and neck cancer.

It is **not medically necessary** for any other indication, as there is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Last 6 months of radiology notes if applicable

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Trismus, defined as a tonic spasm of the muscles of mastication from diseases of the trigeminal nerve, is often used to describe mandibular hypomotility of any cause. Mandibular hypomotility is a common symptom in patients suffering from temporomandibular disorders as well as variety pathologies of the masticatory system. It may be related to intra- or extra-articular conditions such as synovitis, osteoarthritis, fibrosis, facial space infections, coronoid hyperplasia, fibrosis following radiation therapy, and tumors involving the head and neck regions. Patients with mandibular hypomotility experience limitations during eating, speaking, and with oral hygiene (Israel 1997, Cohen 2005, Melchers 2009).

The temporomandibular joint (TMJ) is a synovial joint that functions according to the same biological rules as other synovial joints and follows the same principles of joint motion and rehabilitation. Several manual, mechanical, and electromechanical approaches have been used for TMJ mobilization and increasing mouth

opening. The most common methods used are isometric and range of motion exercises, tongue depressor therapy, and mechanical stretching devices (Israel 1997).

The Therabite System (Therabite Corporation, Bryn Mawr, PA) is a handheld patient controlled, mechanical device with two mouthpieces that are inserted between the teeth of the upper and lower jaw. By squeezing the handles, the mouthpieces open and assist the opening of the mouth. The horseshoe-shaped surfaces on the arms come in contact with the teeth and spread the load across 10 anterior teeth in each jaw. This generates less force on the incisors than spatulas or screws and makes the Therabite appliance more comfortable to use. The force applied by squeezing and releasing the handle stretches the fibrosis intermittently. Maximum device opening can be adjusted between 25 and 45 mm using a single screw and can be sequentially increased by the patient or clinician. Similar to other exercise regimens and physiotherapy, the patient must be motivated and must use the device correctly and regularly. Adherence to exercise regimens has a positive effect on outcome, and poor adherence may be a barrier to treatment success (Buchbinder 1993, Gibbons 2007, Melchers 2009).

Medical Technology Assessment Committee (MTAC)

Jaw Motion Rehabilitation Device

04/16/2012: MTAC REVIEW

Evidence Conclusion: In a relatively small unblinded, randomized, controlled trial, Maloney and colleagues (2002) compared the effectiveness of a passive jaw motion device (Therabite) and wooden tongue depressors (WTD) in patients with temporomandibular joint and muscle disorders that did not respond to manual manipulation and bite plane therapy. The authors did not discuss the cause of mouth opening restriction. After undergoing manual manipulation of the mandible combined with flat bite plane therapy for 4 weeks, eligible patients were randomly assigned to one of three treatment groups: Therabite group, wooden tongue depressor group, or control group. Patients in the first 2 intervention groups received treatment for 4 weeks, and the control group received a total of 8 weeks of flat bite plane therapy only. The authors did not discuss compliance with therapy or completeness of follow-up. The results of the trial show that passive jaw motion therapy using Therabite was more effective than using wooden tongue depressor in reducing pain and increasing the maximum interincisal opening.

In a smaller RCT, Buchbinder and colleagues (1993) compared the use of Therabite system plus unassisted exercise vs. tongue blade therapy plus unassisted exercise, or unassisted exercise only for 10 weeks in 21 patients with decreased interincisal opening secondary to radiation therapy after head and neck cancer resection. The initial average maximum interincisal opening (MO) was 21.6 mm. All three groups showed an initial increase in the MO in the first 4 weeks, after which there was only minimal further gain in the unassisted exercise group with or without tongue blade therapy. After 6 weeks of treatment, the net increase in MO in the Therabite group was significantly greater than either of the other 2 groups. In conclusion, evidence from two small RCTs suggest that passive jaw motion rehabilitation using Therabite device may be more effective than unassisted exercise, manual manipulation, and bite plane therapy with or without tongue blade therapy in reducing pain and improving maximum interincisal opening in patients with mandibular hypomobility.

Articles: The literature on the use jaw motion rehabilitation devices for patients with mandibular hypomotility is limited. Only two small RCTs comparing TheraBite to other treatment were identified and critically appraised, Maloney GE, Mehta N, Forgione AG, et al. Effect of a passive jaw motion device on pain and range of motion in TMD patients not responding to flat plane intraoral appliances. *Cranio*. 2002; 20:55-66. See [Evidence Table](#). Buchbinder D, Currivan RB, Kaplan AJ, et al. Mobilization regimens for the prevention of jaw hypomobility in the radiated patient: a comparison of three techniques. *J Oral Maxillofacial Surg*. 1993; 51:863-867.

The use of jaw motion rehabilitation device for mandibular hypomobility does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article (LCA)	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " <i>Ketamine for the Treatment of Depression and Other Psychiatric Disorders</i> " for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

Ketamine (intranasal, intravenous, or subcutaneous) is considered experimental and investigational as its clinical value has not been established. Non-covered diagnoses include but are not limited to:

- Chronic pain
- Depression
- Generalized anxiety and social anxiety disorders
- Substance use disorder
- Suicidal ideation

*Esketamine nasal spray (Spravato) has separate criteria for pharmacy review:

<https://wa-provider.kaiserpermanente.org/static/pdf/provider/clinical-review/list-officeinject.pdf>

For non-covered criteria

If requesting review for this service please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Hayes Review

Ketamine Infusion for Treatment-Resistant Bipolar Depression

Conclusion - D²

A small body of very low-quality evidence found that ketamine infusion rapidly reduces symptoms of severe bipolar depression. Although the antidepressant effects appear to last for only a few days, this can be clinically significant if it improves the mood of severely depressed, potentially suicidal patients. In all of the studies, only a single dose of ketamine was administered; the safety and effectiveness of repeated administration of ketamine for treatment of bipolar depression is unknown. The evidence suggests that ketamine is reasonably safe. Additional large, well-designed studies with adequate follow-up are needed to evaluate the long-term effects of prolonged ketamine treatment.

Insights

- Ketamine is administered by infusion because it does not have good bioavailability via alternative routes, such as oral or intramuscular injection.
- The low oral bioavailability and potential for abuse makes ketamine an unlikely first- or second-line therapy for bipolar depression.
- Persons with bipolar disorder are more apt to seek medical attention when they are depressed; therefore, a careful medical history must be obtained to avoid misdiagnosis of the patient's disorder as major depression.
- None of the reviewed payers had policies available for the use of ketamine to treat bipolar depression.

Ketamine as Primary Therapy for Treatment-Resistant Unipolar Depression Or Posttraumatic Stress Disorder

Conclusion- C (For ketamine as a treatment for treatment-resistant unipolar depression)

D2 (For ketamine as a treatment for posttraumatic stress disorder (PTSD)).

A moderate-size body of low-quality evidence has consistently found that ketamine reduces symptoms of severe treatment-resistant unipolar depression, symptoms of PTSD, or suicidal ideation at short-term follow-up of 1 to 3 days posttreatment; however, the findings at longer-term follow-up of 1 to 4 weeks are mixed. The majority of the studies administered only a single dose of ketamine; the safety and effectiveness of repeated administration of ketamine for treatment of depression or PTSD is unknown. The evidence suggests that ketamine is reasonably safe if complications are properly managed. Additional large, well-designed studies with adequate follow-up are needed to evaluate the long-term effects of prolonged ketamine treatment, to assess simplified ketamine administration via intranasal or subcutaneous routes, to determine the efficacy and safety of ketamine for PTSD treatment, and to evaluate the efficacy and safety of ketamine relative to ECT for unipolar depression.

Insights

- The low oral bioavailability and potential for abuse makes ketamine an unlikely first- or second-line therapy for treatment-resistant unipolar depression or PTSD.
- The reviewed studies found that ketamine is consistently beneficial for 24 hours posttreatment; however, the durability of results at 1 to 4 weeks posttreatment are mixed. Thus, it is unclear whether ketamine provides durable relief of depression or PTSD symptoms.
- As the beneficial effects of ketamine may be limited to 24 hours posttreatment, it is important to establish the safety and effectiveness of repeated administration of ketamine. There is currently a paucity of studies investigating repeated administration of ketamine for unipolar depression or PTSD.
- Several representative payer organizations do not have coverage policies for ketamine monotherapy for unipolar depression or PTSD.

Applicable Codes**Considered Not Medically Necessary - experimental, investigational or unproven:**

CPT® or HCPCS Codes	Description
J3490	Unclassified drugs
<i>Commonly submitted with CPT code(s) 96365, 96366, 96367, or 96368</i>	
ICD-10 Codes	Description

Criteria

For Medicare Members

Source	Policy
Chapter Manual	Medicare Benefits Manual Chapter 11 – End Stage Renal Disease Section 140 - Transplantation
National Coverage Determination (NCD)	Thoracic Duct Drainage (TDD) in Renal Transplants (20.3) Dental Examination Prior to Kidney Transplantation (260.6) Nonselective (Random) Transfusions and Living Related Donor Specific Transfusions (DST) in Kidney Transplantation 110.16
Local Coverage Determination (LCD)	None

For Non-Medicare Members

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. Kidney transplantation is the preferred renal replacement therapy for almost all patients with chronic kidney disease. Most patients with chronic kidney disease or end stage renal disease should be considered for kidney transplant evaluation. However, the patient must have adequate social support systems and a proven record of adherence to medical treatment. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral. Referral to a regionally contracted transplant center for kidney transplant does not guarantee that the patient will be listed or transplanted. These are decisions made at the Transplant Center's discretion.

1. GENERAL PRINCIPLES

- If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, then early referral should be made.
- Patients with a history of malignancy with a moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- Uncontrollable active infection is a contraindication to transplant.
- Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low.^{1,2,3} Exceptions may be made on a case-by-case basis.
- Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products in order to be actively listed.
- Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
- Patients must be willing and able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.

- h. Patients must have a care giver or care givers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
- i. The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.
- j. Evidence of such nonadherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- k. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

2. INDICATIONS FOR KIDNEY TRANSPLANT

Most patients with kidney failure can be considered for transplantation. It is important to note that these are guidelines and should be applied together with careful clinical judgment. The aim is to perform pre-emptive renal transplantation without initiation of standard kidney replacement therapy (hemodialysis/peritoneal dialysis).

- a. All pediatric and adult patients who require dialysis or are expected to require dialysis within the next 12 months can be considered candidates. If possible, patients should be evaluated prior to this time to discuss options for renal replacement therapy.
 - 1. Patients with an estimated GFR ≤ 30 should be informed of, educated about, and considered for potential referral for transplantation.⁴
- b. Known Type 2 diabetes patients, sometimes referred to as type 1.5 diabetes, with BMI <28 , who require low-dose insulin, may be considered for SPK. Input from endocrinology may be needed.
- c. Patients cannot be listed on the UNOS waiting list for a deceased donor kidney until their estimated GFR, calculated by the CKD-EPI creatinine equation (2021) that are refitted without race or the CKD-EPI creatinine-cystatin equation (2012) that are refitted without race, is less than 20ml/min.^{5,6,7}
- d. Estimated GFR for the pediatric population using the Schwartz formula of 10 – 15, or sooner if symptomatic. Symptomology is defined as poor growth/failure to thrive and suboptimal energy level despite adequate caloric support. Patients with estimated GFR <30 may be referred early.

CONTRAINDICATIONS FOR KIDNEY TRANSPLANT

- a. Significant irreversible coronary artery disease and/or left ventricular dysfunction, and irreversible pulmonary disease.
- b. Irreversible peripheral vascular disease, including carotid vascular disease. (Amputation alone is not a contraindication)
- c. Uncontrolled hypertension.

RELATIVE CONTRAINDICATIONS FOR KIDNEY TRANSPLANT

- a. Patients with a BMI ≥ 40 may be referred to the COE for individual consideration and concurrently referred for weight loss intervention.
- b. Active nicotine abuse.
- c. Age: There is no firm upper limit cut-off for kidney transplantation.
- d. When considering candidacy, close attention should be paid to concurrent conditions, such as frailty, that would increase the risk of morbidity and mortality.
- e. Presence of other significant, permanent, irreversible organ failure.

- Copy of final summary report from multidisciplinary transplant team

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage

Background

Kidney transplant is a surgical procedure to implant a healthy kidney into a patient with kidney disease or kidney failure. The kidney transplant may be taken from a living donor or from a recently deceased donor.

The transplant is conducted when the patient has non-reversible, end stage renal failure with a glomerular filtration rate 20 mL/min/1.73m² (0.33 mL/sec/1.73m²) or less. There are several causes for renal failure, but the most common cause is diabetes or hypertension.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	Medicare Benefits Manual Chapter 11 – End Stage Renal Disease Section 140 - Transplantation
National Coverage Determinations (NCD)	Pancreas Transplants (260.3)
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

Note: Simultaneous Pancreas Kidney Transplantation (SPK)¹

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral. It is important to note that these are guidelines and should be applied together with careful clinical judgment. Patient and treating physician should understand the uncertain benefits of successful pancreas transplantation beyond glucose control.

1. GENERAL PRINCIPLES

- If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, then early referral should be made.
- Patients with a history of malignancy with a moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- Uncontrollable active infection is a contraindication to transplant.
- Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low^{2,3,4}. Exceptions may be made on a case-by-case basis.
- Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products in order to be actively listed.
- Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
- Patient must be willing and able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.
- Patient must have a care giver or care givers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
- The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.

- j. Evidence of such non adherence may be: failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- k. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation

2. INDICATIONS FOR SPK TRANSPLANT

- a. Type 1 (as verified by stimulated C-peptide testing or presence of antibodies to glutamic acid decarboxylase, islet cell, insulin, etc.) diabetes mellitus with or approaching end stage renal disease. A diagnosis of Type 1.5 diabetes mellitus may be needed by endocrinology.
 - 1. In selective situations, known Type 2 Diabetes Mellitus patients (also referred to as Type 1.5 DM) with low C peptide and a low BMI (<28), requiring low dose insulin with end stage renal disease or advanced CKD may be considered for SPK.
- b. Optimally and intensively managed by an endocrinologist for at least 12 months for Type 1 diabetes mellitus.⁵
- c. Age 18-55, except under special clinical circumstances.
- d. Must be a candidate for kidney transplantation. Patients cannot be listed on the UNOS waiting list for a deceased donor kidney until their estimated GFR, calculated by the CKD-EPI creatinine equation (2011) that are refitted without race or the CKD-EPI creatinine-cystatin equation (2012) that are refitted without race, is less than 20ml/min.^{6,7,8}

CONTRAINDICATIONS FOR SPK TRANSPLANT

- a. Significant irreversible coronary artery disease and/or left ventricular dysfunction, and irreversible pulmonary disease.
- b. Irreversible peripheral vascular disease, including carotid vascular disease. (Amputation alone is not a contraindication)
- c. Uncontrolled hypertension.

RELATIVE CONTRAINDICATIONS FOR SPK TRANSPLANT

- a. BMI ≥ 35. Patients may be referred to the COE for individual consideration
 - i. May be concurrently referred for weight loss intervention.
- b. Cachexia and/or malnourishment

Footnotes

1. In certain situations where the NTS COE recommends, in discussion with the patient, to proceed with a staged transplant procedure (living donor kidney followed by cadaveric pancreas transplant) due to organ availability, the patient will need to meet the indications for a SPK transplant.

Kyphoplasty

- I. Percutaneous balloon kyphoplasty may be considered medically necessary for the treatment of no more than 3 symptomatic vertebral fractures of the **T5-L5** spine when **ALL of the following criteria are met:**
 - A. Appropriate imaging (plain film x-ray or MRI) has been performed preoperatively and the findings of such imaging correlate unequivocally with the patient's pain; **and**
 - B. There is documentation in the medical record that the member's pain is predominantly, if not solely, related to the demonstrated fracture(s); **and**
 - C. The member has failed to respond to conservative treatment (e.g., analgesics, physical therapy, rest) for at least 6 weeks; **and**
 - D. Prior to the procedure a documented assessment confirms the absence of the following contraindications:
 1. Chronic (>12 months) fracture at the same vertebral level
 2. Untreated symptomatic foraminal or canal stenosis, facet arthropathy, or other significant coexistent spinal or bony pain generators
 3. Bone fragment retropulsion
 4. Symptoms that cannot be related to a fracture
 5. Unstable fracture or requirement for stabilization procedure in same or adjacent spinal region
 6. Active osteomyelitis whether fungal, bacterial or mycobacterial, or any other active infection, including urinary tract infection (UTI)
 7. Uncorrected coagulation disorders
 8. Known allergy to any of the materials used in these procedures
- II. Percutaneous kyphoplasty with a balloon device is not covered for all other indications, including but not limited to the following:
 - A. Acute vertebral fractures due to osteoporosis or trauma (before 6 weeks of conservative therapy as noted above)
 - B. Vertebrae of the cervical spine and thoracic levels T1-5

- C. Stabilization of insufficiency fractures or lesions of the sacrum (sacroplasty) or coccyx (coccygeoplasty)
 - D. Prophylactic treatment for osteoporosis of the spine or for chronic back pain of long-standing duration, even if associated with old compression fracture(s).
 - E. Absence of a confirmed acute or subacute fracture
 - F. Symptoms that cannot be related to a fracture;
 - G. Radicular symptoms that are explained by bone impinging on nerves or another anatomic lesion;
 - H. Unstable fracture;
 - I. Asymptomatic vertebral compression fracture;
 - J. Active osteomyelitis, whether fungal, bacterial or mycobacterial;
 - K. Burst fracture with retropulsed fragments demonstrated by imaging study;
 - L. Uncorrected coagulation disorders; and
 - M. Known allergy to any of the materials used in either procedure
 - N. Compression fractures shown by the medical record to be more than one year old.
- III. Percutaneous vertebral augmentation by any technique other than inflatable balloon is not covered which includes but not limited to the following:
- A. Vertebroplasty – [See separate criteria for vertebroplasty](#)
 - B. Radiofrequency-assisted vertebral augmentation with ultrahigh viscosity cement, including but not limited to Radiofrequency-Targeted Vertebral Augmentation™ (RF-TVA™) with the StabiliT® System
 - C. Mechanical vertebral augmentation using any device other than a balloon device, including but not limited to use of the following:
 - 1. Use of the Kiva® system

Vertebroplasty

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

Effective October 1, 2022

Kaiser Permanente has elected to use coverage guidance from the Noridian Local Coverage Determination (LCD) [L34106 Percutaneous Vertebral Augmentation \(PVA\) for Osteoporotic Vertebral Compression Fracture \(VCF\)](#) for medical necessity determinations for non-Medicare members.

*Note: Provisions in the LCD and related coding article only address Vertebral Augmentation for Osteoporotic Vertebral Compression Fracture (VCF). Coverage will remain available for medically necessary procedures for other conditions not included in the LCD, such as other pathologic vertebral compression fractures.

Percutaneous vertebral augmentation is not covered if the procedure includes the following:

- A. Radiofrequency-assisted vertebral augmentation with ultrahigh viscosity cement, including but not limited to Radiofrequency-Targeted Vertebral Augmentation™ (RF-TVA™) with the StabiliT® System
- B. Mechanical vertebral augmentation using any device other than a balloon device, including but not limited to use of the following:
 - 1. Use of the Kiva®

Percutaneous Sacroplasty – there is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Vertebral compression fractures (VCFs) occur when the bones of the spine become compressed and break. It is

estimated that about five million new vertebral fractures occur worldwide each year. Most common in elderly populations and females, osteoporosis is responsible for more than 1.5 million fractures annually, the majority of which are vertebral. Other potential causes of VCFs include trauma, steroid use, malignancy in the vertebrae, and haemangioma. In any case, VCFs can be asymptomatic and resolve without treatment, however, they are frequently associated with pain, disability, and reduced quality of life (QoL). To add to this, VCFs are a risk factor for subsequent fractures which can lead to additional complications such as kyphosis, impairment of mobility or balance, and increased mortality to name a few (Chitale and Prasad 2013).

The majority of patients with VCFs are successfully treated with conservative management aimed to alleviate symptoms via external bracing, decreased activity and analgesics. Some patients, however, will experience persistent pain and symptoms refractory to medical therapy and may require additional intervention.

Over the last twenty years, two minimally invasive techniques to augment the vertebral bodies and reduce pain have been developed as a treatment option for refractory VCFs. The first technique, percutaneous vertebroplasty, was first introduced in France by Deramond and colleagues in 1984 and later, in 1993, was introduced into clinical practice in the United States (US). The procedure, initially performed to strengthen vertebrae weakened by angiomas, involved injection of polymethylmethacrylate (PMMA) into a collapsed vertebral body under fluoroscopic guidance (Deramond, Depriester et al. 1998). Since then, however, indications for vertebroplasty have expanded to include metastatic vertebral cancer, multiple myeloma, as well as, osteoporotic VCFs that have not responded to conservative therapy. The second procedure, kyphoplasty, was devised in 1998 after mounting concerns over flaws in the vertebroplasty technique. With the same aims and desired outcomes as vertebroplasty, kyphoplasty employs the use of inflatable balloon tamps to restore vertebral height and reduce kyphotic deformity before stabilization with PMMA. It is believed that the cavity formation and the use of more viscous cement introduced with less pressure, compared to vertebroplasty leads to lower risk of cement extravasation (Atalay, Caner et al. 2005; Wardlaw, Cummings et al. 2009).

Medical Technology Assessment Committee (MTAC)

06/07/2001: MTAC REVIEW

Kyphoplasty

Evidence Conclusion: The published evidence consists of one poorly described case series that is insufficient to draw conclusions about the safety and efficacy of kyphoplasty.

Articles: The literature search yielded one published article. The article reported on a study using cadavers and does not have data appropriate for MTAC review. One other published article was received from Kyphon. This was largely a review article; it included one paragraph about the use of the kyphoplasty procedures. No details on study methodology were given so that this study also could not be evaluated. There is also one article documented to be in-press in Spine. An evidence table was created for this case series. Lieberman IH, Dudeney S, Reinhardt M-K, Bell G. Initial outcome and efficacy of "kyphoplasty" in the treatment of painful osteoporotic vertebral compression fractures. Spine 2001; in-press. See [Evidence Table](#).

Kyphoplasty for the treatment of vertebral body compression fractures refractory to maximal medical management does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

07/14/2004: MTAC REVIEW

Kyphoplasty

Evidence Conclusion: The evidence is insufficient to draw conclusions about the safety and efficacy of kyphoplasty. It consists of two small (fewer than 30 patients) case series, one published in 2001 and one with the abstract published electronically in April 2004 ahead of the print version.

Articles: The search yielded 41 articles, most of which were discussion pieces and technical reports. The single new empirical study was an "electronic publication ahead of print" and was not yet available. An inspection of the abstract showed that this was a case series with 27 patients.

Kyphoplasty for the treatment of vertebral body compression fractures refractory to maximal medical management does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

06/06/2005: MTAC REVIEW

Kyphoplasty

Evidence Conclusion: There are no randomized controlled studies that compared the short and long-term outcomes of kyphoplasty with those of the more conservative standard therapies. The Grohs' study compared

kyphoplasty head to head with vertebroplasty however, it was small, nonrandomized and unblinded. Postoperative comparison was made versus baseline condition for each intervention with no direct comparison between the two techniques. The results of the study show that both procedures offered significant pain relief, which was maintained at a lower level with the kyphoplasty. The functional disability on the other hand was significantly improved only with kyphoplasty and not vertebroplasty. The observed improvement was statistically significant for the first year only. The results of the study also indicate that the rate of fracture of an adjacent vertebra seems to be higher with the kyphoplasty vs. vertebroplasty (21% vs. 4%). The other article reviewed was a case series with some advantages: it was relatively large, had inclusion/exclusion criteria, and had objective outcomes. However, like all case series it lacks a control or comparison group and has potential selection and observation bias. Overall its results showed that the pain was completely relieved in 78% of the patients, and, that the vertebral height significantly improved after kyphoplasty. There were no long-term follow-up data to determine the long-lasting effects or late complications of the intervention. In conclusion, the published literature does not provide sufficient evidence to determine the effects of the procedure on the spine, or its long-lasting effect on pain relief. A European multicenter prospective randomized controlled trial comparing kyphoplasty with the standard pharmacological therapy is underway (Ohlin 2004).

Articles: The search yielded 70 articles, most of which were review articles, discussion pieces and technical reports. There was no randomized controlled trial that compared the short and long-term outcomes with conservative therapies. The search revealed a recent nonrandomized study that compared kyphoplasty head-to-head with percutaneous vertebroplasty, as well as several small prospective case series, and retrospective reviews of cases that underwent the procedure. *The following controlled study, as well as the largest case series (N=222), were selected for critical appraisal:* Grohs JG, Matzner M, Trieb K, et al. Minimal invasive stabilization of osteoporotic vertebral fractures. A prospective nonrandomized comparison of vertebroplasty and balloon kyphoplasty. *J Spinal Disord Tech* 2005; 18:238-242. See [Evidence Table](#). Majd ME, Farley S, and Holt RT. Preliminary outcomes and efficacy of the first 360 consecutive kyphoplasties for the treatment of painful osteoporotic vertebral compression fractures. *Spine J.* 2005; 5:244-255. See [Evidence Table](#).

Kyphoplasty for the treatment of vertebral body compression fractures refractory to maximal medical management does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/04/2008: MTAC REVIEW

Kyphoplasty

Evidence Conclusion: The body of evidence on the safety and efficacy of balloon kyphoplasty (BKP) in the treatment of vertebral compression fractures consisted of multiple case series and few non-randomized studies that compared BKP to either vertebroplasty or the standard conservative therapy. Several authors pooled the results of these comparative and non-comparative series in a number of meta-analyses. However, the quality of meta-analyses and the strength of their conclusions depend on the quality of the included studies. The studies included in the published meta-analyses for BKP were too small, and had their methodological flaws and potential selection and observation bias. The comparative studies were non-randomized and the authors did not discuss how and why patients were selected for each of the procedures. There was evidence of publication bias as well as significant heterogeneity between the studies included in the meta-analyses. The studies differed their inclusion/exclusion criteria, outcome measures, scales used, and scoring systems, as well as duration and completeness of follow-up. Moreover, the results were unblinded and many of the outcomes were subjective.

The comparative studies published after the meta-analyses were also too small, non-randomized, unblinded, with relatively short follow-up duration, as well as other validity threats and do not allow making conclusions as regard the efficacy and safety of the procedure. In conclusion, the published literature does not provide sufficient evidence to determine the benefit of the procedure in relieving pain, improving function, and reducing rate of vertebral fractures. There is also insufficient evidence to determine its long-lasting effect on pain relief or its adverse effects on the spine. Large well conducted randomized controlled trials, with long term follow-up duration are needed to objectively compare balloon kyphoplasty to conventional treatment and other percutaneous techniques, and to determine its long-term safety and efficacy in improving function and reducing pain, disability, and complications associated with vertebral compression fractures.

Articles: The search yielded over 90 articles on balloon kyphoplasty. Many were reviews and technical reports. No randomized controlled trials that compared the procedure with vertebroplasty or conservative therapy were identified. There were four meta-analyses of non-randomized controlled studies and case series. All four included almost the same studies, and two were performed by the same group of authors. The search also revealed two non-randomized comparative studies published after the meta-analyses. One (N=21) compared kyphoplasty to vertebroplasty for the treatment of painful osteoporotic or traumatic VCFs, and the other (N=60) compared kyphoplasty with standard medical treatment of osteoporotic or traumatic VCF. The studies on the use of kyphoplasty for severe back pain due to metastatic disease were small case series with no control or comparison

groups. The most recent meta-analysis and the two comparative studies were critically appraised. Taylor RS, Fritzell P, Taylor RJ. See [Evidence Table](#).

Kyphoplasty for the treatment of vertebral body compression fractures refractory to maximal medical management does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

12/07/2009: MTAC REVIEW

Kyphoplasty

Evidence Conclusion: A recently published RCT (Wardlaw et al 2009) compared kyphoplasty plus standard medical therapy to medical therapy alone in 300 patients from 21 sites in eight countries. The trial was randomized and controlled, however kyphoplasty was not compared to a sham procedure or an alternative invasive or noninvasive surgical procedure. The medical therapy was not standardized and varied according to the standard practices of the participating centers, and neither the patients nor the investigators were blinded to the treatment received. Medtronic Spine LLC, the manufacturer of the kyphoplasty balloon technology was involved in the study design, data monitoring, analysis, and reporting of the results. The results of the trial shows that patients in the kyphoplasty group experienced greater reduction in pain and improved function at one month compared to the control group. The significant improvement observed at one month in the short form -36 physical component summary (SF-36 PCS) scale, the primary outcome the trial, declined along the following months and was statistically insignificant by the 12th months, when the controls showed improvement. The results also show a higher rate of vertebral fractures and/or worsening of fractures among the patients in the kyphoplasty group vs. the controls. The difference was not statistically significant, but the study was not powered to detect significant differences in fracture rates. The authors did not report on any cement leakage associated with kyphoplasty.

In conclusion, the published literature does not provide sufficient evidence to determine that kyphoplasty is a safe and an appropriate procedure for relieving pain, improving function, reducing rate of vertebral fractures and disability in patients with vertebral compression fractures.

Articles: The search identified one recent randomized controlled trial (Wardlaw et al 2009) that compared balloon kyphoplasty with non-surgical care for vertebral compression fracture. No randomized controlled trials that compared the procedure with a sham treatment were identified. A relatively small RCT with only 6 months of follow-up compared the kyphoplasty to vertebroplasty in patients with osteoporotic vertebral fractures. Wardlaw et al's RCT was selected for critically appraised. Wardlaw D, Cummings SR, Van Meirhaeghe J. Efficacy and safety of balloon kyphoplasty compared with non-surgical care for vertebral compression fracture (FREE): a randomized controlled trial. *Lancet*. 2009; 373:1016-24. See [Evidence Table](#).

Kyphoplasty for the treatment of vertebral body compression fractures refractory to maximal medical management does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

02/09/2015: MTAC REVIEW

Kyphoplasty

Evidence Conclusion: *Effectiveness* In 2009, Wardlaw and colleagues reported results from an RCT comparing kyphoplasty to non-surgical management (NSM) in 300 patients from 21 sites in eight countries. The results of the trial indicate that patients in the kyphoplasty group experienced greater reduction in pain and improved function at one month compared to the control group. The significant improvement observed at one month in the short form- 36 (SF-36) physical component summary (PCS) scale, the primary outcome the trial, declined along the following months and was statistically insignificant by 12 months. The kyphoplasty group also experienced statistically significant reductions in back pain and improvement in both back function and quality of life scales early on, however, this effect diminished over time (Wardlaw, Van Meirhaeghe et al. 2012). In 2010, Boonen and colleagues expand on the results of the FREE-trial including an additional 12 months of follow-up. With the exception of pain and QoL, most criteria were no longer statistically significant at 24 months indicating that any benefit for both groups occurs within the first year. The investigators do note that averaged scores, across the 24 month period, did show significance when compared with NSM in physical symptoms, as assessed by the SF-36 PCS (3.24 points, 95% CI 1.47-5.01, p=0.0004), and on the QoL scale as assessed by the Euro quality-of-life questionnaire (EQ-5D) (0.12 points, 95% CI, 0.06 to 0.18, p=0.0002). The investigators concluded that, compared with NSM, kyphoplasty rapidly reduces pain and improves function, disability, and QoL over the course of two years (Boonen, Van Meirhaeghe et

al. 2011). [Evidence Table 1] **Safety** At 24 months, the investigators report that the overall frequency of patient with adverse events (AE) and serious adverse events (SAE) was similar between treatment groups. With that said, the investigators did report two serious adverse events, hematoma and urinary tract infection (UTI), that were considered to be related to the procedure. In addition, the investigators identified cement leakage in one patient who had undergone kyphoplasty. Finally, the kyphoplasty group had a higher rate of subsequent vertebral fractures when compared with the NSM group (47.5% vs. 44.1%; 3.4% difference, 95% CI -16.5 to 9.9, $p=0.68$), however, this difference was not statistically significant, and the study was not powered to detect significant differences in fracture rates. The FREE-trial has the advantage of being multi-centered, randomized and controlled. In addition, the analysis was based on intention-to-treat (ITT) and the study was adequately powered. Limitations of the study, however, include an inadequate comparator. Ideally, kyphoplasty should have been compared with a sham procedure or an alternative surgical procedure. Instead, the investigators compare the procedure to conservative management which, with 21 sites spanning eight different countries, was variable and not standardized. To add to this limitation, the differences in the treatment of the control and the intervention groups did not allow for blinding of both patients and the investigators opening the study up to selection and information bias. A further limitation of the study includes the investigators failure to stratify the data in analysis according to indication (osteoporosis vs. myeloma vs. metastasis) limiting the applicability of the results. Finally, it should be noted that the manufacturer of the kyphoplasty balloon technology, Medtronic Spine LLC, was involved in the study design, data monitoring, analysis, and reporting of results. For these reasons, the results of the study should be interpreted with caution and does not provide sufficient evidence to determine safety and effectiveness of kyphoplasty for treating VCF. **Conclusions:** There is insufficient evidence to support the effectiveness of kyphoplasty over non-surgical management for the treatment of VCF caused by osteoporosis, myeloma or malignancy. There is insufficient evidence to support the safety of kyphoplasty for the treatment of VCF caused by osteoporosis, myeloma or malignancy.

Articles: The literature search sought to update the evidence from the end date of the last MTAC review. The search revealed a large quantity of publications including a variety of systematic reviews and retrospective observational studies. No RCTs were identified that compared kyphoplasty to sham treatment. The largest RCT to date, the fracture reduction evaluation (FREE), included 300 patients with 12 months follow-up and was critically appraised by MTAC in 2009 (Wardlaw, Van Meirhaeghe et al. 2012). Since then, Boonen and colleagues have published a follow-up analysis reporting the 24-month outcomes of the FREE trial. The following articles were selected for critical appraisal: Wardlaw D, Cummings SR, Van Meirhaeghe J, et al. Efficacy and safety of balloon kyphoplasty compared with non-surgical care for vertebral compression fracture (FREE): a randomized controlled trial. *Lancet*. 2009; 373(9668):1016-1024. [Evidence Table 1](#). Boonen S, Van Meirhaeghe J, Bastian L, et al. Balloon Kyphoplasty for the treatment of acute vertebral compression fractures: 2-year results from a randomized trial. *JBM*. 2011; 26(7):1627-1637. [Evidence Table 1](#).

Kyphoplasty for the treatment of vertebral body compression fractures refractory to maximal medical management does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Percutaneous Vertebroplasty of Low Back Pain

02/09/2000: MTAC REVIEW

Evidence Conclusion: Efficacy of vertebroplasty in patients with osteoporotic compression fractures cannot be determined from these studies because of the likelihood of selection bias, observation bias, confounding and chance as explanations for some of, or all of, the studies' findings.

Articles: Articles were selected on the basis of study type. Because the literature revealed no randomized control trials or meta-analyses, the 14 cohort studies or case series were reviewed by abstract. The largest case series were selected for critical appraisal and evidence tables were created (Weill A, Chrias J, Simon J, et al. Spinal Metastases: Indications for Results of Percutaneous Injection of Acrylic Surgical Cement. *Radiology*. 1996; 199:241-247. Cortet B, Cotton A, Boutry N, et al. Percutaneous Vertebroplasty in the Treatment of Osteoporotic Vertebral Compression Fractures: An Open Prospective Study. *J Rheumatol*. 1999;26:2222-8.) Weill A, Chrias J, Simon J, et al. Spinal Metastases: Indications for and Results of Percutaneous Injection of Acrylic Surgical Cement. *Radiology* 1996; 199:241-247. See [Evidence Table](#). Cortet B, Cotton A, Boutry N, et al. Percutaneous vertebroplasty in the treatment of osteoporotic vertebral compression fractures: An open prospective study. *J Rheumatol*. 1999;26:2222-8. See [Evidence Table](#). Deramond H, Depriester C, Galibert P, et al. Percutaneous Vertebroplasty with Polymethylmethacrylate: Techniques, Indications, and Results. *Radiologic Clinics of North America*, Vol 36(3); May 1998:533-546. See [Evidence Table](#).

The use of percutaneous vertebroplasty of low back pain has been approved by the FDA and therefore meets *Kaiser Permanente Medical Technology Assessment Criteria*.

Percutaneous Vertebroplasty in Treatment of Osteoporotic Vertebral Fracture**06/06/2005: MTAC REVIEW**

Evidence Conclusion: The studies reviewed do not provide sufficient evidence to determine the efficacy of the procedure, its long-term benefits, or late complications. No direct randomized studies comparing the intervention with standard, non-operative care are available.

Diamond et al's study had the advantage of comparing the intervention with conservative therapy. However, it was not randomized, and conservative therapy was offered to those who denied percutaneous vertebroplasty, which might be a potential source of selection bias. The study was also subject to observation bias as it was not blinded, and all outcomes were subjective. Moreover, the follow-up duration might be insufficient to determine the long-term effects of the vertebroplasty. The Grohs' study compared kyphoplasty head to head with vertebroplasty.

However, it was small, nonrandomized and unblinded. Postoperative comparison was made vs. baseline condition for each intervention with no direct comparison between the two techniques. The results of the study show that both procedures offered significant pain relief, which was maintained at a lower level with the kyphoplasty. The functional disability on the other hand was significantly improved only with kyphoplasty and not vertebroplasty. The results of the study also indicate that the rate of fracture of an adjacent vertebra seems to be higher with the kyphoplasty vs. vertebroplasty (21% vs. 4%). Gangi's study was a case series with potential selection and observation bias, with no control or comparison group, and the authors did not provide sufficient data on patient selection for the intervention, their characteristics, and follow-up, or long-term outcomes.

Articles: The search yielded 179 articles, most of which were review articles, discussion pieces and technical reports. A nonrandomized trial comparing percutaneous vertebroplasty with conservative therapy, and another comparing it to kyphoplasty were identified, as well as several case series. *The two studies with comparison groups, as well as the largest case series (N=868), were selected for critical appraisal:* Diamond T, Champion B, and Clark W. Management of acute osteoporotic vertebral fractures: A nonrandomized trial comparing percutaneous vertebroplasty with conservative therapy. Am J Med. 2003;114:257-265. See [Evidence Table](#).

Grohs JG, Matzner M, Trieb K, et al. Minimal invasive stabilization of osteoporotic vertebral fractures. A prospective nonrandomized comparison of vertebroplasty and balloon kyphoplasty. J Spinal Disord Tech 2005;18:238-242. See [Evidence Table](#). Gangi A, Guth S, Imbert JP, et al. Percutaneous vertebroplasty: Indications, technique, and results. Radiographics. 2003;23:e10-e10. See [Evidence Table](#).

The use of Percutaneous Vertebroplasty in Treatment of Osteoporotic Vertebral Fractures does not meet the Kaiser Permanente Medical Technology Assessment Criteria.

09/04/2009: MTAC REVIEW**Percutaneous Vertebroplasty in Treatment of Osteoporotic Vertebral Fracture**

Evidence Conclusion: There is fair evidence from two randomized controlled trials that vertebroplasty does not have a significant benefit over sham treatment in reducing pain and pain-related disability in patients with osteoporotic vertebral fractures. Kallmes, et al 2009 trial: Kallmes and colleagues randomly assigned 131 patients with 1-3 painful osteoporotic compression vertebral fractures (between T4 and L5), that was <1 year old and not responding to standard medical therapy, to undergo vertebroplasty or a sham treatment that simulated the procedure but without PMMA infusion. The primary outcomes were scores on the modified Roland-Morris Disability Questionnaire (RDQ) and patient's rating of average pain intensity during the preceding 24 hours at 1 month. Patients were allowed to cross over to the other study group after one month. The results of the trial show no significant differences in the primary outcome between the two groups (difference in RDQ score 0.7; 95%CI, -1.3 to 2.8, p=0.49, and difference in pain rating 0.7; 95% CI, -0.3 to 1.7, p=0.19). One serious adverse event occurred in each of the 2 study groups (injury to the thecal sac in the vertebroplasty procedure, and tachycardia and rigors in the control group) At 3 months there was a higher rate of cross over in the control group (43%) than the vertebroplasty group (12%), p<0.001. The study had generally valid methodology, but not without limitations. It was randomized, controlled, blinded, multicenter, with well defined inclusion/ exclusion criteria, sufficient statistical power to detect differences between the study groups, and analysis was based on ITT. The limitations of the trial included allowing cross-over between the two treatment groups after 1 month which did not allow evaluating the long-term efficacy of the procedure. Moreover, no adjustments were made for other medical treatments received, or other causes of pain all of which are potential confounders. Buchbinder, et al 2009: Buchbinder and colleagues randomized 78 patients with one or two painful. MRI confirmed unhealed osteoporotic vertebral fractures. <12 months duration to undergo vertebroplasty or a sham procedure. Patients were followed up for 6 months, and the primary outcome was overall pain at 3 months. Secondary outcomes included functional status and QoL at 1week, 1, 3, and 6 months after the procedures. The trial had generally valid methodology but was relatively small. It was randomized, controlled, blinded, multicenter, with sufficient statistical power to detect significant differences between the study groups, and analysis was based on ITT. The results show no significant difference between the

vertebroplasty and sham treatment in any of the outcomes. The mean reduction in pain was 2.6 +2.9 and 1.9+3.3 respectively with an adjusted difference between the two groups of 0.6; 95% CI, -0.7 to 1.8. Both groups showed a significant reduction of pain at three months vs. baseline. 7 new of clinical vertebral fractures occurred during the 6-month follow-up (three in the vertebroplasty group and 4 in the control group). **Conclusion:** The published literature provides fair evidence that vertebroplasty has no significant benefit over a sham procedure in the treatment of patients with osteoporotic vertebral fractures.

Articles: Two trials on vertebroplasty for osteoporotic spinal fractures were recently published: Buchbinder R, Osborne RH, Ebeling PR, et al. A randomized trial of vertebroplasty for painful osteoporotic vertebral fractures. *N Engl J Med* 2009;36:557-568. Kallmes DF, Comstock BA, Heagerty PJ, et al. A randomized trial of vertebroplasty for osteoporotic spinal fractures. *N Engl J Med* 2009;36:569-579.

The use of Percutaneous Vertebroplasty in Treatment of Osteoporotic Vertebral Fractures does not meet the Kaiser Permanente Medical Technology Assessment Criteria.

02/09/2015: MTAC REVIEW

Percutaneous Vertebroplasty in Treatment of Osteoporotic Vertebral Fracture

Evidence Conclusion: Effectiveness: In the first RCT, detailed in evidence table one, Buchbinder and colleagues included 78 subjects with back pain, ≤12 months in duration, who had up to two VCF evidenced by the presence of vertebral collapse, edema and/or a fracture line on MRI. Patients were randomized into either the vertebroplasty treatment group or a group that received sham procedure. Outcomes were measured at baseline and several points in time up to six months following the procedure. The primary endpoint was overall pain at three months, however, the study also included QoL measures and a survey specific to osteoporotic vertebral fractures.

Ultimately the study found no beneficial effect of vertebroplasty over the sham procedure at any time. In fact, the only significant between-group difference was seen on the Quality of Life Questionnaire of the European Foundation for Osteoporosis (QUALEFFO) total score at one week, favoring the sham group [-4.0 (95%CI -7.8 to -0.2)] (Buchbinder, Osborne et al. 2009). [Evidence Table](#). The second study, by Kallmes and colleagues, also randomized osteoporotic patients with up to three painful VCFs (n=131) to vertebroplasty or sham procedures.

After one month, if patients did not achieve adequate pain relief, the investigators allowed cross-over to the alternate therapy. The primary outcomes, pain and disability, were assessed at one month, however, investigators also describe outcomes up to three months to assess the effects of cross-over. At one month, both the vertebroplasty and sham groups demonstrated substantial improvements, however, no significant differences were seen between groups in either of the primary outcomes. The mean Roland-Morris Disability Questionnaire (RDQ) in the vertebroplasty group was 12.0±6.3 and 13.0±6.4 in the sham group (adjusted treatment effect, 0.7; 95% CI, -1.3 to 2.8; P=0.49). Similarly, the mean pain-intensity rating was 3.9±2.9 in the vertebroplasty group and 4.6±3.0 in the sham group (adjusted treatment effect, 0.7; 95% CI, -0.3 to 1.7; P=0.19). The investigators note, however, that the control group saw a higher rate of cross-over than the vertebroplasty group (51% vs. 13%, P<0.001). Despite this significance, the investigators concluded that improvements in pain and pain-related disability associated with osteoporotic VCF in patients treated with vertebroplasty were similar to the improvements seen in the sham group (Kallmes, Comstock et al. 2009). [Evidence Table](#). **Safety:** Adverse events were documented in both studies and included hospitalizations from the procedure, as well as, subsequent fractures. Cement leakage was not reported by Kallmes and colleagues, however, Buchbinder et al. reported 37% cement leakage rate with no symptomatic events. Neither of the studies provided extended follow-up of safety and adverse events with the longest follow-up limited to six months following procedure. Previous reviews of vertebroplasty failed MTAC criteria with the available evidence offering little value due to methodological limitations such as a lack of randomization, inappropriate comparators and the likelihood of selection bias, observation bias, confounding and chance as explanations for study findings. Currently, however, the literature is more robust with two RCTs that compare vertebroplasty to sham procedures. The design of both studies was strengthened by the use of a sham procedure replicating verbal and visual cues allowing for the blinding of patients. With that said, an additional control group receiving no treatment would have benefited the outcome comparisons. Other limitations include sample size. Despite relatively lax inclusion criteria, both of the studies experienced difficulties recruiting patients resulting in a modification of sample size in the study by Kallmes et al. and the inability to assess two year follow-up in the Buchbinder study. Ultimately, the studies provide adequate evidence to suggest that vertebroplasty is no better than sham treatment for treating patients with VCF due to osteoporosis.

Conclusions: There is evidence to suggest that vertebroplasty is no more effective than sham therapy for the treatment of vertebral compression fractures in osteoporotic patients. There is insufficient evidence to assess the safety of vertebroplasty for the treatment of vertebral compression fractures in osteoporotic patients.

Articles: The search yielded a large quantity of publications relating to vertebroplasty. The majority of the literature was comprised of non-randomized, observational studies, many of which sought to compare vertebroplasty with

kyphoplasty. A supplemental search of the clinical trials database revealed several studies relating to vertebroplasty that are currently recruiting or on-going. Since the last MTAC review, two randomized trials comparing percutaneous vertebroplasty with a sham procedure therapy were published and selected for critical appraisal. The following articles were selected for critical appraisal: Buchbinder R, Osborne RH, Ebeling PR, et al. A randomized trial of vertebroplasty for painful osteoporotic vertebral fractures. NEJM. 2009; 361(6):557-568.

[Evidence Table 1](#). Kallmes DF, Cornstock BA, Heagerty PJ, et al. A randomized trial of vertebroplasty for osteoporotic spinal fractures. NEJM. 2009;261(6):569-571. [Evidence Table 2](#).

The use of Percutaneous Vertebroplasty in Treatment of Osteoporotic Vertebral Fractures does not meet the Kaiser Permanente Medical Technology Assessment Criteria.

Radiofrequency Ablation with Vertebral Augmentation for Painful Metastases

BACKGROUND

The number of patients living with cancer in the United States (US) is estimated to be 4.86 million. Virtually all cancers have the potential to spread, or metastasize, with bone being one of the more common sites of metastasis. Generally speaking, skeletal metastases are associated with debilitating symptoms such as intolerable pain and hypercalcemia compromising the quality of life. Occurrence in the vertebral column, as does with a third of all cancer patients, contributes the additional complexity of complications such as vertebral compression fractures (VCF) and spinal cord or nerve root compression that can cause potentially irreversible loss of neurologic function (Coleman 2000).

Depending on the primary tumor, prognosis is variable with five-year survival ranging from 2% in patients with lung cancer to 44% in those with thyroid cancer. Treatment presents a challenge in that there is no currently available cure, nor has there been any established treatment proven to increase life expectancy. Instead, the goals of treatment aim to control pain, limit complications and preserve function. Depending on individual patient factors, management options range from medications and systemic therapy all the way to surgical resection (Dunning, Butler et al. 2012).

Due to the advanced nature of metastatic cancer and its accompanying comorbidities, populations with skeletal metastases are usually at a higher surgical risk, making minimally invasive techniques an attractive option. Vertebral augmentation (VA) techniques, aimed at stabilizing vertebral compression fractures (VCF), have been documented to provide immediate and sustained relief (Weill, Chiras et al. 1996). In the same way, radiofrequency ablation (RFA), a technique that utilizes thermal energy to destroy cancer cells, has also been demonstrated to reduce pain (Goldberg and Dupuy 2001; Kassamali, Ganeshan et al. 2011). Most recently, RFA and VA, in combination, have been considered a promising treatment option for treating metastatic lesions of the spine (Grönemeyer, Schirp et al. 2002; Schaefer, Lohrmann et al. 2002; Schaefer, Lohrmann et al. 2003).

The STAR™ Tumor Ablation System was developed by DFINE, Inc. (San Jose, CA) specifically for metastatic spinal lesions. The system itself consists of the SpineSTAR™ Ablation Instrument and the corresponding MetaSTAR™ RF Generator which work in unison to deliver energy and provide access and navigation to the tumor within the vertebrae. Subsequent to tumor ablation, stabilization is carried out with the StabiliT® Vertebral Augmentation System, also developed by DFINE, Inc. Put simply, the StabiliT® System allows for the delivery of highly viscous bone cement to the tumor bed. In combination, the procedures require a small incision under local anesthesia with conscious sedation and offer the advantages of unipedicular access, and real-time monitoring of ablation zone allowing for the targeting of tumor cells and controlled cement delivery.

04/20/2015: MTAC REVIEW

Radiofrequency Ablation with Vertebral Augmentation for Painful Metastases

Evidence Conclusion: Effectiveness: In a small RCT, Orgera and colleagues, sought to compare the combined techniques of RFA and VA with VA alone. Following baseline assessment, the investigators randomized 36 patients into the two treatment groups and followed them up for six weeks. Outcomes of interest included surgery success, pain relief and the amount of analgesia administered. The investigators reported a 100% technical success rate in both groups with no significant differences noted between treatment groups with regard to pain as measured on a Visual Analogue Scale (VAS) or Roland Morris Questionnaire (RMQ). In addition, medication use decreased significantly in both groups but the investigators found no significant difference between groups.

Ultimately, the results led the investigators to conclude that the addition of RFA did not offer any additional benefit (Orgera, Krokidis et al. 2014). [Evidence Table 1] A retrospective review of 128 metastatic lesions in 92 patients who underwent 96 procedures was carried out by Anchala and colleagues. The studies intent was to assess the safety

and efficacy of RFA of malignant spinal lesions using the SpineSTAR ablation instrument. The investigators determined that RFA was 'technically successful' in all metastatic lesions. Post-operative pain rated on a Visual Analogue Scale (VAS) demonstrated significant changes at all time points when compared to baseline. The investigators also reported that within the largest institution, 54% of patients reported a decrease in pain medication. Ultimately, the investigators concluded that the STAR system was safely and effectively used in the treatment of spine metastatic osseous lesions (Anchala, Irving et al. 2014). [Evidence Table 2]

Safety Although the follow-up period was limited, Orgera and colleagues reported several complications such as cement leakage (11%), death (5%) and opioid toxicity (8%). Anchala and colleagues, on the other hand, did not explicitly report safety details, but did note asymptomatic cement extravasation in two patients. Although Orgera's study was randomized and blinded, the population size was small and the follow-up period short. Limitations of Anchala's study include the lack of an adequate comparator and retrospective design. The investigators also highlight limitations such as a heterogeneous population and variable availability of data collected from each treatment center. Finally, it should be noted that at least two of the investigators from the retrospective review disclosed financial relationships with the device manufacturer. Collectively, the body of evidence is limited in nature and should be interpreted with caution.

Conclusions: There is insufficient evidence to support the effectiveness of the combination of RFA and VA, compared with VA alone, for the management of pain in metastatic spinal tumors. There is insufficient evidence to support the safety of RFA and VA, compared with VA alone, for the management of pain in metastatic spinal tumors.

Articles: A search of the literature returned a variety of publications relating to both RFA and VA, in general. The majority of publications returned were case studies/series. One study was identified comparing the combination of RFA and VA with balloon kyphoplasty, however, this study was performed in cadaveric models (Dalton, Kohm et al. 2012). A recent study identified in the search, by Song and colleagues, investigated the use of RFA and vertebral augmentation in 12 patients, however, this study was not selected for critical appraisal due to the small sample size and lack of a comparator (Song, Gu et al. 2014). The best evidence identified was a small randomized controlled trial (RCT) comparing RFA+VA with VA alone in patients with multiple myeloma (Orgera, Krokidis et al. 2014). In addition, a retrospective analysis, by Anchala and colleagues, evaluating the combination of RFA with VA for treating metastatic spinal lesions was also included (Anchala, Irving et al. 2014). An additional search of the clinical trials database identified a few prospective observational studies sponsored by DFINE, Inc. currently in the recruitment phase. The following articles were selected for critical appraisal: Orgera G, Krokidis M, Matteoli M, et al. Percutaneous vertebroplasty for pain management in patients with multiple myeloma: is radiofrequency necessary? 2014;37:203-210. See [Evidence Table](#). Anchala PR, Irving WD, Hillen TJ, et al. Treatment of metastatic lesions with a navigational bipolar radiofrequency ablation device: a multicenter retrospective study. Pain Physician. 2014;17:317-327. See [Evidence Table](#).

The use of Radiofrequency Ablation with Vertebral Augmentation for Painful Spinal Metastases does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Kyphoplasty - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
22510	Percutaneous vertebroplasty (bone biopsy included when performed), 1 vertebral body, unilateral or bilateral injection, inclusive of all imaging guidance; cervicothoracic
22511	Percutaneous vertebroplasty (bone biopsy included when performed), 1 vertebral body, unilateral or bilateral injection, inclusive of all imaging guidance; lumbosacral
22512	Percutaneous vertebroplasty (bone biopsy included when performed), 1 vertebral body, unilateral or bilateral injection, inclusive of all imaging guidance; each additional cervicothoracic or lumbosacral vertebral body (List separately in addition to code for primary procedure)
22513	Percutaneous vertebral augmentation, including cavity creation (fracture reduction and bone biopsy included when performed) using mechanical device (eg, kyphoplasty), 1 vertebral body, unilateral or bilateral cannulation, inclusive of all imaging guidance; thoracic
20983	Ablation therapy for reduction or eradication of 1 or more bone tumors (eg, metastasis) including adjacent soft tissue when involved by tumor extension, percutaneous, including imaging guidance when performed; cryoablation
22514	Percutaneous vertebral augmentation, including cavity creation (fracture reduction and bone biopsy included when performed) using mechanical device (eg, kyphoplasty), 1 vertebral body, unilateral or

	bilateral cannulation, inclusive of all imaging guidance; lumbar
22515	Percutaneous vertebral augmentation, including cavity creation (fracture reduction and bone biopsy included when performed) using mechanical device (eg, kyphoplasty), 1 vertebral body, unilateral or bilateral cannulation, inclusive of all imaging guidance; each additional thoracic or lumbar vertebral body (List separately in addition to code for primary procedure)

Sacroplasty - Considered Not Medically Necessary:

CPT® Codes	Description
0200T	Percutaneous sacral augmentation (sacroplasty), unilateral injection(s), including the use of a balloon or mechanical device, when used, 1 or more needles, includes imaging guidance and bone biopsy, when performed
0201T	Percutaneous sacral augmentation (sacroplasty), bilateral injections, including the use of a balloon or mechanical device, when used, 2 or more needles, includes imaging guidance and bone biopsy, when performed

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Laser Treatments for Snoring and Sleep Apnea

- Cautery-Assisted Palatal Stiffening Operation (CAPSO)
- Laser-Assisted Uvulopalatoplasty (LAUP)
- Repose Procedure
- Somnoplasty

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " Laser Treatments for Snoring & Sleep Apnea ", for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe and/or provides better long-term outcomes than current standard services/therapies. These treatments are found to be effective in the treatment of snoring; however, no Kaiser Permanente or Kaiser Permanente Options, Inc. plan covers interventions for the treatment of snoring.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Sleep-disordered breathing includes a spectrum of disorders ranging from primary snoring to obstructive sleep apnea (OSA). Obstructive Sleep Apnea Syndrome (OSAS) is defined as an apnea-hypopnea index of more than five events per hour, and often also have mental or physical effects such as excessive daytime sleepiness. Potential health consequences of OSAS are cardiovascular diseases, neuropsychiatric problems, injuries and increased mortality. Obstructive sleep apnea results from a combination of a structurally small upper airway and a loss of upper airway muscle tone.

Methods of treating OSA include weight loss, nasal continuous positive airway pressure (CPAP), surgical or laser resection of the uvula, tonsils or soft palate, or tracheostomy when all other treatments fail. Surgical treatment approach varies, and the results are affected by age, cause of obstruction, and severity of the disease. The best method of treatment remains controversial.

Medical Technology Assessment Committee (MTAC)

Sleep Apnea – Cautery-Assisted Palatal Stiffening Operation (CAPSO)

BACKGROUND

Obstructive sleep apnea has been treated with uvulopalatopharyngoplasty (UPPP), a surgical procedure on the soft palate using a scalpel. Cautery-assisted palatal stiffening operation (CAPSO) is a procedure that was first used to treat palatal snoring and is proposed as a new treatment for obstructive sleep apnea. With CAPSO, a midline strip of soft palate mucosa is removed, and the wound is allowed to heal by secondary intention. This procedure stiffens the flaccid palate and causes a cessation of palatal snoring (Wassmuth, 2000). Other possible alternatives to UPPP are laser-assisted uvulopalatoplasty (LAUP) and somnoplasty (which uses radiofrequency energy). Possible advantages of CAPSO, LAUP and somnoplasty compared to UPPP are that it is performed under local anesthetic and can be done as an outpatient procedure (Laube, 1999).

08/08/2001: MTAC REVIEW

Cautery-Assisted Palatal Stiffening Operation (CAPSO)

Evidence Conclusion: Only a single small case series is available to evaluate CAPSO for treating obstructive sleep apnea. This represents insufficient evidence to draw conclusions about the effect of CAPSO on health outcomes related to sleep apnea.

Articles: The search yielded 113 articles. Most of the articles were on uvulopalatopharyngoplasty or glossectomy. There were two empirical articles on CAPSO, both were case series. One of the case series (n=25) included patients with obstructive sleep apnea, while the other, report (n=206) included patients who complained of excessive habitual snoring, no attempt was made to diagnose sleep apnea. An evidence table was created for the case series with sleep apnea patients. Wassmuth Z, Mair E, Loube D, Leonard D. Cautery-assisted palatal stiffening operation for the treatment of obstructive sleep apnea syndrome. *Otolaryngol Head Neck Surg* 2000; 123: 55-60. See [Evidence Table](#).

The use of cautery-assisted palatal stiffening operation (CAPSO) in the treatment of sleep apnea does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Sleep Apnea: Repose Procedure

BACKGROUND

The Repose system is one of several new treatments of obstructive sleep apnea (OSA). The Repose is a disposable surgical kit manufactured by Influence Medical Technologies, San Francisco. The kit contains: 1) a self-tapping screw with pre-attached double polypropylene No. 1 sutures; 2) a battery-operated screwdriver and; 3) a suture passer that aids passage of the suture through the tongue. The Repose procedure consists of anchoring the bone to soft-tissue to stabilize the base of the tongue (deRowe et al., 2000).

The Repose system is used under general anesthesia. A screw with pre-attached sutures is inserted at the base of the mandible. The sutures are passed through the tongue base; the two ends are tied together below the tongue mucosa and placed in the mouth floor that supports the tongue base. Tightness of the suspension is determined digitally.

08/08/2001: MTAC REVIEW

Repose Procedure

Evidence Conclusion: The existing scientific evidence does not permit conclusions about the efficacy of the Repose procedure on health outcomes. The best evidence is a case series of 16 individuals with data available on 14 of these. This report is subject to the limitations of case series (selection and observation bias likely).

Articles: The search yielded 113 articles. Most of the articles were on uvulopalatopharyngoplasty or glossectomy. There were three articles on the Repose procedure, one review/discussion piece and two small case series (n=9 and n=15). Because it was the best available evidence, an evidence table was created for the larger case series. DeRowe A, Gunther E, Fibbi A, Lehtimake K, Valatalo K., Maurer J, Ophir D. Tongue-based suspension with a soft tissue-to-bone anchor for obstructive sleep apnea: Preliminary clinical results of a new minimally invasive technique. *Otolaryngol Head Neck Surg* 2000; 122: 100-3. See [Evidence Table](#).

The use of repose procedure in the treatment of sleep apnea does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Somnoplasty for Treating Obstructive Sleep Apnea

BACKGROUND

Sleep-disordered breathing includes a spectrum of disorders ranging from primary snoring to obstructive sleep apnea (OSA). Obstructive Sleep Apnea Syndrome (OSAS) is defined as an apnea-hypopnea index of more than five events per hour, and often also have mental or physical effects such as excessive daytime sleepiness. Potential health consequences of OSAS are cardiovascular diseases, neuropsychiatric problems, injuries and increased mortality. Obstructive sleep apnea results from a combination of a structurally small upper airway and a loss of upper airway muscle tone. Methods of treating OSA include weight loss, nasal continuous positive airway pressure (CPAP), surgical or laser resection of the uvula, tonsils or soft palate, or tracheostomy when all other treatments fail. Surgical treatment approach varies, and the results are affected by age, cause of obstruction, and severity of the disease. The best method of treatment remains controversial. Temperature-controlled radiofrequency tissue ablation (Somnoplasty) may be a less morbid alternative to other invasive surgical procedures. Somnoplasty is performed under local anesthesia in an outpatient setting. The commercially available device made by Gyrus Medical delivers 460 kHz using a radiofrequency generator. Radiofrequency energy is delivered via 22-gauge electrodes with a 10-mm active tip. High frequency alternating current flows into the tissue, creating ionic agitation. This agitation heats the tissue and, when the temperature rises above 47°C, protein coagulation and tissue necrosis take place. The target temperature is between 80°C and 85°C, with a maximum of less than 90°C. The maximum lesion size is two-thirds the diameter of the radiofrequency electrode, or approximately 7mm. During the three weeks following the procedure, there is inflammation, fibrosis and tissue volume reduction (Troell, 2003). The Gyrus Somnoplasty system was cleared by the FDA in 1998 for treating obstructive sleep apnea. Single-level radiofrequency ablation refers to creation of lesions in one area only (base of tongue, soft palate or turbinates). Multi-level radiofrequency ablation refers to its use in more than one area.

04/14/1999: MTAC REVIEW

Somnus Somnoplasty System

Evidence Conclusion: Evidence identification was conducted by searching MEDLINE from 1990 to February 1999 using the terms: somnoplasty, sleep apnea and radiofrequency. The Somnus Company was aware of only one published article related to the use of the Somnoplasty system for obstructive sleep apnea. This article (summarized below) reports data from a single case series of 22 patients treated for snoring, daytime sleepiness and mild obstructive sleep apnea. Results from this study show no changes in Respiratory Distress Index (RDI*) following somnoplasty, statistically significant improvements in partner report of snoring and an improvement of 3.3 points (24-point scale) in self-report of sleepiness.

Articles: Powell, NB, et al *Chest*, 1998;113:1163-74. See [Evidence Table](#)

The use of the Somnus Somnoplasty System for the treatment of obstructive sleep apnea has been approved by the FDA and therefore meets Kaiser Permanente *Medical Technology Assessment Criteria*.

08/08/2001: MTAC REVIEW

Base of Tongue Somnoplasty in the Treatment of Sleep Apnea

Evidence Conclusion: The evaluated study does not provide sufficient evidence to determine the efficacy of base of tongue somnoplasty, in the treatment of sleep apnea, due to its small sample size, together with the other limitations of case series.

Articles: The search yielded 113 articles. Most of the articles were on uvulopalatopharyngoplasty or glossectomy. There was a pilot study done for base of tongue somnoplasty on humans, and another study made on animals. *The best available article for critical appraisal was the pilot study:* Powell N B, Riley R W, et al. Radiofrequency Tongue Base Reduction In Sleep- Disordered Breathing: A Pilot Study. *Otolaryngol Head Neck Surg* 1999; 120: 656-64. See [Evidence Table](#).

The use of base of tongue somnoplasty in the treatment of sleep apnea does not meet the Kaiser Permanente *Medical Technology Assessment Criteria*.

12/05/2005: MTAC REVIEW

Radiofrequency Tissue Ablation (Somnoplasty)

Evidence Conclusion: *Efficacy of Multi-Level Base of Tongue and Soft Palate Procedure:* The best evidence is from a randomized controlled trial comparing radiofrequency ablation of the tongue and soft palate to CPAP and sham ablation (Woodson et al., 2003; Stewart et al., 2005). The three primary outcomes were slowest reaction time (SRT) and two quality of life (QOL) variables. There were no significant differences in the change in SRT in the radiofrequency ablation versus the placebo group, the CPAP group versus the placebo group or the radiofrequency ablation group vs. CPAP group. One of the two QOL variables improved significantly in the radiofrequency ablation group compared to placebo, but there was not a significant difference in QOL change in

the radiofrequency ablation group versus the CPAP group. Among patients in the radiofrequency ablation group, those who had long-term follow-up had significant improvement in SRT, but not QOL compared to baseline. The 2005 publication did not report long-term findings for the CPAP or placebo groups.

Efficacy of Single-Level Base of Tongue Procedure: There were no randomized controlled trials. The best evidence is from a prospective non-randomized study comparing a group of patients who received base of tongue Somnoplasty and peri-operative use of CPAP to a group of patients receiving CPAP only (Woodson et al., 2001). There were no significant between-group differences in the change in subjective self-report outcomes (e.g. sleepiness, SF-36). Objective outcomes were only reported for the radiofrequency ablation group. In the group of 73 patients receiving radiofrequency ablation, the apnea-hypopnea index decreased significantly pre- to post-treatment. This study is subject to selection bias since patients were not randomized to treatment group; there was no between-group comparison for the objective outcomes. **Complications: Single and Multi-level:** Two single-center case series were reviewed; one included 136 patients and was conducted at Stanford University (Kerzirian et al., 2005) and the other included 322 patients and was conducted in Mannheim, Germany (Stuck et al., 2003). Both studies found relatively low complications rates. The Kerzirian study did not identify any moderate or severe complications. The Stuck study found four moderate severity complications and one severe complication. Both of the studies included a combination of patients who received single-level and multi-level radiofrequency ablation, and both included patients who received treatment of the turbinates, as well as those with base of tongue or palate procedures. A limitation of both studies was that they were conducted at centers with extensive experience in somnoplasty and findings may not be generalizable to other institutions. **Overall Conclusions:** There is insufficient evidence on single level base of tongue somnoplasty to draw conclusions about the efficacy of the procedure compared to placebo or the standard treatment, CPAP. There were no RCTs on single level somnoplasty. One non-randomized comparative study did not find significant between-group differences on subjective outcomes. There is evidence from one RCT that multilevel (base of tongue and soft palate) does not improve outcomes compared to sham treatment or placebo. The RCT did not identify significant between-group differences in two of three primary outcomes including the objective outcome, slowest reaction time. Findings from case series suggest that there is a relatively low complication rate, at least in institutions with extensive experience with the technology.

Articles: One randomized controlled trial was identified in the literature search, a comparison of multilevel radiofrequency ablation, sham treatment, and CPAP. There were two publications on the RCT, initial outcomes (Woodson et al., 2003) and long-term follow-up of the active treatment group (Stewart et al., 2005). Both articles were critically appraised in the same evidence table. One other comparative study was identified and critically appraised. This was a non-randomized comparison of a patients receiving single-level base of tongue Somnoplasty and CPAP (Woodson et al., 2001). Several small case series (n<25) on the efficacy of Somnoplasty were identified, but not reviewed further. Two relatively large case series (n>100) on complications of Somnoplasty were identified; both were critically appraised (Kerzirian et al., 2005; Stuck et al., 2003). *The articles critically appraised were:* Woodson BT, Stewart DL, Weaver EM et al. A randomized trial of temperature-controlled radiofrequency, continuous positive airway pressure, and placebo for obstructive sleep apnea syndrome. Otolaryngol Head Neck Surg 2003; 128: 848-861. See [Evidence Table](#). Stewart DL, Weaver EM, Woodson BT. Multilevel temperature-controlled radiofrequency for obstructive sleep apnea: Extended follow-up. Otolaryngol Head Neck Surg 2005; 132: 630-635. Woodson BT, Nelson L, Mickelson S et al. A multi-institutional study of radiofrequency volumetric tissue reduction for OSAS. Otolaryngol Head Neck Surg 2001; 125: 303-311. See [Evidence Table](#). Kerzirian EJ, Powell NB, Riley RW, Hester JE. Incidence of complications in radiofrequency treatment of the upper airway. Laryngoscope 2005; 115: 1298-1304. See [Evidence Table](#). Stuck BA, Starzak K, Verse T et al. Complications of temperature-controlled radiofrequency volumetric tissue reduction for sleep-disordered breathing. Acta Otolaryngol 2003; 123: 532-535. See [Evidence Table](#).

The use of Radiofrequency tissue ablation (somnoplasty) in the treatment of sleep apnea does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

KPWA Medical Policy	None

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Cardiac arrhythmias occur when there is interruption of the normal sinus rhythm. Symptoms include palpitations, dizziness, lightheadedness, syncope, dyspnea, anxiety, weakness, and chest discomfort. One therapeutic option is the implantation of pacemaker which provides electrical impulses to the heart. Conventional pacemakers consist of a pulse generator, which provides electrical impulses, and leads delivering electrical impulses from the generator to the heart. The pulse generator is the battery and is placed in the anterior part of the chest (pre-pectoral) while the leads are placed transvenously.

However, there are several complications associated with traditional pacemakers. Complications due to the pulse generator include hematoma, skin breakdown, and pocket infection (Udo et al., 2012). Complications due to the leads include venous obstruction, lead dislodgement, lead malfunction, lead fractures, and infection (Cheng, Wang, Curtis, & Varosy, 2010; Kirkfeldt et al., 2011; Udo et al., 2012).

Leadless pacemakers have been the center of attention due to its ability to address the limitations of traditional transvenous pacemakers. Two leadless pacemakers have been assessed for single-chamber right ventricular pacing. These include Nanostim LP (Abbott, formerly St. Jude, Lake Bluff, IL) and Micra Transcatheter Pacing System (Medtronic, Minneapolis, MN). Nevertheless, Nanostim is out of the market due to premature battery depletion (Yarlagadda et al., 2018). Leadless pacemakers are composed of a pulse generator, battery, and electrode in the same device (Reddy et al., 2015). It is placed through a catheter and is directly implanted into the right ventricle (Yarlagadda et al., 2018).

The leadless pacemaker's (Nanostim) length is 42 mm and a maximum diameter of 5.99 mm with a battery life ranging from 8.4 to 12.4 years (Reddy et al., 2015). A sheath is placed in the femoral vein, and with a sleeve-based catheter, the device is delivered to the right ventricle. The sleeve is then withdrawn, and the pacemaker is implanted into the endocardium while the device remains docked. The device is then undocked from the catheter but is still connected to the catheter through tether connections. This allows for device measurements and evaluation of stability without the catheter. Repositioning can be performed if the device is not well positioned. Once positioning is assured and the pacemaker parameters are optimal [(R wave amplitude ≥ 5.0 mV) and pacing threshold (≤ 2.0 V at 0.4 ms)] (Yarlagadda et al., 2018), the device is untethered from the catheter resulting in the final implant position (Reddy et al., 2015). The procedure is performed under fluoroscopy. After the procedure, patients are observed over a period of 24 hours and discharged (CADTH 2015). An external programmer is used to program Micra transcatheter pacing system.

Some differences are worth noted. The Nanostim pacemaker is smaller than the traditional pacemaker (<10%), with a battery life ranging between 8.4 years and 12.4 years. The Micra Transcatheter Pacing System pacemaker is 30% smaller than the Nanostim and its estimated battery life ranges from 10 to 15 years. Micra transcatheter pacing is 93% smaller than conventional pacemakers, about the size of a large vitamin capsule (<https://www.medtronic.com/us-en/patients/treatments-therapies/pacemakers/our/micra.html>). The insertion of these devices takes 20 to 45 minutes compared to 60 minutes for the conventional pacemaker (CADTH 2015).

Medical Technology Assessment Committee (MTAC)

Leadless Pacemakers for the treatment of cardiac arrhythmias

Date: 04/21/2019

Evidence Conclusion:

- In patients with cardiac arrhythmias who require single-chamber ventricular pacing, there is insufficient evidence to compare leadless pacemakers with conventional pacemakers. However, serious complications are non-negligible.
- Randomized controlled trials with longer-term follow-up and direct comparisons are warranted.

Articles: PubMed was searched through March 8, 2019 with the search terms ((Nanostim Leadless Pacemaker OR Micra Transcatheter Pacing System OR leadless pacemaker)) AND (traditional pacemakers OR conventional pacemakers). Other search terms included (Nanostim Leadless Pacemaker OR Micra Transcatheter Pacing System OR leadless pacemaker) filters: observational study. The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. Randomized controlled trials, and observational studies were included in the search. Clinicaltrials.gov was also searched. Three studies were retained and reviewed. See [Evidence Table](#).

The use of Leadless Pacemakers for the treatment of cardiac arrhythmias does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Hayes Technology Assessment

Micra Transcatheter Pacing System (Medtronic Inc.) for Single Chamber Pacemaker Indications

Date: July 3, 2022

The Micra TPS is a single-chamber right ventricular pacing device. The device senses electrical activity of the heart via electrodes within the device's titanium capsule. Heart rhythm is monitored for bradycardia. Rate-adaptive pacing therapy is provided based on programmed pacing parameters. The Micra TPS is self-contained and does not require a surgical incision in the chest or intravascular leads. It is inserted via a 23-French catheter placed in the femoral vein and held in place within the right ventricle of the heart via nitinol tines that attach to the myocardium.

Conclusion

A low-quality body of evidence suggests that Micra TPS is associated with a high rate of procedural success and that pacing capture thresholds remained low and stable after implantation for up to 36 months. Major complications are comparable with and perhaps lower for Micra TPS versus TVPM, and revision and retrieval rates are lower for Micra TPS than TVPM. However, the clinical significance of any benefits introduced by use of the Micra TPS is uncertain due to the small body of evidence directly evaluating patient-centered outcomes.

Hayes Rating: C

Background

Food allergy affects 1-3% of children in developing countries, and the prevalence of food allergy has increased dramatically in the past several decades. For many years' scientists believed that delaying the introduction of allergenic foods into an infant's diet was beneficial, though more recent evidence has questioned this assumption. The "Learning Early About Peanut Allergy" (LEAP) Study, sponsored in part by FARE (Food Allergy Research and Education) and the National Institute of Allergy and Infectious Disease, hypothesized that the early introduction of peanuts into the diet of high-risk infants may prevent peanut allergy. LEAP Study design: The LEAP study enrolled 640 "high risk" infants between age 4 months and 11 months. High risk was defined as having moderate to severe eczema (persistent rash affecting > 75% of skin) and/or egg allergy since children with these problems are more likely to develop peanut allergy. All of the infants were skin tested to peanut. Those who had a strongly positive skin test (> 4 mm welt from prick test) were not allowed to continue in the study because they were assumed to have peanut allergy. The rest of the infants were randomly assigned to either consume peanut at least 3 days a week until age 5 (equivalent of 6 tsp peanut butter per week) or to avoid peanuts until age 5. Importantly, all these high-risk infants randomized to consume peanut underwent supervised oral challenge to peanut in the allergy clinic before feeding peanut at home.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
95076	Ingestion challenge test (sequential and incremental ingestion of test items, eg, food, drug or other substance); initial 120 minutes of testing
95079	Ingestion challenge test (sequential and incremental ingestion of test items, eg, food, drug or other substance); each additional 60 minutes of testing (List separately in addition to code for primary procedure)
with dx of peanut allergy

Background

The term 'seasonal affective disorder' (SAD) was first introduced by Rosenthal and colleagues in 1984 who described a series of patients with a history or recurrent depressions that occurred in the fall or winter and spontaneously remitted in the following spring or summer. Two seasonal patterns of SAD have been described; the summer-onset SAD and the fall-onset SAD. The latter, also known as "winter depression", is the most common pattern of the disorder. SAD affects about 5-6% of the population in the U.S. and its prevalence increases with latitude. This ranges from 1.4% in Florida to 9.7% in New Hampshire and 9.9% in Alaska. It is reported that SAD affects patients in their 20s, and that women are more likely than men to develop the disorder.

SAD was previously classified as a mood disorder in which people with normal mental health throughout most of the year experience depressive symptoms in the winter or summer. The Diagnostic and Statistical Manual of Mental Disorders DSM-IV and DSM-5 no longer classifies SAD as a unique mood disorder but describes it as a "specifier" or a subtype that can occur as part of unipolar major depression, bipolar I disorder, or bipolar II disorder. SAD is characterized by typical symptoms of major depression such as low mood, lack of drive, lack of concentration, and decrease in interest. In addition, patients exhibit more atypical depressive symptoms such as hypersomnia, increased appetite with carbohydrate craving, weight gain, irritability, and anger attacks. Symptoms usually resolve in the summer, and rarely progress to manic episodes of bipolar disorder.

The exact mechanism of SAD is still under investigation, but it is hypothesized that it is related to natural seasonal variations in light levels. According to this hypothesis “the phase shift hypothesis” fewer daylight hours in the winter causes a circadian misalignment between the biological clock and solar cycle leading to disturbances in the melatonin levels and longer periods of its synthesis at night. Melatonin, also called circadian hormone, peaks in the darkness and promotes sleep. It is believed that its increased daytime levels contribute to the depressive symptoms of SAD. Other neurotransmitters under circadian control e.g. serotonin, norepinephrine, and dopamine are also believed to have a role in the SAD mood alterations. However, no studies have established a causal relationship between decreasing daylight and the winter SAD.

Three types of treatment are being used for patients with SAD: pharmacological therapy, cognitive behavioral therapy (CBT), and light therapy. Antidepressant medication is an accepted treatment for depression in general, and three SSRIs have shown favorable results with SAD. CBT may help reduce the risk of relapse of major depression, but only few small studies evaluated its effectiveness for SAD.

Light therapy using light boxes was introduced as a treatment for SAD when the disorder was first described in 1984, based on the phase shift hypothesis. Early studies examined the effect of bright white light on circadian rhythm. Other research investigated less intense light and showed that it may have a larger capacity to regulate the biological clock than higher intensity light. A small study showed that blue light with an intensity of about 460 m may have a significant effect on melatonin suppression and circadian phase shifting.

Currently there are a number of commercially available light therapy products. These include bright light boxes, lamps, light visors, and dawn simulators. Light boxes come in different shapes and sizes, and with varied features and intensities of light. There is no well-accepted standard protocol for light therapy. Commonly bright-light therapy (BLT) is applied using a light box containing fluorescent lamps, a reflector and a diffusing screen. For adequate treatment light intensities of 5,000-10,000 lux measured at the level of the eyes, and at a therapeutic distance of 60-80 cm from the light box is considered as a standard requirement. Patients do not need to look directly into the light source as long as the light meets the eye at an angle of 30-60°. Treatment is usually started with using a light intensity of 10,000 lux for 30 minutes. The duration of treatment may be increased in case of insufficient response or when using less powerful light boxes. It is reported that morning administration of BLT offers greater chance of remission, that compliance is the primary factor for success of the therapy, and that the therapeutic effect is demonstrated in 3-7 days and disappears shortly after the treatment is discontinued.

Light boxes are designed to be safe and effective but are not regulated as devices by the Food and Drug Administration (FDA). A number of side effects of light therapy for SAD have been reported but are generally mild and/or transient. These include headache, nausea, agitation, eye strain and blurred vision. Evening light therapy may lead to sleep disturbances. Suicidality, menstrual irregularity, and hypomania in bipolar patients have also been reported. Retinal degeneration after prolonged exposure to intensive light has been noticed in rodents but was not confirmed in humans. However, it is recommended that caution must be used with patients at higher risk of retinal damage or those who need photosensitizing medication.

Medical Technology Assessment Committee (MTAC)

Light Therapy in the Treatment of Seasonal Affective Disorder (SAD)

06/02/2008: MTAC REVIEW

Evidence Conclusion: There is evidence from a meta-analysis of placebo-controlled RCTs (Golden et al., 2005) that bright light therapy and dawn simulation are both effective for treating SAD in non-geriatric adults. Strength of the meta-analysis was that the investigators used strict criteria to ensure that studies had a valid placebo control. Limitations are that studies tended to be small (all had <100 participants) and the minimum treatment duration was 4 days. Moreover, studies had different treatment protocols and thus conclusions cannot be drawn about the effectiveness of a particular approach to light therapy (e.g. lux, frequency of sessions, length of treatment). There is currently no generally accepted protocol for light therapy. When the two RCTs in the meta-analysis with the longest treatment durations and largest sample sizes were examined closely, bright light therapy did not clearly appear to be effective. Avery et al. (2001) did not find that bright light was significantly superior to placebo. Eastman et al. (2005) did not find a significant benefit to light therapy versus placebo for the outcomes change in SIGH-SAD score and response rate. They did find a significant benefit when examining the proportion of participants classified as near complete or complete responders. All of the studies on dawn simulation in the Golden et al. meta-analysis were conducted by the same research group. As the authors pointed out, the evidence would be strengthened if their findings could be replicated by different researchers in other locations. The largest study, Avery et al., (2001) found that dawn simulation was superior to both bright light and placebo for remission of SAD. The RCTs identified that compared light therapy to medication or cognitive-behavioral therapy did not have true placebo control groups and thus, intervention effectiveness beyond the placebo effect cannot be

determined. The Rohan et al. 2007 study found a lower post-treatment SAD score in patients receiving light therapy, CBT or their combination compared to a wait-list control. However, being on a wait-list could have a 'reverse placebo effect' since patients are not expecting to improve before receiving treatment. The Lam et al. (2006) studies did not find significant differences in response rates in groups assigned to light therapy or fluoxetine treatment.

Conclusion: A valid placebo group is important in RCTs of light therapy for SAD. A meta-analysis of placebo-controlled RCTs found a significant benefit of bright light and dawn simulation therapy. The meta-analysis was limited because studies tended to be small and of short duration. The largest RCTs in the meta-analysis did not find a significant benefit to bright light therapy. The evidence on dawn simulation is limited because all studies were done by the same research group and it is not known whether findings are generalizable. RCTs comparing light therapy to antidepressant treatment or psychotherapy did not include true placebo groups.

Articles: The ideal study would be a randomized controlled trial (RCT) or meta-analysis of RCTs that include a placebo or sham intervention. Studies comparing light therapy to medication therapy and/or psychotherapy should also have a placebo group. There was a protocol for a Cochrane review on light therapy for SAD. The protocol was published in 2003, and its status remains unchanged in Cochrane Library 2008, Issue 2. An estimated date for completion of the review is not available. One published meta-analysis was identified (Golden et al., 2005). The Golden study searched the literature to July 2003 and included only placebo-controlled studies. Golden et al. and the two RCTs in the meta-analysis with the largest sample sizes per treatment group and the longest trial duration (Avery et al., 2001; Eastman et al., 1998) were critically appraised. No large placebo-controlled RCTs published after the Golden meta-analysis was identified. There was one newer RCT comparing light therapy to fluoxetine treatment (Lam et al., 2006) and another comparing light therapy to cognitive-behavioral therapy (Rohan et al. 2007). These two new RCTs were also critically appraised. References for studies reviewed are as follows:

The use of light therapy in the treatment of Seasonal Affective Disorder (SAD) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

12/21/2015: MTAC REVIEW

Light Therapy for SAD

Evidence Conclusion: The ideal study for examining the effect of bright light therapy for SAD would be a double-blind randomized controlled trial that compares light therapy to a placebo or sham intervention. Studies comparing light therapy to pharmacological therapy or psychotherapy should also have a placebo group since there is limited evidence from placebo-controlled trials on the effectiveness of antidepressants or cognitive behavioral therapy on SAD. Light therapy versus placebo Martensson et al's meta-analysis, 2015 (Evidence table 1), pooled the results of 8 RCTs that compared light therapy to placebo (low negative air ions, dim red light, and dawn simulator placebo) to determine the effect bright white light (BWL) therapy on SAD. The authors performed two separate sets of meta-analyses; the first analyzed the results week-by-week, and the second analyzed the final results only. The pooled results suggest that BWL had a moderate effect on SAD symptoms compared to the controls (standardized mean difference [SMD] -0.54 (95% CI -0.95, -0.03), and that it reached statistical significance at week two and week three of treatment. The authors concluded that the BWL therapy seems to be effective, but they questioned the validity of the results due to the heterogeneity of the studies, lack of an appropriate placebo or sham light therapy control group, and other methodological limitations including the small sizes, short duration, and complex design of the trials. The results of Martensson et al's meta-analysis show a smaller effect size than that found in the Golden et al's meta-analysis reviewed earlier in MTAC (effect size 0.84, 95% CI 0.60, 1.08). As noted in the 2008 MTAC report, Golden et al's meta-analysis had the advantage of using strict criteria to ensure that studies had a valid placebo control, but was limited by the inclusion of very small studies with large treatment effect, short treatment durations, and the use different treatment protocols, which makes it difficult to draw any conclusion on the effectiveness of a particular approach to light therapy. When the two RCTs in the meta-analysis with the longest treatment durations and largest sample sizes were examined closely, bright light therapy did not clearly appear to be effective. Light therapy versus antidepressants In a Cochrane review on second-generation antidepressants for SAD, Thaler, et al (2011), pooled the results of two small trials (total N=136 participants) that

compared light therapy to fluoxetine and found no significant difference between the two therapies in response or remission of SAD. The trials were small, with limitations and high dropout rates, and the overall response rate (>50% improvement on 24-item HAM-D SIGH-SAD) was 68/100 in the light therapy group and 67/100 in the fluoxetine group. The authors concluded that the overall quality of evidence is a low and insufficient to draw any conclusion on the use of second-generation antidepressants for SAD. The only available RCT of fluoxetine vs. placebo showed a nonsignificant effect in favor of fluoxetine, and the two small trials that compared fluoxetine to light therapy showed no significant differences between the two therapies in the treatment of SAD. [Light therapy versus cognitive behavioral therapy \(evidence table 2\)](#) In a recent RCT, Rohan et al, 2015, compared the treatment outcomes of light therapy versus cognitive behavioral therapy for SAD. The trial randomised 177 participants to receive light therapy (using 23x15.5x3.25 in. SunRay that emits 10,000 lux of cool-white fluorescent light) immediately upon awakening, or to receive cognitive behavioral therapy (CBT-SAD) for 6 weeks. The primary endpoints of the trial were the change in depression severity SIGH-SAD during 6 weeks of therapy, and remission status after treatment. Overall, the results showed improvement in SAD symptoms in the two study groups with no significant differences between them at 6 weeks of treatment. There was no long-term follow-up to examine recurrence rates with each therapy. The trial was a relatively small, single center, RCT conducted mainly among white women. The participants were not blinded to the treatment allocation, which is a potential source of bias, and according to the authors, the primary investigator was the developer of CBT-SAD which is another potential source of bias. More importantly, light therapy was compared to CBT-SAD which has not been thoroughly investigated as a treatment for SAD. Ideally the trial would include a sham light therapy and/or a placebo group to determine the placebo effect of each of the two therapies.

Conclusion: There is insufficient evidence to determine the effectiveness of light therapy for the treatment of SAD. Several national and international guidelines recommend light therapy for SAD giving it a level 1 evidence (Canadian guideline, 2009) or level 2 evidence (AAFP, 2013), others like the British NICE guideline (2009) and the World Federation of Societies of Biological Psychiatry (WFSBP, 2013) are uncertain about the evidence supporting light therapy for SAD.

Articles: The literature search for studies on light therapy for SAD published after the last MTAC review revealed a recent systematic review with meta-analyses on bright light therapy for depression including SAD, a Cochrane review on second-generation antidepressants for SAD, a randomized controlled trial of CBT vs. light therapy for SAD, a crossover RCT investigating the rapid effects of light therapy on SAD, and a retrospective study investigating the appropriate duration of light therapy. The search also identified three small to relatively small RCTs that compared standard bright light vs. dawn simulation, low-intensity blue-enriched white light, or negative air ions, as well as a more recent trial on different intensities of transcranial bright light treatment delivered via the ear canals for SAD. The meta-analysis and the RCT comparing bright light therapy to CBT were selected for critical appraisal. The pooled results of studies comparing antidepressants vs. light therapy in the Cochrane review were included. Mårtensson B, Pettersson A, Berglund L, et al. Bright white light therapy in depression: A critical review of the evidence. *J Affect Disord.* 2015 Aug 15; 182:1-7. See [Evidence Table 1](#). Rohan KJ, Mahon JN, Evans M, et al. Randomized Trial of Cognitive-Behavioral Therapy versus Light Therapy for Seasonal Affective Disorder: Acute Outcomes. *Am J Psychiatry.* 2015 Sep 1; 172(9):862-869. See [Evidence Table 2](#).

The use of light therapy in the treatment of Seasonal Affective Disorder (SAD) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

07/08/2019: MTAC REVIEW

Light Therapy for SAD

Conclusion:

- The search identified one study which is a follow-up of one of the studies assessed in the last review in 2015. The study is of low quality and suggests that CBT may be comparable to LT in terms of recurrence and remission status at next winter. In addition, CBT might be more effective than light therapy two winters later. Studies with higher quality are needed to draw firm conclusions on light therapy and unipolar depression with seasonal pattern in the long-term. There is insufficient (high-quality) evidence for or against the use of light therapy in patients with unipolar major depression with seasonal pattern in the long-term.
- There is insufficient evidence for or against the effectiveness of light therapy as preventive treatment for patients with a history of SAD.

Articles: The search yielded 242 items; but one RCT and one meta-analysis were retained.

The use of light therapy in the treatment of Seasonal Affective Disorder (SAD) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered not covered:

HCPC Codes	Description
E0203	Therapeutic lightbox, minimum 10,000 lux, table top model
A4634	Replacement bulb for therapeutic light box, tabletop model

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

Kaiser Foundation Health Plan of Washington

PATIENT REFERRAL GUIDELINES

Liver Transplant

- Liver Transplant: Adult/Pediatric
- Living-Donor Liver Transplant: Adult – Adult
- Organ Transplantation in Members with HIV/AIDS

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Adult Liver Transplantation (260.1)
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

For Non-Medicare Members

Liver transplantation may be considered for patients with end-stage liver diseases who have no prospect for prolonged survival, or whose quality of life is severely impaired. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral.

1. GENERAL PRINCIPLES

- If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, then early referral should be made.
- Patients with a history of malignancy with a moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- Uncontrollable active infection outside of the hepatobiliary tree is a contraindication to liver transplant.
- Candidates with a history of substance abuse must be free from alcohol and other substance abuse and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low. [1.2.3](#) Exceptions may be made on a case-by-case basis.
 - For patients with a first alcohol-related / liver decompensating event, whose severity of liver disease suggests they are unlikely to survive to reach 6 months alcohol abstinence, see appendix for the "Kaiser Permanente Protocol: Reduced Duration Alcohol Sobriety Pathway to Liver Transplant Listing" (Appendix I).
- Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products to be actively listed.
- Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
- Patients must be willing and able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.
- Patients must have a caregiver or caregivers, who are physically and cognitively able to assist the patient with self-care activities and are able to travel within short notice to the KP approved transplant Center of Excellence.

- i. The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.
- j. Evidence of such non-adherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- k. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

2. INDICATIONS FOR LIVER TRANSPLANT

- a. Acute Fulminant Hepatic Failure. Refer patient as soon as diagnosis is made.
 - i. Progressive Coagulopathy
 - ii. Hepatic Encephalopathy
 - iii. Progressive Hyperbilirubinemia
- b. Chronic Liver Disease – referral is generally not advised until there is a MELD or PELD score of 15, with exceptions for the indications listed below: There is evidence that there is no survival benefit for patients transplanted with a MELD score <15. [4](#)
 - i. Hepatocellular Carcinoma
 - 1. Patients who meet Milan/UCSF criteria for hepatocellular carcinoma may be referred to transplant centers for transplant evaluation.
 - 2. Patients with hepatoblastoma who exceed Milan/UCSF criteria may be considered as liver transplant candidates on a case by case basis. [5](#)
 - 3. Pediatric patients with nonmetastatic and unresectable hepatoblastoma (PRETEXT IV and complex pretext III) should be referred for LT evaluation at the time of diagnosis or no later than after 2 rounds of chemotherapy.
 - 4. Pediatric patients with hepatoblastoma and pulmonary metastases can be considered for liver transplant if, following chemotherapy, a chest CT is clear of metastases or, if a tumor is identified, the pulmonary wedge resection reveal the margins are free of the tumor (AASLD/NASPGHAN guidelines 2014)
 - ii. Intractable Encephalopathy
 - iii. Intractable Ascites/ hepatic hydrothorax
 - iv. Intractable Variceal Bleeding
 - v. Cholestatic Liver Disease:
 - 1. Intractable Pruritis
 - 2. Recurrent Cholangitis
 - 3. Intractable Bone Disease
 - vi. Progressive Hepatopulmonary Syndrome
 - vii. Hepatorenal Syndrome
 - viii. Additional indications for liver transplant for the pediatric population: Urea cycle defects, organic acidemia and other metabolic disorder

3. CONTRAINDICATIONS FOR LIVER TRANSPLANT

- a. Advanced cardiopulmonary disease or any other life limiting disorder not corrected by liver transplantation. All patients should be evaluated for coronary artery disease (CAD) and occult cardiomyopathy. Hepatopulmonary syndrome and hepatorenal syndrome are not contraindications as they are correctable by transplantation.
- b. Patient whose HCC exceeds Milan criteria or whose alpha fetoprotein (AFP) level is greater than 1000 ng/ml should not be referred for transplant until they have been down staged successfully to within Milan criteria and/or an AFP level of less than 500 ng/ml. Exceptions may be made on a case by case basis for hepatoblastoma. [6,7](#)
- c. Absolute contraindication of liver transplant in pediatric patients - Severe multisystem mitochondrial disease

4. RELATIVE CONTRAINDICATIONS FOR LIVER TRANSPLANT

- a. Pulmonary hypertension with pulmonary artery systolic pressure 50 mmHg or mean >35 mmHg (despite optimal medical management).
- b. Renal failure (excluding hepatorenal syndrome)
- c. Active infection outside the hepatobiliary system
- d. Advanced malnutrition
- e. Severe diabetic complications
- f. Inability to control HbA1C <8
- g. Massive obesity
- h. Multiple abdominal surgeries

- i. Significant irreversible neurologic dysfunction.
- j. Highly selected patients with only intra-ductal cholangiocarcinoma may be considered for transplant on a case-by-case basis, at a transplant center with an established cholangiocarcinoma program. [8.9](#)

5. MULTIPLE ORGAN TRANSPLANTS INCLUDING LIVER

Liver transplantation combined with another organ transplant is indicated in special circumstances in pediatric and adult patients. Examples include, but are not limited to, liver/kidney, liver/lung and liver/heart. These combined organ transplants require case by case evaluation.

6. SPECIAL CONSIDERATIONS FOR LIVING DONOR LIVER TRANSPLANT

In addition to the current KP cadaveric donor patient referral guidelines for adults, the following should be considered when presented with a potential living donor liver transplant.

- a. No recipient should be considered for living donor liver transplant if in status 1 fulminant liver failure.
- b. Patients with MELD < 15 but with complications of liver disease that are uncorrectable and not reflected in the MELD score may be considered for living donor liver transplantation on a case by case basis after consultation with a hepatologist.
- c. Recipients with hepatocellular carcinoma (HCC) should meet the same guidelines as listed for cadaveric donor patient referral guidelines.
- d. Living donor liver transplant is not contraindicated for pediatric patients with acute liver failure if patient is a candidate for liver transplant.

7. ADDITIONAL INFORMATION ON LIVER TRANSPLANTATION

For additional information about UNOS policies on organ allocation and candidate criteria, please visit https://optn.transplant.hrsa.gov/media/1200/optn_policies.pdf#nameddest=Policy_09

APPENDIX I:

Reduced Duration Alcohol Sobriety Pathway to Liver Transplant Listing - Kaiser Permanente Protocol

(For Northern California, please consult the "[Reduced Duration Alcohol Sobriety Pathway to Liver Transplant Listing Kaiser Permanente Northern California Protocol](#)", available on the Clinical Library under Northern California)

BACKGROUND / PURPOSE:

- There is data suggesting that the currently utilized 6-month alcohol sobriety rule needed for liver transplant listing may not be the best predictor of relapse on a liver transplant list or post-transplant
- Some liver transplant programs in the United States and Europe accept a reduced duration alcohol sobriety pathway to liver transplant listing
- This protocol is designed to evaluate and qualify Kaiser Permanente patients for liver transplant listing who have not reached 6-months of alcohol sobriety

WHO THIS PATHWAY APPLIES TO:

- This protocol applies to patients with a first alcohol-related / liver decompensating event (as defined below) and whose severity of liver disease suggests they are unlikely to survive to reach 6 months alcohol abstinence (see suggested scenarios below)
- Patient must be without incapacitating hepatic encephalopathy and/or cannot be intubated when evaluated by addiction medicine and supporting gastroenterology and hepatology physician
 - Family/family friends or significant others will not be used as sole historians in the event the candidate is incapacitated with hepatic encephalopathy and/or intubated
- This protocol does not apply to patients who are not presenting with a first liver-decompensating event or who have already reached 6 months alcohol abstinence. Standard criteria for liver transplant listing should be applied to those patients.

Protocol Flow Diagram:

First Alcohol-Related / Liver Decompensating Event¹ & Unlikely to Survive to 6 Months Sobriety²

DEFINITION OF FIRST ALCOHOL-RELATED / LIVER DECOMPENSATION

To help define a potential first alcohol-related / liver decompensating event, try to answer this question: When faced with the knowledge that their alcohol use was linked to a negative effect on their legal status or medical health, did the candidate stop drinking? If no, then the candidate's presentation with severe alcoholic hepatitis or acute on chronic liver failure is not considered their first decompensating event, as it demonstrated poor insight and decision-making. These criteria represent relatively easy to find information within the medical chart that represent exclusion criteria.

- Exclusion of patients with history of hospital admission due to the following complication of alcohol abuse within *the last 2 years*:
 - Alcohol-related hepatitis
 - Alcohol-related pancreatitis
 - Alcohol-related cardiomyopathy
 - Alcohol withdrawal (including delirium tremens and/or seizures)
 - Alcohol psychosis
- Exclusion of patients with history of an emergency room visit due to the following complication of alcohol abuse within *the last 2 years*:
 - Alcohol-related hepatitis
 - Alcohol-related pancreatitis
 - Alcohol-related cardiomyopathy
 - Alcohol withdrawal (including delirium tremens and/or seizures)
 - Alcohol psychosis
 - Alcohol intoxication with or without a complication (like fall or altercation)
- Exclusion of patients with *more than one* failed alcohol rehabilitation attempt within *the last 2 years*
- Exclusion of patients with any previous diagnosis in problem list of the following complications of alcohol abuse within *the last 2 years*:

- Alcohol-related hepatitis
- Alcohol-related pancreatitis
- Alcohol-related cardiomyopathy
- Severe alcohol use disorder
- Exclusion of patients with any previous diagnosis in problem list of alcohol-related cirrhosis at *any time*.
- Exclusion of patients with active polysubstance abuse (any co-substance except for marijuana and/or nicotine) within *the last 2 years*.

UNLIKELY TO SURVIVE TO REACH 6 MONTHS ALCOHOL ABSTINENCE

No comprehensive definition of patients with severe acute alcohol related hepatitis or alcohol related acute on chronic liver failure can be provided. Ultimately, this assessment is left to patient's treating hepatologist and larger treatment team. Some suggested scenarios include:

- Patient with severe acute alcoholic hepatitis (Maddrey's Discriminant Function >32) who is not a candidate for or has failed medical management (including use of prednisolone with or without N-acetylcysteine infusion with resultant 7-day Lille Score > 0.45)
- Inpatient with persistent MELD score > 30 (see 3-month predicted survival based on MELD score below) Inpatient with dialysis dependent hepatorenal syndrome type 1

3-Month Mortality Based on MELD Scores

The estimated 3-month mortality is based on the MELD score highlighted in yellow above.

MELD Score	Mortality Probability
40	71.3% mortality
30-39	52.6% mortality
20-29	19.6% mortality
10-19	6.0% mortality
9 or less	1.9% mortality

2. Liver Transplant Surg. 1997, Vol 3, 304 – 310. The natural history of alcoholism and its relationship to liver transplantation.
3. Alcohol abstinence prior to liver transplantation for Alcoholic Liver Disease (G110807), TPMG New Medical Technology
4. American Journal of Transplantation 5 (2) 203-205, February 2005.
5. Hepatoblastoma (HB) is the most common type of liver cancer in children. The gold standard treatment of HB is perioperative chemotherapy followed by complete resection of tumor. Liver transplantation (LT) for children with HB should be considered (even if beyond Milan criteria) if the tumors are nonresectable or show chemotherapy resistance. LT for children with HB should be considered even with very high AFP levels. LT may be considered even if there is a history of pulmonary metastasis (after thoracotomy and resection +/- chemotherapy). Contraindications to LT for HB: Vascular invasion (including tumor clot).
6. The Milan Criteria for liver patients with HCC is 1 tumor: 5 cm or 2 – 3 lesions, none >3 cm and no vascular invasion. Source: NEJM 1996, 334; 693-699.
7. The UCSF/Region 5 Criteria for liver patients with HCC is 1 tumor: 6.5 cm, or 2 – 3 lesions, none >4.5 cm and total tumor diameter ::8 cm, and no vascular invasion. Hepatology, 2001, 33; 1394-1403.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Liver transplantation or hepatic transplantation is the replacement of a diseased liver with a healthy liver from another person (allograft). Liver transplantation is a viable treatment option for end-stage liver disease and acute liver failure.

Medical Technology and Assessment Committee (MTAC)

Living-Donor Liver Transplant – Adult-to-Adult

BACKGROUND

Living donor liver transplantation (LDLT) was developed as an alternative to cadaveric liver transplantations due to the dramatic shortage of available livers. LDLT to pediatric recipients was introduced into clinical practice in 1989 and the procedures are now performed worldwide. Adult-to-adult LDLT was initiated in the United States in the late 1990s. In 1997, one adult-to-adult LDLT was performed at one center in the U.S. and this grew to 266 procedures at 38 centers in 2000 (Brown et al, 2003). Left lateral segmentectomy, which uses approximately 20% of the hepatic mass, is generally used for LDLT to pediatric donors. However, these grafts provide insufficient liver mass for an average sized adult recipient. With adult recipients, a larger portion of the donor's liver must be taken which poses increased risks to the donor. Adult-to-adult liver transplantation involves either a full left or right hepatic lobe. Initially, all adult LDLT used the smaller left hepatic lobe. The hepatic mass was sufficient for some Asian recipients, but not for the average U.S. patient. Currently, adult-to-adult LDLTs in the U.S. use donation of the right hepatic lobe, which represents about 60% of the hepatic mass. Risks to the donor in adult-to-adult LDLT include the possibility that the donor will not be left with sufficient hepatic function, the possibility of biliary complications, risks associated with blood transfusion, risks associated with surgery and unknown, long-term risks associated with major hepatic resection. (American Society of Transplant Surgeons: Ethics Committee, 2000; Renz and Roberts, 2000; Hayashi & Trotter, 2002). There is an ethical debate on adult-to-adult LDLT centering on the question of whether or not it is acceptable for a consenting healthy individual to undergo this surgery and take the risk of complication or death in order to potentially save the life of a loved one. LDLT programs conduct extensive physical and psychological examinations of donors. Related ethical issues are how to select adult recipients of LDLT (i.e. to what extent are they at risk of dying), how successful LDLT is in adult recipients (i.e. increased life expectancy in recipient vs. risk to donor) and how to allocate cadaveric livers.

04/12/2000: MTAC REVIEW

Living-Donor Liver Transplant – Adult-to-Adult

Evidence Conclusion: The limited amount of evidence available is not sufficient to determine the safety and efficacy of LRLT. Case series reports were the best available evidence. The published case studies have small sample sizes and were not rigorously performed (i.e. did not specify inclusion/exclusion criteria or outcome measurement, had variable and relatively short length of follow-up). In addition, the published studies report on different clinical techniques for performing LRLT and these individual techniques have not been systematically evaluated.

Articles: There were no randomized control trials, meta-analyses or cohort studies. Case series for adult-to-adult transplants all had small sample sizes (<50). Several larger case series included both adults and children as recipients and did not present results separately. Evidence tables were created for those with the largest sample sizes: (n=33) Hashikura, Y, Kawasaki, S, Miyagawa, S, Terada, M, Ikegami, T, Miwa, S, Kubota, T, Mita, A. Living-related donor liver transplantation in adults: Experience at Shinshu University Hospital. Transplantation Proceedings 1999; 31: 1953-4; (N=25) Marcos, A, Fisher, RA, Ham, JA, Shiffman, ML, Sanyal, AJ, Luketic, VAC, Sterling, RK, Posner, MP. Right lobe living donor liver transplantation. Transplantation 1999; 68: 798-803. Hashikura, Y, Kawasaki, S, Miyagawa, S, Terada, M, Ikegami, T, Miwa, S, Kubota, T, Mita, A. Living-related donor liver transplantation in adults: Experience at Shinshu University Hospital. Transplantation Proceedings 1999; 31: 1953-4. [See Evidence Table.](#) Marcos, A, Fisher, RA, Ham, JA, Shiffman, ML, Sanyal, AJ, Luketic, VAC, Sterling, RK, Posner, MP. Right lobe living donor liver transplantation. Transplantation 1999; 68: 798-803.

[See Evidence Table.](#)

The use of Adult to Adult Living Related Donor Liver Transplant treatment of Liver Failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

06/11/2003: MTAC REVIEW

Living-Donor Liver Transplant – Adult-to-Adult

Evidence Conclusion: There is a lack of evidence on the effectiveness of adult-to-adult living-donor liver transplantation compared to cadaveric whole or split-liver transplantation and one small study (Liu) that addresses the effectiveness of LDLT compared to remaining on a wait list for cadaveric transplantation. Liu found a higher survival rate with right lobe LDLT than no transplantation among patients with acute liver failure; however, findings do not necessarily generalize to patients with other indications for transplantation.

The remaining studies are case series. One-year recipient survival rates were 72% in the case series of 308 adults from Japan (Todo) in which 71% of the operations were left-lobe transplantations and 85% for 50 right-lobe operations in the U.S. (Miller). No peri-operative donor mortality was reported in the recent case series articles. Brown identified one donor death among 449 right-lobe adult-to-adult living-donor transplantations performed in the U.S. between 1997 and 2000. Brown's survey found a 14.5% donor complication rate including 6% experiencing biliary leakage and 4.5% needing re-operation. A limitation of the case series data and the Brown survey data is variability in the eligibility criteria and interventions across centers and within centers over time. There are no quality long-term data on outcomes among recipients or donors.

Articles: The search yielded 206 articles, many of which were reviews, opinion pieces or dealt with technical aspects of the procedure. There were no randomized controlled trials. The next preference was given to non-randomized comparative trials. There was one study that compared patients with acute liver failure who did and did not opt for LDLT; this study was reviewed. The remaining studies were case series. Other articles selected were the largest case series (conducted in Japan), the largest case series in the United States and a survey of transplantation programs focusing on donor outcomes. The following four articles were critically appraised: Liu CL, Fan ST, Lo CM et al. Right-lobe live donor liver transplantation improves survival of patients with acute liver failure. *Br J Surg* 2002; 89: 317-322. [See Evidence Table](#). Todo S, Furukawa H, BonJin M et al. Living donor liver transplantation in adults: Outcome in Japan. *Liver Transplantation* 2000; 6 (Suppl 2): S66-S72. [See Evidence Table](#). Miller CM, Gondolesi CE, Florman S. et al. One hundred nine living donor liver transplants in adults and children: A single-center experience. *Ann Surg* 2001; 234: 301-012. Brown RS, Russo MW, Lai M. et al. A survey of liver transplantation from living adult donors in the United States. *N Engl J Med* 2003; 348: 818-825. [See Evidence Table](#).

The use of Adult to Adult Living Related Donor Liver Transplant treatment of Liver Failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Kidney Transplantation in the treatment of HIV+

BACKGROUND

HIV infected patients are at risk for end-stage renal disease caused by HIV-related disease such as HIV-associated nephropathy and hepatitis C infection. HIV-positive patients co-infected with hepatitis B or hepatitis C are also at risk of progression of liver disease (Roland & Stock; Fishman). Until recently, HIV-positive patients have been excluded from organ transplantation programs. A primary reason for this exclusion has been the belief that patients in an immuno-compromised state would be adversely affected by the immunosuppression required for transplantation. Several changes have occurred that have caused some transplant centers to question the exclusion based on HIV infection. Highly active anti-retroviral therapy (HAART) became available in the mid to late 1990s. HAART can prolong survival in HIV-positive patients, thereby increasing the number of patients with stable HIV infection who progress to end-stage organ failure. In addition, there have been improvements in immunosuppressive drug regimens and surgical techniques associated with transplantation. This review will evaluate the evidence published to date on the safety and efficacy of organ transplantation among HIV-positive patients in the HAART era. Kidney transplantation in HIV positive patients was previously reviewed by MTAC in December 2001. At that time, the evidence consisted of several case series with five or fewer HIV-positive patients and the item failed MTAC evaluation criteria. Other types of organ transplantation (liver, lung, heart) have not been reviewed by MTAC.

12/12/2001: MTAC REVIEW

Kidney Transplantation in the treatment of HIV+

Evidence Conclusion: There is insufficient published evidence on which to base a conclusion about the effect of kidney transplant in HIV-positive patients on health outcomes. Although recent changes in the prognosis of HIV-positive individuals suggest that some may benefit from kidney transplant, there are no direct empirical data to support this claim.

Articles: The search yielded 64 articles, many of which dealt with other related procedures or populations or were review articles or opinion pieces. No articles with empirical data were included in the search. Three older case series were identified in the reference list of the Gow review article. Each of these case series included 5 or fewer HIV-positive patients receiving kidney transplants. None of the articles was suitable for critical appraisal.

The use of Kidney Transplantation in the treatment of HIV+ patients with renal failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/11/2004: MTAC REVIEW

Heart, Lung, Kidney, & Liver Transplantation in the treatment of HIV+

Evidence Conclusion: There were two primary issues addressed in this review: 1) evidence on the safety and effectiveness of organ transplantation for HIV-positive individuals and; 2) evidence on whether survival among HIV-positive individuals who receive organ transplants is lower than among HIV-negative individuals. There is no published evidence on the safety and effectiveness of lung transplantation in HIV-positive individuals and only two case reports of heart transplants. There were no articles comparing transplantation to another intervention in HIV-positive patients with end-stage liver or kidney disease. The best published evidence on kidney and liver transplants in HIV-positive individuals is from cohort studies conducted in the HAART era. Abbott did a retrospective study comparing outcomes in HIV-positive and HIV-negative individuals, all of whom were identified in a national database of kidney transplants. Ragni compared survival in a prospective series of HIV-positive patients and a retrospective analysis of selected HIV-negative patients from the UNOS Scientific Registry for Liver Transplantation. In both studies, three-year survival rates did not differ significantly in the HIV-positive and HIV-negative groups. Limitations of both studies include: The relatively small sample sizes of HIV-positive patients, 24 in the Ragni study and 47 in the Abbott study. The HIV-positive and HIV-negative groups may have differed in ways that affected outcomes (despite statistical adjustment for confounding in the Abbott study). The authors commented that clinicians may have selected the healthiest HIV-positive patients for transplantation which might increase the likelihood of a successful outcome compared with the HIV-negative patients. The Abbott study was retrospective and the Ragni study included a prospective group of HIV-positive patients but did a retrospective analysis of the HIV-negative control group. Prospective designs are preferred. A prospective, multi-center uncontrolled study to evaluate the safety and efficacy of kidney and liver transplants performed in HIV-positive patients is currently in its early phases. The study is being coordinated by UCSF. The investigators anticipate enrolling up to 275 transplant recipients and following them for 2-5 years.

Articles: The search yielded 217 articles. Most were opinion pieces, on technical aspects of transplantation in HIV-positive patients and articles on related clinical topics. Empirical studies on specific types of organ transplantation were as follows: Lung There were no studies with empirical data. Heart There were two case reports, each reporting on a single case. The articles were ineligible for critical appraisal. Kidney and Liver There was one study on kidney transplants (Abbott et al., 2004) and one study on liver transplants (Ragni et al., 2003) that compared outcomes in HIV-positive patients to outcomes in HIV-negative patients. Data from HIV-negative patients were taken from national transplantation databases in both studies. These two studies were critically appraised. The largest published series from UCSF included 14 patients, 10 received kidney transplants and 3 received liver transplants (Stock et al. 2003). Newer reports with additional patients have been presented at conferences and discussed in review articles, but the data have not been published in empirical articles. The case series was not critically appraised due to the small sample and availability of comparative studies. There was also a retrospective cohort study evaluating data on kidney transplants from 1987-1997; this study was not critically appraised because it primarily included cases from the pre-HAART era.

The studies reviewed were Abbott KC, Swanson SJ, Agodoa LYC et al. Human immunodeficiency virus infection and kidney transplantation in the era of highly active antiretroviral therapy and modern immunosuppression. *J Am Soc Nephrol* 2004; 15: 1633-1639. See [Evidence Table](#). Ragni MV, Belle SH, Im K et al. Survival of human immunodeficiency virus-infected liver transplant recipients. *J of Infect Dis* 2003; 188: 1412-1420. See [Evidence Table](#).

The use of Heart Transplantation in the treatment of HIV+ patients with heart failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

The use of Lung Transplantation in the treatment of HIV+ patients with lung failure does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

The use of Kidney Transplantation in the treatment of HIV+ patients with renal failure evidence is not sufficient to determine whether HIV infection should or should not be an exclusion for kidney transplantation.

The use of Liver Transplantation in the treatment of HIV+ patients with renal failure the evidence is not sufficient to determine whether HIV infection should or should not be an exclusion for liver transplantation.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
47135	Liver allotransplantation, orthotopic, partial or whole, from cadaver or living donor, any age
47140	Donor hepatectomy (including cold preservation), from living donor; left lateral segment only (segments II and III)
47141	Donor hepatectomy (including cold preservation), from living donor; total left lobectomy (segments II, III and IV)
47142	Donor hepatectomy (including cold preservation), from living donor; total right lobectomy (segments V, VI, VII and VIII)
47146	Backbench reconstruction of cadaver or living donor liver graft prior to allotransplantation; venous anastomosis, each
47147	Backbench reconstruction of cadaver or living donor liver graft prior to allotransplantation; arterial anastomosis, each

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Localization System for External Beam Radiation" for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Prostate cancer is the most commonly diagnosed cancer and second leading cause of death in men in the United States. The treatment options for early-stage prostate cancer include radical prostatectomy, high dose brachytherapy, and high dose external beam radiation therapy (EBRT). Several studies showed improvement in biochemical progression free survival with radiation dose escalation. However, this comes at the cost of higher bladder and bowel toxicity. Investigators found that toxicity due to radiation therapy can be reduced by the use of intensity modulated radiotherapy (IMRT) techniques that focus a high dose radiation to the prostate while decreasing the dose to the bladder and rectum. With the higher doses being delivered with increased conformity,

it is critical that the isocenter of the prostate treatment volume be placed with precision (Kuban 2008, Quigley 2009, Rajendran 2010).

The prostate gland is known to have some movement during the day as the bladder and rectum are filled at different volumes. Two types of motion have been described and may be an issue for treatment planning: 1. Interfraction motion from day-to-day, and 2. Intrafraction movement that is motion occurring while the patient is on the treatment table during radiation delivery. This is thought to be caused by breathing or other biological factors as contraction/relaxation of the pelvic floor and by rectal gas. Target localization during radiation therapy for prostate cancer has two aspects: the initial setup before delivering the radiation, and the subsequent real-time target position monitoring during the actual delivery of radiation. The interfraction position has been addressed by various techniques including ultrasound, infrared cameras, diagnostic CT imaging, and x-ray imaging. The use of implanted markers as gold is accepted as an accurate, reliable, and reproducible method to establish the position of the prostate gland during EBRT treatment. Other techniques used to estimate the motion of prostate during delivery of radiation include transabdominal ultrasound, X-rays, MRI, CT, and fluoroscopy. The use of these technologies may be limited as they may not be available in the treatment room or usable during radiation delivery, provide only a snapshot of the prostate position, result into additional radiation dose, are labor intensive and /or require user skill for image acquisition or interpretation (Kupelian 2006, Rajendran 2010).

In the last few years, the use of an implantable radiofrequency emitting device has been proposed as an alternative to radiopaque fiducial markers and radiographic localization to provide an objective, accurate real-time method of localizing and monitoring prostate position. The Calypso 4D Localization System is based on electromagnetic detection of implanted Beacon transponders that allows the three-dimensional position of the implanted transponders and target isocenter to be tracked at a frequency of 10Hz. This provides continuous real-time localization and monitoring of the prostate. The Calypso System (Calypso Medical, Seattle, WA) consists of three implantable wireless Beacon transponders approximately 8 mm in length and 2mm in diameter, an electromagnetic array, an infrared camera system, and a tracking station. Typically, three transponders are implanted in the right and left base and the apex of the prostate gland under transrectal ultrasound guidance in a manner similar to needle biopsy. The coordinates of the Beacons and the isocenter are identified on the treatment planning CT and entered into the calypso tracking station. Similar to ultrasound localization, the initial localization with the Calypso System is performed using skin marks to align with room lasers. Calypso is used to localize the prostate and the system calculates the initial offset. The couch is shifted until the three offsets are zero. During treatment Calypso monitors and reports the offset between the actual and planned isocenter position (Santanam 2009, Foster 2010, Rajendran 2010).

Potential benefits of the Calypso system include its ability to continuously monitor target position during treatment, with no exposure to ionizing radiation to perform the localization, and without using complicated procedures of acquiring X-ray images. Potential disadvantages on the other hand, are the need for implantation, transponders stability within the implanted tissues, and the absence of any associated image of the targeted areas. The Calypso System has received 510 (K) clearance from the FDA in 2006.

Medical Technology Assessment Committee (MTAC)

Calypso 4D Localization System

12/20/2010: MTAC REVIEW

Evidence Conclusion: The published literature on the Calypso system is very limited and do not provide sufficient evidence to determine the safety of the technology or its effect on patients with localized prostate cancer treated with radiation therapy. The published studies were small case series the majority of which were conducted by the same group of authors many of whom had financial interest with the manufacturer of the technology. The safety of the Calypso system and its effect on improving health outcomes were not examined in randomized controlled trials. Assessing the Impact of Margin Reduction (AIM) study was the largest case series on the Calypso System published to date, and the first with clinical outcomes. However, it was not randomized and used a historical comparison group. It had several other limitations including the significant baseline differences between study participants and the comparison groups, difference in the time of treatment, and variations in the radiation therapy received by the two groups, as well as the absence of long-term follow-up to determine the effect of the technology on the incidence of late complications. Moreover only 83% of the participants were included in the analysis, and the study was funded by the manufacturer.

Articles: The published literature on the Calypso 4D localization system for the prostate is very limited. There are no published randomized controlled trials that compared the effect of the Calypso system versus other localization technologies on reducing radiation toxicity or improving quality of life (QoL) in patients with prostate cancer. The

literature search identified the 'Assessing the Impact of Margin Reduction (AIM)' study that assessed the effect of reducing the planning target volume margins while using real-time tumor tracking on the quality of life of patients with prostate cancer treated with radiation therapy. It did not include a comparison or control group. No trials on the safety of the technology were identified.

The AIM study was selected for critical appraisal: Sandler M, Liu P-Y, Dunn RL, et al. Reduction in patient-reported acute morbidity in prostate cancer patients treated with 81-Gy Intensity-modulated radiotherapy using reduced planning target volume margins and electromagnetic tracking: assessing the impact of margin reduction study. *Urology*. 2010 May;75(5):1004-8. Epub 2010 Feb 13. See [Evidence Table](#)

The use of Calypso 4D localization system (Calypso 4D localization and Tracking with Beacon transponders during external beam radiation therapy [Calypso Medical], GPS for the Body, electromagnetic localization system) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Not Medically Necessary:

CPT® / HCPC Codes	Description
77387	Guidance for localization of target volume for delivery of radiation treatment, includes intrafraction tracking, when performed
G6017	Intra-fraction localization and tracking of target or patient motion during delivery of radiation therapy (e.g., 3D positional tracking, gating, 3D surface tracking), each fraction of treatment

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Lung Cancer Screening with Low Dose Computed Tomography (LDCT) (210.14)
Local Coverage Determinations (LCD)	None
Local Coverage Article	Medicare Coverage of Screening for Lung Cancer with Low Dose Computed Tomography (LDCT)

For Non-Medicare Members

Low-dose CT screening for lung cancer will be covered when the patient meets the following criteria:

Ages 50 through 79: Annual screening for lung cancer with low dose computed tomography is recommended for patients who:

- Have at least a 20 pack-year smoking history,
- Currently smoke or quit less than 15 years ago, and
- Have no significant comorbidities that would preclude surgical treatment or limit life expectancy.

Ages 80 and over: Annual lung cancer screening with LDCT is not recommended.

Discontinuation

Discontinuation of lung cancer screening is recommended at 15 years following the patient's quit date, or as appropriate for health status.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Lung cancer is the third most common cancer and the leading cause of cancer death in the United States. According to the U.S. Preventive Services Task Force (USPSTF), nearly 90% of individuals with lung cancer die of the disease. However, when detected at an early stage, non-small cell lung cancer (NSCLC) has a better prognosis and can be treated with surgical resection. (The majority of lung cancer cases are NSCLC.)

The most important risk factor for lung cancer is smoking, which results in approximately 85% of all U.S. lung cancer cases. The incidence of lung cancer increases with age, occurring most commonly in individuals aged 55 years or older. Increasing age and cumulative exposure to tobacco smoke are the two factors most strongly associated with the occurrence of lung cancer.

The USPSTF found adequate evidence that annual screening with low-dose computed tomography (LDCT) in current and former smokers aged 55 to 79 years who have significant cumulative tobacco smoke exposure can prevent a substantial number of lung cancer deaths. LDCT has greater sensitivity for detecting early-stage cancer than chest X-ray and sputum cytology; however, it also has a very high rate of false positives (about 95%). For the benefits to outweigh the harms, screening needs to be limited to those who are at the highest risk for lung cancer.

Medical Technology Assessment Committee (MTAC)

Low-Dose CT Screening for Lung Cancer

12/12/2001: MTAC REVIEW

Evidence Conclusion: There is no evidence on the diagnostic accuracy of the low-dose CT test for lung cancer screening. That is, an independent, blind, comparison of the low-dose CT tests with a gold standard (e.g. high-dose CT) for an appropriate group of patients. In the Henschke study, only patients with certain findings on low-dose CT were recommended to have high-dose CT. There are also no studies comparing the diagnostic accuracy of low-dose CT screening to the current standard, chest radiography. The only available evidence on low-dose CT screening for lung cancer is prospective reports of screening programs. Henschke set up a protocol to screen individuals at increased risk of lung cancer. They found that more non-calcified nodules, malignant nodules and stage I malignant disease was found using low-dose CT than could be detected by chest radiography. These data suggest that low-dose CT may be useful for lung cancer screening. The data presented in the Henschke study are insufficient for evaluating the question of whether screening with low-dose CT reduces disease-specific mortality. Even though more nodules and more stage I nodules were identified than with chest radiography, it is not known whether this early identification will lead to decreased mortality from lung cancer. (Previous randomized controlled trials evaluating the effectiveness of chest radiography for lung cancer screening did not find a difference in mortality in the screened and unscreened groups). Alternatively, CT screening may not increase disease-specific survival due to lead-time bias and over diagnosis bias. Randomized controlled trials comparing CT screening to no screening would provide more rigorous information about its effectiveness as a screening strategy.

Articles: The search yielded 54 articles, many of which were review articles, opinion pieces or dealt with technical aspects of the procedure. There were no randomized controlled trials or meta-analyses. Five case series with relevant clinical outcomes were identified. Four were studies conducted in Japan and one was a study conducted at Cornell University. Of the four Japanese studies, there were two studies by Sone et al. and two studies by Kaneko et al. The Sone articles were an earlier and later report on the same project, as were the Kaneko articles. Neither of the Japanese screening projects had specific clinical inclusion and exclusion criteria. The Sone study screened the general population and the Kaneko study screened people who were members of a non-profit organization, the Anti-Lung Cancer Association (ACLA). In addition, neither Japanese screening project appeared to have a consistent protocol that was followed. The Cornell University study by Henschke et al. screened only individuals at high-risk of lung cancer and had clear eligibility criteria as well as screening and follow-up protocols. None of the articles were designed to evaluate the diagnostic characteristics of the low-dose CT test (e.g. sensitivity, specificity). *An evidence table was created for the Henschke study:* Henschke CI, McCauley DI, Yankelevitz DF, Naidich DP, McGuinness G, Miettinen OS, Libby DM, Pasmantier MW et al. Early Lung Cancer Action Project: Overall design and findings from baseline screening. *Lancet* 1999; 354: 99-105. See [Evidence Table](#)

The use of CT Scanning in the screening of lung cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria 2* for effectiveness of diagnostic test.

Low-Dose CT Screening for Lung Cancer

8/15/2011: MTAC REVIEW

Evidence Conclusion: The National Lung Screening Trial (NLST), a large RCT that included 53,454 participants, examined whether screening high-risk individuals for lung cancer annually for three years with either LDCT or chest x-ray would reduce lung cancer mortality. Results from the NLST suggest that in high-risk patient's annual lung cancer screening for three years using LDCT reduced lung-cancer mortality with a number needed to screen to prevent one cancer death of 320. However, before recommending a screening test there are other factors to consider such as overdiagnosis, cost-effectiveness, false positive results, and other potential harms such as radiation-induced cancer. The effect of overdiagnosis and radiation-induced cancer could not be directly measured in this trial and cost-effectiveness analyses are currently underway. With regard to false positive results, across the three rounds of screening, 96.4% of the positive results in the LDCT and 94.5% in the x-ray group were false positive results. Additionally, 39.1% of subjects in the LDCT group and 16.0% in the x-ray group had at least one positive screening test during the screening phase of the trial (NLST 2011). A recent interim analysis from a RCT that included 2,472 men who were at high-risk for lung cancer examined whether yearly lung

cancer screening using LDCT in combination with a medical interview and physical exam would reduce lung cancer mortality compared to yearly medical interview and physical exam alone. After approximately 3 years of follow-up, significantly more men in the intervention group were diagnosed with lung cancer [intervention 60 (4.7%) vs. control 34 (2.8%), $P=0.02$]. However, there was no significant difference in lung cancer mortality between the two groups [intervention 20 (1.6%) vs. control 20 (1.7%), $P=0.84$]. Conclusion: Results from the NLST suggest that screening high-risk patients with LDCT annually for three years may reduce lung-cancer mortality; however, despite these positive results there are many other questions that still need to be answered such as screening frequency and duration. In 2007, the California Technology Assessment Forum evaluated the use of low-dose spiral computed tomography (LDCT) screening for lung cancer. They concluded that while the use of LDCT to screen for lung cancer in high-risk populations appeared promising, there was insufficient published evidence to recommend the use of LDCT outside of the investigational setting. Since the 2007 technology assessment, two randomized controlled trials (RCTs) were selected for review that examined the effectiveness of screening high-risk individuals for lung cancer using LDCT compared to chest x-ray.

Articles: The following studies were critically appraised: National Lung Screening Trial (NLST). Reduced lung-cancer mortality with computed tomographic screening. *N Engl J Med* 2011. [Epub ahead of print] See [Evidence Table](#) Infante M, Cavuto S, Lutman FR, et al. A randomized study of lung cancer screening with spiral computed tomography: three-year results from the DANTE trial. *Am J Respir Crit Care Med* 2009; 180:445. See [Evidence Table](#)

The use of CT Scanning in the screening of lung cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria 2* for effectiveness of diagnostic test.

Low-Dose CT Screening for Lung Cancer

10/15/2012: MTAC REVIEW

Evidence Conclusion: The Danish Lung Cancer Screening (DLCST), a RCT that included 4,104 participants, examined whether screening high-risk individuals yearly with LDCT would reduce lung cancer mortality compared to usual care (no screening). Results from this trial suggest that after 5 years of screening, LDCT did not reduce lung cancer mortality or all-cause mortality compared to usual care. Significantly more lung cancers were diagnosed in the screening group compared to the control group (69 vs. 24, $P<0.001$), and more were early stage (48 vs. 21, $P=0.002$). There was no significant difference in the number of late stage lung cancer (21 vs. 16, $P=0.51$). The diagnostic false positive rate was 7.9% at baseline, 1.7% at year 1, 2.0% at year 2, 1.6% year 3, and 1.9% year 4. One limitation of this trial is that the sample size may be insufficient and the duration of follow-up may not be long enough to detect a reduction in mortality (Saghir 2012) The Multicentric Italian Lung Detection (MILD), a RCT that included 4,099 participants, examined whether screening high-risk individuals yearly or every two years with LDCT would reduce lung cancer mortality compared to usual care (no screening). Results from this trial suggest that after 5 years of follow-up, annual or biennial screening with LDCT did not reduce lung cancer mortality compared to usual care. The incidence of lung cancer was significantly higher in LDCT screening groups compared to the control group ($P=0.025$), but not in the annual versus the biennial groups ($P=0.24$). Due to recruitment issues the trial may be underpowered to detect differences in mortality. Additionally, at baseline more subjects in the control group were current smokers (Pastorino 2012). Conclusion: Results from the NLST suggest that screening high-risk patients with LDCT annually for three years may reduce lung-cancer mortality; however, despite these positive results there are many other questions that still need to be answered such as screening frequency and duration, and the effects of cumulative radiation exposure. Results from other RCTs have not shown a mortality benefit; however, these trials may be underpowered.

Articles: Low-dose CT screening for lung cancer was previously reviewed in 2001 and 2011. Since the 2011 review, two randomized controlled trial were identified that assessed the benefits and harms of screening for lung cancer using low-dose CT in high risk patients. The following studies were critically appraised: Saghir Z, Dirksen A, Ashraf H, et al. CT screening for lung cancer brings forward early disease. The randomized Danish Lung Cancer Screening Trial: status after five annual screening rounds with low-dose CT. *Thorax*. 2012; 67:296-301. See [Evidence Table](#) Pastorino U, Rossi M, Rosato V, et al. Annual or biennial CT screening versus observation in heavy smokers: 5-year results of the MILD trial. *Eur J Cancer Prev*. 2012; 21:308-315. See [Evidence Table](#)

The use of CT Scanning in the screening of lung cancer does not meet the *Kaiser Permanente Medical Technology Assessment Criteria 2* for effectiveness of diagnostic test.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
71271	Computed tomography, thorax, low dose for lung cancer screening, without contrast material(s)
Diagnosis Codes	Description
Z87.891	Personal history of nicotine dependence
F17.210	Nicotine dependence, cigarettes, uncomplicated
F17.211	Nicotine dependence, cigarettes, in remission
F17.213	Nicotine dependence, cigarettes, with withdrawal
F17.218	Nicotine dependence, cigarettes, with other nicotine-induced disorders
F17.219	Nicotine dependence, cigarettes, with unspecified nicotine-induced disorders

National Coverage Determinations (NCD)	Laser Procedures (140.5)
Local Coverage Determinations (LCD)	None
Local Coverage Article	None

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Low level laser therapy (LLLT) is a non-invasive therapeutic option which uses low intensity light at a wavelength ranging from 540 to 830 nm. LLLT produces photochemical reactions and enhance the metabolism of cells. The photochemical reactions change the permeability of cell membrane, increase accumulation of mRNA and result in cell proliferation. After the light is applied, there is activation of photoacceptors, located in the mitochondria, followed by protein synthesis (through several mechanisms). The process reduces pain, causes anti-inflammatory effects, cell proliferation, neovascularization, and balancing immune system. LLLT uses photons at a non-thermal radiation and does not produce heat. In addition, no destruction of the surrounding tissue is reported. Since the density of LLLT is inferior to 5.0 W/cm², the technique is also called cold laser. (Rayegani, Raeissadat, Heidari, & Moradi-Joo, 2017).

Low-level light with different wavelengths is applied to a specific site. This is followed by absorption of the light by the tissue. The red or infrared light causes the photochemical response and regeneration described above. The wavelengths vary between 600 to 700 nm for small penetration and 780 to 950 nm for more profound penetration. The procedure is short, and no pain, sound, vibration or heat is generated. (<https://www.healthline.com/health/cold-laser-therapy#procedure>).

The clinical application of low-level laser therapy is broad, but it's mainly used for pain reduction. The current review will focus on knee pain (osteoarthritis/musculoskeletal disorders), painful diabetic neuropathy, and carpal tunnel syndrome.

The incidence and prevalence of osteoarthritis vary and depend on its definition. In the United States, its incidence is lower in African Americans than Caucasians (Nelson, 2018). Based on United States data ranging from 2007 to 2008, 7% of adults over age 25 had symptomatic knee osteoarthritis (Nelson, 2018). Knee osteoarthritis (KOA) is a degenerative disease characterized by gradual loss of cartilage. Symptoms of KOA include pain, limited range of motion, bony swelling, deformity, instability, disability, and reduced quality of life. The diagnosis is clinical; imaging can be performed if the diagnosis is not clear. Conservative therapy includes exercise therapy, non-steroidal anti-inflammatory drugs (NSAIDs), and low-level laser therapy (LLLT) (Stausholm et al., 2019).

Carpal tunnel syndrome is characterized by tingling, pain, even numbness in the wrist/hand. It is the result of compression of the median nerve.

Medical Technology Assessment Committee (MTAC)

12/20/2010: MTAC Review

Lower Level Laser Therapy for Pain

Evidence Conclusion: *Back pain* - A meta-analysis of 7 RCTs that included 384 participants assessed the effects of LLLT in patients with non-specific low-back. Because the studies included in the meta-analysis were heterogeneous with respect to population, intervention, and comparison group, it is difficult to draw conclusions on the clinical effect of LLLT for low back pain (Yousefi-Nooraie 2008). A double-blind RCT that included 80 participants was conducted after the meta-analysis and compared the effectiveness of LLLT on pain and functional capacity in patients with acute and chronic low back pain caused by lumbar disc herniation (LDH). Patients were randomized to one of four treatment groups: LLLT + hot pack (acute back pain), placebo LLLT + hot pack (acute back pain), LLLT + hot pack (chronic back pain), and placebo LLLT + hot pack (chronic back pain). After treatment, there were statistically significant improvements in pain, range of motion, and disability in all groups with respect to all outcome parameters. However, there was no statistically significant difference between the four treatment groups for any of the treatment parameters. This study had several limitations. The sample size may have been too small to detect between group differences and the follow-up duration was only 3 weeks (Ay 2010). *Neck pain* - A recent meta-analysis of 16 RCTs that included 820 participants assessed the safety and efficacy of LLLT in treating acute and chronic neck pain. Subjects with acute neck pain who were treated with LLLT were significantly more likely to experience an improvement in pain compared to subjects treated with placebo (RR 1.69, 95% CI 1.22 to 2.33). Patients with chronic neck pain treated with LLLT also experienced greater reductions in pain compared to patients receiving placebo (WMD 19.86, 95% CI 10.04 to 29.68). Results from this analysis also suggest that the effects of treatment may last as long as 22 weeks. Side-effects included tiredness, nausea, headache, and increased pain. Side-effects were generally mild and did not differ from those in the placebo group. Trials included in the meta-analysis were small RCTs that were heterogeneous with respect to laser parameters, application technique, and intended rationale for treatment (Chow 2009). A small double-blind RCT that included 60 participants investigated the clinical effects of LLLT in patients with acute neck pain with radiculopathy. Results from this study suggest that compared to placebo, patients treated with LLLT experienced significantly greater improvements in arm pain, disability, and neck mobility. There was no significant difference in neck pain between the two groups. All adverse events occurred in the LLLT group and included: transitional worsening of pain (6/30), persistent nausea (1/30), and increased blood pressure (1/30). Results from this study are generalizable to patients with acute neck pain with radiculopathy with severe levels of pain and moderate to severe levels of disability (Konstantinovic 2010). *Carpal tunnel syndrome - LLLT vs. placebo* A double-blind RCT that included 36 patients with mild to moderate carpal tunnel syndrome (CTS) evaluated the therapeutic effects of LLLT versus placebo for the treatment of CTS. The primary outcome measures included: pain, grip strength, symptom severity, functional status, and motor and sensory peak latency. After treatment there was no significant differences between LLLT and placebo for any of the outcomes except for pain. Patients who were treated with LLLT experienced a greater reduction in pain compared to patients treated with placebo. However, after 2 weeks of follow-up, patients who received LLLT showed significant improvement in pain, symptom severity, functional status, and grip strength. There was no significant difference in sensory peak latency or motor latency between the groups after treatment or after 2 weeks of follow-up. This was a small trial with a short duration of follow-up (Chang 2008). Another RCT that included 81 patients and compared LLLT to placebo found no significant difference with regard to pain and functional capacity between the two treatment groups after 12 weeks of follow-up (Evcik 2007). **LLLT vs. ultrasound** An RCT that included 50 patients with mild to moderate CTS (90 wrists) compared the efficacy of LLLT and ultrasound for the treatment of CTS. Results from this study suggest that compared to patients treated with LLLT, patients treated with ultrasound showed significant improvements in pain, pinch strength, grip strength, and electroneurographic measurements (Bakhtiary 2004). **Splinting vs. splinting + ultrasound vs. splinting + LLLT** A recent RCT that included 100 wrists of patients with mild to moderate CTS investigated the effectiveness of splinting, ultrasound, and LLLT for the management of CTS. The primary outcome measures were symptom severity, functional status, pain, median

nerve sensory velocity, and median nerve motor distal latency. For all measurements, the combination of a splint plus ultrasound or LLLT was significantly better than the use of a splint alone. Patients who were treated with a splint plus LLLT experience significantly greater reductions in pain and symptom severity compared to patients treated with a splint plus ultrasound. Results from this study should be interpreted with caution as power was not addressed, it was not stated if an ITT analysis was performed, 4 patients did not finish therapy, 6 patients were lost to follow-up, and splint compliance was not addressed (Dincer 2009). **Conclusion:** There is insufficient evidence to determine the safety and efficacy of LLLT for the treatment of: Low back pain, Neck pain, and Carpal tunnel syndrome

Articles: A meta-analysis of RCT and an RCT published after the meta-analysis were identified that addressed the safety and efficacy of LLLT for the treatment of low back pain. The literature search also revealed a meta-analysis and RCT that looked at LLLT for the treatment of neck pain. Several RCT were identified that addressed the efficacy of LLLT for the treatment of carpal tunnel syndrome. Trials were selected for review if they had more than 25 participants and compared LLLT alone or in combination with another therapy to placebo or another active treatment. The following studies were critically appraised: Ay S, Doğan SK, and Evcik D. Is low-level laser therapy effective in acute or chronic low back pain? *Clin Rheumatol* 2010; 29:905-910. See [Evidence Table](#). Bakhtiary AH and Rashidy-Pour A. Ultrasound and laser therapy in the treatment of carpal tunnel syndrome. *Aust J Physiother* 2004; 50:147-151. See [Evidence Table](#). No. CD005107.DOI: 10.1002/14651858.CD005107.pub4. See [Evidence Table](#).

The use of low-level laser therapy for pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

01/13/2020: MTAC Review

Lower Level Laser Therapy for Pain

Evidence Conclusion:

- Low evidence supports the effectiveness (reduction of pain and disability) of LLLT (with or without exercise therapy) in patients with knee osteoarthritis compared to placebo/sham.
- There is insufficient evidence to assess the safety of LLLT in patients with knee osteoarthritis or musculoskeletal disorders.
- There is also insufficient evidence to compare LLLT versus physical therapy or NSAIDs.
- The evidence is insufficient to assess quality of life.
- There is insufficient evidence to assess the effectiveness and safety of LLLT in patients with painful diabetic neuropathy.
- Low evidence indicates that LLLT may be more effective than placebo on the short-term, but there is insufficient evidence to compare LLLT vs ultrasound or as adjunct to other treatment for patients with carpal tunnel syndrome.

Articles: PubMed was searched through January 3, 2020. Search terms included Low level laser therapy OR LightForce OR Cold laser treatment OR cold laser therapy OR LLLT AND with variations. The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. Filters included meta-analysis and randomized controlled trials. The search yielded several articles. The following articles (under summary) were reviewed. [See Evidence Table](#).

The use of low-level laser therapy for pain does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met

Non-Medicare - Considered Not Medically Necessary

CPT® or HCPC Codes	Description
S8948	Application of a modality (requiring constant provider attendance) to one or more areas; low-level laser; each 15 minutes
0552T	Low-level laser therapy, dynamic photonic and dynamic thermokinetic energies, provided by a physician or other qualified health care professional

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

**To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).

For Non-Medicare Members

Kaiser Permanente has elected to use the Lower Limb Prosthesis (KP-0487) MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist, including the Prosthetics & Orthotics practitioner

***MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

A large number of lower limb prosthetic designs are now available. The choice of the most appropriate prosthetic depends on factors such as amputation level, height, weight, and activity level of the amputee. Prosthetics fall mainly under two broad functional groups: non-microprocessor-controlled prosthetics and microprocessor-controlled prosthetics. The normal gait cycle is comprised of the stance phase, the period when the leg is on the ground, and the swing phase, the period when the leg is off the ground. Non-microprocessor-controlled prosthetics incorporate friction, pneumatic, or hydraulics in the joint to control the swing and stance phases of gait. While they have helped amputees gain mobility these prosthetics have limitations. Prosthetics that utilize friction to control the swing phase can only be adjusted for one walking speed. Pneumatic and hydraulics prosthetics allow amputees to change their walking speed; however, these prosthetics do not incorporate adaptive stance phase control. The lack of adaptive stance phase control requires the amputee to lock the knee mechanism in full extension during stance to avoid buckling. The limitations of the non-microprocessor-controlled prosthetics result in gait asymmetries which may contribute to problems such as increased energy expenditure and secondary disabilities.

Microprocessor-controlled prosthetics incorporate sensors that measure angles and movement every 20 millisecond and alter the damping of the hydraulic unit for each phase of gait. This technology is intended to normalize the swing and stance phase of gait over a wide range of walking speeds. Potential benefits of this technology include: decreased effort in walking, improved gait symmetry, reduced need for muscular compensation on the contralateral limb, fewer falls, and more stable gait on uneven terrain, ramps, inclines, and stairs (Berry 2009, Segal 2006).

C-leg® is a microprocessor-controlled knee joint system with hydraulic stance and swing phase control. In 1999, C-Leg® (Otto Bock Healthcare, Duderstadt, Germany) received FDA approval.

Medical Technology Assessment Committee (MTAC)

Lower Limb Prosthesis

08/11/2004: MTAC REVIEW

Evidence Conclusion: The few studies published in peer-reviewed journals, included a small number of selected active participants, and do not provide sufficient evidence on effectiveness of the microprocessor-controlled lower limb prosthesis.

Articles: The search yielded 32 articles. The majority dealt with the technical aspects and mechanisms of action of the prostheses. The search did not reveal any randomized controlled trials. There was a pilot study (N=10) that compared the cognitive demand of walking using the intelligent prosthesis with the conventional damped knees. Another open crossover study of six amputees that compared the gait symmetry, energy expenditure, and patient impressions of the intelligent prosthesis to the standard pneumatic swing-phase control knee was also identified. The other reports/studies revealed by the search were small descriptive case series with less than 25 participants. None of the articles was selected for critical appraisal.

The use of microprocessor-controlled lower limb prostheses in the treatment of lower limb amputation does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/07/2006: MTAC REVIEW

Lower Limb Prosthesis

Evidence Conclusion: The few studies published in peer-reviewed journals, included small numbers of participants, and do not provide sufficient evidence to determine the effectiveness and benefit of the microprocessor-controlled lower limb prosthesis.

Articles: The search yielded 43 articles. The majority dealt with the technical aspects and mechanisms of action of the prostheses. The search identified one recent (Klute 2006) * small randomized controlled that compared the functional mobility and daily activity level of microprocessor-controlled hydraulic knee vs. the non-microprocessor hydraulic knee. Eighteen transfemoral amputees agreed to enroll in the study, but the majority withdrew before randomization. Eight amputees were randomized, and only five completed the trial. The other reports/studies revealed by the search were small comparative non-randomized studies or case series with less than 10 participants each. *None of the articles were selected for critical appraisal.*

The use of microprocessor-controlled lower limb prostheses in the treatment of lower limb amputation does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

10/18/2010: MTAC REVIEW

Lower Limb Prostheses

Evidence Conclusion: *Energy expenditure* - Two studies investigated the use of microprocessor-controlled prosthetics and non-microprocessor-controlled prosthetics with respect to energy expenditure. Both studies used a non-randomized, non-blinded cross-over design. The first study found no significant difference in energy efficiency; however, there was an increase in physical activity related energy expenditure when subjects used the microprocessor-controlled prosthetic (Kaufman 2008). The second study compared energy expenditure at self-selected typical and fast walking paces on a motorized treadmill. There was no significant difference in heart rate at either pace; however, when subjects used the microprocessor-controlled prosthetic there was a small, but statistically significant decrease in energy expenditure (Seymour 2007). *Walking speed and dynamics* - Seymour and colleagues also found that on a standardized walking obstacle course when subjects wore the microprocessor-controlled prosthetic they were significantly faster, took less steps, and had less step-offs than when they used the non-microprocessor-controlled prosthetic (Seymour 2007). Another study found that when subjects wore the microprocessor-controlled prosthetic walking speeds on a variety of surfaces improved and self-reported falls and stumbles decreased (Kahle 2008). Significant improvements in stair decent, hill decent time, hill affected side step length, and falls/stumbles were also found when subjects used a microprocessor-controlled prosthetic compared to when they used a mechanical prosthetic (Hafner 2007). Additionally, after

receiving the microprocessor-controlled limb, subjects demonstrated significant improvements in gait and balance (Kaufman 2007). *Preference* - In a survey of 368 amputees, the majority of participants reported improvements with the microprocessor-controlled prosthetic compared to the non-microprocessor-controlled prosthetic with regard to comfort, security, maneuverability, cosmetic attributes, adverse events, and safety (Berry 2009). The prosthesis evaluation questionnaire (PEQ) measures subjective prosthesis function and prosthesis-related quality of life. Three studies found improvement in PEQ scores when subjects used the microprocessor-controlled prosthetic (Hafner 2007, Kahle 2008, Kaufman 2008).

Conclusion: As the majority of the published studies to date are small and non-randomized it is hard to draw firm conclusions regarding the superiority of microprocessor-controlled prosthetics compared to non-microprocessor-controlled prosthetics; however, results from the above studies suggest that the microprocessor-controlled prosthetics decreased energy expenditure, improved walking speed and dynamics, and improved PEQ scores.

Articles: The literature search revealed several studies that compared non-microprocessor-controlled prosthetics and microprocessor-controlled prosthetics. The majority of the studies were small comparative non-randomized studies or case series with less than 20 participants. Studies with more than 10 participants were reviewed. One randomized trial was identified; however, it was not selected for review as it included only 8 participants.

The following studies were critically appraised: Berry D, Olson MD, and Larntz K. Perceived stability, function, and satisfaction among transfemoral amputees using microprocessor and non-microprocessor-controlled knees: a multicenter survey. *J Prosthet Orthot* 2009; 21:32-42. [See Evidence Table](#). Hafner BJ, Willingham LL, Buell NC, et al. Evaluation of function, performance, and preference as transfemoral amputees' transition from mechanical to microprocessor control of the prosthetic knee. *Arch Phys Med Rehabil* 2007; 88:207-217. [See Evidence Table](#). Kahle JT, Highsmith MJ, and Hubbard SL. Comparison of non-microprocessor knee mechanism versus C-Leg® on prosthesis evaluation questionnaire, stumbles, falls, walking tests, stair descent, and knee performance. *J Rehabil Res Dev* 2008; 45:1-14. [See Evidence Table](#). Kaufman KR, Levine JA, Brey RH, et al. Gait and balance of transfemoral amputees using passive mechanical and microprocessor-controlled prosthetic knees. *Gait Posture* 2007; 26:489-493. [See Evidence Table](#). Kaufman KR, Levine JA, Brey RH, et al. Energy expenditure and activity of transfemoral amputees using mechanical and microprocessor-controlled prosthetic knees. *Arch Phys Med Rehabil* 2008; 89:1380-1385. [See Evidence Table](#). Seymour R, Engbreston B, Kott K, et al. Comparison between C-Leg® microprocessor-controlled prosthetic knee and non-microprocessor controlled prosthetic knees: a preliminary study of energy expenditure, obstacle course performance, and quality of life survey. *Prosthet Orthot Int* 2007; 31:51-61. [See Evidence Table](#).

The use of microprocessor-controlled lower limb prostheses in the treatment of lower limb amputation does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

H CPC Codes	Description
L5010	Partial foot, molded socket, ankle height, with toe filler
L5020	Partial foot, molded socket, tibial tubercle height, with toe filler
L5050	Ankle, Symes, molded socket, SACH foot
L5060	Ankle, Symes, metal frame, molded leather socket, articulated ankle/foot
L5100	Below knee (BK), molded socket, shin, SACH foot
L5105	Below knee (BK), plastic socket, joints and thigh lacer, SACH foot
L5150	Knee disarticulation (or through knee), molded socket, external knee joints, shin, SACH foot
L5160	Knee disarticulation (or through knee), molded socket, bent knee configuration, external knee joints, shin, SACH foot
L5200	Above knee (AK), molded socket, single axis constant friction knee, shin, SACH foot
L5210	Above knee (AK), short prosthesis, no knee joint (stubbies), with foot blocks, no ankle joints, each
L5220	Above knee (AK), short prosthesis, no knee joint (stubbies), with articulated ankle/foot, dynamically aligned, each
L5230	Above knee (AK), for proximal femoral focal deficiency, constant friction knee, shin, SACH foot
L5250	Hip disarticulation, Canadian type; molded socket, hip joint, single axis constant friction knee, shin, SACH foot
L5270	Hip disarticulation, tilt table type; molded socket, locking hip joint, single axis constant friction knee, shin, SACH foot
L5280	Hemipelvectomy, Canadian type; molded socket, hip joint, single axis constant friction knee, shin,

	SACH foot
L5301	Below knee (BK), molded socket, shin, SACH foot, endoskeletal system
L5312	Knee disarticulation (or through knee), molded socket, single axis knee, pylon, SACH foot, endoskeletal system
L5321	Above knee (AK), molded socket, open end, SACH foot, endoskeletal system, single axis knee
L5331	Hip disarticulation, Canadian type, molded socket, endoskeletal system, hip joint, single axis knee, SACH foot
L5341	Hemipelvectomy, Canadian type, molded socket, endoskeletal system, hip joint, single axis knee, SACH foot
L5400	Immediate postsurgical or early fitting, application of initial rigid dressing, including fitting, alignment, suspension, and one cast change, below knee (BK)
L5410	Immediate postsurgical or early fitting, application of initial rigid dressing, including fitting, alignment and suspension, below knee (BK), each additional cast change and realignment
L5420	Immediate postsurgical or early fitting, application of initial rigid dressing, including fitting, alignment and suspension and one cast change above knee (AK) or knee disarticulation
L5430	Immediate postsurgical or early fitting, application of initial rigid dressing, including fitting, alignment and suspension, above knee (AK) or knee disarticulation, each additional cast change and realignment
L5500	Initial, below knee (BK) PTB type socket, nonalignable system, pylon, no cover, SACH foot, plaster socket, direct formed
L5505	Initial, above knee (AK), knee disarticulation, ischial level socket, nonalignable system, pylon, no cover, SACH foot, plaster socket, direct formed
L5510	Preparatory, below knee (BK) PTB type socket, nonalignable system, pylon, no cover, SACH foot, plaster socket, molded to model
L5520	Preparatory, below knee (BK) PTB type socket, nonalignable system, pylon, no cover, SACH foot, thermoplastic or equal, direct formed
L5530	Preparatory, below knee (BK) PTB type socket, nonalignable system, pylon, no cover, SACH foot, thermoplastic or equal, molded to model
L5535	Preparatory, below knee (BK) PTB type socket, nonalignable system, no cover, SACH foot, prefabricated, adjustable open end socket
L5540	Preparatory, below knee (BK) PTB type socket, nonalignable system, pylon, no cover, SACH foot, laminated socket, molded to model
L5560	Preparatory, above knee (AK), knee disarticulation, ischial level socket, nonalignable system, pylon, no cover, SACH foot, plaster socket, molded to model
L5570	Preparatory, above knee (AK), knee disarticulation, ischial level socket, nonalignable system, pylon, no cover, SACH foot, thermoplastic or equal, direct formed
L5580	Preparatory, above knee (AK), knee disarticulation, ischial level socket, nonalignable system, pylon, no cover, SACH foot, thermoplastic or equal, molded to model
L5585	Preparatory, above knee (AK), knee disarticulation, ischial level socket, nonalignable system, pylon, no cover, SACH foot, prefabricated adjustable open end socket
L5590	Preparatory, above knee (AK), knee disarticulation, ischial level socket, nonalignable system, pylon, no cover, SACH foot, laminated socket, molded to model
L5595	Preparatory, hip disarticulation/hemipelvectomy, pylon, no cover, SACH foot, thermoplastic or equal, molded to patient model
L5600	Preparatory, hip disarticulation/hemipelvectomy, pylon, no cover, SACH foot, laminated socket, molded to patient model
L5610	Addition to lower extremity, endoskeletal system, above knee (AK), hydracadence system
L5611	Addition to lower extremity, endoskeletal system, above knee (AK), knee disarticulation, four-bar linkage, with friction swing phase control
L5613	Addition to lower extremity, endoskeletal system, above knee (AK), knee disarticulation, four-bar linkage, with hydraulic swing phase control
L5614	Addition to lower extremity, exoskeletal system, above knee (AK), knee disarticulation, four-bar linkage, with pneumatic swing phase control
L5616	Addition to lower extremity, endoskeletal system, above knee (AK), universal multiplex system, friction swing phase control
L5617	Addition to lower extremity, quick change self-aligning unit, above knee (AK) or below knee (BK), each
L5618	Addition to lower extremity, test socket, Symes
L5620	Addition to lower extremity, test socket, below knee (BK)

L5622	Addition to lower extremity, test socket, knee disarticulation
L5624	Addition to lower extremity, test socket, above knee (AK)
L5626	Addition to lower extremity, test socket, hip disarticulation
L5628	Addition to lower extremity, test socket, hemipelvectomy
L5629	Addition to lower extremity, below knee, acrylic socket
L5630	Addition to lower extremity, Symes type, expandable wall socket
L5631	Addition to lower extremity, above knee (AK) or knee disarticulation, acrylic socket
L5632	Addition to lower extremity, Symes type, PTB brim design socket
L5634	Addition to lower extremity, Symes type, posterior opening (Canadian) socket
L5636	Addition to lower extremity, Symes type, medial opening socket
L5637	Addition to lower extremity, below knee (BK), total contact
L5638	Addition to lower extremity, below knee (BK), leather socket
L5639	Addition to lower extremity, below knee (BK), wood socket
L5640	Addition to lower extremity, knee disarticulation, leather socket
L5642	Addition to lower extremity, above knee (AK), leather socket
L5643	Addition to lower extremity, hip disarticulation, flexible inner socket, external frame
L5644	Addition to lower extremity, above knee (AK), wood socket
L5645	Addition to lower extremity, below knee (BK), flexible inner socket, external frame
L5646	Addition to lower extremity, below knee (BK), air, fluid, gel or equal, cushion socket
L5647	Addition to lower extremity, below knee (BK), suction socket
L5648	Addition to lower extremity, above knee (AK), air, fluid, gel or equal, cushion socket
L5649	Addition to lower extremity, ischial containment/narrow M-L socket
L5650	Additions to lower extremity, total contact, above knee (AK) or knee disarticulation socket
L5651	Addition to lower extremity, above knee (AK), flexible inner socket, external frame
L5652	Addition to lower extremity, suction suspension, above knee (AK) or knee disarticulation socket
L5653	Addition to lower extremity, knee disarticulation, expandable wall socket
L5654	Addition to lower extremity, socket insert, Symes, (Kemblo, Pelite, Aliplast, Plastazote or equal)
L5655	Addition to lower extremity, socket insert, below knee (BK) (Kemblo, Pelite, Aliplast, Plastazote or equal)
L5656	Addition to lower extremity, socket insert, knee disarticulation (Kemblo, Pelite, Aliplast, Plastazote or equal)
L5658	Addition to lower extremity, socket insert, above knee (AK) (Kemblo, Pelite, Aliplast, Plastazote or equal)
L5661	Addition to lower extremity, socket insert, multidurometer Symes
L5665	Addition to lower extremity, socket insert, multidurometer, below knee (BK)
L5666	Addition to lower extremity, below knee (BK), cuff suspension
L5668	Addition to lower extremity, below knee (BK), molded distal cushion
L5670	Addition to lower extremity, below knee (BK), molded supracondylar suspension (PTS or similar)
L5671	Addition to lower extremity, below knee (BK)/above knee (AK) suspension locking mechanism (shuttle, lanyard, or equal), excludes socket insert
L5672	Addition to lower extremity, below knee (BK), removable medial brim suspension
L5673	Addition to lower extremity, below knee (BK)/above knee (AK), custom fabricated from existing mold or prefabricated, socket insert, silicone gel, elastomeric or equal, for use with locking mechanism
L5676	Additions to lower extremity, below knee (BK), knee joints, single axis, pair
L5677	Additions to lower extremity, below knee (BK), knee joints, polycentric, pair
L5678	Additions to lower extremity, below knee (BK), joint covers, pair
L5679	Addition to lower extremity, below knee (BK)/above knee (AK), custom fabricated from existing mold or prefabricated, socket insert, silicone gel, elastomeric or equal, not for use with locking mechanism
L5680	Addition to lower extremity, below knee (BK), thigh lacer, nonmolded
L5681	Addition to lower extremity, below knee (BK)/above knee (AK), custom fabricated socket insert for congenital or atypical traumatic amputee, silicone gel, elastomeric or equal, for use with or without locking mechanism, initial only (for other than initial, use code L5673 or L5679)
L5682	Addition to lower extremity, below knee (BK), thigh lacer, gluteal/ischial, molded
L5683	Addition to lower extremity, below knee (BK)/above knee (AK), custom fabricated socket insert for other than congenital or atypical traumatic amputee, silicone gel, elastomeric or equal, for use with or without locking mechanism, initial only (for other than initial, use code L5673 or L5679)

L5684	Addition to lower extremity, below knee, fork strap
L5686	Addition to lower extremity, below knee (BK), back check (extension control)
L5688	Addition to lower extremity, below knee (BK), waist belt, webbing
L5690	Addition to lower extremity, below knee (BK), waist belt, padded and lined
L5692	Addition to lower extremity, above knee (AK), pelvic control belt, light
L5694	Addition to lower extremity, above knee (AK), pelvic control belt, padded and lined
L5695	Addition to lower extremity, above knee (AK), pelvic control, sleeve suspension, neoprene or equal, each
L5696	Addition to lower extremity, above knee (AK) or knee disarticulation, pelvic joint
L5697	Addition to lower extremity, above knee (AK) or knee disarticulation, pelvic band
L5698	Addition to lower extremity, above knee (AK) or knee disarticulation, Silesian bandage
L5699	All lower extremity prostheses, shoulder harness
L5700	Replacement, socket, below knee (BK), molded to patient model
L5701	Replacement, socket, above knee (AK)/knee disarticulation, including attachment plate, molded to patient model
L5702	Replacement, socket, hip disarticulation, including hip joint, molded to patient model
L5703	Ankle, Symes, molded to patient model, socket without solid ankle cushion heel (SACH) foot, replacement only
L5704	Custom shaped protective cover, below knee (BK)
L5705	Custom shaped protective cover, above knee (AK)
L5706	Custom shaped protective cover, knee disarticulation
L5707	Custom shaped protective cover, hip disarticulation
L5710	Addition, exoskeletal knee-shin system, single axis, manual lock
L5711	Additions exoskeletal knee-shin system, single axis, manual lock, ultra-light material
L5712	Addition, exoskeletal knee-shin system, single axis, friction swing and stance phase control (safety knee)
L5714	Addition, exoskeletal knee-shin system, single axis, variable friction swing phase control
L5716	Addition, exoskeletal knee-shin system, polycentric, mechanical stance phase lock
L5718	Addition, exoskeletal knee-shin system, polycentric, friction swing and stance phase control
L5722	Addition, exoskeletal knee-shin system, single axis, pneumatic swing, friction stance phase control
L5724	Addition, exoskeletal knee-shin system, single axis, fluid swing phase control
L5726	Addition, exoskeletal knee-shin system, single axis, external joints, fluid swing phase control
L5728	Addition, exoskeletal knee-shin system, single axis, fluid swing and stance phase control
L5780	Addition, exoskeletal knee-shin system, single axis, pneumatic/hydra pneumatic swing phase control
L5781	Addition to lower limb prosthesis, vacuum pump, residual limb volume management and moisture evacuation system
L5782	Addition to lower limb prosthesis, vacuum pump, residual limb volume management and moisture evacuation system, heavy-duty
L5785	Addition, exoskeletal system, below knee (BK), ultra-light material (titanium, carbon fiber or equal)
L5790	Addition, exoskeletal system, above knee (AK), ultra-light material (titanium, carbon fiber or equal)
L5795	Addition, exoskeletal system, hip disarticulation, ultra-light material (titanium, carbon fiber or equal)
L5810	Addition, endoskeletal knee-shin system, single axis, manual lock
L5811	Addition, endoskeletal knee-shin system, single axis, manual lock, ultra-light material
L5812	Addition, endoskeletal knee-shin system, single axis, friction swing and stance phase control (safety knee)
L5814	Addition, endoskeletal knee-shin system, polycentric, hydraulic swing phase control, mechanical stance phase lock
L5816	Addition, endoskeletal knee-shin system, polycentric, mechanical stance phase lock
L5818	Addition, endoskeletal knee-shin system, polycentric, friction swing and stance phase control
L5822	Addition, endoskeletal knee-shin system, single axis, pneumatic swing, friction stance phase control
L5824	Addition, endoskeletal knee-shin system, single axis, fluid swing phase control
L5826	Addition, endoskeletal knee-shin system, single axis, hydraulic swing phase control, with miniature high activity frame
L5828	Addition, endoskeletal knee-shin system, single axis, fluid swing and stance phase control
L5830	Addition, endoskeletal knee-shin system, single axis, pneumatic/swing phase control

L5840	Addition, endoskeletal knee-shin system, four-bar linkage or multiaxial, pneumatic swing phase control
L5845	Addition, endoskeletal knee-shin system, stance flexion feature, adjustable
L5848	Addition to endoskeletal knee-shin system, fluid stance extension, dampening feature, with or without adjustability
L5850	Addition, endoskeletal system, above knee (AK) or hip disarticulation, knee extension assist
L5855	Addition, endoskeletal system, hip disarticulation, mechanical hip extension assist
L5856	Addition to lower extremity prosthesis, endoskeletal knee-shin system, microprocessor control feature, swing and stance phase, includes electronic sensor(s), any type
L5857	Addition to lower extremity prosthesis, endoskeletal knee-shin system, microprocessor control feature, swing phase only, includes electronic sensor(s), any type
L5858	Addition to lower extremity prosthesis, endoskeletal knee-shin system, microprocessor control feature, stance phase only, includes electronic sensor(s), any type
L5859	Addition to lower extremity prosthesis, endoskeletal knee-shin system, powered and programmable flexion/extension assist control, includes any type motor(s)
L5910	Addition, endoskeletal system, below knee (BK), alignable system
L5920	Addition, endoskeletal system, above knee (AK) or hip disarticulation, alignable system
L5925	Addition, endoskeletal system, above knee (AK), knee disarticulation or hip disarticulation, manual lock
L5930	Addition, endoskeletal system, high activity knee control frame
L5940	Addition, endoskeletal system, below knee (BK), ultra-light material (titanium, carbon fiber or equal)
L5950	Addition, endoskeletal system, above knee (AK), ultra-light material (titanium, carbon fiber or equal)
L5960	Addition, endoskeletal system, hip disarticulation, ultra-light material (titanium, carbon fiber or equal)
L5961	Addition, endoskeletal system, polycentric hip joint, pneumatic or hydraulic control, rotation control, with or without flexion and/or extension control
L5962	Addition, endoskeletal system, below knee (BK), flexible protective outer surface covering system
L5964	Addition, endoskeletal system, above knee (AK), flexible protective outer surface covering system
L5966	Addition, endoskeletal system, hip disarticulation, flexible protective outer surface covering system
L5968	Addition to lower limb prosthesis, multiaxial ankle with swing phase active dorsiflexion feature
L5969	Addition, endoskeletal ankle-foot or ankle system, power assist, includes any type motor(s)
L5970	All lower extremity prostheses, foot, external keel, SACH foot
L5971	All lower extremity prostheses, solid ankle cushion heel (SACH) foot, replacement only
L5972	All lower extremity prostheses, foot, flexible keel
L5973	Endoskeletal ankle foot system, microprocessor controlled feature, dorsiflexion and/or plantar flexion control, includes power source
L5974	All lower extremity prostheses, foot, single axis ankle/foot
L5975	All lower extremity prostheses, combination single axis ankle and flexible keel foot
L5976	All lower extremity prostheses, energy storing foot (Seattle Carbon Copy II or equal)
L5978	All lower extremity prostheses, foot, multiaxial ankle/foot
L5979	All lower extremity prostheses, multiaxial ankle, dynamic response foot, one-piece system
L5980	All lower extremity prostheses, flex-foot system
L5981	All lower extremity prostheses, flex-walk system or equal
L5982	All exoskeletal lower extremity prostheses, axial rotation unit
L5984	All endoskeletal lower extremity prostheses, axial rotation unit, with or without adjustability
L5985	All endoskeletal lower extremity prostheses, dynamic prosthetic pylon
L5986	All endoskeletal lower extremity prostheses, dynamic prosthetic pylon
L5987	All lower extremity prostheses, shank foot system with vertical loading pylon
L5988	Addition to lower limb prosthesis, vertical shock reducing pylon feature
L5990	Addition to lower extremity prosthesis, user adjustable heel height
L5999	Lower extremity prosthesis, not otherwise specified

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Low Vision Aides and Devices

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Refractive Lenses (L33793)
Local Coverage Article	Refractive Lenses – Policy Article (A52499) <i>*Low vision aids (V2600, V2610, V2615) will be denied as noncovered because coverage under the Medicare prosthetic benefit is limited to persons with congenital absence or surgical removal of the lens of the eye.</i>

For Non-Medicare Members

- A. To qualify for low vision aides or devices a member must have best corrected vision of 20/70 or worse in the better eye with glasses or contacts on.
 1. The following codes are identified and coverable per contract for low vision aides and devices:
 - **V2600** – Handheld low vision aids and other non-specific mounted aids.
 - **V2610** – Single Lens Spectacles mounted low vision aids
 - **V2615** – Telescope and other compound lens system, including distance vision telescopic, near vision telescopic and compound microscopic lens system.
 - **92354** – Fitting of spectacle mounted low vision aid: single element system
 - **92355** – Fitting of spectacle mounted low vision aid: Telescopic or compound lens system

If requesting one or more of these items, please send the following documentation to support medical necessity:

- Clinical notes from requesting provider &/or specialist indicating corrected visual acuity

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

A wide variety of rehabilitation options are available to help people with low vision live and/or work more effectively, efficiently, and safely. Most people can be helped with one or more low vision treatment options. The more commonly prescribed devices are: Handheld low vision aids and other non-spectacle mounted aids, Single lens spectacle mounted low vision aids, Telescopic and other compound lens system, including distance vision telescopic, near vision telescopes and compound microscopic lens system.

Applicable Codes

Medicare – Considered not medically necessary

Non-Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
V2600	Handheld low vision aids and other nonspectacle mounted aids
V2610	Single lens spectacle mounted low vision aids
V2615	Telescopic and other compound lens system, including distance vision telescopic, near vision telescopes and compound microscopic lens system

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
92354	Fitting of spectacle mounted low vision aid; single element system
92355	Fitting of spectacle mounted low vision aid; telescopic or other compound lens system

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Laparoscopic Uterine Nerve Ablation (LUNA) for Dysmenorrhea

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Laparoscopic Uterine Nerve Ablation (LUNA) for Dysmenorrhea," for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

Kaiser Permanente has elected to use the Laparoscopic Uterosacral Nerve Ablation (LUNA) (A-0284) MCG* for medical necessity determinations. This procedure is not covered per MCG guidelines. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Dysmenorrhea refers to painful cramping in the lower abdomen that occurs during or just before the menses. The cramping sensation is often accompanied by other symptoms, including sweating, headaches, nausea and vomiting. Dysmenorrhea is sometimes divided into two sub-categories. Primary dysmenorrhea is menstrual pain without any identifiable organic pathology and generally first occurs in women younger than 20. Secondary dysmenorrhea is menstrual pain associated with an identifiable pathological condition, such as endometriosis, cervical stenosis or pelvic adhesions, and is most often seen in women over 20 (Stenchever, 2001).

Non-steroidal anti-inflammatory drugs (NSAIDS) are the standard therapy for primary dysmenorrhea. These act by suppressing prostaglandin levels. Although the pathogenesis of primary dysmenorrhea is still not known, there

is a close association between dysmenorrhea symptoms and an elevated level of prostaglandin F2a. Oral contraceptive pills (OCPs) are also a commonly prescribed medication treatment for primary dysmenorrhea. OCPs may relieve dysmenorrhea because of a modulating effect on the hypothalamus or a direct reduction in the amount of endometrium present (Stenchever, 2001). Treatment of secondary dysmenorrhea generally involves treating the underlying condition.

Pelvic nerve surgery can be used to treat primary dysmenorrhea that fails to respond to medical therapy and can be used in conjunction with other surgical procedures for secondary dysmenorrhea, such as operative laparoscopy for endometriosis. Laparoscopic uterine nerve ablation (LUNA) involves the use of laser or cauterization to destroy nerves in the uterosacral ligaments, at the point where they insert into the cervix. Doyle first reported that vaginal transection of the uterosacral nerves could be effective for dysmenorrhea in 1955. LUNA is generally associated with few side effects. Potential rare complications include uterine prolapse and bladder dysfunction. There is also a second type of pelvic nerve surgery, laparoscopic presacral neurectomy (LPN). This involves the total removal of the presacral nerves that lie within the boundary of the interiliac triangle and is generally believed to have more side effects than LUNA. More radical surgery, such as hysterectomy, is the treatment of last resort for patients with persistent dysmenorrhea (Proctor et al., 2006; Johnson et al., 2004).

LUNA for dysmenorrhea has not been previously reviewed for MTAC.

Medical Technology Assessment Committee (MTAC)

Laparoscopic Uterine Nerve Ablation

04/03/2006: MTAC REVIEW

Evidence Conclusion: Evidence from the two largest and highest quality RCTs (Johnson et al., 2004; Vercellini et al., 2003) suggests that laparoscopic uterine nerve ablation (LUNA) is not an effective treatment for secondary dysmenorrhea (dysmenorrhea among women with symptoms of endometriosis). The Vercellini study was limited by lack of an intention to treat analysis on pain outcomes. There is insufficient evidence to draw conclusions about laparoscopic uterine nerve ablation (LUNA) as a treatment for primary dysmenorrhea. There is evidence from only one well-done RCT comparing LUNA to a control group (Johnson et al., 2004). However, this study was designed to evaluate LUNA for pelvic pain, not specifically dysmenorrhea. The study included some women who did not present with dysmenorrhea and results were not stratified according to baseline dysmenorrhea status. There were four main pain outcomes. In addition to dysmenorrhea, these were non-menstrual pelvic pain, deep dyspareunia and dyschezia. In the intention to treat analysis, the Johnson study found one statistically significant outcome at $p < 0.05$. This was reduction in dysmenorrhea, favoring the LUNA group ($p = 0.045$). If the investigators had adjusted for multiple comparisons (i.e. the four primary pain outcomes), the difference in treatment success between the LUNA and control groups would not have been statistically significant.

Articles: There was a Cochrane Collaboration systematic review on surgical interruption of pelvic nerve pathways for dysmenorrhea. The Cochrane literature search identified two high-quality RCTs on LUNA for dysmenorrhea. These two RCTs, which were also identified in the Medline search, were critically appraised. The remainder of the RCTs identified by Cochrane were small and had methodological flaws. The Cochrane Collaboration investigators searched the literature through June 2004. No RCTs on LUNA for dysmenorrhea were identified that were published after the Cochrane search data. *The RCTs reviewed were* Johnson NP, Farquhar CM, Crossley S et al. A double-blind randomized controlled trial of laparoscopic uterine nerve ablation for women with chronic pelvic pain. BJOG 2004; 111: 950-959. See [Evidence Table](#).

The use of laparoscopic uterine nerve ablation in the evaluation of dysmenorrhea does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Kaiser Foundation Health Plan of Washington

PATIENT REFERRAL GUIDELINES

Lung Transplant ^{i, ii, iii}

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. The following are current, generally accepted, guidelines for lung & heart/lung transplantation. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral, rather should be applied together with careful clinical judgment.

For Non-Medicare Members

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. The following are current, generally accepted, guidelines for lung & heart/lung transplantation. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral, rather should be applied together with careful clinical judgment.

1. GENERAL PRINCIPLES

- a. If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, early referral should be made.
- b. Patients with a history of malignancy with moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- c. Uncontrollable active infection is a contraindication to transplant.
- d. Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low. [4.5.6](#) Exceptions may be made on a case-by-case basis.
- e. Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products in order to be actively listed.
- f. Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
 - i. Patients must have a care giver or care givers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
 - ii. Evidence of non-adherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.

- g. Patients must be willing and able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.
- h. The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.
 - i. Evidence of such non-adherence may be failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list.
- i. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

2. INDICATIONS FOR LUNG TRANSPLANT

- a. Must meet all prerequisites listed in the General Principles section
- b. Any disease state in which transplantation has become an accepted mode of treatment worldwide including
 - i. Chronic obstructive pulmonary disease (COPD), which may include asthma, chronic bronchitis, emphysema and/or Alpha 1 antitrypsin deficiency
 - ii. Idiopathic pulmonary fibrosis
 - iii. Sarcoidosis
 - iv. Connective tissue disease-related pulmonary fibrosis
 - v. Eosinophilic granulomatosis
 - vi. Bronchiectasis
 - vii. Cystic fibrosis (CF)
 - viii. Pulmonary hypertension (both primary and secondary)
 - ix. Lymphangiomyomatosis (LAM)
 - x. Interstitial lung disease not otherwise defined.
- c. Patients should be referred for transplant evaluation by a pulmonologist or a cardiologist who has accumulated data defining both the disease as potentially treatable by transplantation and progression is occurring despite maximal medical therapy.
- d. Early referral is strongly encouraged for progressive lung disease with a poor prognosis⁷
- e. Ideally, the patient should be ambulatory with rehabilitation potential.

3. CONTRAINDICATIONS FOR LUNG TRANSPLANT

- a. Must meet all prerequisites listed in the General Principles section
- b. Invasive mechanical ventilator support⁸.
- c. Unresolved infection (except in cystic fibrosis and bronchiectasis).
- d. Uncontrolled chronic infection (i.e., HIV with detectable viral load)
- e. Other systemic diseases including but not limited to:
 - i. Diabetes with end organ effects; i.e., renal, cardiac or uncorrectable peripheral vascular disease. Insulin use itself is not a contraindication.
 - ii. Uncontrolled hypertension.
 - iii. Significant neurologic disease impairing cognitive function.
 - iv. Malnutrition⁹
 - v. Obesity >140% ideal body weight or BMI >32 kg/m² ^{10, 11}(with an understanding that a BMI <30 may be necessary for transplantation).
 - 1. May wish to consider initiating transplant workup if patient has pulmonary fibrosis and BMI >32 (but <34) if showing willingness to lose weight.
 - vi. Advanced hepatic dysfunction.
 - vii. Advanced renal dysfunction (creatinine clearance < 50 ml/min. after maximum therapy). However, patients with underlying cardiopulmonary causes of low creatinine clearance can be considered for transplant on a case-by-case basis.
 - viii. Evidence of clinically significant obstructive coronary artery disease and/or LVEF <40%. ¹²
 - ix. Active or unresolved peptic ulcer disease.
 - x. Chronic opiate use: Patients should be seen by a pain management specialist for alternative forms of therapy.
 - xi. Uncorrectable bleeding diathesis or clotting disorder

RELATIVE CONTRAINDICATIONS

- a. Patients with previous thoracotomy and/or sclerosing procedures should be considered on a case by case basis.

- b. Systemic corticosteroid therapy >10 mgs prednisone daily.
- c. Esophageal dysmotility and reflux. Surgical repair may be necessary.¹³
- d. Age >70 for lung transplant referral.
- e. Symptomatic osteoporosis.
- f. Major mechanical chest deformity (such as kyphoscoliosis).
- g. Short stature patients (in USA 4'11" for females and 5'4" for males) are significantly disadvantaged and early consideration of multiple listing is encouraged.

PATIENT PROFILE FOR COMMON DIAGNOSES LUNG TRANSPLANT REFERRAL GUIDELINES

Any or all of the listed guidelines for each disease entity should raise consideration for lung transplantation evaluation. Clinical correlation is always of primary importance.

1. GROUP A – Obstructive Lung Disease ^{14, 15} (See Table 1 Below)
 1. FEV1 < 25 %
 2. DLCO < 40%
 3. Hypoxemia; PO2 < 55
 4. Hypercapnia; PCO2 > 51¹⁶
 5. Bode Index > 5
2. GROUP B – Pulmonary Arterial Hypertension (See Table 1 Below)^{17, 18, 19}
 - a. Patients with clinically significant PAH should be evaluated by physicians experienced in treating pulmonary hypertension and have received maximum available pharmacological treatment.
 - b. Possible indications for referral include:
 - i. Pericardial Effusion²⁰
 - ii. World Health Organization (WHO) (New York Heart Association) class 3 or 4
 - iii. Lack of improvement in WHO Class 3 or 4 and/or lack of improvement in 6-minute walk test of < 350 meters, despite maximum pharmacological therapy.
 - c. Definite indications, after maximum pharmacologic treatment for referral include: ²¹
 - i. Mean RA > 15 mmHg
 - ii. Cardiac Index < 2L per minute. Untreated, the mean survival for patients with these criteria is 10-11 months.

GROUP C – Cystic Fibrosis ²²(See table 1 Below)

- a. FEV1 < 40%
- b. PO2 < 55
- c. Clinical deterioration, especially in young female patients, as characterized by increasing number of hospitalizations, including recurrent pneumothoraxes, rapid fall of FEV1, recurrent major hemoptysis uncontrolled by embolization and/or increasing cachexia should prompt consideration for transplant referral.
- d. PCO2 > 51
- e. Patients with Burkholderia cepacia have a relative contraindication.

GROUP D – Restrictive Lung Disease) ^{22, 23}(See Table 1 Below)

- a. Force Vital Capacity < 80%²²
- b. Decline in Forced Vital Capacity of ≥10% and/or decline in DLCO ≥ 15% during 6 months of follow-up²²
- c. Diffusing Capacity (corrected for alveolar volume) < 60%
- d. Evidence of interstitial lung disease on HRCT in conjunction with one or more of the above.

Referral to lung transplant program should be considered when a definitive diagnosis of usual interstitial pneumonitis (UIP) or idiopathic pulmonary fibrosis (IPF) is made and may be considered for the diagnosis of fibrotic nonspecific interstitial pneumonitis (NSIP).

OTHER CONDITIONS

Other conditions for which transplant may be appropriate include the Lung diseases described in Table 1 below.²⁴

Table 1: Lung allocation score (LAS) primary diagnostic groupings for lung transplant candidates

LAS lung disease diagnosis grouping	
Group A (obstructive lung disease)	<ul style="list-style-type: none"> • Chronic obstructive pulmonary disease (COPD), with or without alpha-1-antitrypsin deficiency, due to chronic bronchitis and/or emphysema • Lymphangioleiomyomatosis (LAM) • Bronchiectasis, including primary ciliary dyskinesia • Sarcoidosis with a mean pulmonary artery (PA) pressure ≤ 30 mmHg
Group B (pulmonary vascular disease)	<ul style="list-style-type: none"> • Idiopathic pulmonary arterial hypertension (iPAH, formerly known as primary pulmonary hypertension [PPH]) • Eisenmenger's syndrome • Other pulmonary vascular diseases
Group C (cystic fibrosis or immunodeficiency disorders)	<ul style="list-style-type: none"> • Cystic fibrosis (CF) • Immunodeficiency disorders such as hypogammaglobulinemia
Group D (restrictive lung disease)	<ul style="list-style-type: none"> • Idiopathic pulmonary fibrosis (IPF) • Pulmonary fibrosis due to other causes • Sarcoidosis with mean PA pressure > 30 mmHg • Obliterative bronchiolitis (nonretransplant)

ADDENDUM

GUIDANCE FOR LUNG TRANSPLANT FOR IRREVERSIBLE PULMONARY FAILURE FROM COVID-19

Background: Transplant has been successful for other conditions, including infections, that lead to irreversible pulmonary failure, so this disease has some familiar aspects within the lung transplant community. Because of the specific conditions surrounding the effects of SARS-CoV-2, and because much of the mechanism underlying the development of lung injury and recovery are still unclear, the following elements are recommended for any consideration for referral of and authorizations for potential candidates for lung transplant. The below represent elements, *IN ADDITION TO THE USUAL CRITERIA PROVIDED IN THE CMS LUNG PATIENT REFERRAL GUIDELINES*:

1. Age under 65 if ECMO has been used as bridge to transplant
2. Disease has progressed in spite of maximal non-invasive ventilatory support
3. No other significant organ dysfunction exists
4. Sufficient time for recovery must be allowed: once on invasive mechanical support or ECMO, referral should not be considered fewer than 4-6 weeks after ventilator-dependent or ECMO-supported pulmonary failure
5. Patients on prolonged O₂ therapy other than mechanical support or ECMO should be given sufficient time to determine irreversibility of the condition (usually three months) and should be ambulatory with good opportunity for rehabilitation.
6. Evidence of irreversible lung disease (bullae, fibrosis) must be present
7. The ability to gain patient, not surrogate, approval for transplant is an essential ethical concept in light of the relatively poor long-term outcomes from lung transplant
8. Ability to do adequate pulmonary rehabilitation while on support for respiratory failure
9. Have 2 negative SARS-CoV-2 PCR tests at least 24 hours apart with one of the samples being a deep respiratory specimen.
10. Transplants should be performed only at lung transplant programs experienced in the highest risk lung transplants including familiarity with transplanting patients with ECMO bridging to transplant. Furthermore, they should have:
 - a. Broad donor pool (represented by low time to transplant measures), and
 - b. Low wait-list mortality

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Lung transplant is a last resort treatment for end stage lung disease. The first human transplant was conducted in 1965. The first successful single lung transplant was done in 1983.

The diseases treated by lung transplants include:

- chronic obstructive pulmonary disease (COPD), including emphysema;
- idiopathic pulmonary fibrosis;
- cystic fibrosis;
- idiopathic (formerly known as "primary") pulmonary hypertension;

- alpha 1-antitrypsin deficiency;
- replacing previously transplanted lungs that have since failed;
- other causes, including bronchiectasis and sarcoidosis.

Prior to 2005, donor lungs were allocated by the United Network for Organ Sharing on a first-come, first-serve basis to patients on the transplant list. This was replaced by the current system, in which prospective lung recipients of age of 12 and older are assigned a lung allocation score or LAS, which takes into account various measures of the patient's health. The new system allocates donated lungs according to the immediacy of need rather than how long a patient has been on the transplant list. Patients who are under the age of 12 are still given priority based on how long they have been on the transplant waitlist. The length of time spent on the list is also the deciding factor when multiple patients have the same lung allocation score.

Patients who are accepted as good potential transplant candidates must carry a pager with them at all times in case a donor organ becomes available. These patients must also be prepared to move to their chosen transplant center at a moment's notice and relocate to within close proximity of the center. Such patients may be encouraged to limit their travel within a certain geographical region in order to facilitate rapid transport to a transplant center.

Evidence and Source Documents

The scientific literature is periodically reviewed, and patient selection criteria are updated when new efficacy data becomes available.

Kaiser Permanente Committee on Medically Emerging Technology:

Transplant, Lung, Double-7/12/91-Double lung transplantation is efficacious for appropriately selected patients.

Transplant, Lung, Single-7/12/91 Single lung transplantation is efficacious for appropriately selected patients.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
32850	Donor pneumonectomy(s) (including cold preservation), from cadaver donor
32851	Lung transplant, single; without cardiopulmonary bypass
32852	Lung transplant, single; with cardiopulmonary bypass
32853	Lung transplant, double (bilateral sequential or en bloc); without cardiopulmonary bypass
32854	Lung transplant, double (bilateral sequential or en bloc); with cardiopulmonary bypass

Medicare – Considered not medically necessary

Non-Medicare – Considered medically necessary when criteria in the applicable policy statements listed above are met

CPT® or HCPC Codes	Description
0494T	Surgical preparation and cannulation of marginal (extended) cadaver donor lung(s) to ex vivo organ perfusion system, including decannulation, separation from the perfusion system, and cold preservation of the allograft prior to implantation, when performed
0495T	Initiation and monitoring marginal (extended) cadaver donor lung(s) organ perfusion system by physician or qualified health care professional, including physiological and laboratory assessment (eg, pulmonary artery flow, pulmonary artery pressure, left atrial pressure, pulmonary vascular resistance, mean/peak and plateau airway pressure, dynamic compliance and perfusate gas analysis), including bronchoscopy and X ray when performed; first two hours in sterile field
0496T	Initiation and monitoring marginal (extended) cadaver donor lung(s) organ perfusion system by physician or qualified health care professional, including physiological and laboratory assessment (eg, pulmonary artery flow, pulmonary artery pressure, left atrial pressure, pulmonary vascular resistance, mean/peak and plateau airway pressure, dynamic compliance and perfusate gas analysis), including bronchoscopy and X ray when performed; each additional hour (List separately in addition to code for primary procedure)

S2060	Lobar lung transplantation *S codes not covered by Medicare
--------------	---

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

04/06/2021	MPC approved proposed changes from KP National Transplant Services. Requires 60-day notice, effective date September 1, 2021.
01/10/2022	MPC approved proposed changes from KP National Transplant Services. 60-day notice is not required.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Lutetium Lu 177 Dotatate (Lutathera)

- Somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs)

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, Lutetium Lu 177 Dotatate (Lutathera) , for medical necessity determinations. Use the Non-Medicare criteria below.

For Non-Medicare Members

Candidates must meet ALL of the following:

- 1) Presence of metastasized or locally advanced, unresectable (with curative intent) gastroenteropancreatic neuroendocrine tumors (GEP-NET) **and**
- 2) Ki-67 protein \leq 20% (patients with higher-grade disease need to be evaluated on case-by-case basis) **and**
- 3) Progressive disease under somatostatin analog therapy (SSA) **and**
- 4) At least 18 years of age **and**
- 5) Target lesions overexpressing somatostatin receptors as demonstrated on ^{68}Ga -DOTATATE PET/CT scan within last 3 months **and**
- 6) Monitoring labs must be conducted within the first 4 weeks of injection (baseline); 4-6 weeks after each Lutathera injection and 2 days prior to subsequent Lutathera injections

Contraindications:

- 1) Women who are or may be pregnant, as this agent can cause fetal harm when administered to a pregnant woman (pregnancy category X) **or**
- 2) Women who are breast feeding **or**
- 3) Pediatric patients (<18 years of age)

Lutathera Therapy is not covered when:

- 1) Recent surgery, radioembolization, chemoembolization, radiofrequency ablation or chemotherapy within 4 weeks prior to initiation of Lutathera treatment.
- 2) Known brain metastases unless these metastases have been treated and stabilized.
- 3) Uncontrolled congestive heart failure (NYHA II, III, IV)
- 4) Treatment with *short-acting* somatostatin analog therapy (SSA) that cannot be interrupted for 24 hours before Lutathera administration, or treatment with *long-acting* (LAR) somatostatin analog therapy SSA that cannot be interrupted for at least 4 weeks before initiation of Lutathera

- a) Patient may go on short acting somatostatin analog therapy (SSA) as a bridge between LAR injection and Lutathera treatment, but this must be stopped 24 hrs. before Lutathera treatment.
- 5) Prior external beam radiation therapy to >25% of the bone marrow.
- 6) Current spontaneous urinary incontinence making it unsafe to administer Lutathera

[Please click here to view clinical criteria for PET Scan: Gastroenteropancreatic Neuroendocrine Tumors \(GEP-NET\)](#)

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Gastroenteropancreatic neuroendocrine tumors are rare. It is estimated that approximately one out of 27,000 people are diagnosed with gastroenteropancreatic neuroendocrine tumors (GEP-NETs) per year (Voelker, 2018). However, their incidence has increased in the last thirty years (Cives & Strosberg, 2018). Neuroendocrine tumors of the midgut represent the most common malignant gastrointestinal neuroendocrine tumors. Overall survival rate is less than 50% especially in patients with metastatic disease (Modlin, Lye, & Kidd, 2003; Yao et al., 2008). Initial therapy includes somatostatin analogue (Caplin, Pavel, & Ruzsniowski, 2014). However, there exists a lack of second-line treatment for neuroendocrine tumors (except for everolimus for nonfunctional neuroendocrine tumors (Yao et al., 2016)) if first-line treatment fails. Radiolabeled somatostatin analogue, Lutetium-177, has been the center of attention and it may be promising for the management of advanced neuroendocrine tumors (NETs).

Lutathera or Lutetium Lu 177 dotatate is a radioactive targeted therapy. The medication binds to somatostatin receptors which are present on certain tumors. Once Lutathera binds to the receptor, it enters the cell and uses radiation to cause damage. However, it does not impact normal cells. Lutathera delivers beta- and gamma radionuclides to cancerous cells with a maximum particle range of 2 mm and a half-life of 160 hours (van der Zwan et al., 2015). It is administered as four infusions separated by eight weeks interval.

On January 29, 2018, the Food and Drug Administration approved lutetium Lu 177 dotatate (LUTATHERA, Advanced Accelerator Applications USA, Inc.) a radiolabeled somatostatin analog, for the treatment of somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs), including foregut, midgut, and hindgut neuroendocrine tumors in adults.

Medical Technology Assessment Committee (MTAC)

Lutetium Lu 177 Dotatate (Lutathera) for Somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs)

01/14/2019: MTAC Review

Evidence Conclusion:

- There is limited evidence comparing Lu-Dotatate and octreotide
 - Based on one RCT with moderate risk of bias, Lu-Dotatate may be more effective than octreotide LAR in adult population with predominantly low grade, higher level of expression of somatostatin receptors gastroenteropancreatic NETs who failed initial therapy.
 - However, Octreotide results in lower adverse events than Lu-Dotatate.
- In non-comparative studies, low evidence suggests that Lu-Dotatate may be effective and safe in patients with advanced gastroenteropancreatic neuroendocrine tumors.

Articles: PubMed was searched through October 19, 2018. Search terms include ((Lutathera OR lutetium Lu 177 dotatate OR lutetium 177 dotatate OR Lu-177 OR 177Lu-DOTATATE)) AND (Neuroendocrine tumors OR pancreatic neuroendocrine tumors OR gastrointestinal neuroendocrine tumors). The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. Several articles were identified but only one RCT (NETTER-1 trial) met the inclusion criteria. Clinicaltrials.gov was also searched on October 11, 2018 and identified several ongoing studies with no available results. See [Evidence Table](#).

The use of Lutetium Lu 177 Dotatate (Lutathera) for Somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs) does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
A9513	Lutetium Lu 177, dotatate, therapeutic, 1 mCi

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Lymphedema Therapy/ Lymphedema Therapy Training

- Complete Decongestive Therapy
- Lymphatic Venous Anastomosis (LVA) for the Treatment of Lymphedema

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

Complete Decongestive Therapy (CDT) is comprised of four components: Manual lymph drainage (MLD), compression bandaging, exercises and skin care. The goals of CDT are to reduce lymphedema, increase mobility and range of motion (ROM), decrease the risk of cellulitis, and ultimately providing for a better quality of life. The goal of CDT training is to educate the patient and/or the caregiver to be successful in performing decongestive techniques. In the process of learning lymphedema therapy techniques, the patient's lymphedema may improve and stabilize. However, the goal of therapy and training is to transfer the knowledge and skills to the patient, or their caregiver so ongoing decongestive techniques can be performed by the patient or their caregiver, not to necessarily completely decongest the affected limb. Ongoing responsibility for completion and maintenance of decongestion is with the patient and/or the caregiver.

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	Lymphedema Decongestive Treatment (A52959)

For Non-Medicare Members

Complete Decongestive therapy is considered medically necessary if **ALL of the following** are met:

1. The treating or consulting practitioner (within the scope of their practice) documents a diagnosis of primary or secondary lymphedema and specifically orders CDT training **and**
2. CDT training is not routinely covered prophylactically, but patients at risk (such as having recent surgical removal of lymph nodes) who are "Stage 0" can be approved for up to 2 visits for patient education on future management **and**
3. The patient or patient's caregiver has the ability to understand and provide home-based exercise and management, as the patient and/or caregiver will need to be able to manage the condition on their own after discharge **and**
4. CDT training services must be performed by a licensed PT or OT that has received specific training for this service **and**
5. The frequency and duration of services must be necessary and reasonable. CDT services are comprised of up to 15 sessions over a 2-12-week period **and**

6. A CDT course of training is generally expected to occur no more than once per lifetime. However, if medically necessary, refresher training will be approved for 1-2 sessions to review CDT techniques and measure for compression garments

Continued therapy may be indicated if ONE of the following are met:

1. 15 visits can extend beyond 12 weeks, if treatment is interrupted by chemotherapy or radiation therapy **or**
2. Severe lymphedema that is showing progress with decreasing limb girth, more appointments may be approved if **ALL of the following** are met:
 - a. Documentation of the patient's condition before, during and after therapy supports that progress was measurably sustainable **and**
 - b. Documentation indicates clear objective evidence of improvement, generally within the first week or 10 days of therapy (changes in weight, extremity circumference, etc.) **and**
 - c. Member or their caregiver has not yet mastered and demonstrated understanding of complex decongestive therapy techniques. For continued training to be approved, there must be documentation of the amount of further training required and an assessment if the patient or caregiver will be able to learn these techniques in a reasonable period of time.
 - d. The goal of lymphedema therapy is not to fully decongest the affected limb, rather it is to transfer the skills and knowledge of lymphedema therapy techniques to the member or their caregiver.

Complete Decongestive Therapy is NOT covered when:

1. Therapy is limited to exercise or elevation of the affected area and is not CDT
2. Therapy does not include ongoing patient education
3. Therapy treatment is designed principally for temporary benefit
4. The patient or patient caregiver do not have the capacity to learn and perform CDT techniques within a reasonable amount of time

Covered Diagnosis

1. Primary lymphedema
2. Secondary lymphedema caused by:
 - a. destruction of lymph nodes by radiation therapy or surgery for treatment of cancer.
 - b. destruction of lymph system by:
 - trauma or
 - recurrent episodes of cellulitis in the affected limb (two episodes of cellulitis requiring antibiotic or
 - the result of severe chronic venous insufficiency

Lymphatic Venous Anastomosis (LVA) for the Treatment of Lymphedema:

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Last 6 months of radiology if applicable

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Primary lymphedema refers to lymphedema that is caused by the imperfect or abnormal development/lymphatic dysplasia of the lymph vascular system. Primary lymphedema may be due to such causes as Milroy's Disease, Meige's Disease, Turner Syndrome Noonan Syndrome, Klippe-Trenaunay Syndrome, Parks Weber Syndrome, Prader-Willi Syndrome, Emberger Syndrome and other genetic and non- genetic syndromes (also known as hereditary and sporadic lymphedema). Secondary lymphedema is caused by known factors that damage the lymphatic system. Causes of secondary lymphedema include Filariasis, surgery and/or radiation for cancer, cancer, trauma, infection, and chronic venous insufficiency. Obesity is an independent risk factor for

lymphedema. The most common cause of secondary lymphedema in developed countries is treatment for cancer, especially breast cancer, due primarily to the removal and/or damage of lymph nodes, and damage to lymph vessels. Complete decongestive therapy can be effective for both primary and secondary lymphedema.

Differential diagnosis must include medical conditions which cause swelling which are *not* considered lymphedema and should be treated medically. These conditions include hepatic/renal disorders, congestive heart failure, venous obstruction (DVT) and in some cases, immobility of the limb where the muscle pump is not active, hypoproteinemia, malnutrition, malabsorption syndromes, sepsis, allergic reactions, lipedema, myxedema (disorder of the thyroid), fluid retention syndrome, neurological conditions which can cause weakness or paralysis resulting in immobility of the limbs and even as a side-effect of certain medications and self-inflicted swelling.

Lymphedema can co-occur with other conditions and may be amenable to CDT treatment, especially if the condition is chronic and medical treatment has not completely resolved the edema. **Chronic venous insufficiency** can lead to lymphedema because as the increased amount of fluid in the interstitium which is filtered from the capillaries begins to overwhelm the lymphatic system and can cause damage to the lymphatics, this usually occurs in Stage 2 of CVI. If the conditions are chronic and swelling continues, they may be amenable to a course of CDT.

Evidence and Source Documents

Medicare B Issues Notice 177, Page 14, 15, 16

Lymphatic Venous Anastomosis (LVA) for the Treatment of Lymphedema BACKGROUND

Lymphedema is the accumulation of fluid in the lymphatic system. Lymphedema is an imbalance between interstitial fluid production and the transport capacity of the lymphatic system ("The diagnosis and treatment of peripheral lymphedema: 2013 Consensus Document of the International Society of Lymphology," 2013). It is caused by congenital anomalies of the lymphatic vessels or any factors that damage the lymphatic system. Lymphedema is classified as primary or secondary depending on etiology. Primary lymphedema is due to a congenital malformation of the lymphatic vessels. It manifests, more commonly, by edema of the lower limbs at birth which can be present up to two years after birth. Secondary lymphedema is due to infection, injury/trauma, inflammation, obesity, cancer and cancer treatment, and chronic venous insufficiency.

Patients may experience swelling, pain, discomfort, heaviness, limited range of motion, and skin lesions. The diagnosis is made by history, physical exam, and measurements (Mehrra, B. et al., 2019).

The treatment of lymphedema can be difficult. However, the foundation of treatment is conservative and multimodal. Multimodal treatment consists of general measures along with compression therapy and physiotherapy. General measures include self-monitoring, limb elevation, maintenance of adequate body weight through diet and exercise, avoidance of skin infection or injury, avoidance of limb constriction. Compression therapy includes bandaging, compression garments, and intermittent pneumatic compression. Physiotherapy is comprised of manual lymphatic drainage and complete decongestive therapy (Mehrra, B. et al., 2019).

Complete decongestive therapy, also called complex decongestive therapy, complex decongestive physiotherapy, or decongestive lymphatic therapy is comprised of two phases: the first phase which is the treatment phase involves manual lymphatic drainage, limb compression, skin care, and exercise. This occurs every day five days per week and lasts two to four weeks. The second phase also called the maintenance phase entails compression garments, self-compression bandaging at night, skin care, exercise, and, if necessary, self-manual lymphatic drainage (Mehrra, B. et al., 2019). The treatment is provided by a health care professional. However, patients or caregivers can treat themselves especially in the second phase of the treatment after being trained.

Medical Technology Assessment Committee (MTAC)

Lymphatic Venous Anastomosis

06/20/2011: MTAC REVIEW

Evidence Conclusion: There is insufficient published evidence to determine the efficacy and safety of lymphatic venous anastomosis in the treatment breast cancer-related lymphedema.

Articles: The literature on the on lymphatic venous anastomosis (LVA) for the treatment of breast cancer-related lymphedema (BCRL) is very limited; the search did not reveal any meta-analyses or randomized controlled trials that evaluated efficacy or safety of the procedure. The empirical study published on the LVA for the treatment (BCRL) was a small case series with ten patients.

The use of lymphatic venous anastomosis (LVA) for the treatment of post-breast cancer lymphedema does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Complete decongestive therapy for the treatment of lymphedema

04/08/2019: MTAC REVIEW

Evidence Conclusion:

- Low evidence indicates no difference between complete decongestive therapy and compression bandaging or garments in terms of reduction in limb volume, edema volume, limb-related volume change, QOL, and arm function in patients with secondary lymphedema due to breast cancer treatment on the short and mid-terms (≤ 1 year).
- There is insufficient evidence for or against the effectiveness of complete decongestive therapy training in term of lymphedema reduction.
- Moderate quality study suggests that decongestive lymphedema therapy may be safe.

Articles: PubMed was searched from 2012 to March 20, 2019 with the search terms Complete decongestive therapy OR complex decongestive therapy OR complex decongestive physiotherapy OR decongestive lymphatic therapy. The search was limited to English language publications and human populations. The reference lists of relevant studies were reviewed to identify additional publications. RCTs and observational studies were included as filters. See [Evidence Table](#).

The use of Complete decongestive therapy for the treatment of lymphedema does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Hayes Technology Brief

Hayes, Inc. Hayes Technology Brief. Microsurgical Treatment of Lymphedema Following Breast Cancer Surgery. Lansdale, PA: Hayes, Inc.; 7/2013

Interregional New Technologies Committee (INTC) Review

02/02/2021: SCPMG Evidenced-Based Medicine

Overall Conclusion:

- The body of literature on LYMPHA for prevention of secondary extremity lymphedema consists of six comparative studies (including 2 RCTs) and eight non-comparative studies and involved a total of 1,067 participants (range: N=10 to N=380). Follow-up periods ranged from 3 months to 4 years. Most studies involved breast cancer patients, but several studies included patients with other types of cancer.
- The included studies were at high risk of bias and most had small sample sizes. There was also heterogeneity in terms of cancer type, lymphedema classification, treatment courses, and follow-up times. However, the studies consistently demonstrated substantial reductions in risk of lymphedema occurrence with the LYMPHA, compared with standard care.
- Incidence of lymphedema in the included studies ranged from 0% to 12.5%, with lymphedema occurring transiently in some patients and persisting in others. The highest rate of persistent lymphedema was 9% (in a retrospective case series, N=27). The overall quality of the evidence on the efficacy of LYMPHA was found to be low.
- Four studies (1 small RCT; 1 small prospective case series; 2 retrospective) reporting safety outcomes did not indicate any serious concerns regarding safety or complications associated with LYMPHA for prevention of secondary lymphedema. The overall quality of the evidence on the safety of LYMPHA is very low.
- We applied the ROBIS (i.e., risk of bias in systematic reviews) tool to the Hayes, Inc. assessment and found risk of bias in their review to be low.
- Given the overall low quality of the body evidence on LYMPHA, there remains a need for large, high-quality comparative studies or RCTs to draw a conclusion regarding the efficacy and safety of LYMPHA for prevention of secondary lymphedema, compared with standard care.

Applicable Codes

Complete Decongestive Therapy (CDT) - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
--------------------	-------------

97140	Manual therapy techniques (eg, mobilization/ manipulation, manual lymphatic drainage, manual traction), 1 or more regions, each 15 minutes
97535	Self-care/home management training (eg, activities of daily living (ADL) and compensatory training, meal preparation, safety procedures, and instructions in use of assistive technology devices/adaptive equipment) direct one-on-one contact, each 15 minutes
S8950	Complex lymphedema therapy, each 15 minutes

Lymphatic Venous Anastomosis (LVA) - Considered not medically necessary:

CPT® or HCPC Codes	Description
No specific codes – often submitted as <i>38999 Unlisted procedure, hemic or lymphatic system</i>	

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To** verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, "Magnetic Resonance Guided Focused Ultrasound for Treatment of Uterine Fibroids (MRgFUS)" for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies (and/or) provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Uterine fibroids (or leiomyoma) are benign tumors of the uterus with a rich blood supply that may cause excessive bleeding and pelvic pain. The prevalence of uterine fibroids is estimated to be 20-40% in women older than 35. Hysterectomy is the standard permanent treatment for women who do not have a strong desire to retain their uterus. Other treatments include watchful waiting, medical management with hormonal therapy, myomectomy (local surgical removal) and uterine artery embolization (UAE). UAE is covered for GHC members when recommended by a GHC physician.

The ExAblate 2000 system (Insightec Ltd., Israel) is a minimally invasive, uterine-sparing treatment for uterine fibroids. The system is used in conjunction with a commercially available MRI scanner, the GE Signa 1.5T MR imaging system. A special coil is required to use the GE device with the ExAblate system. The MRI is used for planning, and also for monitoring during the procedure. The treatment is also known as MR guided focused ultrasound (MRI-FUS or MRgFUS).

During the procedure, focused ultrasound waves heat the targeted fibroid tissue to approximately 65-85o C. causing cell necrosis. Over time, the necrotic tissue is absorbed by the body. The treatment can take several hours, and it requires collaboration between a gynecologist and a radiologist.

The ExAblate system was approved by the FDA in October 2004 for ablation of uterine fibroid tissue in pre- or peri- menopausal women with symptomatic uterine fibroids who want a uterine sparing procedure. Patients must have a uterine size of <24 weeks' gestation and have completed child-bearing. Prior to commercial availability in the U.S., the ExAblate system was used in Europe (since 2002) and, to a limited extent, in Japan.

The ExAblate 2000 technology for ablation of uterine fibroids has not been reviewed previously by MTAC.

Medical Technology Assessment Committee (MTAC)

Magnetic Resonance Guided Focused Ultrasound in the Treatment of Uterine Fibroids

06/04/2008: MTAC REVIEW

Evidence Conclusion: In the FDA pivotal study in which 109 women were treated using the ExAblate 2000 technology (Stewart et al., 2006), there was a statistically significant improvement in self-reported symptoms pre- and post-treatment. The Funaki et al. (2007) case series did not report pre- and post-comparisons. 25 out of 69 women (53%) reported improving a great deal or being symptom-free 3 months after being treated. An additional 17 women (28%) said their symptoms were somewhat improved. In both studies, the main outcomes were self-report measures. A sham or comparison group is needed in this type of study to evaluate the extent to which treatment with ExAblate had a placebo effect on women's perception of their symptoms. None of the published studies focused on objective health outcomes such as bleeding or anemia. There is insufficient evidence to draw conclusions about the safety and effectiveness of the ExAblate 2000 technology for ablation of uterine fibroids. The empirical literature consists of case series. There are no studies comparing this technology to sham treatment or other accepted treatments such as UAE and myomectomy.

Articles: The Medline search yielded 35 articles. There was also an unpublished FDA document from October 2004, entitled, "Summary of safety and effectiveness data". The pivotal study submitted by InSightec to the FDA was a cohort study with n=109 receiving MRI-FUS with ExAblate and n=83 receiving hysterectomy. The FDA document describes pre- and post-treatment findings in each group but does not present statistical comparisons comparing results in the two groups. Several subsequent published articles described subjective treatment effects in the 109 patients who received ExAblate in the FDA pivotal study. These include Hindley et al., 2004 (short-term outcomes) and Stewart et al., 2006 (6- and 12- month outcomes). No published articles were identified that compared the ExAblate and hysterectomy groups in the FDA pivotal study. No published randomized or non-randomized controlled studies were identified that compared ExAblate to sham or to a less invasive alternative treatment such as uterine artery embolization or myomectomy. Two studies were identified that compared different protocols of MRI-FUS. One was a small study in which one of the two groups received a GnRh agonist pre-treatment and the other evaluated compared a standard and slightly modified treatment guideline with the ExAblate system. Stewart et al. also published an article in 2007 that combined and re-evaluated data from the FDA study and other case series sponsored by Insightec. This article included selected data and post-hoc analyses which can be misleading and thus was not evaluated further. The Stewart et al., 2006 study reporting the clinical outcomes from the FDA pivotal trial was critically appraised. In addition, a case series from Japan with a reasonably large sample size was critically appraised. References are: Stewart EA et al. Clinical outcomes of focused ultrasound surgery for treatment of uterine fibroids. *Fertil and Steril* 2006; 85: 22-29. See [Evidence Table](#).

The use of Magnetic resonance guided focused ultrasound in the treatment of uterine fibroids does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Magnetic Resonance-Guided Focused Ultrasound (MRgFUS)

07/25/2016: Medical Technology Assessment Team (MTAT) Review

Evidence Conclusion:

The studies identified in this assessment have limitations that make it difficult to have confidence in the estimates regarding efficacy and safety of MRgFUS or MR-HIFU for treatment of uterine fibroids. Given the small sample sizes of most of the studies, the lack of evidence on long-term health and pregnancy outcomes, and a substantial concern about the existence of confounding in study design:

1. There is low quality evidence that MRgFUS or MR-HIFU is as efficacious as hysterectomy and UAE for treating symptomatic uterine fibroids. The available evidence suggests MRgFUS or MR-HIFU is *less efficacious* than hysterectomy and UAE for treating symptomatic uterine fibroids.
2. There is very low-quality evidence that MRgFUS or MR-HIFU is as safe as hysterectomy and UAE for treating symptomatic uterine fibroids.

The potential benefits of MRgFUS or MR-HIFU for treating uterine fibroids should be weighed against the potential harms (e.g., need for re-intervention following treatment). Additional large, high quality longitudinal studies are needed to assess the long-term efficacy and safety of MRgFUS or MR-HIFU for treating uterine fibroids.

Articles: Two systematic reviews (Clark, 2014; Canadian Agency for Drugs and Technologies in Health (CADTH), 2016 (Chen, Pitre, Kaunelis, & Singh, 2016)) and one technology assessment (Hayes, Inc., 2014) addressing efficacy and/or safety of MRgFUS or MR-HIFU were identified. The most comprehensive systematic review of comparative studies involving any type of MRgFUS versus hysterectomy, myomectomy, or UAE is from CADTH. We therefore used the CADTH report as our primary evidence source. Our update search identified one pilot randomized controlled trial (PROMISe Trial; Jacoby, et al., 2016) that assessed the efficacy and safety of MRgFUS compared to a sham procedure. Therefore, a total of three comparative studies (two from the CADTH report and one from our update search) were selected for inclusion in the SCPMG EBM assessment. CADTH (2016) found that MRgFUS (or MR-HIFU) was associated with more re-interventions but also fewer complications compared with hysterectomy and UAE. The review included RCTs, non-randomized studies, and economic evaluations assessing the clinical effectiveness and safety of uterine-preserving interventions in women with symptomatic uterine fibroids. Interventions of interest included myomectomy, myolysis, UAE, uterine artery occlusion (UAO), or endometrial ablation. They were compared with each other or with hysterectomy. The search for health technology assessments, systematic reviews, meta-analyses, and guidelines was limited to documents published since January 1, 2005, while the search for randomized controlled trials (RCTs), controlled clinical trials, cohort studies, and economic studies was not limited by publication year. A total of two non-randomized observational studies comparing MRgFUS versus hysterectomy and UAE (Taran et al., 2009 and Ikink et al., 2014, respectively) were reviewed and appraised (last CADTH search date: November 24, 2015).

The use of Magnetic resonance guided focused ultrasound in the treatment of uterine fibroids does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered not medically necessary:

CPT® or HCPC Codes	Description
0071T	Focused ultrasound ablation of uterine leiomyomata, including MR guidance; total leiomyomata volume less than 200 cc of tissue
0072T	Focused ultrasound ablation of uterine leiomyomata, including MR guidance; total leiomyomata volume greater or equal to 200 cc of tissue

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Massage Therapy

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None

Medicare covers massage when delivered by a physical therapist as part of the rehabilitation plan of care. It is not covered when delivered by a massage therapist who is not licensed as a physical therapist.

For Non-Medicare Members

- A. Massage therapy is indicated when **ALL of the following** are met:
1. An assessment and diagnosis documents objective physical and functional limitations.
 2. It will have physical therapeutic benefits.
 3. It has been ordered by the treating physician.
 4. The condition or the level of function can be expected to improve significantly within a reasonable and generally predictable period of time with massage treatment.

OR

- B. The patient is terminally ill, and the therapy is needed for comfort.

Massage therapy is not covered when:

1. It is provided for prevention, recreation (spa therapy) or stress reduction.
2. It is directed at the maintenance of current level of functioning.
3. The patient has achieved therapeutic goals or is not showing meaningful progress.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

This service is covered when it is described as a benefit in the consumer's coverage contract and the consumer receives a health plan referral. Special work groups that have included licensed massage therapists identified the clinical conditions and screening criteria in order to determine clinical appropriateness for the service.

Low back pain (LBP) is a major health problem in the modern society. More than two thirds of the population will experience low back pain at some time in their lives. LBP is usually benign and self-limiting; almost 90% of all patients with acute low back pain will get better quickly regardless of therapy. The remaining 10% may develop chronic back pain and disability.

LBP is associated with a complex dysfunction and impaired endurance of the paraspinal muscles. Different therapies including exercise and spinal manipulation are often recommended, yet their clinical effectiveness has not been documented. Research on the effectiveness of these therapies has yielded inconsistent results.

The use of massage therapy for back pain has a long history. Massage therapy may have the potential to increase the blood flow in the muscles, enhance muscle tone, reduce muscle fatigability, and improve muscle endurance. It may relax the mind and increase the pain threshold. Massage is considered a safe treatment with no risk or adverse effects. It is, however, contraindicated when several other conditions are present, including acute inflammations, skin infections, unhealed fractures, and burns.

Massage is rubbing or kneading part of the body usually with the hands to stimulate circulation and make the muscles or joints suppler. It is also defined as soft tissue manipulation using the hands or a mechanical device. Massage can be applied to the lumbar region only or to the whole body. It is usually used as an adjunct therapy for other physical treatments; however, many massage therapists use it as the only intervention. Examples of soft tissue massage are Shiatsu, Rolfing, Swedish massage, reflexology, myofascial release, craniosacral therapy, and Bindege webs massage. Massage therapy is applied through various techniques including friction, kneading, hacking, petrissage, neuromuscular, trigger, and pressure points.

Massage therapists are licensed by the state of Washington. Licensure requires a minimum of 500 hours of training at an accredited school of massage therapy.

Medical Technology Assessment Committee (MTAC)

Massage Therapy in the Treatment of Chronic Neck and Back Pain

11/2001: MTAC REVIEW

Evidence Conclusion: Two of the studies reviewed show that massage is an effective therapy for non-specific subacute and chronic low back pain (Cherkin, Preyde). Cherkin's study did not compare massage to a placebo or no treatment. Preyde's study, which compared massage to sham treatment, had a short follow-up duration. On the other hand, Pope et al found no significant difference between massage, spinal manipulation, corset, and transcutaneous muscle stimulation (TMS). Various confounding factors may affect the outcome of massage therapy including the type of massage given, number and duration of treatment sessions, experience of the therapists, size of massage area, amount of pressure, as well as the type of injury or problem, chronicity, level of stress, and other aggravating factors. Many of the studies reviewed did not address or adjust for these variables. Further research is needed to study the patients' variables and to help ascertain which type of low back pain will respond best to massage therapy. Studies with a longer-term follow-up are also needed to determine the elements and techniques of massage therapy that will give the most benefit. Use of a control group with a placebo or no treatment would also strengthen the validity of the results.

Articles: The search yielded 32 articles. There were two systematic reviews, with no statistical pooling or meta-analysis due to the heterogeneity of the studies. There were eight randomized, controlled trials. Massage was the main therapy under investigation in only two of the RCTs revealed by the search. *The studies selected for critical appraisal were:* Cherkin, D., Eisenberg, D., et al. Randomized trial comparing traditional Chinese medical acupuncture, therapeutic massage, and self-care education for chronic low back pain. Arch Intern Med 2001; 161: 1081-1088 See [Evidence Table](#). Preyde, M., Effectiveness of massage therapy for subacute low-back pain: a randomized controlled trial. CMAJ 2000; 162: 1815-20 See [Evidence Table](#). Pope, M.H., et al. A prospective randomized three-week trial of spinal manipulation, transcutaneous muscle stimulation, massage, and corset in the treatment of subacute low back pain. Spine 1994; 22: 2571-2577 See [Evidence Table](#).

The use of massage therapy in the treatment of chronic neck and back pain meets the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
97124	Therapeutic procedure, 1 or more areas, each 15 minutes; massage, including effleurage, petrissage and/or tapotement (stroking, compression, percussion)
97140	Manual therapy techniques (eg, mobilization/ manipulation, manual lymphatic drainage, manual traction), 1 or more regions, each 15 minutes
with type of service massage	

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

**To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

Medicare Medical Policy Development

Kaiser Permanente Medicare Advantage Medical Policies identify the clinical criteria for determining when medical services are considered 'reasonable and necessary' (medically necessary). Medicare Advantage plans are required by CMS to provide the same medical benefits to Medicare Advantage members as Original Medicare. As such, whenever possible, Medicare Advantage Medical Policies are based on Medicare coverage manuals, National Coverage Determinations (NCDs), and Local Coverage Determinations (LCDs) when available. If there is no applicable NCD or LCD for the service under review, then per CMS other evidence-based criteria may be applied. In addition, each member's unique, clinical situation is considered in conjunction with current CMS guidelines

Kaiser Permanente Medicare Medical Policy Hierarchy

The following hierarchy is used to determine Kaiser Permanente Medicare Advantage (MA) Medical Policy:

- ***CMS Coverage Manuals or other CMS-based Resource***
Coverage provisions in interpretive manuals are instructions that are used to further define when and under what circumstances items or services may be covered (or not covered). Other CMS-based resources include, but are not limited to, documentation such as Medicare Learning Network (MLN) and Federal Register (FR) publications.
- ***National Coverage Determinations (NCD)***
For some services, procedures, and technologies, CMS has developed an NCD, which is to be applied on a national basis for all Medicare beneficiaries. Once published in a CMS program instruction, the NCD is binding on all Medicare Advantage plans. (1)
- ***Local Coverage Determinations (LCD), Articles (LCA), and other contractor-based bulletins***
When there is no NCD or other coverage provision outlining medical necessity criteria within a Medicare manual, or when there is a need to further define an NCD, then the Medicare Administrative Contractor (MAC) for a service area may develop an LCD. (2) Noridian Healthcare Solutions (Noridian) is the designated MAC for the state of Washington.
- ***Retired LCD/LCD***
LCDs are retired due to lack of evidence of current problems with utilization, or in some cases because the material is addressed by a National Coverage Determination (NCD), a coverage provision in a CMS interpretative manual or an article. Most LCDs are not retired because they are incorrect. The guidance in the retired LCD may still be helpful in assessing medical necessity. (3)
- ***Commercial Medical Policies***
In coverage situations where there is no NCD, LCD, or guidance on coverage in original Medicare manuals, a Medicare Advantage Organization (MAO) may adopt the coverage policies of other MAOs in its service area. (4)
However, if the MAO decides not to use coverage policies of other MAOs in its service area, the MAO:
 - Must make its own coverage determination;
 - Must provide CMS an objective evidence-based rationale relying on authoritative evidence such as:
 - Studies from government agencies (e.g., the FDA);
 - Evaluations performed by independent technology assessment groups (e.g. BCBSA); and
 - Well-designed controlled clinical studies that have appeared in peer review journals; and
 - In providing its justification, the MAO may not use conclusory statements with no accompanying rationale (e.g., "It is our policy to deny coverage for this service.")
- ***MCG™ Care Guidelines***
If no policy criteria are available within an NCD, LCD, coverage manual, or existing medical policy for the services in question, MCG™ guidelines may be applied at the discretion of the physician reviewer.

Kaiser Permanente may consider some services to have insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies (and/or) provides better long-term outcomes than current standard services/therapies. When a procedure or device is deemed to have “insufficient evidence” by Kaiser Permanente, the term “insufficient evidence” does not mean the procedure or device has not been approved by the Food and Drug Administration (FDA). Rather, it means the procedure or device does not meet Kaiser Permanente’s objective, evidence-based technology assessment based on authoritative evidence. See the [Kaiser Permanente Medical Technology Assessment Committee](#) for further details regarding their evidence-based evaluation process.

Noridian may also provide coverage or non-coverage guidance in a Part B News Article published on the [noridianmedicare.com](#) website. Thus, these articles may be used in Medicare Advantage coverage decisions even though they are not in the form of an LCD or an LCA.

In some instances, one Medicare A/B MAC processes all of the claims for a particular Medicare-covered item or service for all Medicare beneficiaries around the country. This generally occurs when there is only one provider of a particular item or service (for example, certain pathology and lab tests furnished by independent laboratories). In this situation, MA plans must follow the coverage policy reflected in an LCD issued by the A/B MAC that enrolled the provider and processes all of the Medicare claims for that item or service. (5)

For genetic and molecular diagnostic testing, Noridian has implemented the guidelines published by Palmetto GBA under the Molecular Diagnostic (MoIDX) Program for their Jurisdiction F (J-F) service area. (6). MoIDX guidelines, when available, should be applied to requests for genetic and molecular diagnostic testing. In the absence of a guideline for a genetic test the above hierarchy will apply.

[5] - 90.5 – Creating New Guidance

(Rev. 120, Issued: 01-16-15, Effective: 01-01-15, Implementation: 01-01-15)

In coverage situations where there is no NCD, LCD, or guidance on coverage in original Medicare manuals, a Medicare Advantage Organization (MAO) may adopt the coverage policies of other MAOs in its service area. However, if the MAO decides not to use coverage policies of other MAOs in its service area, the MAO:

- Must make its own coverage determination;
- Must provide CMS an objective evidence-based rationale relying on authoritative evidence such as:
 - Studies from government agencies (e.g., the FDA);
 - Evaluations performed by independent technology assessment groups (e.g. BCBSA); and
 - Well-designed controlled clinical studies that have appeared in peer review journals; and
 - In providing its justification, the MAO may not use conclusory statements with no accompanying rationale (e.g., “It is our policy to deny coverage for this service.”)

The requirement that an MA plan provide coverage for all Medicare-covered services is not intended to dictate care delivery approaches for a particular service. MA plans may encourage enrollees to see more cost-effective provider types than would be the typical pattern in original Medicare, as long as those providers are licensed and working within the scope of their licenses and the plan complies with the provider anti-discrimination rules set forth in 42 CFR §422.205.

An MA plan’s flexibility to deliver care using cost-effective approaches should not be construed to mean that Medicare coverage policies do not apply to the MA program. If original Medicare covers a service only when certain conditions are met, then such conditions must be met in order for the service to be considered part of the

original Medicare benefits component of an MA plan. An MA plan may cover the same service when the conditions are not met, but these benefits would then be defined as supplemental.

Criteria For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, " Micronutrient Panel Testing " for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that micronutrient testing provides better long-term outcomes than current standard services/therapies.

Micronutrient testing, also known as functional intracellular analysis, essential metabolic analysis, intracellular micronutrient analysis, or leukocyte nutrient analysis, is a blood test consisting of multiple micronutrient levels intended to assess nutritional deficiencies and offer supplementation suggestions. Micronutrient tests are considered **not medically necessary**.

Some examples of commercially available micronutrient tests include but are not limited to the following:

- Genova Diagnostics ION Profile®
- IntraCellular Diagnostics EXA Test®
- SpectraCell Laboratories Micronutrient Test
- VibrantAmerica Micronutrients

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Micronutrient testing assesses the level of multiple nutrients in the body. These panels may include measurement of numerous vitamins, minerals, amino acids, fatty acids, oxidation products, organic acids, toxins and antioxidants. The test results are proposed to help determine the cause of various symptoms, such as hair loss and fatigue, and various disease processes. Antioxidant function testing (e.g., Spectrox™) has been proposed as a method to evaluate the ability of cells to resist damage caused by free radicals and other forms of oxidative stress. SpectraCell Laboratories, Inc., (Houston, TX) offers a micronutrient testing panel proposed to measure how micronutrients function within the white blood cell. The Individual Optimal Nutrition (ION) (Genova Diagnostics, Asheville, NC) is a blood test that measures levels of vitamins, minerals, antioxidants, and organic, fatty, and amino acids. ExaTest®, offered by IntraCellular Diagnostics, Inc® (Medford, OR) is an intracellular tissue analysis of mineral electrolytes. The test is proposed to provide information on mineral electrolyte deficiencies or imbalances not available by blood testing. The analysis is made from an epithelial cell scraping from the sublingual area. The sample is analyzed using high energy photos (x-rays).

Currently, there is insufficient evidence in the published, peer-reviewed, scientific literature to establish the clinical utility of nutrient panel testing or antioxidant function testing or to demonstrate that the use of such testing results in improved health outcomes.

Applicable Codes

Micronutrient Test (identified by the volume of lab tests for vitamins, minerals, amino acids, antioxidants, and metabolites for diagnoses such as fatigue)

The following is a list of codes that will not be covered when billed for a Micronutrient Test. This is not an all-inclusive list.

CPT® Codes	Description
82136	Amino acids, 2 to 5 amino acids, quantitative, each specimen
82180	Ascorbic acid (Vitamin C), blood
82306	Vitamin D; 25 hydroxy, includes fraction(s), if performed
82310	Calcium; total
82379	Carnitine (total and free), quantitative, each specimen
82495	Chromium
82525	Copper
82607	Cyanocobalamin (Vitamin B-12)
82652	Vitamin D; 1, 25 dihydroxy, includes fraction(s), if performed
82725	Fatty acids, nonesterified
82746	Folic acid; serum
82978	Glutathione
83735	Magnesium
83785	Manganese
84207	Pyridoxal phosphate (Vitamin B-6)
84252	Riboflavin (Vitamin B-2)
84255	Selenium
84425	Thiamine (Vitamin B-1)
84446	Tocopherol alpha (Vitamin E)
84590	Vitamin A
84591	Vitamin, not otherwise specified
84597	Vitamin K
84630	Zinc
86353	Lymphocyte transformation, mitogen (phytomitogen) or antigen induced blastogenesis

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

**To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Microvolt T-Wave Alternans

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Microvolt T-Wave Alternans 20.30
Local Coverage Determinations (LCD)	None
Local Coverage Article	Decision Memo for Microvolt T-wave Alternans

For Non-Medicare Members

Kaiser Permanente has elected to use the Microvolt T-Wave Alternans (MTWA) (A-0399) MCG* for medical necessity determinations. This service is not covered per MCG guidelines. This procedure is not covered per MCG guideline. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

The term alternans applies to conditions characterized by the sudden appearance of a periodic beat-to-beat change in some aspect of cardiac electrical or mechanical behavior. Many different examples of electrical alternans have been described clinically; a number of others have been reported in the laboratory.

T-wave alternans has long been recognized as a marker of electrical instability in acute ischemia, where it may precede ventricular tachyarrhythmia. Studies have shown that T wave (or ST-T) alternans can also precede non-ischemic ventricular tachyarrhythmias. Considerable interest has recently been shown in the detection of microvolt T wave alternans as a noninvasive marker of the risk of ventricular tachyarrhythmia in patients with chronic heart disease.

Assessment of left ventricular ejection fraction (LVEF), Holter monitoring, and signal-averaged late potentials are the principal non-invasive means of determining the risk of ventricular arrhythmias after myocardial infarction (MI).

However, these measures of vulnerability to arrhythmias have been found to be less predictive of arrhythmic events than invasive electrophysiologic testing.

Microvolt T-wave alternans testing is performed by placing high-resolution electrodes, designed to reduce electrical interference, on a patient's chest prior to a period of controlled exercise (CMS, 2005). These electrodes detect tiny beat-to-beat changes, on the order of one-millionth of volt, in the EKG T-wave. Spectral analysis is used to calculate these minutes voltage changes. Spectral analysis is a sensitive mathematical method of measuring and comparing time and the electrocardiogram signals. Software then analyzes these microvolt changes and produces a report to be interpreted by a physician.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	Percutaneous image-guided lumbar decompression (PILD) for lumbar spinal stenosis (150.13)
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	Decision Memo for PERCUTANEOUS IMAGE-GUIDED LUMBAR DECOMPRESSION for Lumbar Spinal Stenosis (CAG-00433R)

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Lumbar spinal stenosis (LSS) is one of the most common degenerative diseases of the lumbar spine, and the most common indication for spinal surgery in elderly patients. LSS is a condition where the dural sac and nerve roots are compressed by a combination of degenerative features including bulging of the intervertebral discs, hypertrophy of the facet joints, and thickening of the ligamentum flavum. In LSS the space within the spinal canal narrows leading to asymptomatic compression of the nerves and ultimately symptomatic neurogenic claudication, which is described as pain, paresthesia, weakness or heaviness radiating to lower extremities that occurs with walking or prolonged standing. The severity of these symptoms varies widely among patients, and may be disabling in some (Deer 2011, Brown 2012, Popov 2012, Wong 2012).

Conservative therapies for LSS include rest, pain medication, and physical therapy with or without epidural steroid injections. If these therapies fail, the patient may be advanced to more invasive surgical procedures. The goal of any surgical treatment of LSS is the relief of symptoms by adequate neural decompression while preserving as much of the anatomy, stability, and biomechanics of the lumbar spine as possible. Until the last decade, open spinal surgery was the standard treatment of LSS. The traditional surgical approach involves performing a wide, bilateral decompression laminectomy and resection of the medial portion of the facet joints to decompress the affected neural elements. This can successfully alleviate nerve compression symptoms but has the drawback of

the open approach including the amount of soft tissue dissection, blood loss, postoperative pain, muscular atrophy, and potential for iatrogenic instability of the spinal segment (Popov 2012).

A number of less-invasive surgical techniques have been developed in recent years as an alternative to the traditional spine surgeries to limit the injury to the patient's native anatomy and reduce complication rates. These procedures are particularly attractive to spine surgeons for their small-skin incision, minimization of soft tissue injury, reduction of blood loss, infection rates, hospitalization time, narcotic usage, and minimization of physiological stress on the patient. Minimally invasive lumbar decompression techniques include the unilateral lumbar laminotomy for bilateral decompression, micro-endoscopic decompressive laminectomy, and lumbar micro-decompression (Deer 2010, Payer 2011, Smith 2012).

The *mild*® (Minimally Invasive Lumbar Decompression) procedure (Vertos Medical Inc., Aliso Viejo, California) is a minimally invasive alternative to open or endoscopic lumbar decompression in the treatment of lumbar spinal stenosis. *Mild*® treats LSS by removing small but adequate portions of the interlaminar bone (laminotomy) and partial excision (debulking) of the ligamentum flavum (LF) to restore space in the spinal canal while minimizing trauma to the surrounding tissue and bony structure. The procedure is typically performed under intravenous sedation monitored anesthesia and fluoroscopic guidance. The *mild*® device kit is comprised of a single-use 6 gauge (5.1 mm diameter) *mild*® portal cannula with trocar to access into the soft tissue of the posterior lumbar spine, followed by a Bone Sculptor Rongeur which is used to precisely sculpt small pieces of lamina prior to tissue resection of the hypertrophic ligamentum flavum, then the *mild*® Tissue Sculpture is used to remove ligamentous and fibrous tissues from the hypertrophic ligamentum flavum (Deer 2010, 2011, Wong 2012).

The Vertos Medical *mild*® Device Kit was FDA approved through the 510k process as a set of specialized surgical instruments intended to be used to perform lumbar decompressive procedures for the treatment of various spinal conditions (FDA website accessed June 26, 2012).

Medical Technology Assessment Committee (MTAC)

Minimally Invasive Lumbar Decompression

08/20/2012: MTAC REVIEW

Evidence Conclusion: There is insufficient published evidence to determine that *mild*® Vertos procedure leads to similar or better outcomes than traditional surgery among in patients with symptomatic spinal stenosis who failed conservative therapy. There is limited published literature on the procedure. No published randomized controlled trials compared the procedure to the traditional surgical approach, or to other less invasive surgical techniques. The only published RCT to date was a small study that compared the outcomes of *mild*® procedure to epidural steroid injection (ESI) in patients with symptomatic spinal stenosis and painful lower limb neurogenic claudication. The authors indicated that patients had to fail conservative therapy to be included in the trial, yet the procedure was compared to epidural steroid injection (ESI), which is considered a conservative management. In addition, the epidural steroid was delivered through interlaminar injections and not the preferable transforaminal route to maintain blinding (according to the author). The other published studies were prospective or retrospective case series with potential biases and were all funded by Vertos Medical the manufacturer of *mild*® device.

Articles: The literature search revealed one small RCT that compared the *mild*® procedure with epidural steroid injection, two multicenter observational studies with no control group, and few small prospective and retrospective case series. The RCT and the prospective multicenter observational study with one-year follow-up were selected for critical appraisal: Brown LL. A double-blind, randomized, prospective study of epidural steroid injection vs. the *mild*® procedure in patients with symptomatic lumbar spinal stenosis. *Pain Practice*. 2012; 12:333-341. See [Evidence Table](#). Mekhail N, Vallejo R, Coleman MH, et al. Long-term results of percutaneous lumbar decompression *mild*® for spinal stenosis. *Pain Practice*. 2012;12:184-193. See [Evidence Table](#).

The use of minimally invasive lumbar decompression for treatment of spinal stenosis does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Transcatheter Edge-to-Edge Repair (TEER) for Mitral Valve Regurgitation (20.33)
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Decision Memo	Transcatheter Mitral Valve Repair (TMVR) (CAG-00438R)

For Non-Medicare Members

Transcatheter mitral valve repair using a device approved by the U.S. Food and Drug Administration for use in mitral valve repair may be considered medically necessary for patients with symptomatic, primary mitral regurgitation who are considered at prohibitive risk for open surgery.

Prohibitive risk for open mitral valve repair surgery may be determined based on the following:

- The documented presence of a Society for Thoracic Surgeons predicted mortality risk of 12% or greater
- AND/OR**
- The documented presence of a logistic EuroSCORE of 20% or greater

Transcatheter mitral valve repair with a device approved by the U.S. Food and Drug Administration may be considered medically necessary for patients with heart failure and moderate-to-severe or severe* symptomatic secondary mitral regurgitation despite the use of maximally tolerated guideline-directed medical therapy**.

* Moderate to severe or severe MR may be determined by:

- Grade 3+ (moderate) or 4+ (severe) MR confirmed by echocardiography
- New York Heart Association (NYHA) functional class II, III, or IVa (ambulatory) despite the use of stable maximal doses of guideline-directed medical therapy and cardiac resynchronization therapy (if appropriate) administered in accordance with guidelines of professional societies.

**Optimal guideline directed medical therapy (GDMT) - see reference below:

<https://www.jacc.org/doi/10.1016/j.jacc.2020.11.022>

Transcatheter mitral valve repair is considered investigational in all other situations.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Name of the Food and Drug Administration (FDA) approved device to be used

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Transcatheter mitral valve repair (TMVR) is used in the treatment of mitral regurgitation. A TMVR device involves clipping together a portion of the mitral valve leaflets as treatment for reducing mitral regurgitation (MR); currently MitraClip® is the only one with Food and Drug Administration (FDA) approval.

U.S. FDA–MitraClip Clip Delivery System (MitraClip CDS) (Abbott Vascular, Menlo Park, CA): The MitraClip CDS received FDA approval through the PMA process on October 24, 2013. It is indicated for the percutaneous reduction of significant symptomatic mitral regurgitation (MR $\geq 3+$) due to primary abnormality of the mitral apparatus (degenerative MR) in patients who have been determined to be at prohibitive risk for mitral valve surgery by a heart team, which includes a cardiac surgeon experienced in mitral valve surgery and a cardiologist experienced in mitral valve disease, and in whom existing comorbidities would not preclude the expected benefit from reduction of the mitral regurgitation. The device is contraindicated in patients who cannot tolerate procedural anticoagulation or post procedural antiplatelet regimen, and those with active endocarditis of the mitral valve, rheumatic mitral valve disease, or evidence of intracardiac, inferior vena cava or femoral venous thrombus. The MitraClip system consists of implant catheters and the MitraClip device, a permanent implant that attaches to the mitral valve leaflets. The procedure results in a double opening of the mitral valve that allows greater closure and reduces mitral regurgitation.

Medical Technology Assessment Committee (MTAC)

MitraClip System

BACKGROUND

Mitral regurgitation (MR) is the second most common valvular heart disease after aortic stenosis. The natural history of severe MR without surgical intervention is poor, leading to worsening LV failure, pulmonary hypertension, atrial fibrillation and death. It is reported that without surgical treatment, patients with severe symptomatic MR have an annual mortality rate of 5% per year, and as high as 60% at 5 years if associated with significant heart failure (Mauri 2010).

MR is broadly categorized as primary or secondary. Primary MR, also known as degenerative MR (DMR), describes an abnormality of the leaflets varying from a prolapse of an isolated segment in a normally shaped valve, to multiple segment prolapse involving one or both leaflets in a valve with significant excessive tissue and large annular size. Secondary MR, also known as functional MR (FMR), is secondary to left ventricular (LV) remodeling with structurally preserved mitral leaflets. Surgical mitral valve repair/replacement remains the gold standard for the treatment of symptomatic MR, though it has some controversy in FMR due to the lack of clear survival benefit and high recurrence rates of MR at 1 year after surgery. Current guidelines recommend MV surgery in patients with moderate to severe (grade 3+) or severe (4+) MR associated with symptoms or evidence of LV dysfunction. Surgical repair of the valve before the onset of limiting symptoms or LV dysfunction can restore normal life expectancy and quality of life. The conventional surgery for MV repair/replacement is an open-heart surgery performed under cardiopulmonary bypass. It is reported that as many as 49% of patients in need of MR repair or replacement are considered at high surgical risk and are denied surgical treatment due to their age, advanced LV systolic dysfunction, previous bypass surgeries, or significant comorbidities. Patients who do not qualify for surgical correction of the MV are treated with medical therapy alone, which may reduce their symptoms, but does not stop the disease progression (Estevez-Loureiro 2013 Mauri 2013, Vakil 2013, Wan 2013, Munkholm-Larsen 2014). In the past 15 years, percutaneous valve therapy has been advancing rapidly especially for the aortic and pulmonic valve replacement. This development of percutaneous mitral valve (MV) therapies has been slower due to the anatomy of the MV and its relationship with the left ventricle. A number of devices for MV repair have been introduced as potential alternatives to open surgical procedures; many have failed, and more

are at different stages of investigation. Percutaneous or minimally invasive repair systems target the MV leaflets, annulus or the left ventricle, e.g. the NeoChord DS1000, the Carillon Mitral Contour System, and the MitraClip system. The latter is the only one in clinical use across the United States and Europe (Munkholm-Larsen 2014, Rana 2015).

The concept of the MitraClip system (Abbott Vascular, Menlo Park, California) is based on the edge-to-edge repair technique developed by Alfieri and colleagues in the early 2000s. This technique involves suturing of the middle scallops of the anterior and posterior MV leaflets resulting in a double orifice valve. The MitraClip is a single-sized system that consists of a 4mm wide cobalt chromium clip with two foldable arms designed to grasp the moving leaflets; a 10Fr delivery catheter, with a radiopaque distal tip, and a 24-Fr steerable sleeve. The procedure is performed in the cardiac catheterization laboratory under general anesthesia, anticoagulation, and fluoroscopic and transesophageal echocardiographic guidance. The MV is accessed via the femoral vein and right atrium then to the left atrium via a transseptal puncture. The system is advanced into the left ventricle and the clip is deployed for permanent approximation of the anterior and posterior MV leaflets creating a double orifice MV during diastole. Reduction in MR is assessed by echocardiography during the procedure, and more than one clip may be used at the operator's discretion. At the end, the catheters are withdrawn, and the patient treated with aspirin for 6 months and clopidogrel for 30 days (Wan 2013, Vakil 2013, Munkholm-Larsen 2014, Rana 2015). Several anatomic parameters must be satisfied to determine the appropriate patients for the procedure. These differ for patients with DMR and FMR. Anatomical criteria for DMV include flail width and gap size, prolapse location, length of posterior MV leaflet (PMVL) and MV orifice size. The criteria for MV anatomy include coaptation depth and length, the MV orifice size, and the MV transvalvular gradient. Lesions ideal for MitraClip lie within the central portion at the coaptation line, have a flail width <15 mm with a flail gap <10mm, and as the MitraClip reduces the MV orifice, the preimplantation area should be >40 mm². A hypoplastic posterior leaflet is a contraindication, and heavy calcification, fibrosis, or deep clefts within the clip grasping area have potential for clip implantation failure. The percutaneous MV repair with the MitraClip system depends heavily on echo-imaging during the implantation and early on for assessing the suitability for clip placement, which is the cornerstone for the success of the technique. It has been reported that some technical aspects of the MitraClip implantation remain operator dependent and have not been fully standardized, and that the correct strategy for patients with complex valve anatomy remains controversial (Paranskaya 2013, Rana 2015).

The MitraClip treatment of MR is less invasive than surgery but may be associated with potentially life-threatening complications. The incidence of the reported procedure-related complications is generally low and varies considerably between studies. These included bleeding that require >2 units of blood transfusion (the most common), vascular access site complications, transseptal puncture (which may also cause to aortic root needle puncture), partial clip detachment, clip attachment to a single leaflet, leaflet injury or laceration, mitral valve stenosis, mitral valve injury, acute heart failure, and stroke (Bakker 2013). According to the device manufacturer and the FDA (approval in October, 2013), MitraClip implantation is indicated for the percutaneous reduction of significant symptomatic mitral regurgitation (MR ≥ 3+) due to primary abnormality of the mitral valve (degenerative MR), who have been determined to be at prohibitive risk for mitral valve surgery by a heart team, which includes a cardiac surgeon experienced in mitral valve surgery and a cardiologist experienced in mitral valve disease, and in whom existing comorbidities would not preclude the expected benefit from reduction of the mitral regurgitation. It is contraindicated in patients who cannot tolerate anticoagulation required during the procedure or antiplatelet therapy required after the procedure; in patients with active MV endocarditis; rheumatic MV disease; and in patients with evidence of femoral venous, inferior vena cava, or intracardiac thrombus. (<http://mitraclip.com>, and FDA webpage accessed July 17, 2015)

08/17/2015: MTAC REVIEW

MitraClip System

Evidence Conclusion:

There is evidence from EVEREST II RCT with 4 years of follow-up, that the implantation of MitraClip is less effective than surgery in improving the mitral regurgitation in patients with moderate or severe symptomatic mitral valve regurgitation who are suitable candidates for conventional surgery. The is low quality, but consistent evidence from observational studies and registries that implantation of MitraClip in patients with symptomatic moderate or severe symptomatic mitral valve regurgitation who are at high surgical risk, is feasible and is associated with clinical improvement and relatively low risk of major adverse events. However, there is no evidence to date to determine the durability of clinical improvements and optimal criteria for patient selection. There is insufficient evidence to determine the outcomes of MitraClip device by etiology of mitral regurgitation (FMR or DMR). Two ongoing RCTs (COPAT in the US and RESHAPE-HF trial in Europe) are comparing MitraClip implantation versus medical therapy in high surgical risk patients, and their results may provide more evidence on the relative safety and efficacy of implanting the device in these patients.

Articles: The literature search revealed EVEREST I feasibility trial; EVEREST II randomized controlled with four publications (the last of which reported on 4-years follow-up outcomes); 4 other nonrandomized

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	4/09/2018 Noridian Retired LCD for Monitored Anesthesia Care (MAC) (L34100) . These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an LCD. Most LCDs are not retired because they are incorrect. The criteria should be still referenced when making an initial decision. However, if the decision is appealed, the retired LCD cannot be specifically referenced. Maximus instead looks for "medical judgment" which could be based on our commercial criteria or literature search. Medical necessity review is no longer required for Medicare members. However, providers are expected to validate medical necessity per Medicare's guidance in retired LCD L34100 (see above).
Local Coverage Article	None

For Non-Medicare Members

Effective until March 1, 2023

Monitored anesthesia care (MAC) is considered medically necessary during gastrointestinal endoscopic procedures when there is documentation by the operating physician and the anesthesiologist that demonstrates any of the following higher risk situations exist:

- Prolonged or therapeutic endoscopic procedure requiring deep sedation**; Such as endoscopic ultrasound (EUS), double balloon enteroscopy (push endoscopy), transanal endoscopic microsurgery (TEM), endoscopic retrograde cholangio-pancreatography (ERCP) or
- A history of or anticipated intolerance to standard sedatives (e.g., patient on chronic high dose narcotics or high dose benzodiazepines, or has an unstable neuropsychiatric disorder which would prevent cooperation); or
- Increased risk for complication due to severe comorbidity. American Society of Anesthesiologists **ASA class IV physical status or greater** (as documented by Anesthesia)
- Pediatric age group (16 years and younger); or
- Pregnancy; or

- History of active drug or alcohol abuse; (marijuana use, either daily or intermittent, does not by itself require MAC anesthesia) or
- Morbid obesity (BMI>40); or
- Uncooperative or acutely agitated patients (e.g., delirium, organic brain disease, senile dementia); or
- Spasticity or movement disorder complicating procedure; or
- Increased risk for airway obstruction due to anatomic variant including any of the following:
 - Documented history of previous problems with anesthesia or sedation; or
 - History of stridor or severe sleep apnea requiring oxygen **and** bipap; or
 - Dysmorphic facial features, such as Pierre-Robin syndrome or trisomy-21; or
 - Presence of significant oropharyngeal abnormalities, such as tonsillar hypertrophy or oropharyngeal mass, as documented by Anesthesia; or
 - Neck abnormalities including but not limited to short neck, obesity involving the neck and facial structures, limited neck extension, decreased hyoid-mental distance (less than 3 cm in an adult), neck mass, cervical spine disease or trauma, tracheal deviation, or advanced rheumatoid arthritis as documented by Anesthesia; or
 - Jaw abnormalities including but not limited to micrognathia, retrognathia, trismus, or significant malocclusion as documented by Anesthesia

Effective March 1, 2023

Monitored anesthesia care (MAC) is considered an acceptable clinical option during gastrointestinal endoscopic procedures when there is documentation by the operating physician and the anesthesiologist that demonstrates any of the following higher risk situations exist:

- Prolonged or therapeutic endoscopic procedure requiring deep sedation**; Such as endoscopic ultrasound (EUS), double balloon enteroscopy (push endoscopy), transanal endoscopic microsurgery (TEM), endoscopic retrograde cholangio-pancreatography (ERCP) or
- A history of or anticipated intolerance to standard sedatives (e.g., patient on chronic high dose narcotics or high dose benzodiazepines, or has an unstable neuropsychiatric disorder which would prevent cooperation);
- Member is currently using Suboxone or
- Increased risk for complication due to severe comorbidity. American Society of Anesthesiologists **ASA class III* or greater physical status** (as documented by Anesthesia)
- Pediatric age group (16 years and younger); or
- Pregnancy; or
- History of active drug or alcohol abuse; (marijuana use, either daily or intermittent, does not by itself require MAC anesthesia) or
- Morbid obesity (BMI>40); or
- Uncooperative or acutely agitated patients (e.g., delirium, organic brain disease, senile dementia); or
- Spasticity or movement disorder complicating procedure; or
- Increased risk for airway obstruction due to anatomic variant including any of the following:
 - Documented history of previous problems with anesthesia or sedation; or
 - History of stridor or severe sleep apnea requiring oxygen **and** bipap; or
 - Dysmorphic facial features, such as Pierre-Robin syndrome or trisomy-21; or
 - Presence of significant oropharyngeal abnormalities, such as tonsillar hypertrophy or oropharyngeal mass, as documented by Anesthesia; or
 - Neck abnormalities including but not limited to short neck, obesity involving the neck and facial structures, limited neck extension, decreased hyoid-mental distance (less than 3 cm in an adult), neck mass, cervical spine disease or trauma, tracheal deviation, or advanced rheumatoid arthritis as documented by Anesthesia; or
 - Jaw abnormalities including but not limited to micrognathia, retrognathia, trismus, or significant malocclusion as documented by Anesthesia

[*ASA Physical Status Classification System](#) – please click here to see ASA PS Classification table

ASA PS Classification	Definition	Adult Examples, Including, but not Limited to:	Pediatric Examples, Including but not Limited to:	Obstetric Examples, Including but not Limited to:
ASA I	A normal healthy patient	Healthy, non-smoking, no or minimal alcohol use	Healthy (no acute or chronic disease), normal BMI percentile for age	
ASA II	A patient with mild systemic disease	Mild diseases only without substantive functional limitations. Current smoker, social alcohol drinker, pregnancy, obesity (30<BMI<40), well-controlled DM/HTN, mild lung disease	Asymptomatic congenital cardiac disease, well controlled dysrhythmias, asthma without exacerbation, well controlled epilepsy, non-insulin dependent diabetes mellitus, abnormal BMI percentile for age, mild/moderate OSA, oncologic state in remission, autism with mild limitations	Normal pregnancy*, well controlled gestational HTN, controlled preeclampsia without severe features, diet-controlled gestational DM.
ASA III	A patient with severe systemic disease	Substantive functional limitations; One or more moderate to severe diseases. Poorly controlled DM or HTN, COPD, morbid obesity (BMI ≥40), active hepatitis, alcohol dependence or abuse, implanted pacemaker, moderate reduction of ejection fraction, ESRD undergoing regularly scheduled dialysis, history (>3 months) of MI, CVA, TIA, or CAD/stents.	Uncorrected stable congenital cardiac abnormality, asthma with exacerbation, poorly controlled epilepsy, insulin dependent diabetes mellitus, morbid obesity, malnutrition, severe OSA, oncologic state, renal failure, muscular dystrophy, cystic fibrosis, history of organ transplantation, brain/spinal cord malformation, symptomatic hydrocephalus, premature infant PCA <60 weeks, autism with severe limitations, metabolic disease, difficult airway, long term parenteral nutrition. Full term infants <6 weeks of age.	Preeclampsia with severe features, gestational DM with complications or high insulin requirements, a thrombophilic disease requiring anticoagulation.
ASA IV	A patient with severe systemic disease that is a constant threat to life	Recent (<3 months) MI, CVA, TIA or CAD/stents, ongoing cardiac ischemia or severe valve dysfunction, severe reduction of ejection fraction, shock, sepsis, DIC, ARD or ESRD not undergoing regularly scheduled dialysis	Symptomatic congenital cardiac abnormality, congestive heart failure, active sequelae of prematurity, acute hypoxic-ischemic encephalopathy, shock, sepsis, disseminated intravascular coagulation, automatic implantable cardioverter-defibrillator, ventilator dependence, endocrinopathy, severe trauma, severe respiratory distress, advanced oncologic state.	Preeclampsia with severe features complicated by HELLP or other adverse event, peripartum cardiomyopathy with EF <40, uncorrected/decompensated heart disease, acquired or congenital.
ASA V	A moribund patient who is not expected to survive without the operation	Ruptured abdominal/thoracic aneurysm, massive trauma, intracranial bleed with mass effect, ischemic bowel in the face of significant cardiac pathology or multiple organ/system dysfunction	Massive trauma, intracranial hemorrhage with mass effect, patient requiring ECMO, respiratory failure or arrest, malignant hypertension, decompensated congestive heart failure, hepatic encephalopathy, ischemic bowel or multiple organ/system dysfunction.	Uterine rupture.
ASA VI	A declared brain-dead patient whose organs are being removed for donor purposes			

(ASA, 2002, 2018; American Society for Gastrointestinal Endoscopy [ASGE], 2002, 2003, 2012, 2018)
Not Medically Necessary:

The routine assistance of an anesthesiologist or Certified Registered Nurse Anesthetist (CRNA) for patients not meeting the above criteria who are undergoing standard upper or lower gastrointestinal endoscopic procedures is considered not medically necessary. (American College of Gastroenterology [ACG], American Gastroenterological Association [AGA] & ASGE, 2004; ASGE, 2002, 2003, 2012).

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Each year in the United States, 145,000 people will be diagnosed with colon cancer; 54,000 will die. Getting recommended colorectal cancer screening could potentially save the lives of up to 60% of these patients. Increasing patient participation in routine screening is a matter of serious concern.

With the increased emphasis on prevention and the importance of the role of colonoscopy as a tool there is a need to evaluate the use of monitored anesthesia care in conjunction with endoscopic evaluation. Kaiser Permanente has developed this policy in response to our findings.

Medical Technology Assessment Committee (MTAC)

Monitored Anesthesia Care (MAC) for Gastrointestinal Endoscopic Procedures 2/22/2010: MTAC REVIEW

Evidence Conclusion: The following are conclusions based on a review of several systematic reviews, meta-analyses, randomized controlled trials, and published internal data on sedation involving propofol compared to standard sedation: There is good evidence of improved patient satisfaction and reductions in discharge and

recovery times with propofol used alone or in combination with other agents compared to standard sedation for colonoscopy exams. There is fair evidence from a KP SCAL-based comparative study of improved cecal intubation rates with propofol used as a single agent for sedation during colonoscopy. The evidence is of insufficient quantity or quality to draw definitive conclusions on differences in polyp detection. There is less comparative data on EGD procedures, but some evidence of improved recovery and patient satisfaction with propofol sedation. The evidence is of insufficient quantity and/or quality to draw definitive conclusions on comparative risk of serious adverse events, including death, neurologic injury, endotracheal intubations, bleeding, and colonic perforations during these procedures. There does not appear to be a significant difference in the risk of cardiopulmonary and respiratory events with propofol compared to standard sedation and no evidence of greater risk for serious adverse events for either colonoscopy or EGD procedures in lower risk patients (ASA I or II). Following the review of one systematic review and two comparative observational studies, the evidence is of insufficient quantity and quality to draw definitive conclusions on the safety of anesthesiologist- versus non anesthesiologist-directed or administered propofol sedation in GI endoscopy. Controlled prospective studies with standardized protocols, patient selection, and reporting are needed. Serious Adverse Events. The best available comparative evidence from the United States is a large observational registry study that suggests comparable rates of serious adverse events for anesthesiologist-directed propofol under monitored anesthesia care and gastroenterologist-administered propofol during colonoscopy procedures (0.16% and 0.14%) but a significantly increase risk of serious adverse events with gastroenterologist-administered propofol for upper endoscopy procedures, including EGDs (0.16% vs 0.5%). However, it is likely that these events differentially occurred in higher risk patients (ASAI III) who were also included in the study. Overall Cardiopulmonary Adverse Events. There is evidence from the same study of a significant increased risk of overall cardiopulmonary events with endoscopic-administered propofol in ASA I or II patients undergoing colonoscopy and upper endoscopy. The majority of the cardiopulmonary events are most likely to be of minor clinical consequence, but the challenge remains to identify which cardiopulmonary events are more likely to result in serious adverse events and what risk factors are specific to upper versus lower endoscopy procedures. The evidence is of insufficient quantity and quality to draw conclusions on the safety of RN-administered propofol as compared to standard sedation for colonoscopy and EGD in ASA I and II patients. Based on a review of several systematic reviews and randomized controlled trials, there is no evidence of a significant increase in risk of adverse events with propofol compared to standard sedation and the risks appear to be comparable. However, these studies were not adequately sampled to detect or compare rates of serious adverse events. Comparative data from large and well-designed observational studies is needed. The existing series of RN-administered propofol are large and report low rates of adverse events.

MONITORED ANESTHESIA CARE (MAC) FOR CHRONIC MARIJUANA USERS UNDERGOING GASTROINTESTINAL ENDOSCOPIC PROCEDURES

BACKGROUND

Marijuana use

Marijuana is the most commonly used federally illegal drug in the United States. Its use has significantly increased across the country in recent years, especially among young people and in the states that have legalized the recreational cannabis use. It is estimated that approximately 3 in 10 people who use marijuana have marijuana use disorder, the risk of which is higher among those who begin using it before the age of 18. The National Survey on Drug Use and Health National Institute on Drug Abuse estimated that 5.1% (or about 14.2 million people) aged 12 or older in 2020 had a cannabis use disorder in the past 12 months (2020 National Survey on Drug Use and Health National Institute on Drug Abuse and CDC website).

The term “Marijuana” is commonly used interchangeably with “Cannabis”; however, they don’t mean exactly the same thing. Cannabis refers to all products derived from the plant *Cannabis sativa* that includes more than 500 compounds among which are cannabinoids, terpenoids, and flavonoids. Marijuana on the other hand refers to the dried flowers, leaves, stems, and seeds of the cannabis plant that contain substantial amounts of tetrahydrocannabinol (THC) that is primarily responsible for the effects of marijuana on a person’s mental state. The main cannabinoids in the cannabis are delta-9-tetrahydrocannabinol (THC) and cannabidiol (CBD), each with its own effects and uses. THC is the main psychoactive compound in cannabis and is responsible for the “high” that most people associate with cannabis. CBD is also a psychoactive cannabinoid, but is non-intoxicating and non-euphoric, i.e., does not cause a “high”. It is often used to help reduce inflammation and pain, and also to ease nausea, migraine, seizures, and anxiety. (Andre et al, 2016, Boninin et al, 2018, Bakshi, et al 2019, Balant, et al 2021, Irvine, et al 2022, and the CDC website)

Marijuana use has negative clinical effects on different body organs and systems including the respiratory, cardiovascular, and central nervous system, gastrointestinal tract, and others. These vary by the quantity and chronicity of the marijuana used. However, it can be difficult to determine the quantity of the active compound of the marijuana consumed as the formulations of the products and their CBD-to-THC-content ratios are very heterogeneous. Research suggests that cannabis users require significantly higher doses of sedation for upper endoscopic procedures compared with nonusers. Propofol, a primary anesthetic agent, is metabolized through similar enzymatic pathways as the THC and cannabis users may present a higher-than-normal risk for subanesthetic dosing, leading to greater incidence of awareness or recall. They are also at a higher risk of adverse events such as bronchospasm, laryngospasm, tachycardia, and others (Twardowski, et al 2019, Imasogie et al 2021, Ladha et al, 2021).

With the increasing prevalence of cannabis use among adults, and with the known effects of marijuana on the different systems it is important that anesthesia professionals consider the potential effects of cannabis use when providing perioperative care to chronic marijuana users.

Monitored anesthesia care (MAC)

Monitored anesthesia care is defined by the American Society of Anesthesiologists (ASA) as a planned procedure during which the patient undergoes local anesthesia together with sedation, and analgesia provided by an anesthesiologist. I.e., it is an anesthesia technique combining local anesthesia with parenteral drugs for sedation and analgesia. The purpose of the conscious sedation during MAC is providing the patient with safe sedation, comfort, and control of pain and anxiety. The patients under conscious sedation maintain ventilatory and cardiovascular function and are able to respond to verbal and tactile stimulation. The discretion and judgment of an experienced anesthesiologist are required for the safety and efficacy as the airway of the patient is not secured. The attending anesthesiologist should be aware of the possibility of airway obstruction, desaturation, or even aspiration due to the possibility of deep sedation after infusion of a combination of two or more drugs (GHISI, et al 2005, Sohn and Ryu 2016. In contrast, moderate sedation /analgesia (conscious sedation) is a drug induced depression of consciousness during which patients respond purposefully to verbal commands alone or with light tactile stimulation. No interventions are required to maintain a patent airway, spontaneous ventilation is adequate and cardiovascular function is usually maintained.

MAC allows for the safe administration of a maximal depth of sedation more than that provided during moderate sedation. The qualified anesthesiologist /provider is able to adjust the sedation level from full

© 2012, Kaiser Foundation Health Plan of Washington. All Rights Reserved.

[Back to Top](#)

consciousness to general anesthesia during the procedure according to the patient needs and procedural requirements. An essential component of MAC is the periprocedural anesthesia assessment and understanding of the comorbidities and management of the patient's actual or anticipated physiological instabilities during a diagnostic or therapeutic procedure. MAC may include the administration of sedatives and/or analgesics often used for moderate sedation, however the qualified MAC provider is focused exclusively and continuously on the patient for any attendant airway, hemodynamic and physiologic instabilities, and must be prepared and qualified to convert to general anesthesia. The provider's ability to intervene to rescue a patient's airway from any sedation-induced compromise is required. On the other hand, moderate sedation is not expected to induce the level of sedation that would impair the patient's respiratory function or ability to maintain the integrity of his or her airway, and the moderate sedation provider or anesthesiologist focus is on the procedure itself. (ASA 2018)

The use of MAC is increasing for a variety of diagnostic and therapeutic procedures in and outside of the operating room due to the rapid postoperative recovery with the use of relatively small amounts of sedatives and analgesics compared to general anesthesia. Procedures performed with MAC include eye surgery, otolaryngologic surgery, cardiovascular procedures, pain procedures, and endoscopy. Sedation and analgesia during MAC are provided by an anesthesia care team following the same preoperative evaluation, perioperative management, monitoring, and postoperative recovery care used for general or regional anesthesia (Sohn and Ryu 2016).

Some researchers found that the overall rate of complications during and after MAC may be similar to that for general anesthesia. These potential complications associate with MAC include

- Respiratory complications, including airway obstruction, respiratory depression with hypoxemia and hypercarbia, and aspiration due to depression of airway reflexes.
- Cardiovascular compromise, including hypotension, cardiac ischemia, cardiac arrest, and arrhythmias.
- Complications related to patient movement
- Burn injuries, particularly involving the head and neck
- Local anesthetic systemic toxicity (LAST)

10/10/2022: MTAC REVIEW

Evidence Conclusion: To date, there are no published literature on the comparative efficacy and safety of monitored anesthesia care and moderate sedation for patients on chronic marijuana use undergoing gastrointestinal endoscopic procedures.

Additional research is needed to determine the efficacy and safety of MAC in these patients.

Articles: The literature search did not reveal any published RCTs or observational studies that compared the outcomes of MAC versus moderate conscious sedation for GI endoscopic procedures in adults on chronic marijuana use. The published literature mainly discussed the effects of cannabis use on the anesthesia risk, the dose of propofol required, the need for using adjuncts such as fentanyl and ketamine, and or the risk of adverse cardiac or respiratory events during or immediately after anesthesia.

The use of Monitored Anesthesia Care (MAC) For Chronic Marijuana Users Undergoing Gastrointestinal Endoscopic Procedures does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
00731	Anesthesia for upper gastrointestinal endoscopic procedures, endoscope introduced proximal to duodenum; not otherwise specified
00811	Anesthesia for lower intestinal endoscopic procedures, endoscope introduced distal to duodenum; not otherwise specified
00812	Anesthesia for lower intestinal endoscopic procedures, endoscope introduced distal to duodenum; screening colonoscopy
00813	Anesthesia for combined upper and lower gastrointestinal endoscopic procedures, endoscope introduced both proximal to and distal to the duodenum

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

^{MDCRPC} Medical Director Clinical Review and Policy Committee

^{MPC} Medical Policy Committee

Revision History	Description
05/05/2015	Slight changes were made to the existing policy, which included the following: <ul style="list-style-type: none"> Removal of the 70-age limit Definition of pediatric age group as 16 years and younger Clarification of "high dose" & "unstable" "as documented by anesthesia" language was added
09/08/2015	Revised LCD L34100
10/3/2016	Added prolonged procedure clarification
09/06/2017	Changed BMI to 40
10/19/2017	Added examples of prolonged procedures
04/09/2018	MA retired LCD 34100
05/23/2018	Removed the language regarding the Mallampati score
09/04/2018	Added specific language regarding marijuana use
05/05/2020	MPC approved to adopt updates to align with ASA class ASGE recommendations. Requires 60-day notice, effective date 9/1/2020. Removed deleted CPT codes 00740 and 00810 and added CPT code 00732.
06/16/2020	Removed 00732 (ERCP)
11/02/2021	MPC approved to remove the prior-authorization requirement for Medicare members, effective January 1, 2022.
09/06/2022	MPC approved the MAC criteria update for ASA class from IV to III and the inclusion of coverage for members with current suboxone use. 60-day notice required; effective 2/1/2023.
12/06/2022	Updated MAC effective date to 3/1/2023 per Provider Relations.
12/07/2022	Added MTAC Review for Monitored Anesthesia Care (MAC) For Chronic Marijuana Users Undergoing Gastrointestinal Endoscopic Procedures to criteria.

Clinical Review Criteria

Magnetic Resonance Enterography (MR per OS) for the Diagnosis and Monitoring of Crohn's and Celiac Diseases

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Magnetic Resonance Imaging (MRI) (220.2)
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

Kaiser Permanente considers magnetic resonance enterography medically necessary to evaluate and monitor Crohn's disease and other small bowel disorders and does not require medical necessity review.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Crohn's disease is a chronic inflammatory disease of the gastrointestinal tract. In 80% of cases it involves the small bowel, more specifically the ileum, and is characterized by luminal, transmural and mesenteric abnormalities. Crohn's usually manifests in early adulthood and typically runs a relapsing and remitting course. Initial diagnosis aims at establishing and characterizing the disease including the location, extent of inflammation, and the presence of stenosis, fistulae or abscesses. Several modalities such as radiology, endoscopy, and serologic markers are being used to diagnose and assess the disease activity. None is recognized as a gold standard, but radiological procedures including small bowel series and fluoroscopic enteroclysis continue to lead the diagnostic tools that examine the small bowel in its entirety. Because there is no known cure, and the condition is typically relapsing, patients with Crohn's disease normally undergo several radiological investigations during the course of the disease to monitor the treatment response, recurrence, and /or development of complications (Negaard 2007, 2008, Masselli 2006, Lin 2008).

Celiac disease is a gluten-sensitive enteropathy of the gastrointestinal tract that affects the small intestine in genetically susceptible individuals at any age. The disease is relatively common in European countries and occurs less frequently in the US. Celiac disease has a wide range of nonspecific clinical manifestations which make it challenging to diagnose. It may be silent and go clinically undetected or present with symptoms that range from fatigue and abdominal pain to weight loss, diarrhea, and malabsorption with steatorrhea. In children it may be associated with apathy, anorexia, and muscle wasting. It is reported that a small-intestine biopsy is mandatory to confirm the diagnosis of celiac disease. Imaging plays a role in suggesting celiac disease in adults with intestinal disorders, and in ruling out complicating lesions in patients with known disease (Paolantonio 2007).

The traditional imaging techniques used to evaluate the small bowel are the conventional barium studies e.g. small bowel follow-through or conventional enteroclysis (CE) Historically CE has been the radiological method of

choice. It was found to be highly accurate for diagnosing Crohn's disease and detecting partially or non-obstructive lesions that may not be demonstrated by cross-sectional imaging techniques. The procedure involves distension of the entire small bowel with barium suspension which when adequate, would allow the radiological demonstration of mucosal abnormalities and provide functional information on the ability of the small bowel to distend. CE, however, exposes the patient to ionizing radiation, may be hindered by the overlapping bowel loops, and does not provide information on the transmural and extramural extension, or other complications of the disease such as fistulae and abscesses (Schreyer 2004, Bernstein 2005, Masselli 2008).

Computed tomographic (CT) enterography, magnetic resonance (MR) enterography, and MR enteroclysis are emerging techniques for small bowel imaging. They have a benefit over traditional barium fluoroscopic techniques in their ability to visualize superimposed bowel loops and extraluminal extensions, and complications. CT provides excellent temporal and spatial high-resolution images of the small bowel, and is less susceptible to motion artifacts than MRI, but at the cost of radiation exposure. MRI on the other hand, has several advantages over CT, such as its superior tissue contrast, ability to provide direct cross-sectional imaging in multiple planes, functional or real-time examination of the bowel, and lack of ionizing radiation exposure which is particularly important in Crohn's patients who need repeated evaluation. The real-time imaging can be helpful in evaluating the progress of bowel filling with contrast agents during enteroclysis, determining the ability of the narrowed areas to distend, and improving differentiation of contractions from strictures. In addition, the gadolinium contrast agents used in MRI are known to have an excellent safety profile and can be used in patients with iodine contrast allergies, renal insufficiency, or during pregnancy. MRI, however, has inferior spatial and temporal resolution compared to CT, and its image quality may be degraded by artifacts from bowel peristalsis. Other reported constraints for MRI use include the limited number and access to MR scanners as well as its high cost (Rieber 2000, Bruining 2006, Fidler 2007).

MRI for small bowel disease may be performed by MR enteroclysis (luminal contrast) or MR enterography (MRI per OS, oral contrast). MR enteroclysis requires the fluoroscopic passage of a nasojejunal catheter and controlled administration of significant volumes (up to 3 liters) of enteric contrast agents. The small bowel can be filled with manual injection or hand-held infusion pumps while the patient is in the scanner. The procedure is associated with significant patient discomfort particularly due to the catheter introduction and manipulation, as well as the profuse diarrhea which results from the infused contrast medium. Moreover, the continuous infusion of the contrast agent may result in gastro-esophageal reflux especially in the obstructed patient, leading to potential vomiting and aspiration (Negaard 2007, Lohan 2007).

To achieve a compromise between patient tolerability and reproducible diagnostic image acquisition, MRI techniques with oral contrast (MR enterography) have been introduced. For this procedure, the patient is required to ingest a large amount of fluid (1.5-2 liters) to distend the stomach and small bowel in continuity. Various substances and volumes have been added to the oral solutions to increase the bowel distension. It is reported that there is no agreement on the optimal oral contrast, but investigators found that high osmolality of the contrast e.g. mannitol, improves the bowel distension. MR enterography may be associated with adverse effects such as diarrhea, nausea, abdominal pain, ileus due to the increased fluid content, and other side effects (Masselli 2006, Lohan 2007).

Medical Technology Assessment Committee (MTAC)

Magnetic Resonance Enterography (MR per OS)

02/02/2009: MTAC REVIEW

Evidence Conclusion: Most of the published studies on MR imaging of the small bowel used the enteroclysis technique that requires intubation of the proximal small bowel followed by the administration of contrast agent. Few studies performed MR enterography where the contrast material is ingested orally. Different modalities for the diagnosis of Crohn's disease were used as reference standards, as there is no non-surgical gold standard to date.

In the studies reviewed, MR imaging was used for patients with suspected or confirmed Crohn's disease to characterize the disease, assess the extent and severity of bowel inflammation, and detect any stenosis, fistula, or other associated lesions. In both MR techniques, good distension of the small bowel loops during examination is essential to accurately evaluate the bowel wall pathology because collapsed loops may hide the disease or falsely identify a collapsed segment as a thickened wall. Negaard et al's study (2007) included 40 participants with known or suspected Crohn's. All participants were examined with both MR techniques, and the diagnosis of the disease was based on clinical evaluation, ileoscopy with histopathology, capsule endoscopy, or surgery. The study had several limitations, no comparison was made to with conventional enteroclysis, and lesions in jejunum and proximal ileum were not evaluated. Moreover, the reference standards were performed 2-3 months after the

MR imaging, which may affect the presence or absence of some disease-related findings. The overall results of the study show that bowel distension was statistically significantly inferior in MR enterography compared to MR enteroclysis at both the jejunal and ileal levels. The difference was, however, insignificant for the terminal ileum. The accuracy of the two MR imaging techniques had similar sensitivity in assessing the intestinal wall thickness, enhancement and ulcer detection, when compared to reference standards used in the study. MR enteroclysis was more sensitive and specific than MR enterography in detecting intestinal stenosis, but less specific for the three other measures. MR enterography was associated with bowel obstruction in two patients one of which required abdominal surgery to treat the condition. Masselli and colleagues' study (2008) compared the diagnostic accuracy of MR enterography, with MR enteroclysis, and conventional enteroclysis as a reference standard in 40 patients with histologically proven Crohn's disease. All participants underwent conventional enteroclysis and either the MR enteroclysis or enterography on an alternating basis. The study was small and had several limitations. Its overall results show that conventional enteroclysis detected significantly more mucosal and mural abnormalities, but less mesenteric findings vs. MR enteroclysis and MR enterography. There was no significant difference between the two MR imaging techniques in the image quality, or assessment of mural stenosis and fistulae. However, MR enterography was statistically significantly inferior in bowel distension vs. MR or conventional enteroclysis. It was also inferior to MR enteroclysis in detecting the involved affected segments, superficial erosions, and deep ulcers. Conclusions: The published studies indicate that MR enterography may be inferior to conventional and MR enteroclysis in bowel distension, and detection of some associated lesions. There is insufficient evidence to determine the role of MR enterography in the diagnosis or assessment of celiac disease. There is insufficient evidence to determine the role of MR enterography in monitoring patients with Crohn's or celiac disease. There is insufficient evidence to determine the safety of the MR enterography in patients with Crohn's or celiac disease.

Articles: The literature search revealed over three hundred publications. The majority was reviews, articles that dealt with the technical aspects of the tests, or that were unrelated to the current review. The studies on the use of MR imaging for the evaluation of small bowel diseases mainly included patients with Crohn's disease; only one small retrospective case series evaluated the test for patients with celiac disease. The literature on MR enterography was very limited compared to MR enteroclysis. One study compared both MR techniques (enteroclysis and enterography) to conventional enteroclysis, and one to a combination of reference standards. The technology was also compared to capsule endoscopy or CT enterography in two small studies. The test was mainly used for the initial assessment of known or suspected Crohn's. Only one small study that included patients with recurrent disease was identified, but there were no published studies on the use of MR enterography for monitoring treatment response. The studies that compared MR enterography of the small bowel to conventional enteroclysis and/or MR enteroclysis, and that had more valid methodology and data analysis, were selected for critical appraisal. Negaard A, Paulson V, Sandvick L, et al. A prospective randomized comparison between two MRI studies of the small bowel in Crohn's disease, the oral contrast methods and MR enteroclysis. *Eur Radiol* 2007;17:2294-2301. [See Evidence Table](#). Masselli G, Casciani E, Poletini E, et al. Comparison of MR enteroclysis with MR enterography and conventional enteroclysis in patients with Crohn's disease. *Eur Radiol*. 2008;18:438-47. [See Evidence Table](#).

The use of Magnetic Resonance Enterography (MR per OS) for the diagnosis and monitoring of Crohn's and celiac diseases does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Magnetic resonance imaging (MRI) studies of the brain may be medically necessary when the following criteria are met:

I. Evaluation of headache:

Brain MRI is not indicated for any of the following headache diagnoses in the absence of focal neurological deficits: migraine, cluster headache, tension-type headache, or chronic stable headache.

MRI can be considered for 1 or more of the following –

- a. Chronic headache with a change in character/pattern (e.g., more frequent, increased severity, or duration) not explained after evaluation of common causes (e.g., medication overuse syndrome or cervicogenic headache) and failure to respond to standard medical management
- b. Suspected aneurysm rupture/leak or AVM. Typically described as a new onset (< 48 hours) of “worst headache in my life” or “thunderclap” headache. A thunderclap type headache is a sudden onset new headache reaching maximum intensity within 2-3 minutes, lasting more than 5 minutes.
- c. Prior history of stroke or intracranial bleed with sudden onset of severe headache
- d. New onset of headache and any of the following:
 - i. Onset of headache before age 6 years
 - ii. Onset of headache after age 50 years not explained after evaluation of common causes (e.g., medication overuse syndrome or cervicogenic headache)
 - iii. A combination of acute, new, or fluctuating neurologic deficits such as unilateral sensory deficits, unilateral limb weakness, speech difficulties, visual loss, lack of coordination, gait disturbance, seizures, otherwise unexplained vomiting, otherwise unexplained acute hypertension, cranial nerve abnormality, mental status changes, or with papilledema or other signs of increased intracranial pressure
 - iv. Clinical signs and symptoms strongly suggesting metastatic cancer as the cause of the headache
 - v. Significantly immunocompromised patient (i.e., patient with HIV or immunosuppression)
 - vi. Patients with risk factors for cerebral venous thrombosis:
 1. Pregnancy or post-partum
 2. Known history of active coagulation disorder (e.g., sickle cell crisis, or clinical signs of active coagulation disorder)
 - vii. Fever or meningismus with suspected CNS cause
 - viii. Reproducible headache immediately preceded by physical exertion, sexual activity, Valsalva maneuver, or positional change, e.g., leaning forward
- e. MRI can be considered in a **pediatric age (0-16 years old)** patient with worsening headache and **1 or more** of the following:
 - i. Occipital location

- ii. Age < 6 years
- iii. Repeatedly awakens child from sleep or is present upon awakening

- II. **Acute, new, or fluctuating neurologic symptoms or deficits** such as **1 or more** of the following:
 - a. Ataxia or gait disturbance without other cause
 - b. Change in speech or language (e.g., dysarthria, aphasia)
 - c. Cranial nerve palsy (not otherwise explained (e.g., Bell's Palsy or diabetic CN III palsy)
 - d. Focal sensory /motor deficit suggesting brain or spinal cord cause (e.g., unilateral numbness or paresthesia's of face, arm and leg *OR* arm and leg)
 - e. Horner syndrome (unilateral miosis, ptosis, facial anhidrosis)
 - f. Papilledema
 - g. New visual disturbance (e.g., diplopia, visual field defect, nystagmus, visual loss)
- III. **Evaluation of known or suspected seizure disorder and 1 or more** of the following:
 - a. New onset of a seizure (first focal seizure or first unprovoked generalized seizures)
 - b. Newly identified change in seizure activity/pattern not otherwise explained.
 - c. Medically refractory epilepsy
 - d. Preoperative evaluation when surgery being considered
 - e. Seizure in child younger than 2 years, excluding those with febrile seizures
- IV. **Evaluation of movement disorders** – **Not indicated for **typical** Parkinson's Disease, essential tremor, primary dystonia, restless leg syndrome, or tics/spasms which can be duplicated at will*
 - a. Evaluation of suspected Parkinson's with atypical feature(s) or unresponsive to levodopa
 - b. Evaluation of new non-Parkinson symptoms in known Parkinson's disease complicating the evaluation of the current condition
 - c. Evaluation of other movement disorder to exclude a structural lesion (e.g., suspected Huntington disease, chorea, atypical parkinsonian syndromes, hemiballismus, secondary dystonia)
 - d. Prior to surgery or deep brain stimulation in patient with known Parkinson disease
- V. **Evaluation of new or acutely worsened cognitive impairment with unclear cause (to rule out large frontal tumor or frontal stroke). Not indicated if the patient has a classic Alzheimer 's history of several years of progressive decline. CT may be sufficient if MRI cannot be done. Must meet ALL of the following:**
 - a. Change in mental status with a mental status score of either Mini-Mental State Exam (MMSE) or Montreal Cognitive Assessment (MoCA) of less than 26 or other similar mental status instruments showing at least mild cognitive impairment **AND**
 - b. A completed medication review and exclusion of medical causes (e.g., thyroid function testing, liver function testing, complete blood count, electrolytes, and B12) without cause found
- VI. **Evaluation of known or suspected inflammatory disease or infection** (e.g., meningitis or abscess) for **1 of the following:**
 - a. Intracranial abscess or brain infection with acute altered mental status *OR* positive lab findings (such as elevated WBC's) *OR* follow up assessment during or after treatment completed
 - b. Meningitis with positive signs and symptoms (such as fever, headache, mental status changes, stiff neck) *OR* positive lab findings (such as abnormal lumbar puncture fluid exam)
 - c. Suspected encephalitis with a headache, altered mental status *OR* positive lab finding, (such as elevated WBC's)
 - d. Endocarditis with suspected septic emboli
 - e. Central nervous system (CNS) involvement in members with known or suspected vasculitis or autoimmune disease with positive lab findings
- VII. **Evaluation of vertigo/dizziness** **All patients should have full neurologic examination, medication review, orthostatic vitals, and Dix-Hallpike test for peripheral vertigo prior to consideration of MRI. MRI can be considered appropriate if **1 or more** of the following signs or symptoms suggestive of a CNS lesion:*
 - a. Brainstem findings (e.g., dysarthria, Horner syndrome, double vision, vertical nystagmus) **OR**
 - b. Cerebellar findings (e.g., ataxia/incoordination of voluntary movements, intention tremor, disorder of equilibrium or gait, diminished muscle tone) **OR**
 - c. Focal neurologic findings (e.g., weakness, numbness, paresthesia's on one side of body) **OR**

- d. Acute or rapidly progressing unilateral hearing loss

VIII. Evaluation of syncope, with 1 or more of the following:

- a. Concurrent bowel or bladder incontinence
- b. Witnessed tonic-clonic seizure
- c. Strong clinical suspicion of symptomatic third ventricular cyst

IX. Precocious puberty (central), as indicated by ALL of the following:

- a. Clinical findings suggestive of central precocious puberty
- b. Patient has been evaluated by pediatric endocrinologist

X. Global developmental delay or developmental delay with abnormal neurological examination (initial evaluation)

XI. Other indications for a brain MRI

- a. Multiple sclerosis – known or strong clinical suspicion after discussion with neurology
 - i. Frequency after diagnosis: annually to monitor for new lesions or following clinical flare up
- b. Trauma to the head with acute, new, or fluctuating neurologic findings
- c. Brain tumor, mass, or metastasis – known or strong clinical suspicion based on history and physical exam
- d. Routine surveillance of previously diagnosed brain tumor based on treatment plan from neuroscience specialty or oncology
- e. Initial evaluation of stroke/TIA
- f. Evaluation of known or suspected congenital abnormality with any acute, new, or fluctuating neurologic, motor, or mental status changes (hydrocephalus, craniosynostosis)
- g. Evaluation of suspected acute subarachnoid hemorrhage (SAH) if CT scan is non-diagnostic
- h. Evaluation of known or suspected cerebrospinal fluid (CSF) leakage
- i. Follow-up of a recent brain hemorrhage to check for underlying tumor or AVM
- j. Immunocompromised member (e.g., transplant recipients, HIV with CD4 < 200, primary immunodeficiency syndromes, hematologic malignancies) with focal neurologic symptoms, headaches, behavioral, cognitive, or personality changes
- k. Pre-operative evaluation for brain/skull surgery, stereotactic radiosurgery
- l. Post-operative/procedural evaluation - A follow-up study may be needed to help evaluate a member's progress after treatment, procedure, intervention or surgery. Documentation requires a medical reason that clearly indicates why additional imaging is needed for the type and area(s) requested
- m. Suspected acoustic neuroma include IAC protocol (to ensure that imaging looks in detail at that part of the anatomy)
- n. Anatomy or structural defect evaluation – e.g., when Chiari malformation is clinically suspected
- o. Suspected intracranial vasculitis
- p. Evaluation of neurological signs or symptoms in sickle cell disease
- q. Unexplained acute unilateral hearing loss after other reasonable causes ruled out
- r. Optic neuritis – consider orbit MRI in addition to brain MRI
- s. Abnormal eye findings on physical or neurologic examination (e.g., papilledema, pathologic nystagmus, ocular nerve palsies, new onset anisocoria, visual field deficit)
- t. Horner's syndrome with symptoms localizing the lesion to the central nervous system
- u. Trigeminal neuralgia if medication is not effective or if atypical features/exam (e.g., bilateral, hearing loss, dizziness/vertigo, visual changes, sensory loss, numbness, pain >2 min, pain outside trigeminal nerve distribution, progression)
- v. Bell's palsy - only if atypical signs, or no improvement at four months, or facial twitching/spasms prior to onset
- w. Psychological changes with neurological deficits on exam or after completion of a full neurological assessment by a neurologist that suggests a possible neurologic cause
- x. Multiple cranial neuropathies.

If requesting this service (or these services), please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

MRI can detect a variety of conditions of the brain such as cysts, tumors, bleeding, swelling, developmental and structural abnormalities, infections, inflammatory conditions, or problems with the blood vessels. It can determine if a shunt is working and detect damage to the brain caused by an injury or a stroke.

MRI of the brain can be useful in evaluating problems such as persistent headaches, dizziness, weakness, and blurry vision or seizures, and it can help to detect certain chronic diseases of the nervous system, such as multiple sclerosis.

In some cases, MRI can provide clear images of parts of the brain that can't be seen as well with an X-ray, CAT scan, or ultrasound, making it particularly valuable for diagnosing problems with the pituitary gland and brain stem.

Applicable Codes

Non-Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met

Medicare – Medical Necessity Review not required

CPT® or HCPCS Codes	Description
70551	Magnetic resonance (eg, proton) imaging, brain (including brain stem); without contrast material
70552	Magnetic resonance (eg, proton) imaging, brain (including brain stem); with contrast material(s)

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Magnetic Resonance Imaging (MRI) (220.2)
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
KPWA Medical Policy	Due to the absence of a NCD, LCD, or other coverage guidance specific to breast MRI, KPWA has chosen to use their own Clinical Review Criteria for indications for breast MRI , for medical necessity determinations. Use the Non-Medicare criteria below.

Effective until November 1, 2023

For Non-Medicare Members

- I. Breast MRI may be indicated for **One or more of the following**:
 - A. **Breast abnormality evaluation** needed, as indicated by **One or more of the following**:

Note: If an area of distortion is found on mammography, a breast ultrasound should be the next step to confirm. If breast ultrasound shows a correlate, that area can then be biopsied under ultrasound guidance. If a breast ultrasound biopsy cannot be done of the area for some reason or is unsuccessful, and tomosynthesis guided or stereotactic guided breast biopsy is also not an option, consultation with a breast surgeon is recommended. MRI is not indicated in this situation.

 1. A single 6-month MRI for f/u if requested by the radiologist who attempted or performed the original MRI guided biopsy
 2. Breast MRI is covered for members with suspected silicone (not saline) implant leaks or rupture when **ALL** of the following have been met:
 - a. Implants were placed as a result of **ONE of the following**:
 - Medically necessary lumpectomy or complete or partial mastectomy due to disease, injury or illness (such as breast cancer, chronic and severe fibrocystic disease, or infection unresponsive to medical therapy, chest wall surgery, or trauma) resulting in significant deformity;
 - Prophylactic mastectomy to prevent the onset of breast cancer when a clinical determination has been made that there is a high risk for breast cancer
 - b. Records must document need for this test for evaluation and management
 - c. A recent mammogram and/or ultrasound (depending on local breast center protocol) does not confirm leakage
 - d. The leakage is not the result of a cosmetically placed implant as this would be a complication of a non-covered service
 - e. It is not being requested for routine surveillance of a silicone implant

B. Breast cancer diagnosis (new within the last 3 months) and **ONE or more** of the following:

1. After positive nipple-areolar biopsy for Paget disease, to define extent of disease and identify additional disease
2. Assessment of tumor response to neoadjuvant (preoperative) chemotherapy to determine appropriateness of breast-conserving surgery to assist with surgical planning
3. Evaluation of a newly diagnosed invasive breast cancer (e.g., lobular, ductal) (see below**).
4. Evaluation of a newly diagnosed DCIS and there is documentation that the patient is requesting breast conserving surgery (see below**).
5. Post lumpectomy, (within 6 weeks) for assessment of residual disease with the finding of close or positive margins on pathology.

C. Occult breast cancer, suspected (e.g., unknown primary), as indicated by **ALL of the following**:

1. Diagnosis of adenocarcinoma or carcinoma not otherwise specified in **ONE or more of the following**:
 - a. Axillary lymph nodes
 - b. Supraclavicular lymph nodes
2. Mammogram and breast ultrasound show no evidence of cancer.
3. No palpable breast mass suitable for biopsy

D. Annual MRI for breast cancer screening for **One or more of the following**:

****Not indicated for patients who have undergone bilateral mastectomy for risk reduction or for treatment.***

1. A lifetime risk of 20% or greater, as defined by validated models such as the following models: Tyrer-Cuzick, Gail Model, BRCAPro, Claus.
 - a. The specific risk model must be documented in the clinical notes
 - b. If member has had breast or ovarian cancer diagnosed after age 50, calculate the risk *prior* to the diagnosis
2. BRCA1 or BRCA2 mutation carrier
3. Personal history of radiation to chest between ages 10 and 30 years
4. Annual MRI is indicated for individual with a personal history of breast cancer (including DCIS), diagnosed at or before age 50 and treated with breast conservation therapy of the affected breast (lumpectomy). Patients treated with mastectomy (unilateral or bilateral) would not routinely qualify.
5. Other high-risk family history of breast cancer, as indicated by **ONE or more of the following**:
 - Male relative with breast cancer
 - Untested first-degree relative [A*] of BRCA1 or BRCA2 mutation carrier
 - Woman not of Ashkenazi Jewish ancestry, with **ONE or more of the following**:
 - i. First-degree [A*] or second-degree [B*] relative with breast cancer and **ONE or more of the following**:
 - Diagnosed at age 45 years or younger
 - Diagnosed at age 50 years or younger, with limited family history [C*]
 - Diagnosed at age 50 years or younger, who in turn has one or more close blood relatives [D*] with breast cancer, with at least one diagnosed at age 50 years or younger (29)
 - Diagnosed at age 50 years or younger, who in turn has one or more close blood relatives [D*] with epithelial ovarian [E*] cancer diagnosed at any age
 - Diagnosed at age 60 years or younger, with triple-negative breast cancer [F*]
 - Epithelial ovarian [E*] cancer
 - First-degree [A*] or second-degree [B*] relative with 2 breast primaries, with the first primary diagnosed at age 50 years or younger
 - First-degree [A*] or second-degree [B*] relative with breast cancer diagnosed at any age, who in turn has **One** or more of the following:
 - i. Two or more close blood relatives [D*] with breast or epithelial ovarian [E*] cancer diagnosed at any age
 - ii. One or more close male blood relatives [D*] with breast cancer

- First-degree [A] or second-degree relative [B*] with breast cancer who is of ethnicity associated with deleterious mutations, including Icelandic, Hungarian, Swedish, and Dutch
- First-degree [A*] or second-degree relative [B*] with breast or ovarian cancer diagnosed at any age, who in turn has 2 or more close blood relatives [D*] with pancreatic cancer diagnosed at any age
- a. First-degree [A*] or second-degree relative [B*] with pancreatic cancer diagnosed at any age, who in turn has 2 or more close blood relatives [D*] with **ONE** or more of the following:
 - Breast cancer diagnosed at any age
 - Ovarian cancer diagnosed at any age
 - Pancreatic cancer diagnosed at any age
- b. Third-degree relative [H*] with breast or epithelial ovarian [E*] cancer, who in turn has **ONE or more of the following**:
 - One close blood relative [D*] with epithelial ovarian [E*] cancer and another close blood relative [D*] with breast cancer diagnosed at age 50 years or younger
 - Two or more close blood relatives [D*] with breast cancer, with at least one diagnosed at age 50 years or younger
 - Two or more close blood relatives [D*] with epithelial ovarian [E*] cancer
- c. Woman of Ashkenazi Jewish ancestry, with **One or more of the following**:
 - One or more first-degree relatives [A*] with breast cancer or epithelial ovarian cancer
 - Two or more second-degree relatives, [B*] on same side of family, [I*] with breast cancer
 - Two or more second-degree relatives, [B*] on same side of family, [I*] with epithelial ovarian cancer
- d. Patient has diagnosis of, or has first-degree relative [A] with, **One or more of the following**:
 - Bannayan-Riley-Ruvalcaba syndrome
 - Cowden syndrome
 - Li-Fraumeni syndrome

Effective November 1, 2023

- I. Breast MRI may be indicated for **ONE or more of the following**:
- A. Breast abnormality evaluation needed, as indicated by **ONE or more of the following**:
- Note: If an area of distortion is found on mammography, a breast ultrasound should be the next step to confirm. If breast ultrasound shows a correlate, that area can then be biopsied under ultrasound guidance. If a breast ultrasound biopsy cannot be done of the area for some reason or is unsuccessful, and tomosynthesis guided or stereotactic guided breast biopsy is also not an option, consultation with a breast surgeon is recommended. MRI is not indicated in this situation.
1. A single 6-month MRI for f/u if requested by the radiologist who attempted or performed the original MRI guided biopsy
 2. Breast MRI is covered for members with suspected silicone (not saline) implant leaks or rupture when **ALL** of the following have been met:
 - a. Implants were placed as a result of **ONE of the following**:
 - Medically necessary lumpectomy or complete or partial mastectomy due to disease, injury or illness (such as breast cancer, chronic and severe fibrocystic disease, or infection unresponsive to medical therapy, chest wall surgery, or trauma) resulting in significant deformity;
 - Prophylactic mastectomy to prevent the onset of breast cancer when a clinical determination has been made that there is a high risk for breast cancer
 - b. Records must document need for this test for evaluation and management
 - c. A recent mammogram and/or ultrasound (depending on local breast center protocol) does not confirm leakage
 - d. The leakage is not the result of a cosmetically placed implant as this would be a complication of a non-covered service
 - e. It is not being requested for routine surveillance of a silicone implant
 3. Nipple Discharge, a breast MRI is indicated when **ALL of the following** conditions are met:
 - a. Discharge is clear or bloody
 - b. Discharge is unilateral and coming from a single duct
 - c. Discharge is spontaneous (i.e., does not happen only with expression) and persistent (i.e., not a single episode)

- d. Discharge is reproducible on exam
- e. Mammography and ultrasound have been completed and did not detect a pathologic etiology.
*If mammography, ultrasound or ductography were done, and was abnormal, MRI would not be indicated

B. Breast cancer diagnosis (new within the last 3 months) and **ONE or more** of the following:

1. After positive nipple-areolar biopsy for Paget disease, to define extent of disease and identify additional disease
2. Assessment of tumor response to neoadjuvant (preoperative) chemotherapy to determine appropriateness of breast-conserving surgery to assist with surgical planning
3. Evaluation of a newly diagnosed invasive breast cancer (e.g., lobular, ductal) (see below**).
4. Evaluation of a newly diagnosed DCIS and there is documentation that the patient is requesting breast conserving surgery (see below**).
5. Post lumpectomy, (within 6 weeks) for assessment of residual disease with the finding of close or positive margins on pathology.

C. Occult breast cancer, suspected (e.g., unknown primary), as indicated by **ALL of the following**:

1. Diagnosis of adenocarcinoma or carcinoma not otherwise specified in **ONE or more of the following**:
 - a. Axillary lymph nodes
 - b. Supraclavicular lymph nodes
2. Mammogram and breast ultrasound show no evidence of cancer.
3. No palpable breast mass suitable for biopsy

D. Annual MRI for breast cancer screening for **One or more of the following**:

****Not indicated for patients who have undergone bilateral mastectomy for risk reduction or for treatment.***

1. A lifetime risk of 20% or greater, as defined by validated models such as the following models: Tyrer-Cuzick, Gail Model, BRCAPro, Claus.
 - a. The specific risk model must be documented in the clinical notes
 - b. If member has had breast or ovarian cancer diagnosed after age 50, calculate the risk *prior* to the diagnosis
2. Carrier of high-risk[A] breast cancer gene mutation (including but not limited to: BRCA1, BRCA2, CDH1, PALB2, PTEN, STK11, TP53)
3. Personal history of radiation to chest between ages 10 and 30 years
4. Annual MRI is indicated for individual with a personal history of breast cancer (including DCIS), diagnosed at or before age 50 and treated with breast conservation therapy of the affected breast (lumpectomy). Patients treated with mastectomy (unilateral or bilateral) would not routinely qualify.
5. Other high-risk family history of breast cancer, as indicated by **ONE or more of the following**:
 - Male relative with breast cancer
 - Untested first-degree relative [A*] of BRCA1 or BRCA2 mutation carrier
 - Woman not of Ashkenazi Jewish ancestry, with **ONE or more of the following**:
 - ii. First-degree [A*] or second-degree [B*] relative with breast cancer and **ONE or more of the following**:
 - Diagnosed at age 45 years or younger
 - Diagnosed at age 50 years or younger, with limited family history [C*]
 - Diagnosed at age 50 years or younger, who in turn has one or more close blood relatives [D*] with breast cancer, with at least one diagnosed at age 50 years or younger (29)
 - Diagnosed at age 50 years or younger, who in turn has one or more close blood relatives [D*] with epithelial ovarian [E*] cancer diagnosed at any age
 - Diagnosed at age 60 years or younger, with triple-negative breast cancer [F*]
 - Epithelial ovarian [E*] cancer

- First-degree [A*] or second-degree [B*] relative with 2 breast primaries, with the first primary diagnosed at age 50 years or younger
- First-degree [A*] or second-degree [B*] relative with breast cancer diagnosed at any age, who in turn has **One** or more of the following:
 - i. Two or more close blood relatives [D*] with breast or epithelial ovarian [E*] cancer diagnosed at any age
 - ii. One or more close male blood relatives [D*] with breast cancer
- First-degree [A] or second-degree relative [B*] with breast cancer who is of ethnicity associated with deleterious mutations, including Icelandic, Hungarian, Swedish, and Dutch
- First-degree [A*] or second-degree relative [B*] with breast or ovarian cancer diagnosed at any age, who in turn has 2 or more close blood relatives [D*] with pancreatic cancer diagnosed at any age
- a. First-degree [A*] or second-degree relative [B*] with pancreatic cancer diagnosed at any age, who in turn has 2 or more close blood relatives [D*] with **ONE** or more of the following:
 - Breast cancer diagnosed at any age
 - Ovarian cancer diagnosed at any age
 - Pancreatic cancer diagnosed at any age
- b. Third-degree relative [H*] with breast or epithelial ovarian [E*] cancer, who in turn has **ONE or more of the following**:
 - One close blood relative [D*] with epithelial ovarian [E*] cancer and another close blood relative [D*] with breast cancer diagnosed at age 50 years or younger
 - Two or more close blood relatives [D*] with breast cancer, with at least one diagnosed at age 50 years or younger
 - Two or more close blood relatives [D*] with epithelial ovarian [E*] cancer
- c. Woman of Ashkenazi Jewish ancestry, with **One or more of the following**:
 - One or more first-degree relatives [A*] with breast cancer or epithelial ovarian cancer
 - Two or more second-degree relatives, [B*] on same side of family, [I*] with breast cancer
 - Two or more second-degree relatives, [B*] on same side of family, [I*] with epithelial ovarian cancer
- d. Patient has diagnosis of, or has first-degree relative [A] with, **One or more of the following**:
 - Bannayan-Riley-Ruvalcaba syndrome
 - Cowden syndrome
 - Li-Fraumeni syndrome

* See below for the definition:

A - First-degree relatives consist of male or female parents, siblings, or children

B - Second-degree relatives consist of male or female grandparents, grandchildren, aunts, uncles, nieces, nephews, or half- siblings

C - Examples of a limited family history include fewer than 2 first-degree or second-degree female relatives or fewer than 2 female relatives in either maternal or paternal ancestry surviving beyond 45 years of age. (

D - Close blood relatives include first-degree, second-degree, or third-degree relatives on the same side of the family

E - A triple-negative breast cancer is one that is estrogen receptor-negative, progesterone receptor-negative, and human epidermal growth factor receptor 2-negative

F - Two primaries may be either bilateral disease or 2 or more clearly separate ipsilateral tumors, either synchronous or asynchronous

H - Third-degree relatives consist of first cousins, great-aunts, great-uncles, great-grandchildren, or great-grandparents

I - Each side of the family, maternal or paternal, should be considered independently

**Ideally, this should be ordered after discussion with the patient about risks and benefits or per recommendation of a multidisciplinary care conference, if available.

“Don’t routinely order breast MRI in new breast cancer patients.” per The American Society of Breast Surgeons Choosing Wisely initiative:

After a new diagnosis of breast cancer, breast MRI can be useful in selected patients to aid treatment decisions. However, there is a lack of evidence that routine use of MRI lessens cancer recurrence, death from cancer or the need for re-operation after lumpectomy surgery. The routine use of MRI is associated with an increased need for subsequent breast biopsy

procedures, delays in time to treatment and higher cost of care. Increased mastectomy rates can occur if the MRI finds additional cancers or indeterminate findings cause patient anxiety, leading to patient requests for mastectomy.

(<https://www.choosingwisely.org/clinician-lists/breast-surgeons-mris-in-new-breast-cancer-patients/>)

Routine Surveillance of Silicone Breast Implants

Breast MRI is not covered for routine surveillance of silicone breast implants. The FDA made a recommendation (not a requirement) when they re-approved silicone implant use that members receive periodic breast MRIs. The FDA did not fund this screening. The choice of silicone vs saline is a patient preference and the use of MRI in this case cannot be described as medically necessary.

Computer-aided detection applied to breast MRI

No longer requires review

If requesting this service, please send the following documentation to support medical necessity:

- Documentation to support medical necessity (i.e., family history, prior treatment, genetic testing results, other imaging studies and diagnostic results, etc.)
- Applicable CPT code(s)

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Breast Cancer Screening and Lesions:

Mammography has been the standard tool used for breast cancer imaging. Community breast cancer screening programs have found an overall sensitivity of 75% and a specificity of 92%. The sensitivity of mammography in randomized trials is in the range of 68-88% (Elmore et al., 2005).

Due to limitations in the sensitivity of mammography, there has been research into alternative imaging modalities, particularly for women at high-risk of breast cancer. Interest in more accurate screening tests has grown since the identification of the BRCA1 and BRCA2 genes in the mid-1990s. Population-based studies have found that women with BRCA1 mutations have a approximately a 65% risk of developing breast cancer by age 70, and women with BRCA2 mutations have a 45% risk (Saslow et al., 2006). Mammography may not be adequate for detecting breast cancer in women with the BRCA1/2 mutation. In a study of BRCA1/2 mutation carriers who underwent annual mammography, screening detected only 5 out of 9 cases of breast cancer; the remaining were interval cancers (Brekelmans et al., 2001).

Contrast-enhanced magnetic resonance imaging (MRI) is proposed as an adjunct to mammography for women at high-risk of breast cancer. Breast MRI involves the injection of a contrast agent, usually gadolinium. Breast carcinomas tend to enhance, or get brighter, following injection of the contrast agent. MRI may be able to detect small breast lesions missed by mammography. However, contrast-enhanced MRI may not be able to distinguish between breast carcinoma and benign disease which also enhance, thus reducing the specificity of MRI.

The American Cancer Society (ACS) issued guidelines in May 2007 on breast screening with MRI as an adjunct to mammography (Saslow et al., 2007). The recommendations include:

- Annual screening for women with a lifetime risk of $\geq 20\%$, BRCA mutation or untested first-degree relative of BRCA carrier.
- No recommendation for or against screening women with a lifetime risk of 15-20%.
- Recommendation against screening women with $<15\%$ lifetime risk due to insufficient evidence.

The ACS recommends the BRCAPRO or other model largely dependent on family history be used to determine lifetime risk. BRCAPRO is a computer program on a statistical model for estimating an individual's probability of carrying a BRCA1/2 mutation on the basis of their own cancer status, and the history of breast and ovarian cancer among her first- and second-degree relatives (Berry et al., 2002). Other risk models, such as the Gail model risk calculator, which is also based on family history, may be easier to use in the primary care setting. An individual's risk level may vary with the different models (Saslow et al., 2007).

The Kaiser Permanente breast clinic already generally recommends MRI screening for women with known BRCA mutations, who are a first-degree relative of a BRCA carrier but are untested or have a 30-49% lifetime risk.

Silicone Implant Leakage:

Silicone-gel breast implants were first available for commercial use in the early 1960s. It is estimated that 1.5 to 2 million women in the United States have received an artificial breast implant, and the number is growing. Almost four-fifths of these women received the implant for cosmetic purposes to enhance or remodel breast shape, or to correct traumatic or congenital deformities. In only 20% of the cases they received it for breast reconstruction after mastectomy. At least three major generations and over 200 models of silicone gel-filled breast implants have been manufactured. The differences between the generations are primarily in the types of silicone gel and thickness of elastomeric shell. The first generation of silicone gel-filled implants (early 1960s to the mid 1970s) had a thick elastomeric shell with firm silicone gel. The second generation (mid 1970s to late 1980s) had a thin elastomeric shell, and a less viscous gel. The third generation (mid 1980s to date) has a multilayer shell with a barrier layer and thick cohesive viscous silicone gel. In 1993 a newer generation of highly cohesive silicone implants (Style 410) was developed, however it is widely used in Europe and other countries, but not in the US (Brown 2002, Belli 2002, Scaranelo 2004, Gamper 2007, Gorczyca 2007).

Silicone implants may have psychological benefits but could be associated with local complications and systemic effects. Local implant-related complications include wound infection, hematomas, sensory nerve injury, capsular contracture, and implant rupture. The latter is a well-known complication and could range from focal rupture involving pinhole sized holes, through large visible tears, to complete disintegration of the implant shell. Implant rupture can be divided into two major categories: intracapsular (80-90% of all ruptures) and extracapsular. Unlike rupture, gel bleed is microscopic escape of silicone particles through the intact silicone envelope, in the absence of gross holes or tears. This is usually confined to the fibrous capsule that forms around the implant. Implant age, and design were found to be the most important factors associated with rupture. Other potential causes of rupture include trauma, mammography, and history of closed capsulotomy. The age of implant at rupture varied between reports between 4 and 22 years, with means also varying between studies from 11 to 16 years (Cher 2001, Samuels 1994, Gorczyca 2007).

Silicone gel-implant rupture may be clinically silent and pass unnoticed by the patient and the physician. It could remain undetected for years especially when it is contained within the fibrous capsule. A symptomatic rupture may present with local symptoms as breast pain, nodules, capsular contracture, and change in symmetry, size, or shape of the breast. Silicone gel granulomas and chronic disseminated granulomatous inflammation have been associated with implant rupture and gel migration. The potential health implications of silicone implant rupture are greatly debated. Some researchers reported that seepage of silicone and distant migration of the free silicone may lead to serious symptoms and foreign body reactions. Others indicated that it is harmless and does not lead to significant clinical symptoms or activate the humoral immune system (Ahn 2003, Holmich 2004, Gampper 2007).

The clinical diagnosis of asymptomatic implant rupture can be challenging. It was reported that less than one third of ruptures in asymptomatic patients can accurately be detected by experienced plastic surgeons. The gold standard for diagnosing an implant rupture is removal and examination of the implant. Mammography, ultrasonography, computed tomography, and magnetic resonance imaging have all been used in the diagnosis of silicone breast implant rupture. Each was reported to have its specific indications, advantages, and limitations. The type of silicone implant may also be a factor in choosing the modality for evaluating its integrity.

Mammography is a rapid inexpensive test, used routinely for screening, and can easily detect free silicone within the breast parenchyma due to extracapsular rupture. It, however, has a small radiation risk, and limited ability to detect intracapsular rupture which accounts for 80-90% of implant failures. The dense silicone is not easily penetrated by the X-ray energies used for typical screening mammography (Samuels 1994, Gampper 2007, Gorczyca 2007).

Ultrasonography is inexpensive, does not use ionizing radiation, can detect intracapsular rupture, and may also detect small amounts of free silicone mixed within the surrounding breast tissues. However, its usefulness for detecting implant rupture depends on the experience of the operator, type of equipment used, as well as other technical factors. It was also reported that ultrasonography may have its limitations in the evaluation of the posterior aspect of the implant, pectoralis muscle and chest wall (Belli 2002, Gorczyca 2007).

MRI does not use ionizing radiation, has the ability to detect implant rupture, and to localize extensive free silicone. It can also be used with severe capsular contracture. Specialized breast coils increase the image quality and reduce scan time. However, it was reported that MRI cannot detect microscopic silicone leakage (gel bleeds). It is expensive, less available, less comfortable for the patient, and cannot be used among those with pacemakers, or other internal metallic devices that are not compatible with the MRI. Some patients may be claustrophobic and are unable to complete the examination (Beekman 1999, Gorczyca 2007, Gampper 2007)

FDA recommends MRI, with a dedicated breast coil and a magnet of at least 1.5 Tesla, as the current method of choice for detecting silent rupture of silicone gel implant. This is recommended to be performed three years after the implant, then every 2 years thereafter. The FDA also recommends the removal of ruptured breast implants.

With Computer-Aided Detection (CAD):

(Background information quoted from Blue Cross Blue Shield Association Technology Evaluation Center, BCBSA TEC report, June 2006)

Over the past decade, MRI of the breast has been studied in a variety of clinical settings, including both benign and malignant conditions of the breast... While MRI has a very high sensitivity for detecting lesions, its specificity is variable and often quite low because of the difficulty in distinguishing between benign and malignant lesions. The sensitivity for detection of invasive carcinoma overall is above 90%, while specificities between 37% and 90% have been reported (Deurloo et al. 2005a). The low specificity is particularly challenging in younger women, who are more likely to have enhancing benign lesions (Gilhuijs et al., 2002) ...

Some investigators have incorporated additional criteria into the determination of MRI results in an attempt to increase the specificity without compromising sensitivity (Lieberman 2004; Nunes et al. 2001). Descriptive features of lesion morphology such as those used in X-ray mammography may be helpful in this regard. For example, lesions with irregular or spiculated margins are characteristically malignant, while lesions with smooth, regular margins are usually benign (Nunes et al. 1997a) ... CAD systems for MRI... provide easier ways of interpreting the patterns of contrast enhancement and washout across a series of images, which in turn may help identify lesions and their likelihood of being malignant. In contrast to CAD systems used with mammography, CAD for MRI is not aimed primarily at identifying lesions for consideration by a radiologist. Unlike the subtle appearance of lesions on mammography, most cancers enhance on MRI. The challenge is determining which lesions are benign and which are malignant. A large number of images are produced during MRI of the breast: images are taken at varying 'depths' throughout each breast multiplied by the number of times the breast is imaged to capture different time points in the enhancement process... Radiologists view the images to detect suspicious areas, and then they can pick a region of interest and look at the enhancement pattern. However, there may be variations across radiologists in the regions of interest selected and in the precise definition of the region of interest. CAD systems, in contrast, use color-coding and differences in hue to indicate the patterns of enhancement for each pixel in the breast image. It thereby may allow the radiologist to analyze the enhancement patterns systematically, although there is some question about how effective it is in reducing interobserver variability (Gabriel et al. 2005). Some CAD programs apparently incorporate morphological characteristics as well to estimate a probability of malignancy..."

There are several FDA-approved CAD systems for use with MRI of the breast. These include:

- CADstream (Confirma, Inc. Kirkland, WA). Originally cleared in 2003. CADstream version 4.0 was cleared in 2008.
- MRI Soft Tissue Motion Correction Software (Siemens Medical Solutions. Malvern, PA). Cleared September 2005.
- Z3D (Clario Medical Imaging): Cleared September 2008.

Medical Technology Assessment Committee (MTAC)

MRI in the Diagnosis of Breast Cancer and Breast Lesion

02/13/2002: MTAC REVIEW

Evidence Conclusion: All studies reviewed were retrospective, had several limitations, and data were obtained from records. Tan's study showed that MRI had an impact on the clinical management in almost one fifth of the patients. MRI findings were false positive among 61.5 % of the patients who underwent an additional surgery, which was a mastectomy in one case. Olson's study showed that MRI had a sensitivity of 95%, and specificity of 80%. These were based on data obtained from patients who underwent additional breast surgery, not all the sample. The clinical usefulness of a diagnostic test depends not only on its accuracy but also its reliability i.e. the consistency of interpretation on different occasions and by different observers. Mussurakis' study shows that all

[Back to Top](#)

readers achieved a high sensitivity in cancer detection, their specificity however was much lower. The study also revealed a significant inter-observer variability in the interpretation of breast MRI. The high false positive rates, i.e. low specificity, and high inter-observer variability indicate that MRI, with its current limitations, is not an accurate or a reliable technology, compared to the gold standard of biopsy. Randomized trials, with a large study population will be required to confirm the findings and define the patients most likely to benefit from MRI. Moreover, further efforts are needed to improve, and standardize the indications, techniques, and image interpretation.

Articles: The search yielded 63 articles. Selection was based on study type. The majority were reviews, editorials, letters, and commentaries. The literature did not reveal any randomized controlled trials or longitudinal studies.

The following articles were selected for critical appraisal: Tan J E, Schnall M D, et al. Role of magnetic resonance imaging and magnetic resonance imaging-guided surgery in the evaluation of patients with early-stage breast cancer for breast conservation treatment. *Am J Clin Oncol* 1999; 22(4): 414-18 See [Evidence Table](#). Olson JA, Morris EA, et al. Magnetic resonance imaging facilitates breast conservation for occult breast cancer. *Annals of Surgical Oncology* 2000; 7(6): 411-15 See [Evidence Table](#). Mussurakis S et al. Observer variability in the interpretation of contrast enhanced MRI of the breast. *The British Journal of Radiology* 1996; 69: 1009-16. See [Evidence Table](#).

The use of MRI in the diagnosis of breast cancer and breast lesions does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

06/04/2007: MTAC REVIEW

MRI in the Diagnosis of Breast Cancer and Breast Lesion

Evidence Conclusion: The major prospective studies comparing screening asymptomatic women at moderate-to-high risk of breast cancer with MRI and mammography are summarized in Table 1. All of these studies were judged to be of reasonable validity. All studies were prospective and eligibility criteria included an assessment of risk based on genetic and family history factors. In addition, all of the studies included an independent evaluation of MRI and mammograms. The gold standard was biopsy/histology for positive tests in all studies. Gold standards for negative tests varied. Most studies used 1-year follow-up of negative tests to identify false negatives; Kuhl et al., 2005 used 6 months' follow-up. The Lehman et al., 2005 study was the weakest for several reasons. This is the only study in which the authors did not attempt to verify the accuracy of negative tests. In addition, only 4 cases of cancer were identified, a number too small for statistical analysis. The absolute difference in the breast cancer detection rate between combined testing with MRI and mammography and mammography alone ranged from 1% (Kriege et al., 2004) to 5% (Warner et al., 2004; Kuhl et al. 2005). The Kriege study included moderate-to-high risk women ($\geq 15\%$ lifetime risk) whereas the other two studies included only high-risk women. None of the studies reported whether the difference in the breast cancer detection rate with MRI plus mammography versus mammography alone was statistically significant. The recall rate (proportion of women called back for follow-up testing) ranged from 4% to 8% higher with MRI screening than with mammography-alone screening. None of the studies reported the recall rate with combined screening, but this would likely reflect the higher MRI rates. The sensitivity and specificity of combined screening with MRI and mammography versus mammography alone was reported in two studies. Leach et al., 2005 found a higher sensitivity with combined screening (94% versus 40%) and a lower specificity (77% versus 93%). Kuhl et al. (2005) also found a higher sensitivity with combined testing than mammography alone (93% versus 33%) and similar levels of specificity with the two methods (96% and 97%). Neither study reported p-values for the difference in sensitivity and specificity. The Kuhl et al., 2005 study did a sub-analysis by level of risk (see Table 2). The risk categories were moderate-risk (20% lifetime risk) and high-risk (21-40% lifetime risk). The sensitivity of combined screening was 100% in both the moderate and high-risk groups. This was substantially higher than the sensitivity with mammography alone, 50% for the moderate risk group and 25% for the high-risk group. Specificities of combined screening and mammography alone were similar for both risk levels. This analysis is limited in that it is based on a small number of cancer cases, only 6 for the moderate-risk group. This results in imprecise and unreliable statistics and should be viewed as preliminary data. For example, mammography correctly detected 3/6 cancers (50%); if only one additional cancer had been identified, the sensitivity would be dramatically altered to 4/6 (67%). **Conclusion** There is no high-grade evidence on whether combined screening with MRI and mammography improves health outcomes such as breast cancer mortality or overall mortality. The available evidence from 6 prospective studies suggests that combined screening of asymptomatic women at moderate-to-high risk of breast cancer with MRI plus mammography results in a 1-5% absolute increase in the cancer detection rate over mammography alone. The recall rate is substantially higher with MRI alone (4-8%) and would thus be higher with combined screening. Findings of 2 prospective studies are that combined screening substantially improves sensitivity compared to mammography alone and may decrease specificity. Data on women at moderate risk of breast cancer ($\leq 20\%$ lifetime risk) are insufficient to draw conclusions about detection rate or diagnostic accuracy.

Articles: There were no randomized or non-randomized controlled trials that compared health outcomes in high-risk women who received screening with mammography alone versus screening with mammography plus MRI. As reported in the American Cancer Society review (Saslow et al., 2007), there were 6 published prospective studies examining diagnostic yield and/or sensitivity/specificity of mammography compared to MRI for asymptomatic women at moderate-to-high risk of breast cancer. These 6 studies were critically appraised and presented in a joint evidence table. The Kaiser Permanente national breast cancer screening guideline included the topic of breast MRI screening for high-risk women. They identified additional observational studies comparing mammography to MRI. These studies were not included in the MTAC review due to methodological limitations such as a retrospective design, small sample size or only a minority of the study population underwent MRI screening. *The studies reviewed include:* Kriege M et al. for the MRI Screening Study Group. Efficacy of MRI and mammography for breast-cancer screening in women with a familial or genetic predisposition. NEJM 2004; 351: 427-437. See [Evidence Table](#). Kuhl CK et al. Mammography, breast ultrasound, and magnetic resonance imaging for surveillance of women at high familial risk of breast cancer. J Clin Oncol 2005; 23: 8469-8476. See [Evidence Table](#). Leach MO et al. for the MARIBS Study Group. Screening with magnetic resonance imaging and mammography of a UK population at high familial risk of breast cancer: a prospective multicentre cohort study (MARIBS). Lancet 2005; 365: 1769-1778. See [Evidence Table](#). Lehman CD et al. for the International Breast MRI Consortium Working Group. Screening women at high risk of breast cancer with mammography and magnetic resonance imaging. Multicenter comparative multimodality surveillance of women at genetic-familial high risk for breast cancer (HIBCRIT Study). Radiology 2007; 242: 698-715. See [Evidence Table](#). Warner E et al. Surveillance of BRCA1 and BRCA2 mutation carriers with magnetic resonance imaging, ultrasound and mammography, and clinical breast examination. JAMA 2004; 292: 1317-1325. See [Evidence Table](#).

The use of MRI in the screening of high risk patients for breast cancer and breast lesions does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

04/08/2008: MTAC REVIEW

MRI in the Diagnosis of Breast Cancer and Breast Lesion

Evidence Conclusion: *Diagnostic accuracy:* It is hard to determine the diagnostic accuracy of imaging studies used to assess the integrity of breast implants. Visual inspection of the implant after its surgical removal is considered the gold standard for ruptured implants. However, this would not apply to asymptomatic women, as it would not be appropriate or ethical to remove an implant with no evidence of leak or rupture. The majority of the studies on the diagnostic accuracy of MRI or other imaging tests were thus conducted among symptomatic women who requested or were advised to remove the implants. The meta-analysis and the studies reviewed show wide variations in the accuracy of MRI and its predictive values in detecting an implant rupture in symptomatic women. The studies had differences in the equipment used, imaging protocol, description of positive MRI, and surgical criteria for a diagnosis of rupture. There were also some interobserver variations as seen in Collis and colleagues' study (2007). Different generations of implants were used. These varied by manufacturer, model, longevity, long-term integrity of the implant, as well as the implantation site and position. The authors of the majority of studies did not indicate the generation of implants used. Only one study (Collis 2007) included patients who exclusively received the third-generation implants. Holmich (2005) also provided the proportion of women receiving each of the three implant generations. Results of studies among women who received earlier generation of implants might not be generalized to the generation(s) currently used. One other limitation of the studies is the inclusion of self-selected symptomatic women who were requesting removal or replacement of the implants. The higher prevalence of rupture among these women would overestimate the accuracy of the tests, and limit generalization of the results to similar groups of patients. The overall results of the published studies show that the sensitivity of MRI in detecting an implant rupture among symptomatic women ranged from 64% to 90%. The specificity of the test ranged from 43% to 100%, the positive predictive value from 57% to 100% and the negative predictive values from 79% to 90%. Ultrasound came next in its accuracy with a sensitivity ranging from 30% to 69% and specificity ranging from 64% to 81%. Mammography was found to have the lowest sensitivity ranging from 20% to 69%, but with a specificity of 82% to 93%. Collis et al's study among asymptomatic who responded to the invitation for MRI testing showed a wide variation in sensitivity (71-86%) and specificity (48-95%) depending on the radiologist who interpreted the test. This assessment was based only on implants that were surgically removed. *Diagnostic impact:* There is insufficient evidence to determine that MRI may influence the management decisions for detected implant leak. *Therapeutic impact:* There are no published studies on the impact of MRI detection of implant leak on health outcomes.

Conclusions:

- MRI is moderately to highly sensitive, and more specific in detecting implant rupture among self-selected groups of symptomatic women. i.e. in confirming ruptures when suspected.

- There is insufficient evidence on the accuracy of MRI as a screening tool for detecting leak or rupture among asymptomatic women.
- There is insufficient evidence to determine that MRI may influence the management decisions for detected implant leak.
- There is insufficient evidence on the impact of MRI detection of implant leak on health outcomes.

Articles: The literature search revealed over 120 articles. Many were review articles or studies on and safety and durability of the silicone gel implants. The following questions were considered in screening the published articles:

1. What is the diagnostic accuracy of MRI in detecting silicone gel breast implant leak/rupture in asymptomatic and symptomatic women?
2. Would the detection of the implant rupture be using MRI influence management decisions?
3. Does the detection of the implant rupture using MRI have an impact on health outcome?

1. Diagnostic accuracy

The literature search revealed several studies dating back to the early 1990s. There were 2 meta-analyses, and a systematic review on the diagnostic accuracy of MRI for detecting implant rupture among symptomatic women. The more recent meta-analysis, as well as studies that were not included in the analysis and that verified MRI findings with visual inspection of implant after surgical removal were critically appraised. Two studies that included asymptomatic women with a breast implant were identified (Brown 2000, and Collis 2007). In Brown and colleagues' (2000), study, the majority (92%) of the implants was second generation implants, and in Collis et al's study all were 3rd generation implant type. Collis' study was selected for critical appraisal as the second-generation implants are known to be more prone to rupture, and the results of Brown's study may not be generalized to the other generations that are more commonly used.

2. Diagnostic impact

A small study on the clinical impact of MRI was identified and critically appraised.

3. Therapeutic impact

No studies on the impact of technology on patient outcomes were identified by the search.

The following studies were critically appraised:

Cher DJ, Conwell JA, Mandel JS. MRI for detecting silicone breast implant rupture: Meta-analysis and implications. *Ann Plast Surg* 2001; 47:367-380. See [Evidence Table](#). Reynolds HE, Buckwalter KA, Jackson VP, et al. Comparison of mammography, sonography, and magnetic resonance imaging in the detection of silicone-gel breast implant rupture. *Ann Plast Surg* 1994; 33:247-257. See [Evidence Table](#). Beekman WH, Hage JJ, van Amerongen AHM, et al. Accuracy of ultrasonography, and magnetic resonance imaging in detecting failure of breast implants filled with silicone gel. *Scand J Plast Reconstr Hand Surg* 1999; 33:415-418. See [Evidence Table](#). Scaranelo AM, Marques AF, Smialowski EB, et al. Evaluation of the rupture of silicone breast implants by mammography, ultrasonography, and magnetic resonance imaging in asymptomatic patients: correlation with surgical findings. *Sao Paulo Med J* 2004; 122:41-47. See [Evidence Table](#). Holmich LB, Vejborg I, Conrad C, et al. The diagnosis of breast rupture: MRI findings compared with findings of explanation. *Europ J Radiol*. 2005:213-225. See [Evidence Table](#). Collis N, Phil M, Litherland J, et al. Magnetic resonance imaging and explantation investigation of long-term silicone gel implant integrity. *Plast Reconstr Surg* 2007; 120:1401-1406. See [Evidence Table](#). Dobke MK, Middleton MS. Clinical impact of breast implant magnetic resonance imaging. *Ann Plast Surg* 1994; 33:241-246. See [Evidence Table](#)

The use of MRI in the detecting leakage from silicone implants does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

08/03/2009: MTAC REVIEW

MRI in the Diagnosis of Breast Cancer and Breast Lesion

Evidence Conclusion: Published studies by two research groups comparing the specificity of breast MRI with and without CAD assistance for distinguishing between benign and malignant lesions were reviewed. Williams et al. (2007) evaluated 155 breast lesions detected by MRI and found a statistically significant reduction in the false-positive rate (reduced 23%) with CAD enhancement at 100%. Meinel et al. (2006) evaluated 80 lesions and found a statistically significant increase in specificity (from 51% to 81%) when human readers were aided by CAD. A higher specificity (and corresponding low false-positive rate) would contribute to improved diagnosis since fewer women would be subject to unnecessary follow-up tests or procedures. No published studies, however, evaluated whether there was a reduction in the number of biopsies or other procedures, or whether use of CAD contributed to a change in diagnosis. The above findings are insufficient to draw conclusions about the use of CAD systems with breast MRI and its impact on health outcomes. The quantity of published studies is low, and sample sizes of individual studies are small. Only one research group, Williams et al. (2007) did a comparative analysis with a

commercially available CAD system. Moreover, no studies are available on the impact of CAD-enhanced MRI on follow-up procedures or diagnosis.

Articles: The Pubmed search yielded 79 articles. One additional article was identified on the CADStream website (Lehman et al., 2006). BCBSA TEC conducted an assessment in 2006; their search in March of that year identified the same articles as the PubMed search. Most of the articles in the PubMed search were either review articles, dealt with related topics such as other types of cancer, or addressed CAD development of other technical aspects of CAD systems or MRI. Three empirical studies were identified that compared breast MR imaging with and without a CAD system. Two of the articles were published by the same research group (T. Lehman, W DeMartini, S Peacock and others) and the later article (2007) appears to also include lesions included in the earlier article (2006). The 2007 article by this group and the other comparative study were both critically appraised. References are as follows: Williams TC, DeMartini WB, Partridge SC et al. Breast MR imaging: Computer-aided evaluation program for discriminating benign from malignant lesions. Radiol 2007; 244: 94-103. See [Evidence Table](#). Meinel LA, Stolpen AH, Berbaum KS et al. Breast MRI lesion classification: Improved performance of human readers with a backpropagation neural network computer-aided diagnosis (CAD) system. J Magn Reson Imaging 2007; 25: 89-95. See [Evidence Table](#).

The use of computer-aided detection (CAD) applied to breast MRI does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Breast MRI surveillance in women with personal history of breast cancer

Date: 07/13/2020

Evidence Conclusion:

- There is insufficient evidence for or against annual surveillance breast MRI in less than 50 years old women with personal history of breast cancer who were diagnosed with invasive breast cancer.
- High-quality randomized controlled trials comparing annual surveillance breast MRI vs mammography in women <50 years old (even in women aged 50 years and older) with personal history of breast cancer who were diagnosed with invasive breast cancer are rare.
- In women (age 18+) with personal history of breast cancer, (some in this population had heterogeneously & extremely dense breast tissue, genetic/family history) who were diagnosed were invasive breast cancer or DCIS:
 - Although one cohort study indicates no difference in performance between annual surveillance MRI and mammography, retrospective studies suggest that MRI performance may be higher than mammography.
 - In addition, MRI results in increased recall and biopsy rates as well as false positive.
 - Cancer detection rate may be higher in patients undergoing MRI than in that undergoing mammography.
 - The findings also suggest that mammography combined with MRI may be more effective (with low specificity) than mammography alone but recall rate and biopsy rate are high.
 - It is also not clear who may benefit from surveillance breast MRI.
- Impact of MRI on survival was not assessed.

Articles: PubMed was searched through February 14, 2020 with the following search terms (with variations): (((Magnetic Resonance Imaging OR MRI)) AND (breast neoplasm OR breast cancer)) AND (follow-up OR postoperative). Search terms also included surveillance, follow-up, and breast MRI surveillance. The search was limited to English language publications and human populations. The search was filtered by RCTs, systematic review & meta-analysis, and observational studies. The reference lists of relevant studies were reviewed to identify additional publications. See [Evidence Table](#).

The use of Breast MRI for surveillance in women with a personal history of breast cancer, diagnosed under the age of 50 does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
77046	Magnetic resonance imaging, breast, without contrast material; unilateral
77047	Magnetic resonance imaging, breast, without contrast material; bilateral

77048	Magnetic resonance imaging, breast, without and with contrast material(s), including computer-aided detection (CAD real-time lesion detection, characterization and pharmacokinetic analysis), when performed; unilateral
77049	Magnetic resonance imaging, breast, without and with contrast material(s), including computer-aided detection (CAD real-time lesion detection, characterization and pharmacokinetic analysis), when performed; bilateral
C8903	Magnetic resonance imaging with contrast, breast; unilateral
C8905	Magnetic resonance imaging without contrast followed by with contrast, breast; unilateral
C8906	Magnetic resonance imaging with contrast, breast; bilateral
C8908	Magnetic resonance imaging without contrast followed by with contrast, breast; bilateral

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

^{MDCRPC} Medical Director Clinical Review and Policy Committee

^{MPC} Medical Policy Committee

Revision History	Description
05/14/2015	Changed Breast Cancer Diagnosis criteria to include language that clarifies cancer must be newly diagnosed within the last 3 months.
08/04/2015	Criteria was modified for clarifications regarding requests for MR biopsies
09/02/2016	Added indication, "it is not being requested for routine surveillance of a silicone implant," to criteria
01/09/2017	Revised indication to "evaluate response to neoadjuvant chemotherapy"
10/18/2018	Criteria was modified for clarifications under breast abnormality evaluation
01/28/2019	Computer-aided detection applied to breast MRI No longer requires review
12/27/2019	Codes deleted 77058, 77059, C8904, C8907, 0159T
03/02/2021	Added July 2020 MTAC Review. MPC approved to adopt Breast MRI criteria for members with a personal history of breast cancer diagnosed at the age of 50 or younger and elected to have a lumpectomy or partial mastectomy. Requires 60-day notice, effective date 08/01/2021.
05/03/2022	MPC approved to revise the criteria to include educational additions for <i>Breast Cancer Diagnosis</i>
10/17/2022	Clarification of breast center protocols
06/06/2023	MPC approved modifications to the existing MRI Breast criteria to align with recommendations from multiple guideline statements, including NCCN, regarding certain types of nipple discharge and the need for breast MRI to detect cancer. Requires 60-day notice, effective date 11/01/2023.

Local Coverage Determinations (LCD)	MRI and CT Scans of the Head and Neck (L35175) *Medical necessity review not required
Local Coverage Article (LCA)	Billing and Coding: MRI and CT Scans of the Head and Neck (A57215)

For Non-Medicare Members

Adapted from Washington State Department of Labor & Industries Final Imaging Guidelines: Cervical Spine MRI. Retrieved 9/3/2020 from <https://lni.wa.gov/patient-care/treating-patients/treatment-guidelines-and-resources/docs/CervicalSpineChecklist.pdf>

**Note – most acute cervical radicular pain will resolve with time and conservative management. Bulging discs will retract away from the affected nerve root spontaneously in a high percentage of cases. Acute or chronic non-radicular or non-myelopathy neck pain may be associated with painful paresthesia's diffusely in one or both arms; MRI imaging is of low value for sensory symptoms alone.*

Effective until September 1, 2023

I. Acute cervical pain (onset within past 6 weeks)

- Acute cervical radicular pain (radiating into one or both arms) without red flags – cervical spine MRI **not** indicated, medical management should be the initial approach
- Acute cervical pain with radiating pain from the neck into arm **AND 1 or more** of the following red flag conditions present, where the result is likely to lead to emergent surgery: - cervical MRI **may** be indicated

Red Flags:

- Progressive (objective) neurological signs on repeat in-person examination** (i.e. progressive motor weakness present) *(MRI without contrast)*
- Evidence of spinal instability or spinal fracture on any other imaging test** (e.g. plain films or cervical spine CT) *(MRI without contrast)*
- Radiating pain from the neck with compelling clinical argument for one of the following:** *(MRI with or without contrast)*
 - Malignancy

Date Sent: 6/28/23

956

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage.

Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

- b. Infection
- c. Immunosuppression
- d. Bone disc margin destruction on plain radiographs
- e. Trauma with neck pain, on anticoagulants
- 4. **Evidence of neurologic signs suggestive of spinal cord involvement** (e.g. myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia) where the result is likely to lead to immediate surgery or similar intensive intervention

II. Subacute cervical pain (>6 weeks), no prior MRI for the same episode of cervical pain: (MRI without contrast)

- A. Patient has had **at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months, minimum of 3 visits) for *current episode* of neck pain with no significant improvement (remote past history of physical therapy does not qualify)

AND

- B. Clinical evaluation demonstrates **1 or more** of the following:
 - a. Abnormal reflexes or motor deficits in the C5, C6, C7, T1 nerve territory on one side
 - b. Prior neck surgery and significant **new** neurological signs or symptoms, compared to maximal post-op recovery baseline, as defined in a. and b. above
 - c. Evidence of spinal instability or spinal fracture on any other imaging test
 - d. Complex congenital anomaly or deformity of the spine
 - e. Strong suspicion for cervical spinal cord stenosis (e.g. myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia)

OR

- C. Patient's clinical presentation indicates need for urgent surgery or other intensive intervention as determined by a surgeon or interventional specialist, even without 6 weeks of physical therapy.

III. Chronic cervical pain

- A. **Chronic cervical pain (> 3 months) with no prior MRI of cervical spine:** (MRI without contrast) for any of the criteria under subacute cervical spine pain (section II above)

- 1. **Including at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months) for *current episode* of neck pain with no significant improvement (remote past history of physical therapy does not qualify)

- B. **Chronic or recurrent cervical pain (> 3 months) with prior MRI of cervical spine for the same episode of cervical pain with 1 or more of the following:** (MRI without contrast)

- 1. *Should have at least 6 weeks* medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months) for *current episode* of neck pain with no significant improvement (remote past history of physical therapy does not qualify)
- 2. Patient has not been determined to be a surgical candidate in the past:
 - a. Documented significant objective worsening of neurological status on current in-person physical exam (e.g. documented sensory loss, motor weakness, abnormal reflexes in the C5, C6, C7, T1 nerve territory) compared to baseline **OR** electrodiagnostic testing confirming **new** radiculopathy **OR** myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia **OR**
- 3. Patient has been determined to be a definite candidate for cervical spine surgery by neurosurgery/orthopedics, (and **ONE** of the following):
 - a. Progressive changes in objective neurological findings (see 1 above)
OR
 - b. If no objective neurological findings: the surgeon is requesting another MRI prior to surgery and it has been at least 1 year since last cervical MRI
- 4. Prior cervical spine surgery with **1 or more** of the **following** (MRI without contrast):

- a. Objective and new or worsening neurological signs on physical exam compared with maximum post-op recovery baseline (e.g. documented sensory loss, motor weakness, abnormal reflexes in the C5, C6, C7, T1 nerve territory, or new radiculopathy on electrodiagnostic studies **OR** myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia)
- OR**
- b. Other imaging **OR** clinical findings suggest new adverse effects of surgery (e.g., hardware failure or concern for epidural scarring/arachnoiditis)

IV. Suspect Cervical Multiple Sclerosis (MS) (MRI with contrast) if patient has been already evaluated by neurology:

- A. Approved for staging (along with MRI of brain) at time of initial presentation
- B. Known MS diagnosis (confirmed by neurology)—approved for annual surveillance along with Brain MRI

Effective September 1, 2023

I. Acute cervical pain (onset within past 6 weeks)

- A. Acute cervical radicular pain (radiating into one or both arms) without red flags – cervical spine MRI **not** indicated, medical management should be the initial approach
- B. Acute cervical pain with radiating pain from the neck into arm **AND ONE or more** of the following red flag conditions present, where the result is likely to lead to emergent surgery: - cervical MRI **may** be indicated

Red Flags:

- 1. **Progressive (objective) neurological signs on repeat in-person examination** (i.e., progressive motor weakness present) (*MRI without contrast*)
- 2. **Evidence of spinal instability or spinal fracture on any other imaging test** (e.g., plain films or cervical spine CT) (*MRI without contrast*)
- 3. **Radiating pain from the neck with compelling clinical argument for one of the following:** (*MRI with or without contrast*)
 - a. Malignancy
 - b. Infection
 - c. Immunosuppression
 - d. Bone disc margin destruction on plain radiographs
 - e. Trauma with neck pain, on anticoagulants
- 4. **Evidence of neurologic signs suggestive of spinal cord involvement** (e.g., Bilateral “cape-like” sensory loss to suggest syrinx, myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia) where the result is likely to lead to immediate surgery or similar intensive intervention

II. Subacute cervical pain (>6 weeks), no prior MRI for the same episode of cervical pain: (*MRI without contrast*)

- A. Patient has had **at least 6 weeks** medical/conservative treatment (must include **at least 4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up, within the last 3 months) for *current episode* of neck pain with no significant improvement (remote past history of physical therapy does not qualify)

AND

- B. Clinical evaluation demonstrates **ONE or more** of the following:
 - a. Abnormal reflexes or motor deficits in the C5, C6, C7, T1 nerve territory on one side
 - b. Prior neck surgery and significant **new** neurological signs or symptoms, compared to maximal post-op recovery baseline, as defined in a. and b. above
 - c. Evidence of spinal instability or spinal fracture on any other imaging test
 - d. Complex congenital anomaly or deformity of the spine
 - e. Strong suspicion for cervical spinal cord stenosis (e.g., myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia)

OR

- C. Patient’s clinical presentation indicates need for urgent surgery or other intensive intervention as determined by a surgeon or interventional specialist, even without 6 weeks of physical therapy.

III. Chronic cervical pain

- A. **Chronic cervical pain (> 3 months) with no prior MRI of cervical spine:** (MRI without contrast) for any of the criteria under subacute cervical spine pain (section II above)
1. **Including at least 6 weeks** medical/conservative treatment (must include **at least 4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up within the last 6 months) for *current episode* of neck pain with no significant improvement (remote past history of physical therapy does not qualify)
- B. **Chronic or recurrent cervical pain (> 3 months) with prior MRI of cervical spine for the same episode of cervical pain with 1 or more of the following:** (MRI without contrast)
1. **Should have at least 6 weeks** medical/conservative treatment (must include **at least 4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up within the last 6 months) for *current episode* of neck pain with no significant improvement (remote past history of physical therapy does not qualify)
 2. Patient has not been determined to be a surgical candidate in the past:
 - a. Documented significant objective worsening of neurological status on current in-person physical exam (e.g., documented sensory loss, motor weakness, abnormal reflexes in the C5, C6, C7, T1 nerve territory) compared to baseline *OR* electrodiagnostic testing confirming *new* radiculopathy *OR* myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia *OR*
 3. Patient has been determined to be a definite candidate for cervical spine surgery by neurosurgery/orthopedics, (and **ONE** of the following):
 - a. Progressive changes in objective neurological findings (see 1 above)
OR
 - b. If no objective neurological findings: the surgeon is requesting another MRI prior to surgery, and it has been at least 1 year since last cervical MRI
 4. Prior cervical spine surgery with **1 or more** of the **following** (MRI without contrast):
 - a. Objective and new or worsening neurological signs on physical exam compared with maximum post-op recovery baseline (e.g., documented sensory loss, motor weakness, abnormal reflexes in the C5, C6, C7, T1 nerve territory, or new radiculopathy on electrodiagnostic studies *OR* myelopathy signs such as bowel or bladder changes, abnormally increased reflexes, positive Babinski sign, spastic gait ataxia)
OR
 - b. Other imaging *OR* clinical findings suggest new adverse effects of surgery (e.g., hardware failure or concern for epidural scarring/arachnoiditis)
- IV. **Suspect Cervical Multiple Sclerosis (MS)** (MRI with contrast) if patient has been already evaluated by neurology:
- A. Approved for staging (along with MRI of brain) at time of initial presentation
 - B. Known MS diagnosis (confirmed by neurology)—approved for annual surveillance along with Brain MRI
- V. **Interval follow up of known neurosurgical disease** clinical indication for repeat imaging is documented (e.g., intermedullary or extramedullary tumors, bony spine tumors, syrinx, vascular malformation) when ordered by or in consultation with neurosurgery.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
72141	Magnetic resonance (e.g., proton) imaging, spinal canal and contents, cervical; without contrast material
72142	Magnetic resonance (e.g., proton) imaging, spinal canal and contents, cervical; with contrast material(s)
72156	Magnetic resonance (e.g., proton) imaging, spinal canal and contents, without contrast material, followed by contrast material(s) and further sequences; cervical

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

Date Created	Date Reviewed ^{04/}	Date Last Revised
09/18/2020	10/06/2020 ^{MPC} , 10/05/2021 ^{MPC} , 10/04/2022 ^{MPC}	04/04/2023

^{MPC} Medical Policy Committee

Revision History	Description
10/06/2020	MPC approved to adopt new clinical criteria. Requires 60-day notice, effective date 2/1/2021.
04/01/2021	Added clarifying language to clinical criteria.
04/30/2021	Added clarifying language and formatting changes
10/04/2022	MPC approved to include quantifying number of 3 visits for physical therapy of subacute low back pain. 60-day notice required; effective March 1, 2023.
11/01/2022	MPC approved the minor change for MRI-Cervical Spine criteria to include language for MS patients.
04/04/2023	MPC approved to modify MRI criteria with 4 weeks of physical therapy (instead of 6 weeks) and updated indications for cervical spine imaging.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Lumbar Spine MRI

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Lumbar MRI (L37281) *Medical necessity review not required
Local Coverage Article (LCA)	Billing and Coding: Lumbar MRI (A57207)

For Non-Medicare Members

Adapted from Washington State Department of Labor & Industries Guidelines for Advanced Imaging Studies: Lumbar spine checklist. Retrieved 4/22/2020 from https://lni.wa.gov/patient-care/treating-patients/treatment-guidelines-and-resources/_docs/LBchecklist.pdf

Lumbar spine MRI is NOT indicated for the following:

Uncomplicated acute (<6 weeks) low back pain with or without suspected radiculopathy (no red flags) does not warrant the use of MRI, X-ray, CT, myelography or CT xylography, NUC Tc-99m bone scan with SPECT.

Nonspecific lumbar disc abnormalities are commonly found in asymptomatic patients. (Chou, Qaseem et al. 2007) (American College of Radiology 2007)

**Note – most acute lumbar radicular pain will resolve with time and conservative management. Bulging discs will retract away from the affected nerve root spontaneously in a high percentage of cases. Most patients will respond to 6 weeks medical/conservative treatment including physical therapy.*

If advanced imaging is needed, lumbar spine MRI is the preferred imaging modality for the following circumstances unless contraindicated or not tolerated by the patient (i.e., due to presence of ferrous metal in body, or severe anxiety) or unavailable.

Effective until September 1, 2023

I. Acute low back pain (onset within past 6 weeks)

Lumbar spine MRI not indicated unless **ONE or more** of the following red flag conditions are present:

Red Flags:

- 1. Progressive (objective) neurological signs on repeat in-person examination** (i.e., progressive motor weakness present) *(MRI without contrast)*

2. Suspect Cauda Equina syndrome (MRI without contrast) due to the following:

- New onset bilateral neurologic signs and symptoms of cauda equina (e.g., saddle numbness with acute bladder or bowel dysfunction)

*ACR appropriateness recommendation ranks MRI without contrast highest (rating = 9). MRI with and without contrast (rating = 8) depends on clinical circumstances. Other methods: Myelography and postmyelography CT (rating = 6), CT with and without contrast (rating = 5)-may be indicated if MRI is confusing or contraindicated, x-ray, NUC Tc-99m bone scan with SPECT and x-ray myelography are rated < 5.

3. Strong clinical suspicion of spine infection (MRI with and without contrast) and TWO or more of the following:

- Fever
- Immunosuppression (e.g., chronic steroid use, diabetes)
- IV drug use
- Known bacteremia
- Elevated sedimentation rate/c-reactive protein

4. History or strong clinical suspicion of cancer with new onset of low back pain and non-diagnostic plain films and TWO or more of the following (MRI with and without contrast):

- Unexplained weight loss
- Failure of back pain to improve after one month
- Age over 50

*ACP recommends plain radiography for unexplained weight loss, MRI or plain radiography if multiple risk factors present. ACR Guidelines for suspicion of cancer, infection or immunosuppression rate MRI without and with contrast highest (rating = 8). CT without contrast (rating = 6)-useful if MRI is contraindicated or unavailable. Other imaging methods: use of x-ray, NUC Tc-99m bone scan whole body with optional targeted SPECT, myelography and postmyelography CT (appropriateness rating < 6 for these).

5. Suspected vertebral fracture in a patient with pain and non-diagnostic plain films (MRI without contrast)

- Low velocity trauma (e.g., fall from height or struck by object) OR
- Osteoporosis OR
- Age >70 years with other acute fracture(s)

*ACP Guideline recommends: if vertebral compression fracture is suspected due to history of osteoporosis, use of steroids, or age ≥ 70 plain radiography should be completed prior to MRI.

*For low velocity trauma, ACR Guidelines do not support use of NUC Tc-99m bone scan with SPECT, MRI with and without contrast, myelography and postmyelography CT, or x-ray myelography (appropriateness ratings < 5 for these)

II. Subacute Low back pain >6 weeks: (MRI without contrast)

- A.** Patient has had **at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months, minimum of 3 visits) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify)

AND

- **ONE or more** of the criteria under acute low back pain met (from section I above)
- OR**

- Suspected radiculopathy with **ALL of the following** documented in notes:
 - Leg pain is > than back pain present in nerve root distribution (e.g., L5, S1, etc.) **ONE** or more of the following:
 - Positive supine straight leg raising test - radicular leg pain reproduced when the leg is extended >30° and <70° (pain reproduced only in the back is a negative test) or positive crossed straight leg raising test
 - OR**
 - Motor weakness or sensory loss in a radicular distribution (must be in a specific radicular distribution)
 - OR**
 - EMG/NCS confirms acute radiculopathy consistent with the patient's symptoms

*ACP recommendation: consider EMG/NCS testing if symptoms > 1 month. For suspected radiculopathy, ACR Guidelines rate MRI without contrast as most appropriate. CT without contrast may be useful if MRI is not available or contraindicated. MRI with and without contrast may be indicated if noncontrast MRI is nondiagnostic or indeterminate. MRI is preferred over myelography and postmyelography CT but may be indicated if MRI is nondiagnostic. In some circumstances (facet arthropathy, stress fracture and spondylolysis) NUC Tc-99m bone scan with SPECT may be useful. Least appropriate x-ray (appropriateness rating 2).

III. Chronic low back pain

- A. **Chronic low back pain (> 3 months) with no prior MRI of lumbar spine:** (*MRI without contrast*)
All patients should have **at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify) **and must meet ONE of the following:**
 1. Any of the criteria under subacute low back pain (section II above)
 2. Strong clinical suspicion of lumbar spinal stenosis, with documentation of neurogenic claudication (bilateral or unilateral leg pain upon standing that is temporarily relieved by forward flexion or sitting)
- B. **Chronic low back pain (> 3 months) with prior MRI of lumbar spine:** (*MRI without contrast*):
All patients should have at least 6 weeks medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months) for *current episode* of back pain with no significant improvement (remote history of physical therapy does not qualify)
 1. Patient has not been determined to be a surgical candidate in the past
 - a. Documented objective worsening of neurological status on current physical exam (e.g. absence of reflexes, dermatomal sensory changes, radicular motor weakness, etc.) **OR** electrodiagnostic testing confirming new radiculopathy **OR**
 2. Patient has been determined to be a definite candidate for spine surgery by neurosurgery/orthopedics, (and **ONE** of the following):
 - a. Progressive changes in objective neurological findings
 - b. If no objective neurological findings: the surgeon is requesting another MRI prior to surgery and it has been at least 1 year since last lumbar MRI

* ACR Guidelines rate MRI without contrast as most appropriate. CT without contrast may be useful if MRI is not available or contraindicated. MRI with and without contrast may be indicated if noncontrast MRI is nondiagnostic or indeterminate. MRI is preferred over myelography and postmyelography CT but may be indicated if MRI is nondiagnostic. In some circumstances (facet arthropathy, stress fracture and spondylolysis) NUC Tc-99m bone scan with SPECT may be useful. Least appropriate x-ray (appropriateness rating 2).

3. Prior lumbar surgery with **ONE or more** of the following (*MRI with and without contrast*):

- a. Objective and/or new or worsening neurological signs on physical exam (new absence of reflexes, dermatomal sensory changes, radicular motor weakness, or new radiculopathy on electrodiagnostic studies, etc.)
- b. Plain radiography OR clinical findings suggest new adverse effects of surgery
 - (e.g., hardware failure or concern for epidural scarring/arachnoiditis)
- c. New changes to electrodiagnostic studies

*ACR appropriateness rates MRI with and without contrast highest (rating =8), CT without contrast(rating=6) may be indicated in postfusion patients or when MRI is contraindicated or indeterminate. Other methods rated lower: MRI without contrast (rating=6) as contrast is often necessary, myelography and postmyelography CT (rating= 5, x-ray (rating = 5)-flex/extension may be useful, NUC Tc-99m bone scan with SPECT (rating=5)-helps detect and localize pseudoarthrosis, x-ray myelography (rating = 2).

C. Indication not listed: provide clinical justification

Indications here should be well documented. For example, while the vast majority of true radiculopathy cases would meet the criteria, specific syndromes (lateral stenosis, L1-L3 syndromes) may only meet some of these criteria. In these cases, clinical correlation should be clearly documented.

IV. There is no indication for Lumbar MRI for initial or subsequent evaluation of suspected or confirmed MS.

Effective September 1, 2023

I. Acute low back pain (onset within past 6 weeks)

Lumbar spine MRI not indicated unless **ONE or more** of the following red flag conditions are present:

Red Flags:

- 1. Progressive (objective) neurological signs on repeat in-person examination** (i.e. progressive motor weakness present) (*MRI without contrast*)
- 2. Suspect Cauda Equina syndrome** (*MRI without contrast*) due to the following:
 - New onset bilateral neurologic signs and symptoms of cauda equina (e.g., saddle numbness with acute bladder or bowel dysfunction)

*ACR appropriateness recommendation ranks MRI without contrast highest (rating = 9). MRI with and without contrast (rating = 8) depends on clinical circumstances. Other methods: Myelography and postmyelography CT (rating = 6), CT with and without contrast (rating = 5)-may be indicated if MRI is confusing or contraindicated, x-ray, NUC Tc-99m bone scan with SPECT and x-ray myelography are rated < 5.

- 3. Strong clinical suspicion of spine infection** (*MRI with and without contrast*) and **TWO or more** of the following:
 - Fever
 - Immunosuppression (e.g., chronic steroid use, diabetes)
 - IV drug use
 - Known bacteremia
 - Elevated sedimentation rate/c-reactive protein
- 4. History or strong clinical suspicion of cancer with new onset of low back pain and non-diagnostic plain films** and **TWO or more** of the following (*MRI with and without contrast*):
 - Unexplained weight loss
 - Failure of back pain to improve after one month
 - Age over 50

*ACP recommends plain radiography for unexplained weight loss, MRI or plain radiography if multiple risk factors present. ACR Guidelines for suspicion of cancer, infection or immunosuppression rate MRI without and with contrast highest (rating = 8). CT without contrast (rating = 6)-useful if MRI is contraindicated or unavailable. Other imaging methods: use of x-ray, NUC Tc-99m bone scan whole body with optional targeted SPECT, myelography and postmyelography CT (appropriateness rating < 6 for these).

5. **Suspected vertebral fracture in a patient with pain and non-diagnostic plain films** (*MRI without contrast*)

- Low velocity trauma (e.g., fall from height or struck by object) OR
- Osteoporosis OR
- Age >70 years with other acute fracture(s)

*ACP Guideline recommends: if vertebral compression fracture is suspected due to history of osteoporosis, use of steroids, or age ≥ 70 plain radiography should be completed prior to MRI.

*For low velocity trauma, ACR Guidelines do not support use of NUC Tc-99m bone scan with SPECT, MRI with and without contrast, myelography and postmyelography CT, or x-ray myelography (appropriateness ratings < 5 for these)

II. **Subacute Low back pain >6 weeks:** (*MRI without contrast*)

- A. Patient has had **at least 6 weeks** medical/conservative treatment (must include **at least 4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up, within the last 3 months) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify)

AND

- **ONE or more** of the criteria under acute low back pain met (from section I above)
- OR**
- Suspected radiculopathy with **ALL of the following** documented in notes:
 - Leg pain is > than back pain present in nerve root distribution (e.g., L5, S1, etc.) **ONE** or more of the following:
 - Positive supine straight leg raising test - radicular leg pain reproduced when the leg is extended >30° and <70° (pain reproduced only in the back is a negative test) or positive crossed straight leg raising test
 - OR**
 - Motor weakness or sensory loss in a radicular distribution (must be in a specific radicular distribution)
 - OR**
 - EMG/NCS confirms acute radiculopathy consistent with the patient's symptoms

*ACP recommendation: consider EMG/NCS testing if symptoms > 1 month. For suspected radiculopathy, ACR Guidelines rate MRI without contrast as most appropriate. CT without contrast may be useful if MRI is not available or contraindicated. MRI with and without contrast may be indicated if noncontrast MRI is nondiagnostic or indeterminate. MRI is preferred over myelography and postmyelography CT but may be indicated if MRI is nondiagnostic. In some circumstances (facet arthropathy, stress fracture and spondylolysis) NUC Tc-99m bone scan with SPECT may be useful. Least appropriate x-ray (appropriateness rating 2).

III. **Chronic low back pain**

A. **Chronic low back pain (> 3 months) with no prior MRI of lumbar spine:** *(MRI without contrast)*

All patients should have **at least 6 weeks** of medical/conservative treatment (must include at least **4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up within the last 6 months) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify **and must meet ONE of the following**:

1. Any of the criteria under subacute low back pain (section II above)
2. Strong clinical suspicion of lumbar spinal stenosis, with documentation of neurogenic claudication (bilateral or unilateral leg pain upon standing that is temporarily relieved by forward flexion or sitting)

B. **Chronic low back pain (> 3 months) with prior MRI of lumbar spine:** *(MRI without contrast)*:

All patients should have **at least 6 weeks** medical/conservative treatment (must include at least **4 weeks** of physical, including an initial evaluation with PT and at least one follow up therapy within the last 6 months) for *current episode* of back pain with no significant improvement (remote history of physical therapy does not qualify)

1. Patient has not been determined to be a surgical candidate in the past
 - a. Documented objective worsening of neurological status on current physical exam (e.g. absence of reflexes, dermatomal sensory changes, radicular motor weakness, etc.) **OR** electrodiagnostic testing confirming new radiculopathy **OR**
2. Patient has been determined to be a definite candidate for spine surgery by neurosurgery/orthopedics, (and **ONE** of the following):
 - a. Progressive changes in objective neurological findings
 - b. If no objective neurological findings: the surgeon is requesting another MRI prior to surgery and it has been at least 1 year since last lumbar MRI

* ACR Guidelines rate MRI without contrast as most appropriate. CT without contrast may be useful if MRI is not available or contraindicated. MRI with and without contrast may be indicated if noncontrast MRI is nondiagnostic or indeterminate. MRI is preferred over myelography and postmyelography CT but may be indicated if MRI is nondiagnostic. In some circumstances (facet arthropathy, stress fracture and spondylolysis) NUC Tc-99m bone scan with SPECT may be useful. Least appropriate x-ray (appropriateness rating 2).

3. Prior lumbar surgery with **ONE or more** of the following *(MRI with and without contrast)*:
 - a. Objective and/or new or worsening neurological signs on physical exam (new absence of reflexes, dermatomal sensory changes, radicular motor weakness, or new radiculopathy on electrodiagnostic studies, etc.)
 - b. Plain radiography OR clinical findings suggest new adverse effects of surgery (e.g., hardware failure or concern for epidural scarring/arachnoiditis)
 - c. New changes to electrodiagnostic studies

*ACR appropriateness rates MRI with and without contrast highest (rating =8), CT without contrast(rating=6) may be indicated in postfusion patients or when MRI is contraindicated or indeterminate. Other methods rated lower: MRI without contrast (rating=6) as contrast is often necessary, myelography and postmyelography CT (rating= 5, x-ray (rating = 5)-flex/extension may be useful, NUC Tc-99m bone scan with SPECT (rating=5)-helps detect and localize pseudoarthrosis, x-ray myelography (rating = 2).

C. **Indication not listed: provide clinical justification**

Indications here should be well documented. For example, while the vast majority of true radiculopathy cases would meet the criteria, specific syndromes (lateral stenosis, L1-L3 syndromes) may only meet some of these criteria. In these cases, clinical correlation should be clearly documented.

IV. **There is no indication for Lumbar MRI for initial or subsequent evaluation of suspected or confirmed MS.**

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background**Summary of Recommendations**

- Uncomplicated acute LBP and/or radiculopathy are benign, self-limited conditions that do not warrant any imaging studies.
- MRI of the lumbar spine should be considered at any point for those patients presenting with red flags raising suspicion for a serious underlying condition, such as cauda equina syndrome (CES), malignancy, or infection.
- In patients with a history of low-velocity trauma, osteoporosis, or chronic steroid use, initial evaluation with radiographs is recommended.
- In the absence of red flags, first-line treatment for chronic LBP remains conservative therapy with both pharmacologic and nonpharmacologic (eg, exercise, remaining active) therapy.
- If there are persistent or progressive symptoms during or following 6 weeks of conservative management and the patient is a surgery or intervention candidate or diagnostic uncertainty remains, MRI of the lumbar spine has become the initial imaging modality of choice in evaluating complicated LBP.
- MRI is the imaging procedure of choice in patients suspected of cord compression or spinal cord injury.
- Patients with recurrent low back pain and history of prior surgical intervention should be evaluated with contrast-enhanced MRI.

Applicable Codes**Medicare – Medical Necessity review not required**

Non-Medicare - Considered Medically Necessary when criteria in the applicable policy statements listed above are met

CPT® Codes	Description
72148	Magnetic resonance (eg, proton) imaging, spinal canal and contents, lumbar; without contrast material
72149	Magnetic resonance (eg, proton) imaging, spinal canal and contents, lumbar; with contrast material(s)
72158	Magnetic resonance (eg, proton) imaging, spinal canal and contents, without contrast material, followed by contrast material(s) and further sequences; lumbar

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Magnetic Resonance Imaging (220.2)
Local Coverage Determinations (LCD)	None
Local Coverage Article (LCA)	None

For Non-Medicare Members

Effective until May 1, 2023

No review required

Effective until September 1, 2023

I. Acute thoracic back pain (onset within past 6 weeks)

Thoracic spine MRI not indicated unless **ONE or more** of the following red flag conditions are present:

Red Flags:

- A. **Objective neurological signs of thoracic myelopathy (leg weakness and incontinence with +/- spasticity)** (*MRI without contrast*)
- B. **Progressive (objective) neurological signs of thoracic myelopathy (leg weakness and incontinence with +/- spasticity) on repeat examination during a course of conservative care** (i.e., progressive motor weakness present) (*MRI without contrast*)
- C. **Strong clinical suspicion of spine infection with strong clinical concern for thoracic myelopathy or myelitis** (*MRI with and without contrast*) and **TWO or more** of the following:
 - Fever
 - Immunosuppression (e.g., chronic steroid use, diabetes)
 - IV drug use
 - Known bacteremia
 - Elevated sedimentation rate/c-reactive protein

D. History or strong clinical suspicion of cancer (by examination, lab and other ancillary testing) with new onset of thoracic back pain/myelopathy and non-diagnostic plain films and TWO or more of the following (*MRI with and without contrast*):

- Unexplained weight loss
- Failure of back pain to improve after conservative management
- Back pain worse when supine is common in thoracic metastasis
- Age over 50

*ACP recommends plain radiography for unexplained weight loss, MRI or plain radiography if multiple risk factors present. ACR Guidelines for suspicion of cancer, infection or immunosuppression rate MRI without and with contrast highest (rating = 8). CT without contrast (rating = 6)-useful if MRI is contraindicated or unavailable. Other imaging methods: use of x-ray, NUC Tc-99m bone scan whole body with optional targeted SPECT, myelography and postmyelography CT (appropriateness rating < 6 for these).

E. Suspected vertebral fracture in a patient with pain and non-diagnostic plain films (*CT should be done first and MRI can be considered based on clinical findings/possible surgical intervention*)

- Low velocity trauma (e.g., fall from height or struck by object) OR
- Osteoporosis OR
- Age >70 years with other acute fracture(s)

*ACP Guideline recommends: if vertebral compression fracture is suspected due to history of osteoporosis, use of steroids, or age ≥ 70 plain radiography should be completed prior to MRI.

*For low velocity trauma, ACR Guidelines do not support use of NUC Tc-99m bone scan with SPECT, MRI with and without contrast, myelography and postmyelography CT, or x-ray myelography (appropriateness ratings < 5 for these)

II. Subacute Thoracic back pain >6 weeks (with no red flags above): (*MRI without contrast*)

- A. Patient has had **at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months, minimum of 3 visits) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify); if diabetic should be well controlled

AND

- **ONE or more** of the criteria under acute thoracic back pain met (from section I above)
OR
- Suspected thoracic radiculopathy (band of numbness, pain or sensitivity around midsection)
OR
- Motor weakness or sensory loss in a spinal cord distribution (e.g., bilateral sensory loss from mid or low abdomen down, and/or leg weakness, and/or bowel or bladder incontinence)

III. Chronic thoracic back pain (> 3 months) with no prior MRI of thoracic spine (with no red flags above): (*MRI without contrast*)

- A. All patients should have **at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify) **and must meet ONE of the following:**
- Any of the criteria under subacute thoracic back pain (section II above)

IV. Chronic thoracic back pain (> 3 months) with prior MRI of thoracic spine (with no red flags above): (*MRI without contrast*):

- A. All patients should have **at least 6 weeks** medical/conservative treatment (must include 6 weeks of physical therapy within the last 3 months) for *current episode* of back pain with no significant improvement (remote history of physical therapy does not qualify)

- Any of the criteria under subacute thoracic back pain (section II above). If clinical exam is unchanged from prior, should not be repeated more than once every 12 months.

V. Suspect Thoracic Multiple Sclerosis (MS) (MRI with contrast) patient must have been already evaluated by neurology who specifically advises thoracic MRI:

- Should not be part of initial staging unless there are specific findings attributable to the thoracic cord (e.g., MS “hug” or sensory loss beginning mid thorax)
- Not routinely indicated for subsequent imaging for MS

VI. Inflammatory or demyelinating process, suspected (e.g., transverse myelitis, spinal cord abscess, clinically isolated syndrome, conditions mimicking MS, other demyelinating disease), as indicated by **ONE or more of the following (ordered with specific recommendation by neurology/neurosurgery):**

- Ascending numbness or tingling (e.g., from foot to trunk)
- Brown-Sequard syndrome
- Autoimmune inflammatory disorders known to affect spinal cord (Sjogren syndrome, systemic lupus erythematosus, antiphospholipid syndrome)
- MS strongly suspected but MRI of brain and cervical spine nondiagnostic, after consultation with Neurology
- Signs or symptoms strongly indicative of myelopathy (leg weakness and incontinence with +/- spasticity) or myelitis (pain with weakness and incontinence and +/- spasticity)

VII.

A. Pediatric/Adolescent Scoliosis, as indicated by **ONE or more of the following:**

- Congenital scoliosis
- Early-onset scoliosis (age 9 years or younger)
- Neurofibromatosis
- Presurgical planning for adolescent idiopathic scoliosis to assess possible neural axis malformation, as indicated by **ONE or more** of the following:
 - Abnormal neurologic findings on clinical examination
 - Age at first visit 10 years or younger
 - Kyphosis at curve apex
 - Left-sided thoracic curvature
 - Male gender
 - Pain, moderate to severe
 - Rapid curve progression (i.e., more than 1 degree per month)
 - Short segment curve (i.e., less than 6 vertebral segments)
 - Thoracic kyphosis 30 degrees or greater
 - Vertebral abnormalities (e.g., hemivertebrae, block vertebrae) detected on x-ray

B. Adult Scoliosis as indicated by **ONE or more of the following:**

- Abnormal neurologic findings on clinical examination
- Kyphosis at curve apex
- Pain, moderate to severe
- Rapid curve progression (i.e., more than 1 degree per month)
- Short segment curve (i.e., less than 6 vertebral segments)
- Thoracic kyphosis 30 degrees or greater
- Vertebral abnormalities (e.g., hemivertebrae, block vertebrae) detected on x-ray
- Presurgical planning

VIII. Spinal stenosis of thoracic spine, suspected, as indicated by **ALL of the following):**

- Patient being considered for invasive treatment
- Progressive or disabling symptoms of thoracic spine stenosis, as indicated by **ONE or more** of the following:
 - Hyperactive reflexes
 - Muscle weakness
 - Sensory loss
 - Spasticity

- IX.** Stereotactic spine radiotherapy treatment planning
- X.** Syringomyelia in thoracic spine, suspected, as indicated by **ONE or more** of the following:
- Muscle wasting in appropriate thoracic spine dermatomes
 - Sensory loss in appropriate thoracic spine dermatomes
 - Weakness in appropriate thoracic spine dermatomes
 - Bowel/bladder dysfunction
- XI.** Tethered cord, suspected, as indicated by **ONE or more** of the following:
- Anorectal malformation
 - Cutaneous manifestations of occult spina bifida (e.g., nevus, lipoma, tufts of hair, hemangioma, dimple overlying spine, asymmetric gluteal cleft, dermal sinus tract)
 - Gait abnormality or difficulty
 - Urinary dribbling or lack of bladder control
 - Urodynamic tests abnormal
- XII.** **Indication not listed: provide clinical justification**
- Indications here should be well documented.

Effective September 1, 2023

I. Acute thoracic back pain (onset within past 6 weeks)

Thoracic spine MRI not indicated unless **ONE or more** of the following red flag conditions are present:

Red Flags:

- A. Objective neurological signs of thoracic myelopathy (leg weakness and incontinence with +/- spasticity) (MRI without contrast)**
- B. Progressive (objective) neurological signs of thoracic myelopathy (leg weakness and incontinence with +/- spasticity) on repeat examination during a course of conservative care (i.e., progressive motor weakness present) (MRI without contrast)**
- C. Strong clinical suspicion of spine infection with strong clinical concern for thoracic myelopathy or myelitis (MRI with and without contrast) and TWO or more of the following:**
- Fever
 - Immunosuppression (e.g., chronic steroid use, diabetes)
 - IV drug use
 - Known bacteremia
 - Elevated sedimentation rate/c-reactive protein
- D. History or strong clinical suspicion of cancer (by examination, lab and other ancillary testing) with new onset of thoracic back pain/myelopathy and non-diagnostic plain films and TWO or more of the following (MRI with and without contrast):**
- Unexplained weight loss
 - Failure of back pain to improve after conservative management
 - Back pain worse when supine is common in thoracic metastasis
 - Age over 50

*ACP recommends plain radiography for unexplained weight loss, MRI or plain radiography if multiple risk factors present. ACR Guidelines for suspicion of cancer, infection or immunosuppression rate MRI without and with contrast highest (rating = 8). CT without contrast (rating = 6)-useful if MRI is contraindicated or unavailable. Other imaging methods: use of x-ray, NUC Tc-

99m bone scan whole body with optional targeted SPECT, myelography and postmyelography CT (appropriateness rating < 6 for these).

E. Suspected vertebral fracture in a patient with pain and non-diagnostic plain films (*CT should be done first and MRI can be considered based on clinical findings/possible surgical intervention*)

- Low velocity trauma (e.g., fall from height or struck by object) OR
- Osteoporosis OR
- Age >70 years with other acute fracture(s)

*ACP Guideline recommends: if vertebral compression fracture is suspected due to history of osteoporosis, use of steroids, or age ≥ 70 plain radiography should be completed prior to MRI.

*For low velocity trauma, ACR Guidelines do not support use of NUC Tc-99m bone scan with SPECT, MRI with and without contrast, myelography and postmyelography CT, or x-ray myelography (appropriateness ratings < 5 for these)

II. Subacute Thoracic back pain >6 weeks (with no red flags above): (*MRI without contrast*)

- A. Patient has had at least 6 weeks medical/conservative treatment (must include **at least 4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up, within the last 3 months) for current episode of back pain with no significant improvement (remote past history of physical therapy does not qualify); if diabetic should be well controlled

AND

- **ONE or more** of the criteria under acute thoracic back pain met (from section I above)
OR
- Suspected thoracic radiculopathy (band of numbness, pain or sensitivity around midsection)
OR
- Motor weakness or sensory loss in a spinal cord distribution (e.g., bilateral sensory loss from mid or low abdomen down, and/or leg weakness, and/or bowel or bladder incontinence)

III. Chronic thoracic back pain (> 3 months) with no prior MRI of thoracic spine (with no red flags above): (*MRI without contrast*)

- A. All patients should have **at least 6 weeks** medical/conservative treatment (must include **at least 4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up within the last 6 months) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify) **and must meet ONE of the following:**
- Any of the criteria under subacute thoracic back pain (section II above)

IV. Chronic thoracic back pain (> 3 months) with prior MRI of thoracic spine (with no red flags above): (*MRI without contrast*):

- A. All patients should have **at least 6 weeks** medical/conservative treatment (must include at least **4 weeks** of physical therapy, including an initial evaluation with PT and at least one follow up therapy within the last 6 months) for *current episode* of back pain with no significant improvement (remote past history of physical therapy does not qualify) **and must meet ONE of the following:**
- Any of the criteria under subacute thoracic back pain (section II above). If clinical exam is unchanged from prior, should not be repeated more than once every 12 months.

V. Suspect Thoracic Multiple Sclerosis (MS) (*MRI with contrast*) patient must have been already evaluated by neurology who specifically advises thoracic MRI:

- A. Should not be part of initial staging unless there are specific findings attributable to the thoracic cord (e.g., MS “hug” or sensory loss beginning mid thorax)
- B. Not routinely indicated for subsequent imaging for MS

VI. Inflammatory or demyelinating process, suspected (e.g., transverse myelitis, spinal cord abscess, clinically isolated syndrome, conditions mimicking MS, other demyelinating disease), as indicated by **ONE or more** of the following (ordered with specific recommendation by neurology/neurosurgery):

- Ascending numbness or tingling (e.g., from foot to trunk)

- Brown-Sequard syndrome
- Autoimmune inflammatory disorders known to affect spinal cord (Sjogren syndrome, systemic lupus erythematosus, antiphospholipid syndrome)
- MS strongly suspected but MRI of brain and cervical spine nondiagnostic, after consultation with Neurology
- Signs or symptoms strongly indicative of myelopathy (leg weakness and incontinence with +/- spasticity) or myelitis (pain with weakness and incontinence and +/- spasticity)

VII.

A. Pediatric/Adolescent Scoliosis, as indicated by **ONE or more** of the following:

- Congenital scoliosis
- Early-onset scoliosis (age 9 years or younger)
- Neurofibromatosis
- Presurgical planning for adolescent idiopathic scoliosis to assess possible neural axis malformation, as indicated by **1 or more** of the following:
 - Abnormal neurologic findings on clinical examination
 - Age at first visit 10 years or younger
 - Kyphosis at curve apex
 - Left-sided thoracic curvature
 - Male gender
 - Pain, moderate to severe
 - Rapid curve progression (i.e., more than 1 degree per month)
 - Short segment curve (i.e., less than 6 vertebral segments)
 - Thoracic kyphosis 30 degrees or greater
 - Vertebral abnormalities (e.g., hemivertebrae, block vertebrae) detected on x-ray

B. Adult Scoliosis as indicated by **ONE or more** of the following:

- Abnormal neurologic findings on clinical examination
- Kyphosis at curve apex
- Pain, moderate to severe
- Rapid curve progression (i.e., more than 1 degree per month)
- Short segment curve (i.e., less than 6 vertebral segments)
- Thoracic kyphosis 30 degrees or greater
- Vertebral abnormalities (e.g., hemivertebrae, block vertebrae) detected on x-ray
- Presurgical planning

VIII. Spinal stenosis of thoracic spine, suspected, as indicated by **ALL** of the following):

- Patient being considered for invasive treatment
- Progressive or disabling symptoms of thoracic spine stenosis, as indicated by **ONE or more** of the following:
 - Hyperactive reflexes
 - Muscle weakness
 - Sensory loss
 - Spasticity

IX. Stereotactic spine radiotherapy treatment planning

X. Syringomyelia in thoracic spine, suspected, as indicated by **ONE or more** of the following:

- Muscle wasting in appropriate thoracic spine dermatomes
- Sensory loss in appropriate thoracic spine dermatomes
- Weakness in appropriate thoracic spine dermatomes
- Bowel/bladder dysfunction

XI. Tethered cord, suspected, as indicated by **ONE or more** of the following:

- Anorectal malformation
- Cutaneous manifestations of occult spina bifida (e.g., nevus, lipoma, tufts of hair, hemangioma, dimple overlying spine, asymmetric gluteal cleft, dermal sinus tract)

- Gait abnormality or difficulty
- Urinary dribbling or lack of bladder control
- Urodynamic tests abnormal

XII. Indication not listed: provide clinical justification

- Indications here should be well documented.

For covered criteria:

If requesting this service (or these services), please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Magnetic Resonance Imaging (MRI) (220.2)
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Magnetic resonance imaging (MRI) uses magnetic fields and radiofrequency waves to provide images of internal organs and tissues. Among other applications, MRI is widely used to diagnose joint and musculoskeletal disorders especially injuries affecting the knee, shoulder, hip, elbow and wrist.

Conventional MRI may have limits for diagnosing certain conditions such as degenerative cervical spinal disorders in which symptoms are aggravated when patients are standing and relieved when patients are lying down. The closed cylindrical design of standard MRI systems requires patients to be imaged in a supine position. Thus, with conventional non-weight-bearing MRI, the conditions under which symptoms arise are often not reproduced. Biomechanical studies have found a decrease in spinal canal cross-sectional area (or dural sac) and spinal foraminal dimensions with weight-bearing (axial loading) and with flexion and extension. In some cases, MRI findings correlate with patient symptoms. Disk extrusion, disk sequestration and nerve root compression are infrequently seen in asymptomatic patients, leading to the common belief that nerve root compression seen on MRI is clinically relevant. MRI of patients in the supine position may not identify clinically relevant spinal canal and foraminal stenosis, or the degree of nerve root compression (Kumura et al., 2005; Weishaupt & Boxheimer, 2003).

Weight-bearing MRI is proposed as an alternative to conventional MRI imaging. There are two ways to image the weight-bearing spine. One approach is to simulate weight bearing using a special device with conventional MRI machines. A study of patients with symptoms of spinal stenosis (Hiwatashi et al., 2004) found that imaging with axially loaded MR imaging can yield information that results in different treatment decisions than standard MRI.

The Hiwatashi study used a device, consisting of a harness/jacket with straps connected to a footplate that applies an axial load to the patient's spine during imaging in the supine position.

The other approach is to use a vertically open-configuration MRI that allows the patient to be imaged in a weight-bearing position. There are two FDA-approved devices:

- The Indomitable MRI scanner (Fonar) was approved by the FDA in October 2000 for imaging multiple planes of the head and body. It has an open design and the patient-scanning table can be moved to a variety of positions with the patient on it. Scanning positions include a vertical (upright) position, a horizontal (supine) position and an angled position (angles between -20° and 90°). Fonar, the manufacturer, claims that this is the only MRI system that can scan patients in flexion, extension, rotation and lateral bending (Fonar website; FDA website).
- The G-scan (Esaote) was approved by the FDA in August 2004; its use is limited to imaging the ankle, knee, hip, shoulder joint and spine. The scanning table can also be moved to a variety of positions with the patient on it. The table can be rotated to angles between supine (0°) to fully upright (90°). The system also includes specialized knee, hand/wrist, ankle/foot and shoulder coils (Esaote website; FDA website).

Weight-bearing MRI has not been previously reviewed by MTAC.

Assessment questions:

- Diagnostic accuracy: What is the evidence on the ability of upright MRI to accurately detect problems/pathology compared to conventional MRI?
- Diagnostic impact: What is evidence on whether findings from weight-bearing MRI contribute substantially to improved diagnosis compared to conventional MRI?
- Therapeutic impact: What is the evidence that more appropriate therapy is used after weight-bearing MRI compared to conventional MRI?

Medical Technology Assessment Committee (MTAC)

Weight-Bearing MRI

06/04/2007: MTAC REVIEW

Evidence Conclusion: There are no published studies on the diagnostic accuracy (sensitivity/specificity), diagnostic impact or therapeutic impact of upright MRI compared to conventional MRI. One study with the Fonar Upright MRI system (Perez et al., 2007 in press) compared the diagnostic yield of the new device compared to conventional MRI. There was no gold standard comparison; rather, weight-bearing MRI was compared to conventional MRI. 68 pathologies were identified in 89 symptomatic patients by one or both methods. The authors considered a technology to be "superior" if it identified a pathology not detected by the other method or indicated a herniation or spondylolisthesis that was larger in size. Upright MRI was found to be superior to recumbent MRI in 52 out of 68 pathologies identified, and recumbent MRI was found to be superior to upright MRI in 11 cases. The reports by the Washington State Labor and Industries Department and the Washington State Department of Health both also concluded that there was insufficient evidence on the diagnostic accuracy or utility of weight-bearing MRI.

Articles: Diagnostic accuracy: No studies were identified evaluated the sensitivity and specificity of weight-bearing MRI compared to conventional MRI, using an objective comparison. The empirical articles identified in the search generally involved obtaining spinal measurements with patients in various positions. For example, Hirasawa et al. (2007) examined 20 asymptomatic volunteers with the Fonar Indomitable MRI scanner in supine, sitting and standing positions. The primary outcome measures were differences in spinal measurements, specifically mean dural sac cross-sectional area and diameter. One study was identified that compared clinical diagnoses of patients imaged with weight-bearing MRI versus conventional MRI. This study (Ferreiro Perez et al., in press 2007) was critically appraised. See [Evidence Table](#). Diagnostic accuracy: No studies were identified evaluated the sensitivity and specificity of weight-bearing MRI compared to conventional MRI, using an objective comparison. The empirical articles identified in the search generally involved obtaining spinal measurements with patients in various positions. For example, Hirasawa et al. (2007) examined 20 asymptomatic volunteers with the Fonar Indomitable MRI scanner in supine, sitting and standing positions. The primary outcome measures were differences in spinal measurements, specifically mean dural sac cross-sectional area and diameter. One study was identified that compared clinical diagnoses of patients imaged with weight-bearing MRI versus conventional MRI. This study (Ferreiro Perez et al., in press 2007) was critically appraised. See [Evidence Table](#). Diagnostic impact: No studies were identified that evaluated whether findings from weight-bearing MRI contribute substantially to improved diagnosis compared to conventional MRI. Therapeutic impact: No studies were identified that reported quantitative data on whether more appropriate therapy was used after weight-bearing MRI than conventional MRI.

The use of weight-bearing MRI does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Magnetic Resonance Spectroscopy (MRS)

- ADHD
- Autism
- Cerebral Tumors
- Differentiating Tumors from Non-Tumors
- Epilepsy

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Magnetic Resonance Spectroscopy (220.2.1) RETIRED 06/08/2021 NCD Magnetic Resonance Spectroscopy (220.2.1) has been retired. These services still need to meet medical necessity as outlined in the NCD and will require review. NCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an article. Most NCDs are not retired because they are incorrect. Therefore, continue to use NCD 220.2.1.
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting review for this service, please send the following documentation:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Magnetic resonance spectroscopy (MRS) is a non-invasive technique that provides chemical information on metabolites in tissues. It uses strong magnetic fields to generate an exchange of energy between external magnetic fields and protons within tissues. The energy exchange is transmitted back to the machine as a radiofrequency signal which is decoded by computer software. The software produces a waveform with peaks corresponding to the relative concentration of various chemicals. In addition, the specific chemicals that are present are identified--they appear at different locations on a horizontal axis. MRS utilizes the magnetic property of atomic nuclei. The proton is the most commonly studied nucleus. Proton (^1H) MRS defines approximately 15 brain metabolites. These include lipids, lactate, N-acetylaspartate (NAA), glutamate/glutamine (Glx), creatine (Cr), choline (Cho) and myoinositol (ml) (Gulati et al., 2003; Lin et al., 2005; BlueCross BlueShield Association, 2005).

A potential use of MRS is to diagnose conditions when other tests have been negative or inconclusive, or to refine existing diagnoses. For example, an increased Cho signal is believed to indicate the presence of cancerous cells. MRS can be used alone or in combination with magnetic resonance imaging (MRI) which produces anatomic images. In addition, MRS can be used to monitor metabolites to evaluate the effectiveness of therapy by seeing if levels change from elevated back to normal (Lin et al., 2005).

MRS has been used to study various neurologic diseases, including epilepsy, multiple sclerosis, HIV-related neurologic disorders and brain tumors, as well as cerebrovascular and metabolic diseases. One review article stated that MRS's most important use in neurology is quantifying neuronal loss and demonstrating reversible neuronal damage. (Rudkin & Arnold, 1999).

Other imaging tests used for epilepsy include EEG, MRI, FDG PET and CT scanning. ADHD and autism are diagnosed mainly by clinical evaluation. EEG and MRI are sometimes used to provide additional information on autism.

Cerebral Tumors

More than 190,000 people in the United States are diagnosed with primary or metastatic cerebral tumors annually. It is challenging to diagnose and treat cerebral tumors due to the similarity of these lesions to other types of pathologies on conventional imaging, the inaccessibility of the lesions and their proximity to complex brain structures. An accurate non-invasive method for diagnosing cerebral tumors is desirable, especially one that could replace biopsy which has a reported morbidity of 3-4% (AHRQ, 2003, Sibtain et al., 2007; National Brain Tumor Foundation).

Imaging procedures for diagnosing cerebral tumors include CT, MRI, SPECT and PET. CT uses x-rays and MRI uses non-ionizing radio frequency to acquire images. Both methods can generate multiple two-dimensional cross-sections of tissue as well as three-dimensional reconstructions and are generally used in conjunction with stereotactic biopsy. PET scans measure glucose activity which can be translated to a moving picture of the brain. SPECT imaging uses gamma rays to acquire multiple two-dimensional images from multiple angles, which can produce true three-dimensional information.

Magnetic resonance spectroscopy (MRS), a technique related to MRI, is also proposed for imaging cerebral tumors. MRS is a non-invasive technique that provides chemical information on metabolites in tissues. It uses strong magnetic fields to generate an exchange of energy between external magnetic fields and protons within tissues. The energy exchange is transmitted back to the machine as a radiofrequency signal which is decoded by computer software. The software produces a waveform with peaks corresponding to the relative concentration of various chemicals. In addition, the specific chemicals that are present are identified--they appear at different locations on a horizontal axis. MRS utilizes the magnetic property of atomic nuclei. The proton is the most commonly studied nucleus. Proton (1H) MRS defines approximately 15 brain metabolites. These include lipids, lactate, N-acetylaspartate (NAA), glutamate/glutamine (Glx), creatine (Cr), choline (Cho) and myoinositol (ml). A chemical profile that may be characteristic of brain tumors includes an increase in Cho, and a reduction in Cr and NAA (Sibtain et al., 2007; Lin et al., 2005; BlueCross BlueShield Association, 2005).

Potential areas in which MRS may contribute diagnostic information include distinguishing abscesses from tumors, providing a more accurate way to determine the grade of primary tumors than conventional MRI, distinguishing single metastatic brain lesions from primary tumors, providing guidance for biopsy and gamma knife therapy, determining tumor recurrence and differentiating between radiation necrosis and tumor recurrence. MRS can be used alone, or in combination with MRI (AHRQ, 2003; Sibtain et al., 2007).

Several factors may limit the performance of MRS in identifying cerebral tumors. Sudden dramatic changes in the composition of tissue can cause inaccuracies in the magnetic fields. This is relevant for lesions adjacent to bone or air-filled structures such as the sinuses. Moreover, lesions that lie near areas of old infarcts or ischemic changes, or concurrent demyelinating disease, can distort the chemical ratios used in interpretation. In addition, visual interpretation of spectra is difficult and requires special training (AHRQ, 2003; Sibtain et al., 2007).

Medical Technology Assessment Committee (MTAC)

Magnetic Resonance Spectroscopy (MRS)

12/05/2005: MTAC REVIEW

Evidence Conclusion: No published studies were identified on the accuracy of magnetic resonance spectroscopy for diagnosing ADHD or autism. One study was identified on the accuracy of MRS for lateralization

of patients with medically refractory temporal lobe epilepsy. This study (Cendes et al., 1997) included 100 patients and used EEG as the gold standard. Lateralization based on MRS agreed with EEG findings in 87% of cases. Lateralization based on the results of MRS and MRI combined agreed with EEG findings in 86% of cases.

Articles: The ideal study of diagnostic accuracy would report the sensitivity and specificity of MRS and compare this to an independent blinded comparison to a “gold standard” diagnosis.

ADHD and autism None of the studies on ADHD, or ADHD and autism reported the sensitivity and specificity of MRS diagnosis compared to a “gold standard” such as clinical evaluation. The empirical studies reported on preliminary research using MRS to measure the concentrations of various chemicals in the brains of children with ADHD compared to healthy children. One of the articles included children with autism, in addition to children with ADHD and healthy controls. **Epilepsy** None of the studies on epilepsy reported the sensitivity and specificity of MRS diagnosis compared to a “gold standard”. There were several studies examining the correlations between concentrations of chemicals identified by MRS and seizure duration, seizure severity or surgical outcome. One study compared chemical concentrations in patients with epilepsy and normal controls. These were all descriptive studies and were not evaluated further. One study was identified that compared the performance of MRI, MRS and the combination of the two in the lateralization of temporal lobe epilepsy (TLE). This article (Cendes et al., 1997) was critically appraised. No other studies on the diagnostic accuracy of MRS in patients with epilepsy were identified and no studies were identified on diagnostic or therapeutic impact.

The study critically appraised was: Cendes F, Caramanos Z, Andermann F et al. Proton magnetic resonance spectroscopic imaging and magnetic resonance imaging volumetry in the lateralization of temporal lobe epilepsy: A series of 100 patients. *Ann Neurol* 1997; 42: 737-746. See [Evidence Table](#).

The use of Magnetic resonance spectroscopy (MRS) in diagnosing autism, ADHD and epilepsy does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

10/02/2006: MTAC REVIEW

Magnetic Resonance Spectroscopy (MRS)

Evidence Conclusion: No new published studies were identified on the accuracy of magnetic resonance spectroscopy for diagnosing ADHD, epilepsy or autism. No new studies were identified that validate specific chemical profiles that are diagnostic of particular conditions.

Articles: The ideal study of diagnostic accuracy would report the sensitivity and specificity of MRS and include an independent blinded comparison to a “gold standard” diagnosis. **ADHD and autism** - 2005 Review: None of the studies on ADHD, or ADHD and autism reported the sensitivity and specificity of MRS diagnosis compared to a “gold standard” such as clinical evaluation. The empirical studies reported on preliminary research using MRS to measure the concentrations of various chemicals in the brains of children with ADHD compared to healthy children. One of the articles included children with autism in addition to children with ADHD and healthy controls. 2006 Review: The newer studies were similar to those identified in the 2005 search. Studies reported on use of MRS to measure the concentrations of chemicals (i.e. Cho, CR and NAA) in children with autism or ADHD compared to healthy children. None of the studies reported the ability of MRS to diagnose autism or ADHD (i.e. sensitivity and specificity of MRS findings). **Epilepsy** - 2005 Review: None of the studies on epilepsy reported the sensitivity and specificity of MRS diagnosis compared to a “gold standard”. Several studies examined the correlations between concentrations of chemicals identified by MRS and seizure duration, seizure severity or surgical outcome. One study compared chemical concentrations in patients with epilepsy and normal controls. These were all descriptive studies and were not evaluated further. One study compared the performance of MRI, MRS and the combination of the two in the lateralization of temporal lobe epilepsy (TLE). This article (Cendes et al., 1997) was critically appraised. 2006 Review: One meta-analysis was identified. This study (Willmann et al., in press, 2006) assessed the pre-operative value of MRS in identifying the epileptogenic zone (EZ) for epilepsy surgery. Preoperative evaluation of epilepsy patients is outside the scope of the current review and the study was thus not evaluated further.

The use of Magnetic resonance spectroscopy (MRS) in diagnosing autism, ADHD and epilepsy does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

12/03/2007: MTAC REVIEW

Magnetic Resonance Spectroscopy (MRS)

Evidence Conclusion: Three studies were reviewed that reported the sensitivity and specificity of MRS for distinguishing brain tumors from non-tumors, compared to a reference standard. All had relatively small sample sizes, especially as regards the number of patients without tumors, so estimates may not be reliable. One of the studies used combined MRS/MRI findings. Sensitivity ranged from 81% to 90% and specificity from 86% to 100%. The size of the studies was too small to draw conclusions about the accuracy of MRS for differentiating between brain tumors and any specific alternate condition such as radiation necrosis or abscess. There is a lack of

evidence on the diagnostic accuracy of MRS alone compared to conventional imaging, or on MRS plus conventional imaging versus conventional imaging alone. Thus, it is difficult to draw conclusions about the ability of MRS to replace other diagnostic tests. Two studies addressed the impact of MRS on clinical decision-making. Both were case series; Lin et al., 1999 was limited in that it had only 15 patients, and Adamson et al. was retrospective. In the Adamson et al., study, MRS was seen as having a potential positive impact on treatment in 23/78 (29%) of cases. In 2 cases, MRS was seen as having a potential negative impact on treatment. For the remainder of the cases, MRS was viewed as neutral, or patients were lost to follow-up. In the Lin study, which only included 15 patients, MRS was used in place of biopsy in 7 cases, and MRS was correlated with clinical course in 6 cases. MRS did not correlate with clinical course in only 1 patient.

Articles: *Accuracy of MRS* the ideal study of diagnostic accuracy would report the sensitivity and specificity of MRS and include an independent blinded comparison to a “gold standard” diagnosis. Several studies met these criteria and were critically appraised. All had relatively small sample sizes. Rand et al., 1997 and McKnight et al., 2002 evaluated MRS alone and Gajewicz et al., 2003 evaluated MRS in combination with MRI. Rand SD, Prost P, Haughton V et al. Accuracy of single-voxel proton MR spectroscopy in distinguishing neoplastic from nonneoplastic brain lesions. *AJRN* 1997; 18: 1685-1704. See [Evidence Table](#). McKnight TR, von dem Bussche BS, Vigneron DB. et al., Histopathological validation of a three-dimensional magnetic resonance spectroscopy index as a predictor of tumor presence. *J Neurosurg* 2002; 97: 794-802. See [Evidence Table](#). Gajewicz W, Papierz W, Szymczak W et al. The use of proton MRS in the differential diagnosis of brain tumors and tumor-like processes. *Med Sci Monit* 2003; 9: MT97-105. See [Evidence Table](#). Diagnostic impact (does MRS contribute substantially to improved diagnosis and/or replace other diagnostic tests or procedures). There were no studies comparing diagnosis with MRS to diagnosis with conventional imaging. Therapeutic impact of MRS (is more appropriate therapy is used after application of MRS than would be used if the test were not available). Two studies that evaluated the impact of MRS on clinical decision-making were identified and critically appraised: Adamson AJ, Rand SD, Prost RW et al. Focal brain lesions: Effect of single-voxel proton MR spectroscopic findings on treatment decisions. *Radiol* 1998; 209: 73-78. See [Evidence Table](#). Lin A, Blum s, Mamelak AN. Efficacy of proton magnetic resonance spectroscopy in clinical decision making for patients with suspected malignant brain tumors. *J Neuro-Oncol* 1999; 45: 69-81. See [Evidence Table](#).

The use of Magnetic resonance spectroscopy (MRS) in diagnosing cerebral tumors and differentiating tumors from non-tumors does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

***MCG manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Myocardial perfusion exercise stress imaging, such as stress SPECT, involves intravenous injection of a radioactive tracer (eg, thallium, sestamibi, or tetrofosmin), which is taken up by myocardial cells and visualized by a digital gamma camera, thereby reflecting the distribution of blood perfusion throughout the myocardium. A defect in the image with exercise that is not present at rest usually indicates an area of myocardial ischemia. Myocardial perfusion imaging synchronized with ECG (eg, gated SPECT) can assess ventricular function, including ejection fraction, in addition to myocardial perfusion. Myocardial perfusion imaging has been noted by specialty societies to have the most clinical utility in patients who are at intermediate risk for coronary artery disease, in those requiring management or prognostic information, and in those with unexplained and persistent symptoms. Myocardial perfusion imaging systems that combine SPECT and CT technology (also known as "hybrid" systems) are now widely available. It has been noted that myocardial perfusion scans contribute at least 20% of the estimated annual collective radiation dose in the United States, although the lifetime cancer risk from a single myocardial perfusion imaging study is thought to be small. Best-practice methods to maximize diagnostic quality while minimizing radiation exposure have been proposed.

Pharmacologic stress myocardial perfusion imaging, such as pharmacologic stress SPECT, involves intravenous injection of a radioactive tracer (eg, thallium, sestamibi, or tetrofosmin), which is taken up by myocardial cells and visualized by a digital gamma camera, thereby reflecting the distribution of blood perfusion throughout the myocardium. Coronary hyperemia is induced by a vasodilator, such as adenosine, dipyridamole, or regadenoson, or an adrenergic agent such as dobutamine, in lieu of stress via exercise or in addition to submaximal exercise. A defect in the image with stress that is not present at rest usually indicates an area of myocardial ischemia. Myocardial perfusion imaging synchronized with ECG (eg, gated SPECT) can assess ventricular function, including ejection fraction, in addition to myocardial perfusion. Pharmacologic stress testing using the vasodilator agent's adenosine and dipyridamole is contraindicated in patients with severe reactive airway disease (eg, asthma or chronic obstructive pulmonary disease) because of provocation of bronchospasm; regadenoson or dobutamine may be substituted in this population.

Myocardial perfusion imaging has been noted by specialty societies to have the most clinical utility in patients who are at intermediate risk for coronary artery disease, in those requiring management or prognostic information, and in those with unexplained and persistent symptoms. Myocardial perfusion imaging systems that combine SPECT and CT technology (also known as "hybrid" systems) are now widely available. It has been noted that myocardial perfusion scans contribute at least 20% of the estimated annual collective radiation dose in the United States, although the lifetime cancer risk from a single myocardial perfusion imaging study is thought to be small. Best-practice methods to maximize diagnostic quality while minimizing radiation exposure have been proposed.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article (LCA)	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, Myocardial Strain Imaging for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

Myocardial strain imaging is considered medically necessary:

- Prior to, during, or following exposure to oncology medications* that could result in cardiotoxicity

*Including but not limited to – doxorubicin (Adriamycin); trastuzumab (Herceptin, Kanjinti); pertuzumab (Perjeta); ado-trastuzumab emtansine (Kadcyla); fam-trastuzumab deruxtecan (Enhertu); mitoxantrone (Novantrone); liposomal doxorubicin (Doxil)

Myocardial strain imaging is considered experimental, investigational or unproven for all other indications.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Technology Description

Myocardial strain imaging (MSI) involves a sophisticated analysis of images from echocardiography. Reflection of ultrasonic waves from myocardial tissue creates stable patterns of brighter and darker spots (speckles) that can

serve as "fingerprints" to identify specific segments of the myocardial walls. Image processing computer software tracks the movement of these patterns to assess the severity of myocardial damage and abnormal heart function.

Quality of the Evidence

The body of evidence concerning diagnostic and prognostic use of MSI was large in size and overall low in quality. The overall low-quality rating for the body of evidence reflects individual study limitations, wide variability in the MSI parameters used for diagnosis or prognosis in DCM, and the absence of studies evaluating the clinical utility of MSI in patients with DCM. Overall quality was determined based on the balance of benefits and harms and was assessed taking into consideration the quality of individual studies; the precision, directness, and consistency of data; and the applicability of data to general practice.

Conclusion

The available studies have not provided sufficient evidence to evaluate diagnostic uses of MSI in DCM patients due to the small number and diverse applications of MSI in diagnostic studies. Although some prognostic studies found that certain MSI parameters had statistically significant correlations with health outcomes, results were not consistent across studies and the parameter that appeared most accurate for prognosis (early DSR) was measured in only 1 study. Furthermore, no studies of the clinical utility of MSI were identified to evaluate whether the diagnostic and prognostic information obtained from MSI can be used to improve patient management. MSI does not pose any safety concerns. Additional studies are needed to identify the optimal MSI parameters for diagnosis and prognosis in DCM patients and to demonstrate that guidance of care with MSI provides meaningful improvements in health outcomes for DCM patients.

Insights

- MSI can be used to measure many types of changes and rates of change in myocardial length, shape, and rotation in each of the 4 heart chambers. More research is needed to evaluate which of these measurements are most useful for all of the potential diagnostic and prognostic uses of MSI.
- Although the equipment needed to perform echocardiographic MSI is much less complicated than the equipment needed for cardiac magnetic resonance imaging (MRI), MSI may be less accurate and there is little evidence addressing the relative accuracy of these techniques. Only 1 study compared MSI with cardiac MRI; therefore, additional studies are needed to evaluate the relative accuracy of these techniques in patients with DCM.
- MSI may provide some useful diagnostic or prognostic information if cardiac MRI is not available or not feasible.
- Two studies that included exercise testing or cardiac stress testing obtained results that greatly differed from results of measurements obtained solely in resting patients, suggesting that additional MSI studies incorporating exercise and stress testing are needed.

**Kaiser Foundation Health Plan
of Washington****Clinical Review Criteria
Naturopathy**

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria**For Medicare Members**

Naturopathy is not covered by Medicare and is considered a supplemental benefit. Please check member contract for specific coverage language.

For Non-Medicare Members

- I. Authorizations for covered naturopathic treatments beyond three visits require prior approval by the health plan for those plans with alternative medicine benefits.
- II. Clinical review criteria for naturopathy are as follows:
 - A. The patient has an established, documented diagnosis of **ONE of the following**:
 1. Fibromyalgia (The patient has an established, documented diagnosis of fibromyalgia consistent with the 1990 American College of Rheumatology Criteria.)
 2. Chronic arthritis
 3. Chronic fatigue syndrome
 4. Premenstrual syndrome
 5. Irritable bowel syndrome
 6. Menopausal symptoms
 7. Headaches (persistent sinus, muscle tension, migraine)
 8. Chronic sinusitis, defined as persistent sinusitis
 9. Chronic serious otitis media, defined as persistent middle ear fluid for greater than three months
 10. Atopic dermatitis/chronic eczema
 11. Asthma that is mild to moderate in severity and not dependent on oral steroids
 - B. Treatment progress reports submitted to the health plan after the second visit, or at intervals as specified in the referral, must demonstrate the benefit of treatment for continuation of care to be approved.

Review Services will consider each referral request on a case-by-case basis and will consider requests outside the above criteria based on, among other things, clear documentation of objective improvement by the licensed naturopathic physician or the patient's personal physician, as well as a detailed treatment plan.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Naturopathic medicine is a distinct profession of health care that has been in existence since the late nineteenth century. The philosophical approach includes the following principles:

- Utilization of therapies that first do no harm.
- Prevention of disease through healthy lifestyle and control of risk factors.
- Recognition and encouragement of the body's inherent healing abilities.

- Treatment of the whole person – physical, emotional, mental, and spiritual.
- Patient education and cultivation of an attitude of personal responsibility for one's health.

Education standards for naturopathic medicine require at least three years of college level work followed by a four-year curriculum with over 4,000 hours of instruction at an accredited training institution (such as Bastyr University). In addition to conventional basic science courses, students receive training in botanical medicine, therapeutic nutrition, and various physical medicine modalities. Naturopathic physicians are licensed in the state of Washington and in ten other states.

Evidence and Source Documents

There is a small body of literature that supports some of the interventions that naturopaths provide.

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Negative Pressure Wound Therapy Pumps (L33821) for traditional NPWT covered under DME Wound Care (L37228) <i>Mentions disposable NPWT (dNPWT)</i>
Local Coverage Article	Negative Pressure Wound Therapy Pumps (A52511) for traditional NPWT covered under DME
MLN Matters Article	Clarification of Billing and Payment Policies for Negative Pressure Wound Therapy Using a Disposable Device <i>For disposable NPWT provided by Home Health Agency</i>

For Non-Medicare Members

Initial Coverage:

- 1) Traditional Negative Pressure Wound Therapy Pumps (tNPWT)
A traditional NPWT (tNPWT) pump and supplies are covered for wound edema, exudate management and stimulation of granulation for an initial 14-day course when the following main criteria are met:
 - A. Must complete the [Kaiser Permanente initial coverage request form](#) and fax it to the DME staff at 877-290-4632.
 - B. Ulcers and Wounds in the Home Setting:
 1. The patient has a Stage III or IV pressure ulcer, neuropathic/diabetic ulcer, venous insufficiency or arterial ulcer, or a chronic ulcer of mixed etiology. These wounds should have exudate, size and depth to require this specialized therapy. A complete wound therapy program described by criterion 1 and criteria 2, 3, or 4, as applicable depending on the type of wound, should have been tried for 30 days unless edema and/or exudate mandates NPWT.
 - i. For all ulcers or wounds, the following components of a wound therapy program must include a minimum of all of the following general measures prior to application of NPWT:
 - (a) Documentation in the patient's medical record of evaluation, care, and wound measurements by a licensed medical professional.
 - (b) Consideration of the following risk factors is addressed in the documentation
 - (i) Risk for bleeding and hemorrhage
 - (ii) Active treatment with anticoagulants or platelet aggregation inhibitors
 - (iii) Presence of:
 - Friable vessels and infected blood vessels

- Vascular anastomosis
 - Infected wounds
 - Osteomyelitis
 - Exposed organs, vessels, nerves, tendons, and ligaments
 - Sharp edges in the wound (i.e. bone fragments)
 - Spinal cord injury (stimulation of sympathetic nervous system)
 - Enteric fistulas
- (c) Requirement for:
- MRI
 - Hyperbaric chamber
 - Defibrillation
 - Size and weight
 - Use of device near the vagus nerve
 - Use of circumferential dressing application
 - Mode of therapy – intermittent versus continuous negative pressure
- (d) Application of dressings to maintain a moist wound environment.
- (e) Debridement of necrotic tissue if present.
- (f) Evaluation of and provision for adequate nutritional status.
- ii. For Stage III or IV pressure ulcers:
- (a) The patient has been appropriately turned and positioned.
 - (b) The patient's moisture and incontinence have been appropriately managed.
- iii. For neuropathic/diabetic ulcers:
- (a) The patient with diabetes has been on a comprehensive diabetic management program, **and**
 - (b) A foot ulcer has been appropriately off-loaded.
- iv. For venous insufficiency ulcers:
- (a) Compression bandages and/or garments have been consistently applied only after Ankle-Brachial Index has been done per guidelines, and
 - (b) Leg elevation with alternating ambulation has been encouraged.
- C. Goal of therapy is clearly stated
- D. Ulcers and Wounds Encountered in an Inpatient Setting:
1. An ulcer or wound (described in section A above) is encountered in the inpatient setting and, after wound treatments described under sections A-a through A-d have been tried or considered and ruled out, NPWT may be initiated.
 2. The patient has complications of a surgically created wound (for example, dehiscence) or a traumatic wound (for example, pre-operative flap or graft) where there is documentation of the medical necessity for accelerated formation of granulation tissue which cannot be achieved by other available topical wound treatments (for example, other conditions of the patient that will not allow for healing times achievable with other topical wound treatments).
In either of the above situations, NPWT will be covered when treatment continuation is ordered beyond discharge to the home setting.
 3. Skin-flaps or grafts approved as covered by the health plan in advance of the procedure.
- E. Contraindications for use:
1. The presence in the wound of necrotic tissue with eschar, if debridement has not been carried out
 2. Untreated osteomyelitis within the vicinity of the wound
 3. Possibility of malignant cells present in the wound
 4. The presence of a fistula to an organ or body cavity within the vicinity of the wound
 5. Exposed vascular in the wound
 6. Exposed nerves in the wound
 7. Exposed anastomotic site
 8. Exposed organs
 9. Recent lab value for albumin equal to or less than 2.5.
 10. Pediatric patients (newborns, infants and children)
- 2) Disposable, single-use Negative Pressure Wound Therapy for chronic wound and ulcers
- A. The SNAP™ Therapy System (Acelity/KCI) may be used instead of traditional NPWT if **ALL** of the following criteria are met:
- B. Must complete the [Kaiser Permanente initial coverage request form](#) and fax it to the DME staff at 877-290-4632.

- C. These wounds should have exudate, size and depth to require this specialized therapy. A complete wound therapy program described by criterion 1.B.1.i and criteria 1.B.1.ii, 1.B.1.iii, or 1.B.1.iv, as applicable depending on the type of wound, should have been tried for 30 days.
1. Wound size < 13 cm x 13 cm
 2. Wound drainage ≤ 180 mL/week (20mL/day)
 3. Change dressing 2x/week at minimum; dispose of cartridge when full (typical cartridge holds 60 mL)
- D. Contraindications for use of disposable NPWT (SNAP)
1. Inadequately drained wounds
 2. Necrotic tissue such as eschar or adherent slough
 3. Exposed blood vessels, anastomotic sites, organs, tendons, or nerves
 4. Wounds containing malignancy
 5. Fistulas
 6. Untreated osteomyelitis
 7. Actively bleeding wounds
- 3) Single Use Negative Pressure Wound Therapy (s-NPWT) for the Prevention of Surgical Site Infections (SSIs) in Closed Surgical Incisions (*device must be FDA approved for this indication*)
- A. When applied in the operating room after revision of total hip arthroplasty (rTHA) or total knee arthroplasty (rTKA), member must meet **ONE or more of the following**:
1. Body mass index (BMI) > 35kg/m²
 2. Use of non-aspirin blood thinners postoperatively
 3. Current/previous diagnosis of peripheral vascular disease (established through history of intermittent claudication, generalized atherosclerosis, or compromised blood flow on doppler ultrasound)
 4. Current tobacco use (within 30 days)
 5. History of prior infection history at operative site (not within the last 4 weeks)
 6. Operative limb lymphedema
 7. Diabetes
 8. Current use of immunomodulators or corticosteroids
 9. Ongoing malignancy excluding localized skin cancer
 10. Rheumatoid Arthritis
 11. Renal failure or dialysis
 12. Malnutrition (supported by laboratory values of albumin<3.5 g/dL, a total lymphocyte count<1500 cells/mm³, and/or a transferrin level<200 mg/dL)
 13. Liver disease (defined as ongoing chronic infectious or noninfectious liver pathology with associated abnormalities in liver functions)
 14. History of organ transplant
 15. Human immunodeficiency virus infection
- B. Not medically necessary and/or contraindicated for **ONE or more of the following**:
1. Known hypersensitivity to device components
 2. Surgical glue used for wound closure (those patients would not be able to receive ciNPT per the instructions of the manufacturer)

Continued Coverage (tNPWT/SNAP):

For wounds and ulcers described under sections 1 and 2 of Initial Coverage, once placed on any type of NPWT pump with supplies, for coverage to continue a licensed medical professional must do the following:

- 1) Must complete the [Kaiser Permanente continued coverage request form](#) and fax it to the DME staff at 877-290-4632.
- 2) On a regular basis:
 - A. Directly assess the wound(s) being treated with the NPWT pump
 - B. Supervise or directly perform the NPWT dressing changes
- 3) On at least a weekly basis, document changes in the ulcer's dimensions and characteristics and the degree of granulation and management of exudate
 - A. If using SNAP: If wound increases in size or is producing amounts of exudate above the parameters for SNAP, may need to evaluate the need for tNPWT or other wound management strategies.
- 4) Laboratory values at monthly intervals to show a contraindication does not exist

- 5) If these criteria are not fulfilled, continued coverage of the NPWT pump and supplies will be denied as not medically necessary

When Coverage Ends for tNPWT/SNAP:

- 1) For wounds and ulcers described under sections A and B of Initial Coverage, an NPWT pump and supplies will be denied as not medically necessary with any of the following, whichever occurs earliest:
 - A. Criteria for Continued Coverage cease to occur.
 - B. In the judgment of the treating physician, adequate wound granulation has occurred to the degree that NPWT may be discontinued.
 - C. Wound is not healing progressively
 1. Progressive wound healing has failed to occur over the prior 14 days. There must be documented in the patient's medical records quantitative measurements of wound characteristics including wound length and width (surface area), or depth, serially observed and documented, over a specified time interval. The recorded wound measurements must be consistently and regularly updated and must have demonstrated progressive wound healing from week to week.
 2. If using SNAP: If progressive wound healing has failed to occur, or wound increases in size or is producing amounts of exudate above the parameters for SNAP.
 - D. NPWT should be ordered for a 2-week period of time as wounds are expected to change with this therapy. Once equipment or supplies are no longer being used for the patient, whether or not by the physician's order, the provider should be directly contacted and the delivery of further supplies stopped. Traditional NPWT Pumps must be returned to the provider for billing purposes and cleaning.

Supplies for tNPWT:

- 1) Coverage for tNPWT is provided up to a maximum of 6 dressing kits (A6550) per wound per 14-day period unless there is documentation that the wound size requires more than one dressing kit for each dressing change. Dressings should be changed based on the patient's condition and the condition of the wound but normally not more frequently than 3 times a week.
- 2) Coverage for tNPWT is provided up to a maximum of 2 canister sets (A7000) per 14-day period unless there is documentation evidencing a large volume of drainage (greater than 90 ml of exudate per day). For high volume exudative wounds, a stationary pump with the largest capacity canister must be used. Excess utilization of canisters related to equipment failure (as opposed to excessive volume drainage) will be denied as not medically necessary.

Supplies for SNAP replacement:

- 1) Coverage for SNAP is provided up to a maximum of 4 devices per 14-day period unless there is documented evidence of a larger volume of drainage requiring more frequent replacement.
- 2) The two codes of 97607 and 97608 should only be used when the provider is either initially applying an entirely new SNAP device or removing a SNAP device and replacing it with an entirely new one as clinically required. These codes may not be used if only a dressing change is performed for a SNAP system.

Service: Negative Pressure Wound Therapy: non-powered other than SNAP	Criteria Used
PICO	There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, KAISER PERMANENTE will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Negative pressure wound therapy (NPWT) is a wound dressing system that was designed to promote wound healing through the use of subatmospheric pressure to the wound surface. NPWT systems include a vacuum

pump, drainage tubing, and a dressing set. To place the device, the wound is covered or packed with a foam or gauze dressing and then secured using an adhesive film drape. A vacuum pump connected to the draining tube(s) in the wound dressing is used to apply pressure to the wound surface in the range of -50 to -125 mmHg. The precise mechanism through which NPWT aids the healing process is not fully understood; however, it has been suggested that NPWT may aid in the healing process through increasing local blood flow, increasing granulation tissue, reducing bacterial contamination, reducing wound area, reducing edema and exudate, and changes to the microenvironment (AHRQ 2009, Webster 2011).

Negative pressure therapy has been used in clinical applications for over five decades.

The concept of applying topical negative pressure in the management of wounds emerged in the late 1980s and is increasingly used for a wide variety of wounds. The technique is also known as vacuum assisted closure (VAC), negative pressure wound therapy (NPWT), vacuum sealing technique (VST), sealed surface wound suction (SSS), subatmospheric pressure therapy or dressing, foam suction dressing, and vacuum pack technique (VPT). The technology generally involves putting a dressing (foam or gauze) into the wound cavity, connecting it to a vacuum pump, and sealing the area with an adhesive film. The vacuum pump creates and maintains a subatmospheric pressure (intermittent or continuous) in the range of -50 to -125 mmHg. The default setting is -125 mmHg, and the pressure may be titrated up by 25 mmHg increments when there is excessive drainage or a large wound volume, or titrated down when the patient is elderly, nutritionally compromised, or has a risk of excessive bleeding. Dressings are usually changed every 48 hours, or every 12-24 hours if the wound is infected. The mechanism by which NPWT is believed to promote wound healing is unclear. In theory it may increase dermal perfusion, stimulate granulation tissue formation, reduce the edema and interstitial tissue fluid, reverse tissue expansion, and/or reduce bacterial colonization. It is also thought that the vacuum pressure may act as an effective skin graft splint over irregular surfaces. The therapy cannot be used as a replacement for surgical debridement, but as a complementary treatment. It is contraindicated for use in wounds with necrotic tissue, exposed vital structures, untreated osteomyelitis, unexplored fistulae and malignant wounds. Adverse effects include pain and damage to the skin around the wound (Braakenburg 2006, Bovill 2008, Wild 2008, Preston 2008).

Acute and chronic wounds are a major cause of morbidity and impaired quality of life. They affect at least 1% of the population and represent a significant risk factor for hospitalization, amputation, sepsis, and even death. Wound healing is a complex series of events, broadly classified into inflammatory, proliferative, and remodeling phases. The healing process may be compromised by arterial or venous insufficiency which can prevent or delay healing and/or increase the risk of recurrent wound infections. The treatment of difficult-to-manage and chronic wounds remains a significant challenge to practitioners, a cause of pain and discomfort to the patients, and costly (Gregor 2008, Sadat 2008).

For centuries, gauze has been used in local wound care, mainly due to its low price and simplicity. In 1950s, a new concept, that wound healing is optimal when it is kept in a moist environment rather than air dried, was introduced. Since then, a large variety of occlusive or semi-occlusive dressings, topical applications, and other products were developed for the treatment of all kinds of wounds. Modern wound-healing agents include hydrocolloidal, alginates, hydrogels, hydrofiber, paraffin gauze dressings, as well as many other types of moist dressings and topical agents. The choice of the ideal regimen remains controversial due to the lack of good evidence from well conducted RCTs and depends mainly on the clinicians' preference (Chaby 2007, Gregor 2008, Ubbink 2009).

Skin grafts are used to promote healing in complex wounds with tissue loss. Successful skin grafting relies on the ability of the skin graft to integrate with the recipient wound bed. Bolstering the graft to the wound bed by applying a dressing along with positive pressure is used to improve integration with the wound bed and minimize seroma formation. NPWT is an alternative to standard bolstering techniques. It has been suggested that NPWT offers all of the advantage of standard bolstering in addition to other advantages such as active fluid removal and easier patient mobilization (Runkel 2011).

NPWT systems are FDA approved for use in patients with chronic, acute, traumatic, subacute and dehiscent wounds, partial thickness burns, ulcers, flaps, and grafts. The device is contraindicated for use in wounds with exposed vital structures, devitalized tissue, malignant tissue, untreated osteomyelitis, or in patients with untreated coagulopathy or allergy to any component required for the procedure (AHRQ 2009). NPWT was reviewed by MTAC in 1999, 2003, and 2008 for the management of chronic wounds and did not meet MTAC evaluation criteria. It is being re-reviewed for a new indication.

Vacuum Assisted Closure for the Treatment of Wounds

02/10/1999: MTAC REVIEW

Evidence Conclusion: The efficacy of the VST cannot be determined from the combination of these widely disparate studies/case series because of the widely heterogeneous samples, varying methods and application of the technique; small sample sizes, possible selection and observation bias, and the absence of comparison groups. In addition, there are a number of unresolved issues surrounding this technique, including but not limited to:

- which wounds are ideally suited for the application of this technique;
- the optimal conditions in which the technique can/should be applied;
- the ideal pressure required;
- ideal delivery of the negative pressure, e.g., by vacuum pump or bottle;
- when the wound dressing should be applied.

Further studies, preferably blinded, randomized control trials are warranted to determine the efficacy of this technique/device.

Articles: Articles were selected based on study type. There was one prospective clinical trial (Mullner et al, 1997), no meta-analyses or cohort studies, and a few case series. An evidence table for the clinical trial. No evidence tables were created for the case series, as the sample sizes were either too small, or the not described in sufficient detail. Case series were reviewed by abstract, and a brief summary of their findings is included. Mullner T, Mrkonjic L, Kwasny O, Vecsei V. The use of negative pressure to promote the healing of tissue defects: a clinical trial using the vacuum sealing technique. *British Journal of Plastic Surgery* 1997 Apr;50(3):194-9. See [Evidence Table](#).

The use of Vacuum Assisted Closure for the treatment of wounds to promote healing does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Vacuum Assisted Closure in the Treatment of Non-Healing Wounds

08/13/2003: MTAC REVIEW

Evidence Conclusion: The best evidence on VAC consists of two RCTs, each with fewer than 30 patients. Both are limited by their small sample sizes which makes selection bias likely and results in low statistical power. The two studies had different findings. Ford found no significant differences in wound healing between VAC and gel. Joseph found a statistically significant greater reduction in wound volume, width and depth with VAC compared to traditional saline wet-to-moist (WM) dressings. Joseph had the stronger methodology—more complete follow-up and consistency between the unit of randomization and the unit of analysis. Although the Joseph RCT suggests that VAC may be superior to traditional WM dressings, additional research is needed with larger sample sizes and consideration of potential selection bias/confounding.

Articles: The search yielded 144 articles. Many of these were review articles, opinion pieces, dealt with technical aspects of wound closure techniques or were on related procedures. There were two small randomized controlled trials using the VAC system. No non-randomized comparative studies were identified. The two RCTs were critically appraised. Ford CN, Reinhard ER, Yeh D. et al. Interim analysis of a prospective, randomized trial of Vacuum-Assisted Closure versus the Healthpoint System in the management of pressure ulcers. *Ann Plast Surg* 2002; 49: 55-61. See [Evidence Table](#). Joseph E, Hamori CA, Bergman S. A prospective, randomized trial of vacuum-assisted closure versus standard therapy of chronic non-healing wounds. *Wounds* 2000; 12: 60-67. See [Evidence Table](#).

The use of vacuum assisted closure in the treatment of non-healing wounds does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

04/06/2009: MTAC REVIEW

Vacuum Assisted Closure in the treatment of Non-Healing Wounds

Evidence Conclusion: There is a lack of high quality randomized controlled trials on the use of negative pressure therapy for wound healing. The best published clinical evidence consists of few RCTs with flawed methodology. The majority of the studies were small, had inadequate power to detect differences between treatment groups, were unblinded, and had little or no information on the baseline characteristics of the

participants, or causes of dropouts. The trials mainly used surrogate outcomes as reduction in wound size and formation of granulation tissue, rather than complete healing of the ulcer. The largest published trial to date (Blume et al, 2008) randomized 341 patients with diabetic foot ulcers to receive negative pressure wound therapy (NPWT) or advanced moist wound therapy (AMWT). All participants in the two groups also underwent wound debridement and off-loading. The results of the trial showed a significantly higher rate of complete ulcer closure in the patients receiving NPWT vs. AMWTs. The study was randomized and controlled; however, it had several limitations including unblinding of the patients and physicians which is a potential source of bias as it could influence the patient motivation and the care provided. Patients were treated at home or in a hospital setting and there is no indication whether they were given the same care and therapy e.g. equal pressure relief, intermittent or continuous negative atmospheric pressure, debridement, antibiotics, and other potentially confounding factors. Moreover, the study had a high drop-out rate and was financially supported by the manufacturer of the device. **Conclusions:** There is insufficient published evidence to date to determine whether topical negative pressure therapy is more effective than alternative wound dressings as regards rate of healing, pain management and quality of life. There is insufficient published evidence to date to determine that topical negative pressure therapy is safe to use in patients with acute or chronic wounds.

Articles: The search yielded over 300 articles on negative pressure wound therapy. Many were review articles, opinion pieces, dealt with technical aspects of wound closure techniques, or were unrelated to the current review. There were four systematic reviews with or without meta-analyses, four RCTs, and a number of case series published after the last MTAC review of the technology. Gregor et al's 2008 review included both randomized and non-randomized trials but pooled the results of each group of studies for only one surrogate outcome. In two Cochrane reviews (Ubbink 2008, Wasiak 2007), the authors could not pool the results in meta-analyses due to the small number of studies, poor reporting, heterogeneity in endpoints and comparator treatments. Another published meta-analysis (Sadat et al, 2008) included two small negative trials (total of 70 participants) on the use of VAC for various types of ulcers, and one positive larger trial (N= 162) on its use after diabetic foot amputation, which skewed the results of the meta-analysis. Only one RCT (Blume 2008) had clinically important outcomes, relatively large sample size, and generally valid methodology. Both the review with a meta-analysis as well as the RCT with generally valid methodology were selected for critical appraisal: Gregor S, Maegele M, Sauerland S, et al. Negative pressure wound therapy. A vacuum of evidence? Arch Surg 2008; 143:189-196. See [Evidence Table](#).

Blume PA, Ayala J, Walters J, et al. Comparison of negative pressure wound therapy using vacuum-assisted closure with advanced moist wound therapy in the treatment of diabetic foot ulcers. A multicenter randomized controlled trial. Diabetes Care 2008;31: 631-636. See [Evidence Table](#).

The use of vacuum assisted closure in the treatment of non-healing wounds does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Negative Pressure Wound Therapy in the Treatment of Skin Grafts and Flaps

12/19/2011: MTAC REVIEW

Evidence Conclusion: An RCT that included 60 subjects with acute traumatic injuries and skin loss evaluated the effectiveness of NPWT compared to dressings without NPWT. Results from this study suggest that NPWT may lead to less graft loss, less frequent regrafting, and reduced time from patient intervention to discharge compared to with dressings without NPWT (Llanos 2006).

	NPWT	Control	P-value
	Median (range)		
Loss of grafted area (cm ²)	0.0 (0-12)	4.5 (0-53)	0.001
Percentage of graft loss	0.0 (0-62)	12.8 (0-76)	<0.001
Days from grafting to discharge	8 (7-13)	12 (7-23)	0.001
	Number (%)		
Need for 2 nd coverage procedure	5 (16.7)	12 (40.0)	0.045

Conclusion: There is some evidence to support the use of NPWT as a splint or bolster for skin grafts.

Articles: NPWT for skin grafts or skin substitutes was reviewed in 2010 by NHS Quality Improvement Scotland (NHS QIS). This review found some evidence to support the use of NPWT for wounds caused by burns or trauma that require a skin graft as treatment and certain types of venous leg ulcers with split-thickness pinch skin graft. The recommendations from NHS QIS were based on evidence from two high-quality and two low-quality randomized controlled trials (RCTs) as well as several observational studies (NHS QIS 2010). Since the NHS QIS review, the literature search revealed two additional RCTs that evaluated the safety and efficacy of NPWT for skin grafts or skin substitutes. These studies were not selected for review due to methodological limitations (i.e., small

sample size, high loss to follow-up, etc.) (Chio 2010, Petkar 2011). One of the high-quality trials evaluating the use of NPWT was not used for bolstering and therefore was not selected for review (Vuerstaek 2006). The other high-quality trial included in the NIH QIS was selected for review. The following study was selected for critical appraisal:

Llanos S, Danilla S, Barraza C, et al. Effectiveness of negative pressure closure in the integration of split thickness skin grafts. *Ann Surg.* 2006; 244:700-705. See [Evidence Table](#).

The use of negative pressure wound therapy in the treatment of skin grafts and flaps does meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

SNAP & PICO Device

02/09/2015: MTAC REVIEW

Evidence Conclusion: First and foremost, it should be established that there is a lack of evidence to support the general use of NPWT. Previous MTAC critical appraisals have cited a lack of high-quality RCTs evaluating the use of NPWT for wound healing. To date, the best published clinical evidence consists of a few RCTs with flawed methodology due to limitations such as small sample size and inadequate power. Generally speaking, NPWT has been applied to a wide variety of wounds in varying locations, complexity and underlying pathology limiting the ability to make comparisons across studies. This limitation is demonstrated in a various systematic reviews with attempted meta-analyses that have failed to reach any definitive conclusions due to variable endpoints (Mendonca, Papini et al. 2006; Pham, Middleton et al. 2006; Sjögren, Malmjö et al. 2006; Kanakaris, Thanasis et al. 2007; Wasiak and Cleland 2007; Bovill, Banwell et al. 2008; Group 2008; Noble-Bell and Forbes 2008; Ubbink, Westerbos et al. 2008; Ubbink, Westerbos et al. 2008; Dumville, Hinchliffe et al. 2013). **Effectiveness:** In 2011 and 2012, Armstrong and colleagues published an interim and final analysis with the overall aim of comparing NPWT with an ultraportable mechanically powered device with a traditional electrically powered device. Overall, the study enrolled 132 patients with lower-extremity diabetic and venous wounds. The primary outcome measurement was wound size reduction, however, data assessing the time for dressing change and user experience was also collected. The primary end point results indicated that the SNaP treated subjects were non-inferior to the VAC-treated patients at all follow-up points 4, 8, 12 and 16 weeks (p-value of 0.0054, 0.0047, <0.0001, and <0.0001, respectively). Exit surveys addressing quality of life (QoL) and activity were completed by 105 patients (79.5%) with the SNaP group consistently reporting less impact on activities such as sleep, mobility and socializing. Patient reporting of pain and discomfort associated with treatment, however, was similar in both groups with no statistical difference (Armstrong, Marston et al. 2011; Armstrong, Marston et al. 2012). [Evidence Table 1] **Safety:** In terms of safety, device related adverse events (AE) were similar in both groups with maceration being the most commonly reported complication. The investigators ultimately concluded that the treatment of wounds with a mechanically powered NPWT device resulted in similar wound healing outcomes as treatment with a traditional, electrically powered, NPWT device with less impact on the patient's quality of life. The evidence is limited by a variety of factors most notably, the use of an inadequate comparator. While NPWT is widely used, the current body of evidence is limited in supporting its effectiveness in promoting wound healing. Beyond that, limitations of the study's methodology include small sample size, as well as significant differences between groups in terms of wound size and age prior to treatment. Finally, it should be noted that the study was sponsored by Spiracur, Inc. the manufacturers of the SNaP® device. In addition, two of the investigators, Armstrong and Marston, have received research funding from both Spiracur and K.C.I. **Conclusions:** There is insufficient evidence to support the safety of the non-powered NPWT devices for treatment of patients with wounds. There is insufficient evidence to support the effectiveness of the non-powered NPWT devices for treatment of patients with wounds.

Articles: The literature search revealed a variety of articles relating to the general use of NPWT. Only a few articles were directly related to the use of non-powered or non-electrically powered NPWT devices including a small pilot trial (n=30) of the effect of the PICO device on surgical wound healing in patients with Crohn's disease (Pellino, Sciaudone et al. 2014), a small case series (n=20) describing experience with the PICO device (Hudson, Adams et al. 2013), and a small retrospective case-control study (n=78) comparing the SNaP™ device to a variety of other wound therapies (Lerman, Oldenbrook et al. 2010). There were no randomized control trials (RCTs) identified that compared non-powered/electrical NPWT to conventional wound care. Two publications were revealed that presented the interim and final results of a small RCT comparing the SNaP device with a standard powered VAC (Armstrong, Marston et al. 2011; Armstrong, Marston et al. 2012). The following articles were selected for critical appraisal: Armstrong DG, Marston WA, Reyzelman AM et al. Comparison of negative pressure wound therapy with an ultraportable mechanically powered device vs. traditional electrically powered device for the treatment of chronic lower extremity ulcers: A multicenter randomized-controlled trial. *Wound Rep Reg.* 2011; 19(2):173-180. [Evidence Table 1](#). Armstrong DG, Marston WA, Reyzelman AM et al. Comparative effectiveness of mechanically and electrically powered negative pressure wound therapy devices: a multicenter randomized controlled trial. 2012;20(3):332-341. [Evidence Table 1](#)

The use of SNAP & PICO device in the treatment of negative wound pressure therapy does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

10/14/2019: MTAC REVIEW

Evidence Conclusion:

- There is low-moderate quality evidence from a single open-label RCT suggesting that s-NPWT is superior to the traditional NPWT in treating venous leg ulcers (VLUs), or diabetic foot ulcers (DFUs) as regards reducing the wound area, and the ulcer depth and volume as well as time to complete closure in highly selected patients with chronic lower extremity ulcers.
- Low quality evidence from a sub-analysis of one open-label RCT suggests that SNaP may be superior to the traditional NPWT as regards wound size reduction and 50% wound closure when used in a highly selected group of patients with venous leg ulcers.
- There is insufficient evidence to determine the safety of the single use NPWT in patients with lower extremity chronic wounds.

Articles: The literature search for studies on single use NPWT published after the last MTAC review of the technology, revealed one RCT that directly compared the efficacy of PICO versus traditional NPWT in the treatment of chronic ulcers in the lower extremities, and another RCT that compared a single use mechanically powered SNaP Wound Care System versus a traditional NPWT system for the management of venous leg ulcers. The rest of the published studies that evaluated the single use NPWT were either observational studies or RCTs that compared the devices versus conventional wound dressing (such as sterile gauze dressing, absorbent dressings, and silver-impregnated occlusive dressings). The results of these studies were pooled in five meta-analyses (MAs) identified by the search; three of which (Semsarzadeh et al, 2015, Watts et al, 2015, and De Vries et al, 2016) compared the outcomes of NPWT (t-NPWT and s-NPWT combined) versus conventional wound care. One MA (Strugala and Martin 2017); evaluated the effect of s-NPWT versus traditional dressing on the prevention of surgical site complications. and another (Singh et al, 2018) compared the effect of closed incision NPT (using PRAVENA system) also versus traditional dressing on reducing surgical site infections.

The following two RCTs that compared the single use NPWT versus the traditional NPWT were selected for critical appraisal. None of the identified meta-analyses or the trials comparing the single use NPWT versus conventional/standard wound care was included as the aim of the current review is to compare the single use NPWT versus the traditional NPWT. See [Evidence Table](#).

The use of SNAP & PICO device in the treatment of negative wound pressure therapy does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

tNPWT - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

HPCPC Codes	Description
A6550	Wound care set, for negative pressure wound therapy electrical pump, includes all supplies and accessories
A7000	Canister, disposable, used with suction pump, each
E2402	Negative pressure wound therapy electrical pump, stationary or portable
K0743	Suction pump, home model, portable, for use on wounds
K0744	Absorptive wound dressing for use with suction pump, home model, portable, pad size 16 sq. in or less
K0745	Absorptive wound dressing for use with suction pump, home model, portable, pad size more than 16 sq. in but less than or equal to 48 sq. in
K0746	Absorptive wound dressing for use with suction pump, home model, portable, pad size greater than 48 sq. in

Disposable NPWT (including, but not limited to: SNAP, Prevena, V.A.C. VIA) - Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

*not covered by Medicare

CPT/HCPC Codes	Description
97607	Negative pressure wound therapy, (e.g., vacuum assisted drainage collection), utilizing disposable, non-durable medical equipment including provision of exudate management collection system, topical application(s), wound assessment, and instructions for ongoing care, per session; total wound(s) surface area less than or equal to 50 square centimeters
97608	Negative pressure wound therapy, (e.g., vacuum assisted drainage collection), utilizing disposable, non-durable medical equipment including provision of exudate management collection system, topical application(s), wound assessment, and instructions for ongoing care, per session; total wound(s) surface area greater than 50 square centimeters
A9272*	Wound suction, disposable, includes dressing, all accessories and components, any type, each

PICO - Considered Not Medically Necessary:

*not covered by Medicare

CPT/HCPC Codes	Description
97607	Negative pressure wound therapy, (e.g., vacuum assisted drainage collection), utilizing disposable, non-durable medical equipment including provision of exudate management collection system, topical application(s), wound assessment, and instructions for ongoing care, per session; total wound(s) surface area less than or equal to 50 square centimeters
97608	Negative pressure wound therapy, (e.g., vacuum assisted drainage collection), utilizing disposable, non-durable medical equipment including provision of exudate management collection system, topical application(s), wound assessment, and instructions for ongoing care, per session; total wound(s) surface area greater than 50 square centimeters
A9272*	Wound suction, disposable, includes dressing, all accessories and components, any type, each

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

**To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).

^{MDCRPC} Medical Director Clinical Review and Policy Committee

^{MPC} Medical Policy Committee

Revision History	Description
10/26/2015	Changed codes for PICO and SNAP
06/02/2015	Codes Added
09/18/2017	Removed the requirement for Hemoglobin and Hematocrit
09/27/2017	Added LCA and MLN Matters Article
03/03/2020	MPC approved to adopt coverage policy for SNAP; Added October 2019 MTAC Review
04/07/2020	MPC approved to adopt new coverage criteria for SNAP
03/01/2022	MPC approved to adopt coverage criteria for dNPWT for SSI Prevention. 60-day notice required; effective 08/01/2022.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

New and Emerging Medical Technologies and Procedures

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

The following are new and emerging medical technologies which are considered to have unproven benefit because the current scientific evidence is not yet sufficient to establish the impact of these technologies on health outcomes:

CPT® Codes	Description
98975	Remote therapeutic monitoring (eg, respiratory system status, musculoskeletal system status, therapy adherence, therapy response); initial set-up and patient education on use of equipment
98976	Remote therapeutic monitoring (eg, respiratory system status, musculoskeletal system status, therapy adherence, therapy response); device(s) supply with scheduled (eg, daily) recording(s) and/or programmed alert(s) transmission to monitor respiratory system, each 30 days
98977	Remote therapeutic monitoring (eg, respiratory system status, musculoskeletal system status, therapy adherence, therapy response); device(s) supply with scheduled (eg, daily) recording(s) and/or programmed alert(s) transmission to monitor musculoskeletal system, each 30 days
98980	Remote therapeutic monitoring treatment management services, physician or other qualified health care professional time in a calendar month requiring at least one interactive communication with the patient or caregiver during the calendar month; first 20 minutes
98981	Remote therapeutic monitoring treatment management services, physician or other qualified health care professional time in a calendar month requiring at least one interactive communication with the patient or caregiver during the calendar month; each additional 20 minutes (List separately in addition to code for primary procedure)
0014M	Liver disease, analysis of 3 biomarkers (hyaluronic acid [HA], procollagen III amino terminal peptide [PIIINP], tissue inhibitor of metalloproteinase 1 [TIMP-1]), using immunoassays, utilizing serum, prognostic algorithm reported as a risk score and risk of liver fibrosis and liver-related clinical events within 5 years
0015M	Adrenal cortical tumor, biochemical assay of 25 steroid markers, utilizing 24-hour urine specimen and clinical parameters, prognostic algorithm reported as a clinical risk and integrated clinical steroid risk for adrenal cortical carcinoma, adenoma, or other adrenal malignancy
0016M	Oncology (bladder), mRNA, microarray gene expression profiling of 209 genes, utilizing formalin-fixed paraffin-embedded tissue, algorithm reported as molecular subtype (luminal, luminal infiltrated, basal, basal claudin-low, neuroendocrine-like)
0163U	Oncology (colorectal) screening, biochemical enzyme-linked immunosorbent assay (ELISA) of 3 plasma or serum proteins (teratocarcinoma derived growth factor-1 [TDGF-1, Cripto-1], carcinoembryonic antigen [CEA], extracellular matrix protein [ECM]), with demographic data (age, gender, CRC-screening compliance) using a proprietary algorithm and reported as likelihood of CRC or advanced adenomas
0164U	Gastroenterology (irritable bowel syndrome [IBS]), immunoassay for anti-CdtB and anti-vinculin antibodies, utilizing plasma, algorithm for elevated or not elevated qualitative results
0165U	Peanut allergen-specific quantitative assessment of multiple epitopes using enzyme-linked

	immunosorbent assay (ELISA), blood, individual epitope results and probability of peanut allergy
0166U	Liver disease, 10 biochemical assays (a2-macroglobulin, haptoglobin, apolipoprotein A1, bilirubin, GGT, ALT, AST, triglycerides, cholesterol, fasting glucose) and biometric and demographic data, utilizing serum, algorithm reported as scores for fibrosis, necroinflammatory activity, and steatosis with a summary interpretation
0167U	Gonadotropin, chorionic (hCG), immunoassay with direct optical observation, blood
0168U	Fetal aneuploidy (trisomy 21, 18, and 13) DNA sequence analysis of selected regions using maternal plasma without fetal fraction cutoff, algorithm reported as a risk score for each trisomy
0169U	NUDT15 (nudix hydrolase 15) and TPMT (thiopurine S-methyltransferase) (eg, drug metabolism) gene analysis, common variants
0170U	Neurology (autism spectrum disorder [ASD]), RNA, next-generation sequencing, saliva, algorithmic analysis, and results reported as predictive probability of ASD diagnosis
0171U	Targeted genomic sequence analysis panel, acute myeloid leukemia, myelodysplastic syndrome, and myeloproliferative neoplasms, DNA analysis, 23 genes, interrogation for sequence variants, rearrangements and minimal residual disease, reported as presence/absence
0173U	Psychiatry (ie, depression, anxiety), genomic analysis panel, includes variant analysis of 14 genes
0174U	Oncology (solid tumor), mass spectrometric 30 protein targets, formalin-fixed paraffin-embedded tissue, prognostic and predictive algorithm reported as likely, unlikely, or uncertain benefit of 39 chemotherapy and targeted therapeutic oncology agents
0175U	Psychiatry (eg, depression, anxiety), genomic analysis panel, variant analysis of 15 genes
0176U	Cytotoxicity (eg, depression, anxiety), genomic analysis panel, variant analysis of 15 genes
0177U	Oncology (breast cancer), DNA, PIK3CA (phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha) gene analysis of 11 gene variants utilizing plasma, reported as PIK3CA gene mutation status
0178U	Peanut allergen-specific quantitative assessment of multiple epitopes using enzyme-linked immunosorbent assay (ELISA), blood, report of minimum eliciting exposure for a clinical reaction
0179U	Oncology (non-small cell lung cancer), cell-free DNA, targeted sequence analysis of 23 genes (single nucleotide variations, insertions and deletions, fusions without prior knowledge of partner/breakpoint, copy number variations), with report of significant mutation(s)
0180U	Red cell antigen (ABO blood group) genotyping (ABO), gene analysis Sanger/chain termination/conventional sequencing, ABO (ABO, alpha 1-3-N-acetylgalactosaminyltransferase and alpha 1-3-galactosyltransferase) gene, including subtyping, 7 exons
0181U	Red cell antigen (Colton blood group) genotyping (CO), gene analysis, AQP1 (aquaporin 1 [Colton blood group]) exon 1
0182U	Red cell antigen (Cromer blood group) genotyping (CROM), gene analysis, CD55 (CD55 molecule [Cromer blood group]) exons 1-10
0183U	Red cell antigen (Diego blood group) genotyping (DI), gene analysis, SLC4A1 (solute carrier family 4 member 1 [Diego blood group]) exon 19
0184U	Red cell antigen (Dombrock blood group) genotyping (DO), gene analysis, ART4 (ADP-ribosyltransferase 4 [Dombrock blood group]) exon 2
0185U	Red cell antigen (H blood group) genotyping (FUT1), gene analysis, FUT1 (fucosyltransferase 1 [H blood group]) exon 4
0186U	Red cell antigen (H blood group) genotyping (FUT2), gene analysis, FUT2 (fucosyltransferase 2) exon 2
0187U	Red cell antigen (Duffy blood group) genotyping (FY), gene analysis, ACKR1 (atypical chemokine receptor 1 [Duffy blood group]) exons 1-2
0188U	Red cell antigen (Gerbich blood group) genotyping (GE), gene analysis, GYPC (glycophorin C [Gerbich blood group]) exons 1-4
0189U	Red cell antigen (MNS blood group) genotyping (GYPA), gene analysis, GYPA (glycophorin A [MNS blood group]) introns 1, 5, exon 2
0190U	Red cell antigen (MNS blood group) genotyping (GYPB), gene analysis, GYPB (glycophorin B [MNS blood group]) introns 1, 5, pseudoexon 3
0191U	Red cell antigen (Indian blood group) genotyping (IN), gene analysis, CD44 (CD44 molecule [Indian blood group]) exons 2, 3, 6
0192U	Red cell antigen (Kidd blood group) genotyping (JK), gene analysis, SLC14A1 (solute carrier family 14 member 1 [Kidd blood group]) gene promoter, exon 9

0193U	Red cell antigen (JR blood group) genotyping (JR), gene analysis, ABCG2 (ATP binding cassette subfamily G member 2 [Junior blood group]) exons 2-26
0194U	Red cell antigen (Kell blood group) genotyping (KEL), gene analysis, KEL (Kell metallo-endopeptidase [Kell blood group]) exon 8
0195U	KLF1 (Kruppel-like factor 1), targeted sequencing (ie, exon 13)
0196U	Red cell antigen (Lutheran blood group) genotyping (LU), gene analysis, BCAM (basal cell adhesion molecule [Lutheran blood group]) exon 3
0197U	Red cell antigen (Landsteiner-Wiener blood group) genotyping (LW), gene analysis, ICAM4 (intercellular adhesion molecule 4 [Landsteiner-Wiener blood group]) exon 1
0198U	Red cell antigen (RH blood group) genotyping (RHD and RHCE), gene analysis Sanger/chain termination/conventional sequencing, RHD (Rh blood group D antigen) exons 1-10 and RHCE (Rh blood group CcEe antigens) exon 5
0199U	Red cell antigen (Scianna blood group) genotyping (SC), gene analysis, ERMAP (erythroblast membrane associated protein [Scianna blood group]) exons 4, 12
0200U	Red cell antigen (Kx blood group) genotyping (XK), gene analysis, XK (X-linked Kx blood group) exons 1-3
0201U	Red cell antigen (Yt blood group) genotyping (YT), gene analysis, ACHE (acetylcholinesterase [Cartwright blood group]) exon 2
0203U	Autoimmune (inflammatory bowel disease), mRNA, gene expression profiling by quantitative RT-PCR, 17 genes (15 target and 2 reference genes), whole blood, reported as a continuous risk score and classification of inflammatory bowel disease aggressiveness
0204U	Oncology (thyroid), mRNA, gene expression analysis of 593 genes (including BRAF, RAS, RET, PAX8, and NTRK) for sequence variants and rearrangements, utilizing fine needle aspirate, reported as detected or not detected
0205U	Ophthalmology (age-related macular degeneration), analysis of 3 gene variants (2 CFH gene, 1 ARMS2 gene), using PCR and MALDI-TOF, buccal swab, reported as positive or negative for neovascular age-related macular-degeneration risk associated with zinc supplements
0206U	Neurology (Alzheimer disease); cell aggregation using morphometric imaging and protein kinase C-epsilon (PKCe) concentration in response to amylospheroid treatment by ELISA, cultured skin fibroblasts, each reported as positive or negative for Alzheimer disease
0207U	Neurology (Alzheimer disease); quantitative imaging of phosphorylated ERK1 and ERK2 in response to bradykinin treatment by in situ immunofluorescence, using cultured skin fibroblasts, reported as a probability index for Alzheimer disease (List separately in addition to code for primary procedure)
0208U	Oncology (medullary thyroid carcinoma), mRNA, gene expression analysis of 108 genes, utilizing fine needle aspirate, algorithm reported as positive or negative for medullary thyroid carcinoma
0209U	Cytogenomic constitutional (genome-wide) analysis, interrogation of genomic regions for copy number, structural changes and areas of homozygosity for chromosomal abnormalities
0210U	Syphilis test, non-treponemal antibody, immunoassay, quantitative (RPR)
0211U	Oncology (pan-tumor), DNA and RNA by next-generation sequencing, utilizing formalin-fixed paraffin-embedded tissue, interpretative report for single nucleotide variants, copy number alterations, tumor mutational burden, and microsatellite instability, with therapy association
0212U	Rare diseases (constitutional/heritable disorders), whole genome and mitochondrial DNA sequence analysis, including small sequence changes, deletions, duplications, short tandem repeat gene expansions, and variants in non-uniquely mappable regions, blood or saliva, identification and categorization of genetic variants, proband
0213U	Rare diseases (constitutional/heritable disorders), whole genome and mitochondrial DNA sequence analysis, including small sequence changes, deletions, duplications, short tandem repeat gene expansions, and variants in non-uniquely mappable regions, blood or saliva, identification and categorization of genetic variants, each comparator genome (eg, parent, sibling)
0214U	Rare diseases (constitutional/heritable disorders), whole exome and mitochondrial DNA sequence analysis, including small sequence changes, deletions, duplications, short tandem repeat gene expansions, and variants in non-uniquely mappable regions, blood or saliva, identification and categorization of genetic variants, proband
0215U	Rare diseases (constitutional/heritable disorders), whole exome and mitochondrial DNA sequence analysis, including small sequence changes, deletions, duplications, short tandem repeat gene expansions, and variants in non-uniquely mappable regions, blood or saliva,

	identification and categorization of genetic variants, each comparator exome (eg, parent, sibling)
0216U	Neurology (inherited ataxias), genomic DNA sequence analysis of 12 common genes including small sequence changes, deletions, duplications, short tandem repeat gene expansions, and variants in non-uniquely mappable regions, blood or saliva, identification and categorization of genetic variants
0217U	Neurology (inherited ataxias), genomic DNA sequence analysis of 51 genes including small sequence changes, deletions, duplications, short tandem repeat gene expansions, and variants in non-uniquely mappable regions, blood or saliva, identification and categorization of genetic variants
0218U	Neurology (muscular dystrophy), DMD gene sequence analysis, including small sequence changes, deletions, duplications, and variants in non-uniquely mappable regions, blood or saliva, identification and characterization of genetic variants
0219U	Infectious agent (human immunodeficiency virus), targeted viral next-generation sequence analysis (ie, protease [PR], reverse transcriptase [RT], integrase [INT]), algorithm reported as prediction of antiviral drug susceptibility
0220U	Oncology (breast cancer), image analysis with artificial intelligence assessment of 12 histologic and immunohistochemical features, reported as a recurrence score
0221U	Red cell antigen (ABO blood group) genotyping (ABO), gene analysis, next-generation sequencing, ABO (ABO, alpha 1-3-N-acetylgalactosaminyltransferase and alpha 1-3-galactosyltransferase) gene
0222U	Red cell antigen (RH blood group) genotyping (RHD and RHCE), gene analysis, next-generation sequencing, RH proximal promoter, exons 1-10, portions of introns 2-3
0243U	Obstetrics (preeclampsia), biochemical assay of placental-growth factor, time-resolved fluorescence immunoassay, maternal serum, predictive algorithm reported as a risk score for preeclampsia
0244U	Oncology (solid organ), DNA, comprehensive genomic profiling, 257 genes, interrogation for single-nucleotide variants, insertions/deletions, copy number alterations, gene rearrangements, tumor-mutational burden and microsatellite instability, utilizing formalin-fixed paraffin-embedded tumor tissue
0246U	Red blood cell antigen typing, DNA, genotyping of at least 16 blood groups with phenotype prediction of at least 51 red blood cell antigens
0247U	Obstetrics (preterm birth), insulin-like growth factor-binding protein 4 (IBP4), sex hormone-binding globulin (SHBG), quantitative measurement by LC-MS/MS, utilizing maternal serum, combined with clinical data, reported as predictive-risk stratification for spontaneous preterm birth
0248U	Oncology (brain), spheroid cell culture in a 3D microenvironment, 12 drug panel, tumor-response prediction for each drug
0249U	Oncology (breast), semiquantitative analysis of 32 phosphoproteins and protein analytes, includes laser capture microdissection, with algorithmic analysis and interpretative report
0250U	Oncology (solid organ neoplasm), targeted genomic sequence DNA analysis of 505 genes, interrogation for somatic alterations (SNVs [single nucleotide variant], small insertions and deletions, one amplification, and four translocations), microsatellite instability and tumor-mutation burden
0251U	Hepcidin-25, enzyme-linked immunosorbent assay (ELISA), serum or plasma
0252U	Fetal aneuploidy short tandem-repeat comparative analysis, fetal DNA from products of conception, reported as normal (euploidy), monosomy, trisomy, or partial deletion/duplications, mosaicism, and segmental aneuploidy
0253U	Reproductive medicine (endometrial receptivity analysis), RNA gene expression profile, 238 genes by next-generation sequencing, endometrial tissue, predictive algorithm reported as endometrial window of implantation (eg, pre-receptive, receptive, post-receptive)
0254U	Reproductive medicine (preimplantation genetic assessment), analysis of 24 chromosomes using embryonic DNA genomic sequence analysis for aneuploidy, and a mitochondrial DNA score in euploid embryos, results reported as normal (euploidy), monosomy, trisomy, or partial deletion/duplications, mosaicism, and segmental aneuploidy, per embryo tested
0594T	Osteotomy, humerus, with insertion of an externally controlled intramedullary lengthening device, including intraoperative imaging, initial and subsequent alignment assessments, computations of adjustment schedules, and management of the intramedullary lengthening device
0596T	Temporary female intraurethral valve-pump (ie, voiding prosthesis); initial insertion, including

	urethral measurement
0597T	Temporary female intraurethral valve-pump (ie, voiding prosthesis); replacement
0598T	Noncontact real-time fluorescence wound imaging, for bacterial presence, location, and load, per session; first anatomic site (eg, lower extremity)
0599T	Noncontact real-time fluorescence wound imaging, for bacterial presence, location, and load, per session; each additional anatomic site (eg, upper extremity) (List separately in addition to code for primary procedure)
0600T	Ablation, irreversible electroporation; 1 or more tumors per organ, including imaging guidance, when performed, percutaneous
0601T	Ablation, irreversible electroporation; 1 or more tumors, including fluoroscopic and ultrasound guidance, when performed, open
0602T	Glomerular filtration rate (GFR) measurement(s), transdermal, including sensor placement and administration of a single dose of fluorescent pyrazine agent
0603T	Glomerular filtration rate (GFR) monitoring, transdermal, including sensor placement and administration of more than one dose of fluorescent pyrazine agent, each 24 hours
0604T	Optical coherence tomography (OCT) of retina, remote, patient-initiated image capture and transmission to a remote surveillance center unilateral or bilateral; initial device provision, set-up and patient education on use of equipment
0605T	Optical coherence tomography (OCT) of retina, remote, patient-initiated image capture and transmission to a remote surveillance center unilateral or bilateral; remote surveillance center technical support, data analyses and reports, with a minimum of 8 daily recordings, each 30 days
0606T	Optical coherence tomography (OCT) of retina, remote, patient-initiated image capture and transmission to a remote surveillance center unilateral or bilateral; review, interpretation and report by the prescribing physician or other qualified health care professional of remote surveillance center data analyses, each 30 days
0607T	Remote monitoring of an external continuous pulmonary fluid monitoring system, including measurement of radiofrequency-derived pulmonary fluid levels, heart rate, respiration rate, activity, posture, and cardiovascular rhythm (eg, ECG data), transmitted to a remote 24-hour attended surveillance center; set-up and patient education on use of equipment
0608T	Remote monitoring of an external continuous pulmonary fluid monitoring system, including measurement of radiofrequency-derived pulmonary fluid levels, heart rate, respiration rate, activity, posture, and cardiovascular rhythm (eg, ECG data), transmitted to a remote 24-hour attended surveillance center; analysis of data received and transmission of reports to the physician or other qualified health care professional
0609T	Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); acquisition of single voxel data, per disc, on biomarkers (ie, lactic acid, carbohydrate, alanine, laal, propionic acid, proteoglycan, and collagen) in at least 3 discs
0610T	Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); transmission of biomarker data for software analysis
0611T	Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); postprocessing for algorithmic analysis of biomarker data for determination of relative chemical differences between discs
0612T	Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); interpretation and report
0613T	Percutaneous transcatheter implantation of interatrial septal shunt device, including right and left heart catheterization, intracardiac echocardiography, and imaging guidance by the proceduralist, when performed
0614T	Removal and replacement of substernal implantable defibrillator pulse generator
0615T	Eye-movement analysis without spatial calibration, with interpretation and report
0616T	Insertion of iris prosthesis, including suture fixation and repair or removal of iris, when performed; without removal of crystalline lens or intraocular lens, without insertion of intraocular lens
0617T	Insertion of iris prosthesis, including suture fixation and repair or removal of iris, when performed; with removal of crystalline lens and insertion of intraocular lens
0618T	Insertion of iris prosthesis, including suture fixation and repair or removal of iris, when performed; with secondary intraocular lens placement or intraocular lens exchange
0619T	Cystourethroscopy with transurethral anterior prostate commissurotomy and drug delivery,

	including transrectal ultrasound and fluoroscopy, when performed
0620T	Endovascular venous arterialization, tibial or peroneal vein, with transcatheter placement of intravascular stent graft(s) and closure by any method, including percutaneous or open vascular access, ultrasound guidance for vascular access when performed, all catheterization(s) and intraprocedural roadmapping and imaging guidance necessary to complete the intervention, all associated radiological supervision and interpretation, when performed
0621T	Trabeculectomy ab interno by laser
0622T	Trabeculectomy ab interno by laser; with use of ophthalmic endoscope
0623T	Automated quantification and characterization of coronary atherosclerotic plaque to assess severity of coronary disease, using data from coronary computed tomographic angiography; data preparation and transmission, computerized analysis of data, with review of computerized analysis output to reconcile discordant data, interpretation and report
0624T	Automated quantification and characterization of coronary atherosclerotic plaque to assess severity of coronary disease, using data from coronary computed tomographic angiography; data preparation and transmission
0625T	Automated quantification and characterization of coronary atherosclerotic plaque to assess severity of coronary disease, using data from coronary computed tomographic angiography; computerized analysis of data from coronary computed tomographic angiography
0626T	Automated quantification and characterization of coronary atherosclerotic plaque to assess severity of coronary disease, using data from coronary computed tomographic angiography; review of computerized analysis output to reconcile discordant data, interpretation and report
0627T	Percutaneous injection of allogeneic cellular and/or tissue-based product, intervertebral disc, unilateral or bilateral injection, with fluoroscopic guidance, lumbar; first level
0628T	Percutaneous injection of allogeneic cellular and/or tissue-based product, intervertebral disc, unilateral or bilateral injection, with fluoroscopic guidance, lumbar; each additional level (List separately in addition to code for primary procedure)
0629T	Percutaneous injection of allogeneic cellular and/or tissue-based product, intervertebral disc, unilateral or bilateral injection, with CT guidance, lumbar; first level
0630T	Percutaneous injection of allogeneic cellular and/or tissue-based product, intervertebral disc, unilateral or bilateral injection, with CT guidance, lumbar; each additional level (List separately in addition to code for primary procedure)
0631T	Transcutaneous visible light hyperspectral imaging measurement of oxyhemoglobin, deoxyhemoglobin, and tissue oxygenation, with interpretation and report, per extremity
0632T	Percutaneous transcatheter ultrasound ablation of nerves innervating the pulmonary arteries, including right heart catheterization, pulmonary artery angiography, and all imaging guidance
0633T	Computed tomography, breast, including 3D rendering, when performed, unilateral; without contrast material
0634T	Computed tomography, breast, including 3D rendering, when performed, unilateral; with contrast material(s)
0635T	Computed tomography, breast, including 3D rendering, when performed, unilateral; without contrast, followed by contrast material(s)
0636T	Computed tomography, breast, including 3D rendering, when performed, bilateral; without contrast material(s)
0637T	Computed tomography, breast, including 3D rendering, when performed, bilateral; with contrast material(s)
0638T	Computed tomography, breast, including 3D rendering, when performed, bilateral; without contrast, followed by contrast material(s)
0639T	Wireless skin sensor thermal anisotropy measurement(s) and assessment of flow in cerebrospinal fluid shunt, including ultrasound guidance, when performed
0640T	Noncontact near-infrared spectroscopy studies of flap or wound (eg, for measurement of deoxyhemoglobin, oxyhemoglobin, and ratio of tissue oxygenation [StO2]); image acquisition, interpretation and report, each flap or wound
0641T	Noncontact near-infrared spectroscopy studies of flap or wound (eg, for measurement of deoxyhemoglobin, oxyhemoglobin, and ratio of tissue oxygenation [StO2]); image acquisition only, each flap or wound
0642T	Noncontact near-infrared spectroscopy studies of flap or wound (eg, for measurement of deoxyhemoglobin, oxyhemoglobin, and ratio of tissue oxygenation [StO2]); interpretation and report only, each flap or wound

0643T	Transcatheter left ventricular restoration device implantation including right and left heart catheterization and left ventriculography when performed, arterial approach
0644T	Transcatheter removal or debulking of intracardiac mass (eg, vegetations, thrombus) via suction (eg, vacuum, aspiration) device, percutaneous approach, with intraoperative reinfusion of aspirated blood, including imaging guidance, when performed
0645T	Transcatheter implantation of coronary sinus reduction device including vascular access and closure, right heart catheterization, venous angiography, coronary sinus angiography, imaging guidance, and supervision and interpretation, when performed
0646T	Transcatheter tricuspid valve implantation/replacement (TTVI) with prosthetic valve, percutaneous approach, including right heart catheterization, temporary pacemaker insertion, and selective right ventricular or right atrial angiography, when performed
0647T	Insertion of gastrostomy tube, percutaneous, with magnetic gastropexy, under ultrasound guidance, image documentation and report
0648T	Quantitative magnetic resonance for analysis of tissue composition (eg, fat, iron, water content), including multiparametric data acquisition, data preparation and transmission, interpretation and report, obtained without diagnostic MRI examination of the same anatomy (eg, organ, gland, tissue, target structure) during the same session
0649T	Quantitative magnetic resonance for analysis of tissue composition (eg, fat, iron, water content), including multiparametric data acquisition, data preparation and transmission, interpretation and report, obtained with diagnostic MRI examination of the same anatomy (eg, organ, gland, tissue, target structure) (List separately in addition to code for primary procedure)
0650T	Programming device evaluation (remote) of subcutaneous cardiac rhythm monitor system, with iterative adjustment of the implantable device to test the function of the device and select optimal permanently programmed values with analysis, review and report by a physician or other qualified health care professional
0651T	Magnetically controlled capsule endoscopy, esophagus through stomach, including intraprocedural positioning of capsule, with interpretation and report
0652T	Esophagogastroduodenoscopy, flexible, transnasal; diagnostic, including collection of specimen(s) by brushing or washing, when performed (separate procedure)
0653T	Esophagogastroduodenoscopy, flexible, transnasal; with biopsy, single or multiple
0654T	Esophagogastroduodenoscopy, flexible, transnasal; with insertion of intraluminal tube or catheter
0655T	Transperineal focal laser ablation of malignant prostate tissue, including transrectal imaging guidance, with MR-fused images or other enhanced ultrasound imaging
0656T	Vertebral body tethering, anterior; up to 7 vertebral segments
0657T	Vertebral body tethering, anterior; 8 or more vertebral segments
0658T	Electrical impedance spectroscopy of 1 or more skin lesions for automated melanoma risk score
0659T	Transcatheter intracoronary infusion of supersaturated oxygen in conjunction with percutaneous coronary revascularization during acute myocardial infarction, including catheter placement, imaging guidance (eg, fluoroscopy), angiography, and radiologic supervision and interpretation
0660T	Implantation of anterior segment intraocular nonbiodegradable drug-eluting system, internal approach
0661T	Removal and reimplantation of anterior segment intraocular nonbiodegradable drug-eluting implant
0662T	Scalp cooling, mechanical; initial measurement and calibration of cap
0663T	Scalp cooling, mechanical; placement of device, monitoring, and removal of device (List separately in addition to code for primary procedure)
0664T	Donor hysterectomy (including cold preservation); open, from cadaver donor
0665T	Donor hysterectomy (including cold preservation); open, from living donor
0666T	Donor hysterectomy (including cold preservation); laparoscopic or robotic, from living donor
0667T	Donor hysterectomy (including cold preservation); recipient uterus allograft transplantation from cadaver or living donor
0668T	Backbench standard preparation of cadaver or living donor uterine allograft prior to transplantation, including dissection and removal of surrounding soft tissues and preparation of uterine vein(s) and uterine artery(ies), as necessary
0669T	Backbench reconstruction of cadaver or living donor uterus allograft prior to transplantation; venous anastomosis, each
0670T	Backbench reconstruction of cadaver or living donor uterus allograft prior to transplantation;

	arterial anastomosis, each
HCCP Codes	Description
C1761	Catheter, transluminal intravascular lithotripsy, coronary
C9759	Transcatheter intraoperative blood vessel microinfusion(s) (e.g., intraluminal, vascular wall and/or perivascular) therapy, any vessel, including radiological supervision and interpretation, when performed
C9760	Non-randomized, non-blinded procedure for NYHA class II, III, IV heart failure; transcatheter implantation of interatrial shunt, including right and left heart catheterization, transeptal puncture, transesophageal echocardiography (TEE)/intracardiac echocardiography (ICE), and all imaging with or without guidance (e.g., ultrasound, fluoroscopy), performed in an approved investigational device exemption (IDE) study
C9761	Cystourethroscopy, with ureteroscopy and/or pyeloscopy, with lithotripsy, and ureteral catheterization for steerable vacuum aspiration of the kidney, collecting system, ureter, bladder, and urethra if applicable
C9762	Cardiac magnetic resonance imaging for morphology and function, quantification of segmental dysfunction; with strain imaging
C9763	Cardiac magnetic resonance imaging for morphology and function, quantification of segmental dysfunction; with stress imaging
C9764	Revascularization, endovascular, open or percutaneous, lower extremity artery(ies), except tibial/peroneal; with intravascular lithotripsy, includes angioplasty within the same vessel(s), when performed
C9765	Revascularization, endovascular, open or percutaneous, lower extremity artery(ies), except tibial/peroneal; with intravascular lithotripsy, and transluminal stent placement(s), includes angioplasty within the same vessel(s), when performed
C9766	Revascularization, endovascular, open or percutaneous, lower extremity artery(ies), except tibial/peroneal; with intravascular lithotripsy and atherectomy, includes angioplasty within the same vessel(s), when performed
C9767	Revascularization, endovascular, open or percutaneous, lower extremity artery(ies), except tibial/peroneal; with intravascular lithotripsy and transluminal stent placement(s), and atherectomy, includes angioplasty within the same vessel(s), when performed
C9768	Endoscopic ultrasound-guided direct measurement of hepatic portosystemic pressure gradient by any method (list separately in addition to code for primary procedure)
C9769	Cystourethroscopy, with insertion of temporary prostatic implant/stent with fixation/anchor and incisional struts
C9772	Revascularization, endovascular, open or percutaneous, tibial/peroneal artery(ies), with intravascular lithotripsy, includes angioplasty within the same vessel (s), when performed
C9773	Revascularization, endovascular, open or percutaneous, tibial/peroneal artery(ies); with intravascular lithotripsy, and transluminal stent placement(s), includes angioplasty within the same vessel(s), when performed
C9774	Revascularization, endovascular, open or percutaneous, tibial/peroneal artery(ies); with intravascular lithotripsy and atherectomy, includes angioplasty within the same vessel (s), when performed
C9775	Revascularization, endovascular, open or percutaneous, tibial/peroneal artery(ies); with intravascular lithotripsy and transluminal stent placement(s), and atherectomy, includes angioplasty within the same vessel (s), when performed
C9776	Intraoperative near-infrared fluorescence imaging of major extra-hepatic bile duct(s) (e.g., cystic duct, common bile duct and common hepatic duct) with intravenous administration of indocyanine green (ICG) (list separately in addition to code for primary procedure)
C9777	Esophageal mucosal integrity testing by electrical impedance, transoral (list separately in addition to code for primary procedure)
C9778	Colpopexy, vaginal; minimally invasive extraperitoneal approach (sacrospinous)
G2170	Percutaneous arteriovenous fistula creation (AVF), direct, any site, by tissue approximation using thermal resistance energy, and secondary procedures to redirect blood flow (e.g., transluminal balloon angioplasty, coil embolization) when performed, and includes all imaging and radiologic guidance, supervision and interpretation, when performed
G2171	Percutaneous arteriovenous fistula creation (AVF), direct, any site, using magnetic-guided arterial and venous catheters and radiofrequency energy, including flow-directing procedures

	(e.g., vascular coil embolization with radiologic supervision and interpretation, when performed) and fistulogram(s), angiography, veinography, and/or ultrasound, with radiologic supervision and interpretation, when performed
K1009	Speech volume modulation system, any type, including all components and accessories
K1018	External upper limb tremor stimulator of the peripheral nerves of the wrist
K1019	Monthly supplies for use of device coded at K1018
S1091	Stent, noncoronary, temporary, with delivery system (Propel)

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

^{MPC} Medical Policy Committee

Revision History	Description
07/07/2020	Created document including new codes from 04/2020 and 07/2020.
01/01/2021	Added new codes from 10/2020 and 01/2021.
07/06/2021	Updating applicable coding, including new codes released 04/01/21 and 07/01/2021.
06/15/2022	Updated codes for remote therapeutic monitoring

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Next Generation Sequencing for Advanced Cancer (somatic/tissue testing)

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Next Generation Sequencing (NGS) (90.2)
Local Coverage Determinations (LCD)	9/30/2015 - Noridian retired LCD for Genetic Testing (L24308) . These services still need to meet medical necessity as outlined in the LCD and will require review. LCDs are retired due to lack of evidence of current problems, or in some cases because the material is addressed by a National Coverage Decision (NCD), a coverage provision in a CMS interpretative manual or an LCD. Most LCDs are not retired because they are incorrect. The criteria should be still referenced when making an initial decision. However, if the decision is appealed, the retired LCD cannot be specifically referenced. Maximus instead looks for "medical judgment" which could be based on our commercial criteria or literature search. MolDX: Plasma-Based Genomic Profiling in Solid Tumors (L39230) (Guardant360®)
Local Coverage Article (LCA)	MolDX: Plasma-Based Genomic Profiling in Solid Tumors (A58975) (Guardant 360®)
Decision Memo	Decision Memo for Next Generation Sequencing (NGS) for Medicare Beneficiaries with Advanced Cancer (CAG-00450R) FDA-approved tests (not all-inclusive) FoundationFocus™ CDxBRCA Assay (Foundation Medicine, Inc.) FoundationOne CDx (Foundation Medicine, Inc.) FoundationOne Liquid CDx (Foundation Medicine, Inc.) Guardant360® CDx (Guardant Health, Inc.) Oncomine™ Dx Target Test (Thermo Fisher Scientific, Inc.) Praxis™ Extended RAS Panel (Illumina, Inc.) MSK-IMPACT™ (Memorial Sloan Kettering Cancer Center's (MSK) IMPACT (Integrated Mutation Profiling of Actionable Cancer Targets))

For Non-Medicare Members

Effective until 02/01/2023

- I. Next Generation Sequencing can **only be covered for the following solid cancer types:**
 1. stage III (Effective 01/01/2023) or IV non-small cell lung cancer (RCW [48.43.810](#))

© 2020, Kaiser Foundation Health Plan of Washington. All Rights Reserved.

[Back to Top](#)

Date Sent: 6/28/23

1012

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage.

Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

2. stage IV pancreatic carcinoma
3. stage IV colon carcinoma
4. stage IV prostate (Effective 01/01/2023)
5. stage IV ovarian (Effective 01/01/2023) (RCW [48.43.810](#))
6. stage IV endometrial (Effective 01/01/2023) (RCW [48.43.810](#))
7. stage IV biliary (Effective 01/01/2023) (RCW [48.43.810](#))
8. stage IV gastric (Effective 01/01/2023) (RCW [48.43.810](#))
9. stage IV esophageal (adeno and squamous) gastroesophageal (Effective 01/01/2023) (RCW [48.43.810](#))
10. stage IV breast (ER or PR positive) (Effective 01/01/2023) (RCW [48.43.810](#))

II. In addition, the member must meet **ALL of the following**:

1. The individual is a candidate for a targeted therapy associated with a specific tumor biomarker or disease site
2. Results of testing will directly impact clinical decision making
3. The testing method is considered to be scientifically valid and proven to have clinical utility based on prospective evidence

1. **EITHER** of the following:

- Identification of the specific biomarker or risk assessment using a Gene Expression Classifier (GEC)/Next Generation Sequencing is required in order to initiate a related therapy and the therapy has been validated by the National Comprehensive Cancer Network™ (NCCN Guidelines™) as a category 1, 2A, or 2B recommendation for the individual's tumor type or disease site **OR**
- Identification of the specific biomarker or use of a GEC/Next Generation Sequencing has been demonstrated in published peer-reviewed literature to improve diagnosis, management or clinical outcomes for the individual's condition being addressed

III. The following panels meet Kaiser Permanente coverage criteria in regard to actionable mutations:

A. SymGene Focus – NGS Lung Cancer Panel (CellNetix) -

ALK ARAF BRAF EGFR ERBB2 KRAS MAP2K1 MET MTOR NRAS RET ROS1 TP 53

B. SymGene Focus - NGS Colon Cancer Panel (CellNetix) -

BRAF KRAS MLH1 MSH2 MSH6 NRAS PIK3CA PMS2 POLD1 POLE

C. SymGene NGS Cancer Panel (CellNetix) -

AKT1	ALK	APC	ARAF	ATM	BCL2L11	BRAF
BRCA1	BRCA2	BTK	CCND1	CDK4	CDK6	CDKN2A
CSF1R	CTNNB1	DDR2	EGFR	EPHA2	ERBB2	ERBB4
ESR1	FGFR1	FGFR2	FGFR3	FLT1 (VEGFR1)	FLT3	FLT4
FOXL2	FYN	GLI2	GNA11	GNAQ	GNAS	HDAC2
HRAS	IGF1R	JAK2	JAK3	KDR (VEGFR2)	KIT	KRAS
LCK	LYN	MAP2K1 (MEK1)	MAP2K2 (MEK2)	MDM2	MET	MLH1
MSH2	MSH6	MST1R (RON)	MTOR	NOTCH1	NRAS	NTRK2

PDGFRA	PDGFRB	PIK3CA	PMS2	POLD1	POLE	PTCH1
PTEN	RAF1	RB1	RET	ROS1	SMAD4	SMO
SRC	STK11	TEK	TERT	TP53	TSC1	TSC2
VHL	YES1					

*If the submission is for a different vendor, it will be redirected to SymGene for HMO. For POS and PPO, a similar narrow panel limited to the genes above can be considered on a case by case basis.

- IV. Molecular testing for hematology-oncology indications is **considered experimental, investigational or unproven in the following situations:**
- there is insufficient evidence to support molecular testing for the specific tumor type or disease site
 - the requested gene(s) or biomarker(s) are correlated with a known therapy, but that therapy has not been validated for the specific tumor type or disease site

Individual or targeted gene testing can be covered for specific, actionable mutations for cancer types that panel testing is not covered.

Please see the list of **non-covered** genetic panels on the KPWA criteria page – [Genetic Panel Testing](#). This includes, but is not limited to:

- FoundationOne
- Caris Life Sciences – MI Profile
- Guardant360

Repeat testing is non-covered.

Effective 02/01/2023

- I. Next Generation Sequencing can **only be covered for the following solid cancer types:**
1. Stage III or IV non-small cell lung cancer
 2. stage IV pancreatic carcinoma
 3. stage IV colon carcinoma
 4. stage IV prostate
 5. stage IV ovarian
 6. stage IV endometrial
 7. stage IV biliary
 8. stage IV gastric
 9. stage IV esophageal (adeno and squamous) gastroesophageal
 10. stage IV breast (ER or PR positive)
- II. In addition, the member must meet **ALL of the following:**
1. The individual is a candidate for a targeted therapy associated with a specific tumor biomarker or disease site
 2. Results of testing will directly impact clinical decision making
 3. The testing method is considered to be scientifically valid and proven to have clinical utility based on prospective evidence
 4. **EITHER** of the following:
 - Identification of the specific biomarker or risk assessment using a Gene Expression Classifier (GEC)/Next Generation Sequencing is required in order to initiate a related therapy and the therapy has been validated by the National Comprehensive Cancer Network™ (NCCN Guidelines™) as a category 1, 2A, or 2B recommendation for the individual's tumor type or disease site **OR**

- Identification of the specific biomarker or use of a GEC/Next Generation Sequencing has been demonstrated in published peer-reviewed literature to improve diagnosis, management or clinical outcomes for the individual's condition being addressed
- III. The following panels meet Kaiser Permanente coverage criteria in regard to actionable mutations —any of these three labs can be used:
- CellNetix SymGene Panel
 - Oncoplex (University of Washington)
 - Caris Life Sciences

*If the submission is for a different vendor, it will be redirected to one of the above preferred labs A-D for HMO. For POS and PPO, a similar narrow panel limited to the genes above can be considered on a case-by-case basis if labs A-D are unacceptable.

- IV. Molecular testing for hematology-oncology indications is **considered experimental, investigational or unproven in the following situations:**
- there is insufficient evidence to support molecular testing for the specific tumor type or disease site
 - the requested gene(s) or biomarker(s) are correlated with a known therapy, but that therapy has not been validated for the specific tumor type or disease site

Individual or targeted gene testing can be covered for specific, actionable mutations for cancer types that panel testing is not covered.

Please see the list of **non-covered** genetic panels on the KPWA criteria page – [Genetic Panel Testing](#). This includes, but is not limited to:

- FoundationOne
- Guardant360

Repeat testing is non-covered.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Symgene 79 NGS Cancer Panel:

CPT® or HCPC Codes	Description
88374 (x2)	Morphometric analysis, in situ hybridization (quantitative or semi-quantitative), using computer-assisted technology, per specimen; each multiplex probe stain procedure
81445	Targeted genomic sequence analysis panel, solid organ neoplasm, DNA analysis, and RNA analysis when performed, 5-50 genes (eg, ALK, BRAF, CDKN2A, EGFR, ERBB2, KIT, KRAS, NRAS, MET, PDGFRA, PDGFRB, PGR, PIK3CA, PTEN, RET), interrogation for sequence variants and copy number variants or rearrangements, if performed
88381	Microdissection (ie, sample preparation of microscopically identified target); manual
G0452	Molecular pathology procedure; physician interpretation and report

Symgene Focus- Targeted NGS Cancer Panel (Lung):

© 2020, Kaiser Foundation Health Plan of Washington. All Rights Reserved.

[Back to Top](#)

Date Sent: 6/28/23

1015

These criteria do not imply or guarantee approval. Please check with your plan to ensure coverage.

Preauthorization requirements are only valid for the month published. They may have changed from previous months and may change in future months.

CPT® or HCPC Codes	Description
81445	Targeted genomic sequence analysis panel, solid organ neoplasm, DNA analysis, and RNA analysis when performed, 5-50 genes (eg, ALK, BRAF, CDKN2A, EGFR, ERBB2, KIT, KRAS, NRAS, MET, PDGFRA, PDGFRB, PGR, PIK3CA, PTEN, RET), interrogation for sequence variants and copy number variants or rearrangements, if performed
88374 (x2)	Morphometric analysis, in situ hybridization (quantitative or semi-quantitative), using computer-assisted technology, per specimen; each multiplex probe stain procedure
88360	Morphometric analysis, tumor immunohistochemistry (eg, Her-2/neu, estrogen receptor/progesterone receptor), quantitative or semiquantitative, per specimen, each single antibody stain procedure; manual
88381	Microdissection (ie, sample preparation of microscopically identified target); manual
G0452	Molecular pathology procedure; physician interpretation and report

Symgene Focus- Targeted NGS Cancer Panel (Colon):

CPT® or HCPC Codes	Description
81445	Targeted genomic sequence analysis panel, solid organ neoplasm, DNA analysis, and RNA analysis when performed, 5-50 genes (eg, ALK, BRAF, CDKN2A, EGFR, ERBB2, KIT, KRAS, NRAS, MET, PDGFRA, PDGFRB, PGR, PIK3CA, PTEN, RET), interrogation for sequence variants and copy number variants or rearrangements, if performed
88381	Microdissection (ie, sample preparation of microscopically identified target); manual
G0452	Molecular pathology procedure; physician interpretation and report

Caris Life Sciences – Effective 02/01/2023

CPT® or HCPC Codes	Description
81479	Unlisted molecular pathology procedure

Oncoplex (University of Washington) - Effective 02/01/2023

CPT® or HCPC Codes	Description
81445	Targeted genomic sequence analysis panel, solid organ neoplasm, DNA analysis, and RNA analysis when performed, 5-50 genes (eg, ALK, BRAF, CDKN2A, EGFR, ERBB2, KIT, KRAS, NRAS, MET, PDGFRA, PDGFRB, PGR, PIK3CA, PTEN, RET), interrogation for sequence variants and copy number variants or rearrangements, if performed

FoundationOne® (Foundation Medicine) –

Medicare: Considered Medically Necessary when criteria in the applicable policy statements listed above are met

Non-Medicare: Considered Not Medically Necessary, use preferred vendors above

CPT® or HCPC Codes	Description
0239U	Targeted genomic sequence analysis panel, solid organ neoplasm, cell-free DNA, analysis of 311 or more genes, interrogation for sequence variants, including substitutions, insertions, deletions, select rearrangements, and copy number variations <i>FoundationOne® Liquid CDx</i>
0037U	Targeted genomic sequence analysis, solid organ neoplasm, DNA analysis of 324 genes, interrogation for sequence variants, gene copy number amplifications, gene rearrangements, microsatellite instability and tumor mutational burden <i>FoundationOne CDx™</i>

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

Date Created	Date Reviewed	Date Last Revised
08/04/2020	08/04/2020 ^{MPC} , 08/03/2021 ^{MPC} , 08/02/2022 ^{MPC} , 09/06/2022 ^{MPC}	01/24/2023

^{MPC} Medical Policy Committee

Revision History	Description
08/04/2020	MPC approved to adopt new clinical criteria. Requires 60-day notice, effective date 01/01/2021.
11/13/2020	Added codes from CellNetix
09/06/2022	MPC approved to expand solid cancer types to include: stage IV prostate, stage IV ovarian , stage IV endometrial , stage IV biliary , stage IV gastric, stage IV esophageal (adeno and squamous) gastroesophageal, stage IV breast (ER or PR positive). Also approved Caris and Oncoplex as contracted lab vendors. 60-day notice required; effective 2/1/2023.
10/26/2022	Refiled 60 day notice. Adjusted effective dates for advanced cancers to 1/1/23 per RCW 48.43.810
01/24/2023	Added Applicable codes for FoundationOne® NGS testing

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria Neonatal Facility Level of Care Guidelines

• NICU

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	None
Local Coverage Article	None
Kaiser Permanente Medical Policy	Due to the absence of an active NCD, LCD, or other coverage guidance, Kaiser Permanente has chosen to use their own Clinical Review Criteria, Neonatal Facility Level of Care Guidelines for medical necessity determinations. Refer to the Non-Medicare criteria below.

For Non-Medicare Members

Kaiser Permanente has elected to use the following Neonatal Facility Levels of Care Guidelines from MCG* for medical necessity determinations.

- Neonatal Facility, Level II (LOC-005)
- Neonatal Facility, Level III (LOC-006)
- Neonatal Facility, Level IV (LOC-007)

For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

Based on the Kaiser National Payment Integrity Clinical Review processes, these medical criteria provide guidance for NICU and neonatal care levels 2 through 4. Level 1 admission and discharge criteria was intentionally omitted as it now replaces routine nursery care. Specific information regarding neonatal level of care may be requested through National Clinical Review.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- All clinical notes from requesting provider

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

This chart follows the American Academy of Pediatrics recommendation to use uniform, nationally applicable definitions and consistent standards of service to improve neonatal outcomes.

Definitions, Capabilities, and Provider Types¹

Level of Care	Capabilities	Provider Types
Level I <i>Well Newborn Nursery</i>	<ul style="list-style-type: none"> ✓ Provide neonatal resuscitation at every delivery ✓ Evaluate and provide postnatal care to stable term newborn infants ✓ Stabilize and provide care for infants born 35–37 wk gestation who remain physiologically stable ✓ Stabilize newborn infants who are ill and those born at <35 wk gestation until transfer to a higher level of care 	<ul style="list-style-type: none"> ✓ Pediatricians ✓ Family physicians ✓ Nurse practitioners ✓ Other advanced practice registered nurses
Level II <i>Special Care Nursery</i>	Level I Capabilities plus: <ul style="list-style-type: none"> + Provide care for infants born ≥32 wk gestation and weighing ≥1500 g who have physiologic immaturity or who are moderately ill with problems that are expected to resolve rapidly and are not anticipated to need subspecialty services on an urgent basis + Provide care for infants convalescing after intensive care + Provide mechanical ventilation for brief duration (<24 h) or continuous positive airway pressure or both + Stabilize infants born before 32 wk gestation and weighing less 1500 g until transfer to a neonatal intensive care facility 	Level I Providers plus: <ul style="list-style-type: none"> + Pediatric hospitalists + Neonatologist + Neonatal nurse practitioners as appropriate
Level III <i>NICU</i>	Level II Capabilities plus:² <ul style="list-style-type: none"> + Provide sustained life support + Provide comprehensive care for infants born <32 wks gestation and weighing <1500 g and infants born at all gestational ages and birth weights with critical illness + Provide prompt and readily available access to a full range of pediatric medical subspecialists, pediatric surgical specialists, pediatric anesthesiologists, and pediatric ophthalmologists + Provide a full range of respiratory support that may include conventional and/or high-frequency ventilation and inhaled nitric oxide + Perform advanced imaging, with interpretation on an urgent basis, including computed tomography, MRI, and echocardiography 	Level II Providers plus: <ul style="list-style-type: none"> + Pediatric medical subspecialists + pediatric anesthesiologists + Pediatric surgeons + Pediatric ophthalmologists with appropriate qualifications
Level IV <i>Regional NICU</i>	Level III Capabilities plus: <ul style="list-style-type: none"> + Located within an institution with the capability to provide surgical repair of complex congenital or acquired conditions + Maintain a full range of pediatric medical subspecialists, pediatric surgical subspecialists, and pediatric anesthesiologists at the site + Facilitate transport and provide outreach education 	Level III Providers plus: <ul style="list-style-type: none"> + Pediatric surgical subspecialists

Criteria**For Non-Medicare Members**

Kaiser Permanente has elected to use the Coagulation Factor VIIa – (NovoSeven) (KP-0452) MCG* for medical necessity determinations. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG Manuals are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Last 12 months of clinical notes from requesting provider &/or specialist (hematology, primary care physician)

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Glanzmann's disease (aka Glanzmann's thrombasthenia) is a platelet disorder characterized by a deficiency in the platelet membrane glycoproteins (GP) IIb-IIIa. It is one of several hereditary platelet disorders typified by normal platelet numbers and a prolonged bleeding time. NovoSeven® may also be appropriate for use with patients who have other bleeding disorders such as Glanzmann's thrombasthenia or Bernard-Soulier's thrombasthenia.

NovoSeven® (manufactured by Novo Nordisk, Denmark) is a product containing recombinant coagulation Factor VII. It has been used to prevent bleeding and treat hemorrhage during surgery in patients with hemophilia A with a Factor VIII inhibitor, hemophilia B with a Factor IX inhibitor and acquired deficiencies in Factors VIII or IX.

NovoSeven® has been approved by the FDA as a biological product.

People with hemophilia A (approximately 85% of hemophilia patients) lack the blood clotting protein, factor VIII and people with hemophilia B lack factor IX. The severity of the condition varies, depending on the amount of clotting factor in the blood. About 70% of individuals with hemophilia A have less than 1 percent of the normal amount of clotting factor and are considered to have severe disease. Treatment of hemophilia A or B consists of replacement of the deficient factor.

Approximately 20-50% of severe hemophilia A patients and 1.5-3% of hemophilia B patients (Kulkarni, 2001) develop antibodies called inhibitors that block the activity of the replacement clotting factor. Management of hemophilia patients with inhibitors is challenging. Injection of high quantities of clotting factors is sometimes effective at neutralizing the inhibitors and allowing sufficient quantities of the factors to circulate. Another treatment is injection of porcine factor VIII, which is often sufficiently different from human factor VIII to go unrecognized by inhibitors. However, many patients have cross-reactive antibodies to Porcine FVIII concentrates. Removing the antibody from the plasma (plasmapheresis), in combination with injections of clotting factor, is sometimes used.

Another approach to treatment is the use of bypassing agents, treatments that induce hemostasis independent of the presence of factors VIII and IX. Prothrombin complex concentrates (PCCs) and activated prothrombin complex concentrates (aPCC) were developed in the 1970s. They are derived from human plasma and contain the vitamin K-dependent coagulation proteins.

Recombinant activated Factor VII (rFVIIa) or NovoSeven is also a bypassing agent. This product is derived from cultured baby hamster kidney cells using recombinant DNA technology. Because it does not contain any human serum or proteins, NovoSeven has a low risk of infecting patients with human viruses that could be present in plasma-derived products. NovoSeven has a relatively short half-life and injections must be given frequently. The initial recommended dose is 90 ug/kg every two hours until cessation of bleeding. PCCs and aPCCs have been associated with thromboembolic side effects and it is also possible that there is a risk of thrombosis with NovoSeven (Kulkarni, 2001).

NovoSeven (manufactured by Novo Nordisk, Denmark) has been available in the European Union since 1996. In 1999, NovoSeven was approved by the FDA for the treatment of bleeding episodes in hemophilia A or B patients with inhibitors to factors VIII or IX. It is available in the US through Novo Nordisk Pharmaceuticals, New Jersey.

Major bleeding is a common and potentially serious complication in high-risk **cardiovascular surgeries** and is a well-known risk factor for postoperative morbidity and mortality. Excessive blood loss frequently requires the transfusion of allogenic blood, blood products, and surgical re-exploration when appropriate. Re-exploration may not reveal a surgically repairable source of bleeding in up to 50% of cases. Both massive blood transfusion and re-exploration are associated with longer intensive care and hospital stay, wound infection, higher morbidity, and reduced survival rates. The high risk of bleeding and its consequences have prompted cardiac surgeons to explore the off-label use of recombinant factor VIIa as an alternative haemostatic agent for postoperative bleeding (Murphy 2007, Zangrillo 2009, Goksedef 2010, Chapman 2011).

Recombinant factor VIIa (rFVIIa; NovoSeven®, NovoNordisk, Copenhagen, Denmark) is a recombinant DNA preparation of activated blood coagulation factor VII. It is an engineered preparation of factor VIIa produced in cultured baby hamster kidney cells and is nearly identical to plasma-derived factor VIIa in structure and function. At the pharmacological level, it is to some degree different from the natural FVIIa (nFVIIa). Its pharmacologic action induces thrombin generation on locally activated platelets and contributes to the formation of a stabilized clot at the site of vessel injury. NovoSeven received market approval by the US Food and Drug Administration (FDA) in 1999 for the treatment of bleeding episodes in hemophilia A or B patients with inhibitors to Factor VIII or Factor IX respectively. In 2005, it was further approved by the FDA for the treatment of bleeding episodes and for the prevention of bleeding in surgical interventions or invasive procedures in patients with acquired hemophilia. NovoSeven is licensed in Europe for the treatment of congenital factor VII deficiency and Glanzmann's thrombasthenia refractory to platelet administration (Ratko 2004, Al-Ruzzeh 2008, Gill 2009, Zangrillo 2009, Logan 2011, Goksedef 2012, Guzzette 2012).

Over the last decade, rFVIIa (NovoSeven) has been increasingly used off-label for a wide range of disorders including life threatening bleeding after body and brain trauma, intracranial hemorrhage, major abdominal surgeries, drug-induced coagulopathy, platelet disorders, intraoperative or postoperative hemorrhage, and a number of other conditions. The vast majority of adults and pediatric patients who have received rFVIIa received it for an off-label indication. It is also being used off-label for pediatric and adult cardiac surgery. However, its use in these patients is controversial and widely debated due to the concern about its safety especially for the potential increase the risk of thromboembolic events. Cardiac surgery patients are already at high risk of myocardial ischemia, arterial and venous thrombosis before, during, and after the surgery due to either or both the underlying pathology and the surgery performed with cardiopulmonary bypass or cross clamping. The reported mortality and complication rate among cardiac surgery patients receiving rFVIIa ranged from 19-40%. The issue of the appropriate dosing is also a major concern (Ratko 2004, Al-Ruzzeh 2008, Gelsomino 2008, Gill 2009, Zangrillo 2009, Logan 2011, Goksedef 2012, Guzzette 2012).

Medical Technology Assessment Committee (MTAC)

NovoSeven®

10/10/2001: MTAC REVIEW

Evidence Conclusion: There is insufficient published scientific evidence on which to base conclusions about the effect of NovoSeven® on health outcomes in people with Glanzmann's disease.

Articles: The search yielded 7 articles. Two were review articles, two were case studies (report on only one patient) and three were case series, each of which included five or fewer patients with Glanzmann's disease. Due to the small sizes of the case series, no evidence tables created.

The use of NovoSeven® in the treatment of Glanzmann's disease does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

NovoSeven®

12/10/2003: MTAC REVIEW

Evidence Conclusion: There are no studies comparing NovoSeven to another treatment for hemophilia patients with inhibitors. A comparison to the alternative bypass agents, prothrombin complex concentrates (PCCs) or activated prothrombin complex concentrates (aPCC), might be feasible. In the Scharrer study, 7 (25%) of the patients had failed PCCs/aPCCs, but neither of the other two studies attempted to select patients who had failed treatment with another bypass agent. Non-comparative clinical data suggests that NovoSeven is effective at achieving hemostasis in 80-90% of bleeding episodes. There are data on both in-home and surgical use of NovoSeven. There was a low rate of thrombosis associated with treatment in the published data.

Articles: The search yielded 71 articles, many of which were reviews, opinion pieces, overviews or dealt with technical aspects of the treatment. There were no randomized or non-randomized studies with hemophilia patients with inhibitors that compared NovoSeven to an alternate treatment. One randomized controlled trial was identified with hemophilia patients, but this compared two doses of NovoSeven. The remaining empirical studies were case series. The RCT was critically appraised, not for comparative data, but because it was a reasonably well-designed study with the target population. In addition, two of the largest case series using NovoSeven to treat hemophilia patients with inhibitors were critically appraised. The articles reviewed are as follows: Shapiro AD, Gilchrist S, Hoots WK. Prospective, randomized trial of two doses of rFVIIa (NovoSeven) in hemophilia patients with inhibitors undergoing surgery. *Thromb Haemost* 1998; 80: 773-778. See [Evidence Table](#). Key NS, Aledort LM, Beardsley D. Home treatment of mild to moderate bleeding episodes using recombinant factor VIIa (NovoSeven) in hemophiliacs with inhibitors. *Thromb Haemost* 1998; 80: 912-918. See [Evidence Table](#). Scharrer I et al. Recombinant factor VIIa for patients with inhibitors to factor VIII or IX or factor II deficiency. *Hemophilia* 1999; 5: 253-259. See [Evidence Table](#).

The use of NovoSeven® in the treatment of Hemophilia does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

NovoSeven®

02/11/2013: MTAC REVIEW

Evidence Conclusion: There is a lack of published high-quality studies on the off-label use of rFVIIa in cardiac surgery. To date only two RCTs evaluated the use of rFVIIa in adult cardiac surgery; one was a very small pilot study with 20 patients that assessed the prophylactic use of the therapy, and the other was conducted among 172 patients (Gill 2009, evidence table 3) to evaluate the effectiveness and safety of rFVIIa in 172 patients bleeding after cardiac surgery requiring cardiopulmonary bypass. Both trials lacked statistical power to detect significant differences between the study groups. The rest of the published studies were observational with or without matched comparison groups. A number of these observational studies compared outcomes of patients receiving rFVIIa to matched groups using propensity score (PS) analysis. This method is used to adjust for selection bias in observational studies of causal effect, when RCTs are unfeasible, unethical, or too costly to conduct. PS matching adjusts for observed variables and can only decrease but not eliminate the selection bias. It may also reduce the study's external validity as only a subset of the treated patients is used in the analysis. The majority of the published studies were conducted over a long period of time; the administration of rFVIIa was based on the guidelines of each institution, but was ultimately made by at the discretion of the operating team, and may have evolved throughout the study period as the experience with using the therapy increased (Anderson 2012). There were no consistent well-defined and measurable endpoints to evaluate the efficacy of the therapy. In addition, the published studies followed different protocols for the threshold for using rFVIIa and its dose. This ranged from prophylactic use as a haemostatic agent in the operating room, to a rescue therapy for

patients with refractory bleeding. Rescue therapy is defined as situations in which rFVII is used when patients continue to bleed excessively despite having received maximal standard haemostatic therapy, the definition of which varied between institutions (Guzette 2012). The dosage of rFVIIa ranged between studies from 9-192 µg/kg, and was used either repeatedly or in a single dose. The results of the RCTs and the four comparative observational studies on the use of rFVIIa in adult cardiac surgery were pooled in three meta-analyses (Zangrillo 2009, Ponschab 2011, and Yank 2011). The pooled results of the two more recent meta-analyses comprising a total 470 patients, showed no significant effect of rFVIIa on reducing mortality compared to usual care, but a statistically significant increase in the occurrence of stroke (calculated number needed to harm of 26). The meta-analyses showed a lower but statistically insignificant rate of re-exploration and a trend towards the lower blood loss and need for transfusion with the use of rFVIIa. Gill and colleagues' RCT found a statistically significant lower rate of re-operation rates and need for blood transfusion, and a statistically insignificant increase in serious adverse events in the adult cardiac surgery patients who received rFVIIa. In conclusion, the available evidence suggests that rFVIIa use in adult cardiac surgery patients may result in an increased risk of stroke and lower re-exploration rate without a significant mortality benefit. Larger randomized controlled trials with sufficient power are needed to verify the results of the meta-analyses and clearly assess the benefits and risks of the off-label use of rFVIIa in cardiac surgery patients.

Articles: The literature search for studies on the use of rFVIIa (NovoSeven) for adults undergoing cardiac surgery revealed two meta-analyses, two randomized controlled trials, and a number of observational prospective and retrospective studies with or without comparison groups. The search also identified an updated Cochrane review and other meta-analyses and systematic reviews that included trials on the use of rFVII for any off-label indication including cardiac surgery. Among these, there was one review (Yank 2011) prepared for the agency for Healthcare Research and Quality (AHRQ) that included a meta-analysis of studies on the use of the rFVIIa for adult cardiac surgery. The two meta-analyses on the use of rFVIIa or cardiac surgery patients were conducted by the same group of authors, but the more recent analysis included an additional RCT and focused on the rates of thromboembolic events associated with the use of rFVIIa. Two meta-analyses of trials using rFVII for adult patients undergoing cardiac surgery as well as the most recent RCT among cardiac surgery patients were selected for critical appraisal. Zangrillo A, Mizzi A, Biondi-Zoccai G, et al. Recombinant activated factor VII in cardiac surgery: a meta-analysis. *J Cardiothoracic Vasc Anesth.* 2009;23:34-40. [Evidence Table](#). Ponschab M, Landoni G, Biondi-Zoccai G, et al. Recombinant activated factor VII increases stroke in cardiac surgery: a meta-analysis. *J Cardiothoracic Vasc Anesth.* 2011;25:804-810. [Evidence Table](#). Gill Ravi, Herbertson M, Vuylsteke A, et al. Safety and efficacy of recombinant activated factor VII A randomized placebo-controlled trial in the setting of bleeding after cardiac surgery. *Circulation* 2009; 120:21-27. [Evidence Table](#).

The use of NovoSeven® in the prevention of cardiac surgery bleeding does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® or HCPC Codes	Description
J7189	Factor VIIa (antihemophilic factor, recombinant), (NovoSeven RT), 1 mcg

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

****To verify authorization requirements for a specific code by plan type, please use the [Pre-authorization Code Check](#).**

Revision History	Description

Clinical Review Criteria

Observation Level of Care

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

PURPOSE

To provide a regional standard for appropriate utilization of observation care that ensures consistent application of the outpatient and acute care benefits for Kaiser Permanente of Washington members regardless of where care is delivered.

POLICY

- A. Observation care will be utilized, when in the judgment of the admitting physician, the patient's presenting medical condition requires services which are reasonable and necessary to evaluate a patient's condition or determine the need for a possible inpatient admission.

Observation care is a set of specific, clinically appropriate services, not a location. Therefore, a patient can be in observation status regardless of where the services are performed, i.e. critical care unit, emergency room, recovery room, telemetry, or on a medical floor. MCG Care Guidelines and the CMS "Two Midnight Rule" may serve as guidance for the attending physician in determining the appropriate use of observation care. (See MCG white paper on "Observation Care 101", by Bill Rifkin, M.D.) Observation services are defined by Centers for Medicare and Medicaid (CMS). See definition on following page.

- B. CMS Manual- "When a physician orders observation care, the patient's status is that of an outpatient. The purpose of observation care is to determine the need for further treatment or for inpatient admission. Thus, a patient receiving observation care may improve and be released or be admitted as an inpatient. A physician's order must specify, "admit to observation" or "observation status" and signed electronically.

Conversion to inpatient status must meet medical necessity for admission and be documented at the time of conversion from observation to inpatient status. A physician's order must specify, "admit to inpatient status" and be signed electronically.

Medical records may be evaluated by Kaiser Permanente of Washington to determine the consistency between the physician order (physician intent), the services actually provided (inpatient or outpatient), and the medical necessity of those services, including the medical appropriateness of the inpatient or observation stay.

- C. A patient in observation care may improve and be released or be admitted as an inpatient. In most instances a placement in observation care will result in a disposition being implemented within 48 hours-either to discharge or continued hospitalization under inpatient status.
- D. If a patient is retained in observation care for 48 hours without being admitted as an inpatient, further observation services may be denied as not reasonable and necessary for the diagnosis or treatment of illness or injury.
- E. Conversion from observation status to inpatient status must meet medical necessity

- F. Medicare does not consider use of observation as a convenience of the patient, the patient's family, or a physician to be appropriate. For example, a decision to keep the patient overnight due to transportation issues or because the procedure could not be scheduled in a timely manner would not qualify.

DEFINITIONS

Medicare CMS definition:

Observation care is a well-defined set of specific, clinically appropriate services, which include ongoing short term treatment, assessment, and reassessment before a decision can be made regarding whether patients will require further treatment as hospital inpatients or if they are able to be discharged from the hospital.

Observation services are commonly ordered for patients who present to the emergency department and who then require a significant period of treatment or monitoring in order to make a decision concerning their admission or discharge.

Observation services are covered only when provided by the order of a physician or another individual authorized by State licensure law and hospital staff bylaws to admit patients to the hospital or to order outpatient tests. In the majority of cases, the decision whether to discharge a patient from the hospital following resolution of the reason for the observation care or to admit the patient as an inpatient can be made in less than 48 hours, usually in less than 24 hours.

In only rare and exceptional cases do reasonable and necessary outpatient observation care span more than 48 hours. For coverage requirements, see the Medicare Benefit Policy manual, Chapter 6.

Medicare Outpatient Observation Notice (MOON):

The MOON informs all Medicare beneficiaries when they are an outpatient receiving observation services and are not an inpatient of the hospital or critical access hospital (CAH).

Beneficiary Notices Initiative (BNI)

RESPONSIBILITIES

TIMELINESS

- A. MOON - The MOON must be delivered to beneficiaries in Original Medicare (fee-for-service) and Medicare Advantage plans. Enrollees who receive observation services as outpatients for more than 24 hours will be issued a MOON by the facility. The hospital or CAH must provide the MOON no later than 36 hours after observation services as an outpatient begin.
- B. If the attending physician intends to place or retain a patient in observation care longer than 48 hours for:
1. a non-medical reason,
 2. or the patient and/or family are unable or unwilling to make other arrangements for care

A coverage determination should be requested of the Health Plan to determine if the stay is approved or denied.

PROCESS

Primary Responsibility	Actions
Facility or CAH	1. Must deliver verbal & written MOON no later than 36 hours after observation services as an outpatient begin.
KP Physician (Kaiser Permanente of Washington) and Contracted MD (Attending/Admitting Physician)	1. Utilizing clinical judgment and CMS 2 Midnight Rule, admits the patient to observation status. (see MCG white paper "Observation Care 101" by Bill Rifkin, M.D.) 2. The KP Physician's order must specify, "admit to observation" and be electronically signed. 3. The history and physical must clearly document the medical intent of the use of observation care and be supported by the patient's presenting medical condition (severity of illness) and plan for observation/treatment (intensity of service). 4. Medical necessity for admission must be met and documented at the time of

Primary Responsibility	Actions
	<p>conversion from observation to inpatient status.</p> <ol style="list-style-type: none"> The KP Physician may change admission status prior to discharge. The patient must be informed before they are transferred or discharged from the hospital if their status is Observation care only for Medicare patients. The KP Physician may convert a patient from inpatient status to observation status. This will cancel the inpatient admission prior to discharge if the physician determines: <ol style="list-style-type: none"> that the inpatient admission is unnecessary or the original order was ambiguous and the KP Physician clarifies that order. Any change in admission status must be supported by medical records (KP Physician notes and orders) and be supported by medical necessity. The KP Physician may change or clarify the admission status through a direct written order, a verbal order given to a CMLN and subsequently signed by the KP Physician. Notification of the Care Management department is required in this instance. <p><i>*The KP Physician/attending physician may not change the patient's status (i.e., inpatient vs. observation) after discharge.</i></p> <p><i>** Through Provider Reconsideration or other review process, coverage decision can be made and/or changed after the patient discharges.</i></p>
<p>CMLN (Care Management Liaison Nurse)</p>	<p>Rounded and Non-Rounded Facilities:</p> <ul style="list-style-type: none"> CMLN will communicate Observation/Inpatient status decision to hospital UM office within 24 hours after hospital services begin or from time of notification. Medicare Observation stays over 24 hours are communicated to hospital UM office. <p>For Rounded Facilities</p> <ol style="list-style-type: none"> When working directly with KP Physician during admission, will discuss status based on CMS 2 Midnight Rule and medical necessity. Based upon the review, the KP Physician may provide additional documentation to support the admission status, or convert the admission status to the identified appropriate status If the patient does not meet Inpatient criteria for the admission status, the CMLN will contact the physician and discuss the results of the review. The CMLN may accept a verbal order from the physician to either clarify or change the admission status. The CMLN must notify the Hospital UM Office of the changes. In the event the attending physician does not provide additional documentation to support the admission status or convert the patient to the appropriate status, the CMLN will: <ol style="list-style-type: none"> contact the Clinical Review Unit (CRU) physician for further review, arrange for a "Peer to Peer" discussion before the patient discharges. If the peer-to-peer results in a change from IP to Obs, notification of the status change to the hospital UM Office before hour 36 will allow for timely MOON delivery. <p>Non- Rounded Facilities</p> <ol style="list-style-type: none"> When not working directly with KP Physician, CMLN will conduct a review for all patients admitted as inpatient utilizing MCG Care Guidelines. CMLN will communicate Observation/Inpatient status decision to hospital UM office within 24 hours after hospital services begin or from time of notification.

Primary Responsibility	Actions
Clinical Review Unit (CRU) (UM Physician Advisor)	<ol style="list-style-type: none"> 1. CRU may contact the KP Physician and review the recommended level of care determination. If additional clinical information is needed to make a determination. 2. CRU will advise the CMLN of the results of the contact. <ul style="list-style-type: none"> • The decision from the Peer-to-Peer discussion will be entered into Care Management workflow system and the outcome communicated to the Hospital UM office for the appropriate actions.

Kaiser Foundation Health Plan of Washington

Clinical Review Criteria

Occipital Nerve Stimulation (ONS) for Primary Headache

NOTICE: Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. (Kaiser Permanente) provide these Clinical Review Criteria for internal use by their members and health care providers. The Clinical Review Criteria only apply to Kaiser Foundation Health Plan of Washington and Kaiser Foundation Health Plan of Washington Options, Inc. Use of the Clinical Review Criteria or any Kaiser Permanente entity name, logo, trade name, trademark, or service mark for marketing or publicity purposes, including on any website, or in any press release or promotional material, is strictly prohibited.

Kaiser Permanente Clinical Review Criteria are developed to assist in administering plan benefits. These criteria neither offer medical advice nor guarantee coverage. Kaiser Permanente reserves the exclusive right to modify, revoke, suspend or change any or all of these Clinical Review Criteria, at Kaiser Permanente's sole discretion, at any time, with or without notice. **Member contracts differ in health plan benefits. Always consult the patient's Evidence of Coverage or call Kaiser Permanente Member Services at 1-888-901-4636 (TTY 711), Monday through Friday, 8 a.m. to 5 p.m. to determine coverage for a specific medical service.**

Criteria

For Medicare Members

Source	Policy
CMS Coverage Manuals	None
National Coverage Determinations (NCD)	None
Local Coverage Determinations (LCD)	Peripheral Nerve Stimulation (L37360)
Local Coverage Article	Billing and Coding: Peripheral Nerve Stimulation (A55531) Response to Comments: Peripheral Nerve Stimulation (A56042)

For Non-Medicare Members

Kaiser Permanente has elected to use the MCG* Occipital Nerve Stimulation (A-0716) for medical necessity determinations. This service is not covered per MCG guidelines. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

See related policy: [Deep Brain Stimulation for Primary Headache](#)

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Headache is a major worldwide health problem disabling millions of people and resulting in considerable economic burden. Up to 40% of patients seen in major headache clinics suffer from chronic daily headache. Chronic headache disorders include migraine, cluster headache, cervicogenic headache, occipital neuralgia, and other types of primary headache (Maizels 1998, Jasper 2008).

Cluster headache (CH), an excruciating headache syndrome, is the most common type of trigeminal autonomic cephalalgias, and is thought to be the most severe primary headache disorder. 10-20% of CH patients develop a chronic form in which the attacks persist for more than one year without remissions, or with remissions lasting less than a month. Acute treatment for the attacks includes injectable or intranasal triptans or oxygen inhalation. About one percent will become refractory to medical treatment and fulfill the criteria of intractable headaches. These patients may get some relief with attack treatments, but the disorder could be disabling and may be associated with depression and suicidality (Magis 2007, Leroux 2008).

Migraine headache is a chronic headache that affects about 15% of the population and is one of the most common problems seen in emergency departments and doctors' offices. Migraine is believed to result from changes in the brain and surrounding blood vessels. The attacks typically last from 4-72 hours and vary in

frequency from daily to less than one per year. Transformed migraines are chronic daily or almost daily headaches (>15/month) that lasts more than 4 hours. There is no cure for migraine, and medications can only help reduce the frequency and severity of disorder (Bigal 2008).

Cervicogenic headache is a chronic hemicranial pain that usually occurs daily. It usually begins at the suboccipital region and spreads anteriorly to the ipsilateral orbital, frontal, and temporal areas. It is typically unilateral but occasionally affects the two sides. It is believed to be due to convergence of upper cervical and trigeminal sensory pathways allowing pain signals to refer from the neck to the trigeminal sensory fields of the head and face. Treatments with pain medication, physical therapy, manipulative treatment, and surgical interventions may provide only some inconsistent temporary relief of pain (Naja 2006).

Various ablative surgical procedures targeting the trigeminal nerve, or the cranial parasympathetic outflow have been tried to treat these patients with intractable headaches. These include gamma knife surgery or root section of the trigeminal nerve, trigeminal tractotomy, microvascular decompression of the trigeminal nerve, glycerol injection of the Gasserian ganglion, and others. However, none of these procedures has a consistent effect, and many are associated with serious complications (Magis 2007).

Electrical stimulation of the brain was first attempted late in the 19th century, but its application for pain control began in the 1960s with spinal cord stimulation. The neurostimulation technique for ablating pain is based on the theory that peripheral nerve stimulation can produce specific focal analgesia and anesthesia. In addition, the technique may alter perception of pain by blocking cell membrane depolarization and axonal conduction with directly applied current (Shealy 1967, Lim 2007, Trentman 2008).

In the early 2000s, neurostimulation therapy emerged as a potential treatment option for a variety of different intractable primary headache disorders. This is an invasive device-based approach that has two broad types:

1. Peripheral therapy that involves branches of the occipital nerve: occipital nerve stimulation (ONS), and supraorbital nerve stimulation.
2. Central which refers to deep-brain stimulation (DBS) approaches e.g. hypothalamic deep brain stimulation used for chronic cluster headache (Schwedt 2009).

The occipital nerve stimulators (ONS) are implanted surgically in a 3-phase procedure: Phase 1. An incision is made over the occipital region at the level of the first cervical vertebra for the subcutaneous implantation of bilateral electrodes. These are tunneled in a cephalad direction so that they come to lie across the path of the greater occipital nerve on each side of the head. Phase 2. Confirmation of the electrode position by testing each separately by an external stimulator. The operator gradually increases the amplitude delivered to the electrodes from 0 to 4 v, and the patient is asked to locate and describe any sensation he /she feels. Correct placement is confirmed by the patient describing a vibrating sensation that radiates at least 4 cm cephalad from the base of the skull, on the side of the tested electrode, and Phase 3. Implantation of the stimulator battery in the pectoral, abdominal, or gluteal region, and connecting it to the electrodes via subcutaneously tunneled leads. The procedure is performed under sedation or general anesthesia, however during the second phase the patients are required to be awake and to be able to identify the position of the occipital electrodes when the electric stimulus is applied. Potential complications of the procedure include lead migration, infection, localized pain, muscle spasm, and lack or loss of effect (Lim 2007, Trentman 2008).

The deep brain stimulation (DBS) of the posterior hypothalamus has been investigated in patients with chronic cluster headaches or SUNCT (short-lasting, unilateral, neuralgiform headache attacks with conjunctival injection and tearing). DBS involves MRI guided stereotactic placement of an electrode into the brain (e.g. thalamus, globus pallidus, or subthalamic nucleus). It is typically implanted unilaterally on the side corresponding to the most severe symptoms. The use of bilateral stimulation using two electrodes has been investigated in patients with bilateral, severe symptoms. Initially, the electrode(s) is/are attached to a temporary transcutaneous cable to validate treatment effectiveness and, if effective, the patient returns to surgery several days later for permanent subcutaneous implantation of the cable and a radiofrequency-coupled or battery-powered programmable stimulator. After implantation, noninvasive programming of the neurostimulation can be adjusted to control the patient's symptoms. The procedures can be performed only by a highly experienced neurosurgeon and may be associated with a small risk of mortality due to intra-cerebral hemorrhage. Before implantation, all patients must undergo complete preoperative neuro-imaging to exclude disorders associated with increased hemorrhagic risk (Leon 2006, Bartsch 2008).

Neither the occipital nerve stimulation nor the deep brain stimulators are approved to date by the U.S. Food and Drug Administration for the treatment or prevention of primary headaches.

Medical Technology Assessment Committee (MTAC)

Occipital Nerve Stimulation (ONS)

08/03/2009: MTAC REVIEW

Evidence Conclusion: The literature on brain stimulation for the treatment of chronic primary headache is limited and does not provide sufficient evidence to determine the efficacy or safety of either occipital or deep brain stimulation therapy for the prevention or treatment of chronic headache. There are no published randomized or nonrandomized controlled trials on the intervention to date. The empirical studies consist of a few very small case series with no comparison groups and a number of case reports. The outcome measures varied between studies as some reported change in pain and others reported on headache frequency intensity, disability and/or medication use. Popeney and Alo's (2003), the largest series on ONS studied the response to occipital nerve stimulation in a series 25 consecutive patients with transformed migraine. A comparison between pre- and post-implant measurements, showed significant reductions in headache frequency, severity, and disability after the implant. The study was only an observational case series with potential biases, and with no control or comparison group to rule out the placebo effect of the implant.

Articles: The search yielded almost four hundred articles. The majority was review articles, opinion pieces, or dealt with technical aspects the procedure. ONS: There were around 15 small prospective and retrospective case series with patient sizes ranging from 3-25, and a number of case reports on peripheral nerve stimulation. Popeney CA, Alo KM. Peripheral neurostimulation for the treatment of chronic disabling transformed migraine. Headache 2003;43:369-375. See [Evidence Table](#).

The use of Occipital Nerve Stimulation (ONS) for the treatment of primary headache does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Medicare

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

Non-Medicare - Considered Not Medically Necessary:

CPT® or HCPC Codes	Description
64555	Percutaneous implantation of neurostimulator electrode array; peripheral nerve (excludes sacral nerve)
64575	Incision for implantation of neurostimulator electrode array; peripheral nerve (excludes sacral nerve)
64585	Revision or removal of peripheral neurostimulator electrode array
64590	Insertion or replacement of peripheral or gastric neurostimulator pulse generator or receiver, direct or inductive coupling
64595	Revision or removal of peripheral or gastric neurostimulator pulse generator or receiver
C1767	Generator, neurostimulator (implantable), nonrechargeable
C1778	Lead, neurostimulator (implantable)
C1787	Patient programmer, neurostimulator
C1816	Receiver and/or transmitter, neurostimulator (implantable)
C1820	Generator, neurostimulator (implantable), with rechargeable battery and charging system
C1822	Generator, neurostimulator (implantable), high frequency, with rechargeable battery and charging system
C1823	Generator, neurostimulator (implantable), nonrechargeable, with transvenous sensing and stimulation leads
C1883	Adaptor/extension, pacing lead or neurostimulator lead (implantable)
C1897	Lead, neurostimulator test kit (implantable)
L8679	Implantable neurostimulator, pulse generator, any type
L8680	Implantable neurostimulator electrode, each
L8681	Patient programmer (external) for use with implantable programmable neurostimulator pulse generator, replacement only
L8682	Implantable neurostimulator radiofrequency receiver
L8683	Radiofrequency transmitter (external) for use with implantable neurostimulator radiofrequency receiver
L8685	Implantable neurostimulator pulse generator, single array, rechargeable, includes extension

L8686	Implantable neurostimulator pulse generator, single array, nonrechargeable, includes extension
L8687	Implantable neurostimulator pulse generator, dual array, rechargeable, includes extension
L8688	Implantable neurostimulator pulse generator, dual array, nonrechargeable, includes extension
L8689	External recharging system for battery (internal) for use with implantable neurostimulator, replacement only
L8695	External recharging system for battery (external) for use with implantable neurostimulator, replacement only

CMS Coverage Manuals	None
National Coverage Determinations (NCD)	Pancreas Transplants (260.3)
Local Coverage Determinations (LCD)	None

For Non-Medicare Members

Transplantation may be considered for patients with end-stage or life-threatening disease who have no prospect for prolonged survival, or whose quality of life is severely impaired. The following are current, accepted guidelines for Pancreas Transplant Alone and Pancreas After Kidney transplantation. These guidelines for referral for transplant evaluation are not intended as an automatic inclusion or exclusion of a candidate for referral. It is important to note that these are guidelines and should be applied together with careful clinical judgment.

1. GENERAL PRINCIPLES

- If clinical parameters of end-stage or life-threatening disease indicate the need for transplantation, then early referral should be made.
- Patients with a history of malignancy with a moderate to high risk of recurrence (as determined after consultation with oncologist considering tumor type, response to therapy, and presence or absence of metastatic disease) may be unsuitable candidates for transplantation. Patients with low risk of recurrence may be considered.
- Uncontrollable active infection is a contraindication to transplant.
- Candidates with a history of substance abuse must be free from alcohol and other substance abuse for six (6) months and have been evaluated by a substance abuse program. The risk of recidivism, which has been documented to negatively impact transplant outcomes, must be addressed and considered to be low.^{1,2,3} Exceptions may be made on a case-by-case basis.
- Candidates for thoracic organ (heart, lung and heart/lung) transplants must be free from tobacco use for the previous six (6) months. Routine monitoring may be required. Specific programs for abdominal organs (liver, intestines, and kidney) may require abstinence from tobacco products in order to be actively listed.
- Candidates must have adequate social support systems and display a proven record of adherence to medical treatment.
- Patients must be able to travel within short notice to the KP approved transplant Center of Excellence and, if necessary, return for treatment of complications.
- Patient must have a care giver or care givers who are physically and cognitively able to assist the patient with self-care activities and are available to travel within short notice to the KP approved transplant Center of Excellence.
- The presence of significant irreversible neurologic dysfunction, active psychological and/or psychiatric conditions, and/or other social behaviors that prevent adherence with a complex medical regimen, are considered contraindications for referral for transplant.

- j. Evidence of such non adherence may be: failure to keep appointments, failure to make steady progress in completing pre-transplant evaluation requirements, failure to accurately follow medication regimens or failure to accomplish the activities required for maintenance on the waiting list
- k. Whenever transplant is considered as an option and discussed with the patient and/or family, consultation with Advanced Life Care Planning/Palliative Care resources is strongly recommended.

2. PANCREAS TRANSPLANT ALONE (PTA/PAK)

- a. Indications for PTA/PAK Transplant
 - i. Type 1 DM with disabling and potentially life threatening complications as seen in brittle diabetes with severe and recurrent episodes of either hypoglycemia (involving seizures, loss of consciousness and/or calls to 911) and or hyperglycemia (episodes of DKA) or hypoglycemic unawareness in which the individual requires constant supervision.
 - ii. Optimally and intensively managed by an endocrinologist for at least 12 months⁴.
 - iii. Age 18 - 55 except under special clinical circumstances.
 - iv. Native or transplanted kidney must be functioning well as evidenced by an accepted formula for GFR or a 24-hour urine for creatinine clearance of >50 ml per minute^{5,6,7}

3. Contraindications for PTA/PAK Transplant

- a. Significant irreversible coronary artery disease and/or left ventricular dysfunction, and irreversible pulmonary disease.
- b. Irreversible peripheral vascular disease, including carotid vascular disease (Amputation alone is not a contraindication).
- c. Uncontrolled hypertension.

Relative Contraindications

- a. BMI \geq 35. Patients may be referred to the COE for individual consideration.
 - i. May be concurrently referred for weight loss intervention.
- b. Cachexia and/or malnourishment

- Copy of final summary report from multidisciplinary transplant team

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Pancreas transplantation is used in patients with type 1 diabetes. After a successful transplantation, many diabetic patients no longer require insulin. Due to the danger of organ rejection in the short- or long-term, pancreas transplant recipients need to take immunosuppressive drugs.

Most pancreas transplants are done in conjunction with (at the same time or following) a kidney transplant. A reason for this combination transplant is that the pancreas induces a strong immune response and therefore requires larger doses of immunosuppressive drugs that can jeopardize kidney function and the transplanted pancreas.

The first clinical pancreas transplant (of any type) was done in 1966. Initially there was a low success rate but clinical outcomes improved in the 1980s due to advances in surgical techniques and the introduction of

cyclosporine for immunosuppression. Newer immunosuppressants, Tacrolimus and mycophenolate mofetil, were introduced in 1994 and 1995, respectively. Since 1994, there have been improved graft survival rates in patients receiving pancreas transplants alone (PTA).

Medical Technology Assessment Committee (MTAC)

Pancreas Transplant

12/12/2001: MTAC REVIEW

Evidence Conclusion: Only one article reported data on patients receiving pancreas transplants alone. The methodology was not well described, and the intervention procedures varied dramatically over time. The article reported on the experience of the institution; it was primarily a review article rather than a research study. The case series portion of this article had inadequately described methodology and is subject to selection and observation biases. Due to lack of quality scientific data, the evidence is insufficient to draw conclusions about the effect of this technology on health outcomes.

Articles: The search yielded 36 articles, many of which were review articles, opinion pieces or dealt with pancreas transplantation in conjunction with kidney transplantation. There were no empirical studies that presented separate data on the outcomes of PTA. There were several case series that included both pancreas transplantation in conjunction with kidney transplantation and PTA, but the data were not divided by type of procedure. Only one article presented some data separately for patients receiving PTA. This was primarily a review article and included case series data. This study was critically appraised:

Sutherland DER, Gruessner RWG, Dunn DL, Matas AJ, Humar A, Kandaweamy R, Mauer M, Kennedy WR, Goetz FC, Robertson RP, Gruessner AC, Najarian JS. Lessons learned from more than 1,000 pancreas transplants at a single institution. *Ann Surg* 2001; 233: 463-501.

The use of Pancreas Transplant alone in the treatment of Juvenile Diabetes does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

Applicable Codes

Considered Medically Necessary when criteria in the applicable policy statements listed above are met:

CPT® Codes	Description
48550	Donor pancreatectomy (including cold preservation), with or without duodenal segment for transplantation
48551	Backbench standard preparation of cadaver donor pancreas allograft prior to transplantation, including dissection of allograft from surrounding soft tissues, splenectomy, duodenotomy, ligation of bile duct, ligation of mesenteric vessels, and Y-graft arterial anastomoses from iliac artery to superior mesenteric artery and to splenic artery
48552	Backbench reconstruction of cadaver donor pancreas allograft prior to transplantation, venous anastomosis, each
48554	Transplantation of pancreatic allograft
48556	Removal of transplanted pancreatic allograft

***Note:** Codes may not be all-inclusive. Deleted codes and codes not in effect at the time of service may not be covered.

Kaiser Permanente has elected to use the Integrated Molecular Pathology (Topographic Genotyping) - PathFinderTG (A-0632) MCG* guideline for medical necessity determinations. This test is not covered per MCG guidelines. For access to the MCG Clinical Guidelines criteria, please see the MCG Guideline Index through the provider portal under Quick Access.

***MCG are proprietary and cannot be published and/or distributed.** However, on an individual member basis, Kaiser Permanente can share a copy of the specific criteria document used to make a utilization management decision. If one of your patients is being reviewed using these criteria, you may request a copy of the criteria by calling the Kaiser Permanente Clinical Review staff at 1-800-289-1363 or access the MCG Guideline Index using the link provided above.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider
- Genetics consult if applicable & requesting provider is not a geneticist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Pathologic analysis of tissue samples is central to the diagnosis of cancer; however, there are some instances when these results may be inconclusive. Pathfinder TG® is a molecular DNA-based cancer diagnostic test that can aid diagnosis when pathology results are inconclusive. The Pathfinder TG® test uses a method known as topographic genotyping that combines pathology and molecular analysis using specific genetic marker panels to identify acquired mutations in a variety of difference types of cancer.

Medical Technology Assessment Committee (MTAC)

Pathfinder TG®

06/18/2012: MTAC REVIEW

Evidence Conclusion: Analytic validity - No studies were identified that evaluated the analytic validity of loss-of-heterozygosity based topographic genotyping with Pathfinder TG® (AHRQ 2010). Clinical validity- Fifteen

© 2012 Kaiser Foundation Health Plan of Washington. All Rights Reserved.

[Back to Top](#)

retrospective studies with methodological limitations were identified that evaluated the clinical validity of loss-of-heterozygosity based topographic genotyping with Pathfinder TG®. Details on patient characteristics, treatments, clinical definitions, and statistical methods were limited. Additionally, only 3 studies had more than 50 patients and it is possible that these publications analyzed the same patient population. There is insufficient high-quality evidence to determine the clinical validity of loss-of-heterozygosity based topographic genotyping with Pathfinder TG® (AHRQ 2010). Clinical utility - No studies were identified that evaluated the clinical utility of loss-of-heterozygosity based topographic genotyping with Pathfinder TG® (AHRQ 2010). Conclusion: There is insufficient evidence to determine the analytic validity, clinical validity, and clinical utility of loss-of-heterozygosity based topographic genotyping with Pathfinder TG®.

Articles: The literature search revealed a 2010 AHRQ technology assessment that evaluated the analytic validity, clinical validity, and clinical utility of loss-of-heterozygosity based topographic genotyping with Pathfinder TG®. Studies were excluded if they had less than 25 subjects. No relevant articles were identified after the 2010 AHRQ review. The following technology assessment was selected for review: Trikalinos TA, Terasawa T, Raman G et al. A systematic review of loss-of-heterozygosity based topographic genotyping with PathfinderTG®. AHRQ Technology Assessment Program (Project ID GEND0308). March 2010. See [Evidence Table](#).

The use of Pathfinder TG® does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or provides better long-term outcomes than current standard services/therapies.

If requesting this service, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Breast cancer is the most common non-skin cancer among women in the United States, and one of the leading causes of cancer death among women of all races. Although the incidence rate has increased, there has been a steady decline in the breast cancer death rate since the early 1990s, mostly due to screening, better awareness, and improved treatment. Early detection and accurate staging and restaging of recurrent breast cancer are important to define appropriate therapeutic strategies and increase the chance of a cure (Bartella 2006, CDC 2010, Pan 2010).

Mammography remains the gold standard screening method for women at average risk for breast cancer. It is relatively inexpensive, requires a low dose of radiation, and reliably identifies malignant tumors especially those that are too small to feel. It can also be used to investigate breast lumps and other symptoms. Although the benefit of mammographic screening is widely accepted, its limitations and failure to detect all breast cancers are also recognized. It is reported that the false negative rate of screening mammography ranges between 20-30%. It also has a low specificity resulting in a large number of unnecessary procedures. It is reported that only 25-45% of the biopsies done based on mammographic abnormalities result in a diagnosis of carcinoma. Diagnostic mammography is commonly used to identify possible breast cancers in women with signs and symptoms and has a higher sensitivity (85-93%) compared with screening mammography (Bartella 2007).

Ultrasound (US) imaging may be used to evaluate abnormalities detected during a breast exam or mammogram and is useful in differentiating solid tumors from fluid filled cysts. It is considered the imaging technique of choice for evaluating palpable masses in women younger than 30 years as well as in pregnant and lactating women. It can also be used for the guidance of interventional procedures and treatment planning for radiation therapy. US is easily accessible, relatively low in cost, and does not involve the use of ionizing radiation. However, it cannot detect microcalcifications, can be time consuming, and its performance is operator dependent (Ferrara 2010).

Breast MRI using a special receiver and injected contrast material is more sensitive and accurate than mammography and ultrasound in detecting invasive lobular cancer. MRI detects blood flow to lesions and does not expose the patient to radiation. The increased blood flow is indicative of vascularization frequently found in cancer. MRI however, has some disadvantages; it can lead to false positive results as both benign and malignant lesions can absorb the contrast, it is less sensitive in detecting in situ cancers, and its interpretation is challenged when the breast is under estrogen modulation during menstrual cycle or HRT use, which affects the glandular tissue of the breast. In addition, MRI is not indicated and/or tolerated by many patients due to renal disease, metallic implants, claustrophobia, large body size, or general medical condition. It is a costly test to use for screening and is not a substitute for mammography. MRI is recommended for screening women at very high risk of breast cancer especially for the BRCA1 and BRCA2 subgroups. Other accepted indications include patients presenting with axillary adenopathy and an unknown primary, patients with equivocal mammograms, the differentiation of scar versus recurrence at lumpectomy site, as well as other indications (Tafreshi 2010, Philpotts 2011, Schilling 2011).

Nuclear breast imaging refers to functional imaging of the breast through the use of radiopharmaceuticals such as 18 F-fluorodeoxyglucose (18FDG) or 99mTc-sestamibi. It takes advantage of the differences in metabolic activity between tumor and normal tissue. Functional imaging can thus show changes in cell metabolism that are due to malignancies as the majority of primary and metastatic cancers take up more glucose than the adjacent normal tissues. Positron emission tomography (PET) with the radiotracer FDG may be able to detect cancer even before vascularization as cancer cell metabolism is usually heightened prior to the stimulation of new vessel growth. It has the potential of improving detection of cancer in dense breasts, illustrating the extent of the disease for surgical planning, and distinguishing between recurrent cancer and scar tissue (Schilling 2011).

The use of whole-body PET (WB- PET) and PET/CT is limited due to the low sensitivity and positive predictive value in detecting early stage breast cancer, invasive lobular and ductal carcinoma in situ, as well regional lymphadenopathy. The reasons reported for this low sensitivity include low spatial resolution, and lower level of FDG tracer uptake in some breast malignancies compared to other cancers (Schilling 2011).

Positron emission mammography (PEM) is a modification of PET that allows for a much more spatial resolution by putting the photon detectors directly on the breast. PEM uses similar principles as PET but is a breast specific imaging tool. Both work through the introduction and detection of a positron-emitting glucose analog 18F-FDG as the imaging radiotracer. The 18F-FDG analog decays by emitting a positron that is annihilated within a few millimeters resulting in emission of two gamma rays that radiate in opposite directions and are detected by the PET instrument. The resolution of PEM is increased by allowing the detectors to be directly placed on the breast. Gentle compression provides the advantage of spreading out the breast tissue for imaging. PEM devices use 2 moving detector heads mounted on compression paddles, with a similar configuration and size as a traditional mammography system. This allows direct correlation of the initial and recurrence images obtained by both devices. PEM images can also be reconstructed into 3D for localization of abnormalities. It is reported that the technique used allows capturing sharp detailed images of breast lesions as small as 2 mm, and the detection of small foci of ductal carcinoma in situ without depending on the presence of calcification for its identification. The whole-body radiation dose the patient receives from PEM is approximately three times higher than that of a mammogram, which may be a barrier to using it as a screening modality in the general population. PEM also cannot take the place of breast cancer staging performed with whole-body PET because PEM is limited to breast views only. It is reported that the same benign conditions that cause high FDG uptake in PET (e.g. infection, inflammation and fat necrosis) may cause false positive results in PEM. Glucose control is another problem with PEM as it is with PET; women with inadequately controlled diabetes cannot undergo either procedure (Tafreshi 2010, Ferrara 2010, Moadel 2011).

PEM 2400 PET scanner and PEM Flex devices have received FDA clearance to perform PET imaging of the breast under gentle compression for patients with confirmed breast cancer.

Medical Technology Assessment Committee (MTAC)

Positron Emission Mammography (PEM)**08/15/2011: MTAC REVIEW**

Evidence Conclusion: Berg et al (2006) study (Evidence table 1) evaluated PEM diagnostic performance in 77 women with 77 index and 15 incidentally discovered lesions, all histologically proven breast cancer. PEM identified 91% of DCIS, and had an overall sensitivity of 93% for the index cancers, and 90% when incidental cancers were included. Combined with conventional imaging (mammography and ultrasonography) the sensitivity of PEM improved to 98%, but with a reduced specificity. The study had its limitations and used nonstandard method for calculating the standardized uptake value (SUV). Berg et al, 2011 (Evidence table 2) examined the diagnostic performance of PEM and its impact on surgical management compared with MRI in 388 women with newly diagnosed, histologically proven breast cancer. The results of the study showed that PEM and MRI had an overall similar accuracy. MRI was more sensitive and less specific than PEM at the lesion level and in detecting incidental additional cancers. MRI was also more accurate than PEM in assessing disease extent and need for mastectomy. Still, as the authors indicate, “the combination of both MRI and PEM did not fully depict the disease extent, particularly in cases with extensive intraductal component, multifocal disease, or multicentric disease, the patient population that would benefit from accurate assessment of the disease extent”. Schilling et al, 2011 (Evidence table 3) also compared the performance of FDG-PEM vs. MRI, including their effect on presurgical planning in 208 patients with newly diagnosed, biopsy proven breast cancer. Only 76% of the participants were included in the analysis. Overall, the results show that PEM and MRI had similar sensitivities of 92.8% in depiction of index cancerous lesions. Similar to the Berg’s study, MRI was more sensitive and less specific than PEM in detecting additional unsuspected ipsilateral lesions but, the difference was statistically insignificant. However, the authors did not discuss if they performed any power analysis to determine the appropriate sample size. The study did not examine whether PEM results alone influenced surgical treatment as all imaging results were available to the surgeons prior to surgery treatment.

Articles: The literature search revealed around two hundred articles on PET exams for the breast. Many were review articles, technical reports, or studies on the diagnostic accuracy of FDG-PET rather than PEM which is the focus of the review. There were a limited number of studies that compared the accuracy of PEM with mammography or MRI, and most were conducted by one PEM working group. The following studies were selected for critical appraisal: Berg WA, Weinberg IN, Narayanan D, et al. High resolution fluorodeoxyglucose positron emission tomography with compression (“positron emission mammography”) is highly accurate in depicting primary breast cancer. *Breast J.* 2006;12:309-323. See [Evidence Table](#). Berg WA, Madsen KS, Schilling K, et al. Breast cancer: comparative effectiveness of positron emission mammography and MR imaging in presurgical planning for the ipsilateral breast. *Radiology.* 2011;25:59-72. See [Evidence Table](#). Schilling K, Narayanan D, Kalinyak JE, et al. Positron emission mammography in breast cancer: presurgical planning f comparison with magnetic resonance imaging. *Eur J Nucl Med Mol Imaging* 2011;25:23-36. See [Evidence Table](#).

The use of Positron Emission Mammography (PEM) does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

- Last 6 months of clinical notes from requesting provider &/or specialist

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Acute stroke is the third leading cause of death and the third most costly adult disease in the United States. Ischemic stroke is the more common type, and hemorrhagic stroke the more serious. Patients with acute ischemic stroke, who have intracranial arterial obstruction, have poorer prognosis and higher probability of deteriorating at 24 hours. When a cerebral artery is occluded, a core of the brain tissues dies rapidly. Surrounding this infarct core is an area of brain tissue that is hypoperfused but does not die quickly due of collateral blood flow. This area is called the ischemic penumbra, and its fate depends on the rapid reperfusion of the ischemic brain. The presence and extent of the ischemic penumbra is time dependent and may vary among patients. 90-100% of those with supratentorial arterial occlusion show an ischemic penumbra in the first 3 hours of a stroke, but only 75-80% may still have penumbral tissue at 6 hours after a stroke onset. Thus, the rapidity of diagnosis, distinction between types of stroke, and determining the extent and duration of ischemia are all critical in selecting the treatment strategy (Wintermark 2005, Muir 2005, Brunser 2009).

The ischemic penumbra is potentially salvageable with the administration of thrombolytic agents, but irreversibly damaged tissue will not benefit from reperfusion and may be at a higher risk of hemorrhage after thrombolytic therapy. Currently intravenous tissue plasminogen activator (tPA) administered within 3 hours of symptom onset is the only FDA approved drug for acute stroke in North America. Clinical trials showed that it can significantly reduce the effects of stroke and reduce permanent disability when administered within a limited time period. Thrombolytic drugs however, can also cause serious bleeding in the brain which could be fatal, and thus it is crucial to determine which patient would likely benefit from or likely to be harmed by the treatment. This narrow time window for using thrombolytic therapy in patients with acute nonhemorrhagic stroke intensified the need for

an accurate, rapid, and accessible neuro-imaging technique that is able to identify and quantify ischemic penumbra. MR perfusion, xenon CT, PET and SPECT have been used but are limited by their availability, cost and/or patient tolerance. Clinical assessment scales that predict arterial occlusion have also been developed but are not highly accurate and their use is restricted to the middle cerebral artery (Lev 2001, Hoeffner 2004, Brunser 2009).

Conventional noncontrast CT (NCCT) is the standard initial imaging modality used to evaluate patients with acute stroke symptoms. It is widely available, convenient, and has a high sensitivity for the detection of intracranial hemorrhage which represents an absolute contra-indication to thrombolytic therapy. The Alberta Stroke Program Early Computed Tomography Score (ASPECTS) was developed and validated in 1990 to quantify early ischemic changes on CT scans in the middle cerebral artery territory, before thrombolytic therapy. However, NCCT provides only anatomic and not physiologic information about the vessels. Researchers found that dynamic imaging after rapid injection of contrast material using CT or MRI allows assessing tissue hemodynamics from respective contrast curves, i.e. bolus tracking. MRI is currently the preferred imaging method for determining the core and penumbra tissue. It is the modality used in major clinical trials evaluating the use of tPA for stroke patients. However, MRI scanners may not be available or accessible in some hospitals and rapid imaging of acute stroke patients is of vital importance. CT scanners on the other hand are widely available in emergency rooms, and recent advances in CT and computer technology permit the calculation of contrast curves on a pixel-by-pixel basis providing high resolution perfusion CT (PCT) maps. Perfusion CT imaging has the potential of providing rapid assessment of the structural and functional status of cerebral vessels in patients who would have already undergone unenhanced head CT to exclude acute hemorrhage (Hoeffner 2004, Nabavi 2007).

PCT imaging, using standard nonionic iodinated contrasts can be performed as an adjunct to conventional CT imaging. It adds only a few minutes to the examination and does not require transferring the patient to another imaging device. PCT can be done with any spiral CT scanner and has the advantage of assessing both reversible and irreversible ischemia by generating parametric maps of cerebral blood volume (CBV), cerebral blood flow (CBF), and contrast mean transit time (MTT). The ultimate goal is to discriminate three types of tissues components: 1. The ischemic core that has the most severe ischemia and is the tissue at maximum risk of infarction, 2. Potentially salvageable tissue with mild to moderate ischemia, and 3. Tissue with normal hemodynamics. Unlike conventional CT which is normally assessed visually, perfusion imaging requires quantification of the enhancement in tissues and blood at certain time points following intravenous injection. By demonstrating a regional reduction in perfusion and prolongation of transit time, functional PCT can potentially make a positive diagnosis of acute cerebral ischemia and assess prognosis within the first few hours of stroke onset, when conventional CT images are typically normal. The perfusion maps can be generated in a short time at any workstation equipped by the appropriate software (Hoeffner 2004, Parsons 2005, Miles 2006, Nabavi 2007, Popiela 2008).

PCT however, has limited spatial coverage (20-48 mm thickness) and may not provide information on an ischemia located outside the scanning level. It also cannot detect small lacunae due to its limited spatial resolution. There is considerable variability in the protocols used for PCT scanning, perfusion post processing techniques, and in the threshold between scanners for CBV, CBF, and time to peak enhancement (TTP). Moreover, the reproducibility of PCT postprocessing has not been fully validated, the quantitative accuracy of the results is debated, and the quantitative analysis of the perfusion maps is still evolving, may be time consuming, and is less convenient in an emergency setting. It also has the disadvantage of exposure to ionizing radiation and use of iodinated contrast which may be associated with contrast-induced nephropathy in high risk patients (Wintermark 2005, 2008, Miles 2006, Kohrmann 2007).

The FDA has cleared several software packages (CT perfusion 4, syngo Neuro PBV, syngo perfusion CT and others) for post processing images acquired with CT imaging systems for patients with suspected stroke.

Medical Technology Assessment Committee (MTAC)

Perfusion computed tomography (PCT) for the Treatment of Acute Stroke

08/03/2009: MTAC REVIEW

Evidence Conclusion: Several small studies assessed the accuracy of PCT in identifying the site of occlusion and characterizing the infarct. All had their advantages and limitations; the majority was multicenter, used MRI or follow-up MRI, CTA or clinical condition as gold standards, and had blind assessment of results. However, they were mainly retrospective, did not assess the time of recanalization and /or combined the results of those who received and did not receive thrombolytic therapy, all of which are potential sources of bias and confounding.

In a small prospective study, Murphy and colleagues (2006) investigated whether PCT can be used to differentiate between penumbra and infarcted tissue. They used noncontrast CT at 5-7 days as a gold standard and showed that the pair of CBV and CBF derived from PCT had a sensitivity and specificity of 97.0% and 97.2% respectively, in differentiating an infarct from a penumbral tissue. Tan and colleagues 2007, retrospectively compared different CT modalities and found that decreased cerebral blood volume (CBV) derived from PCT was more accurate than CT angiography (CTA) in predicting of the anatomic distribution of final infarct core (sensitivity 80.4%, specificity 96.8%), while CTA was more accurate in determining the site of occlusion (sensitivity 94.6%, specificity 100.00%).

Several other small studies including Schramm et al (2004, N=22, Schaeffer 2008, N=45, and Wintermark 2007, N=42) found that the PCT with or without and CTA correlate highly with MRI results in measuring the lesion volume in patients with acute stroke. In conclusion, the overall published evidence suggests that cerebral blood volume and cerebral blood flow values derived from a baseline PCT may have a potential use in differentiating an infarct from penumbral tissue. However, there are no large randomized trials that examined the use of perfusion CT for selection of patients for thrombolysis. All published randomized controlled trials to date used MRI for the selection of the therapeutic strategy based on the presence or absence of tissues at risk. The use of PCT in acute stroke patients needs to be investigated further in large RCTs to determine whether it could be used to guide treatment decisions and improve outcomes.

Articles: The search yielded almost three hundred articles on brain CT in acute stroke patients. Many were review articles, opinion pieces, or dealt with technical aspects of the scan.

The search results were screened for the studies on: 1. Accuracy of PCT in determining the site of vessel occlusion, infarct core, salvageable brain tissue, or collateral flow, and in predicting final infarct volume in patients with suspected acute stroke: The literature search identified around thirty prospective and retrospective studies that evaluated the accuracy of PCT in identifying the site of occlusion and characterizing the infarct. PCT with or without noncontrast CT (NCCT) was compared with MRI, CT angiography, or follow-up NCCT. All studies were small with population sizes ranging from 22 to 44, except for one retrospective study that included 132 patients and evaluated both the accuracy and prognostic value of PCT compared to other CT imaging modalities. The studies presented the results in sensitivity and specificity, or just correlated the findings with those of MRI. Few small studies with sample sizes ranging from 19 to 44 patients, evaluated the accuracy of PCT in predicting prognosis of ischemic stroke. Predicting prognosis was based on comparison with delayed perfusion MRI, follow-up CT, or monitoring the evolution of each patient's clinical condition. The majority of the studies were retrospective, used earlier generations of multiline CT scanners with limited spatial coverage, and no adjustments were made for the potential confounding factors. 2. Impact of PCT in management decisions and patient outcomes: The literature search did not reveal any randomized controlled trials that examined the impact of perfusion CT on the management of ischemic stroke patients and /or clinical outcomes. There was one small case-control study that investigated whether the lesion volume on PCT maps within 3 hours of onset of symptoms would predict final infarct volume, and the effect of intravenous tPA on affected brain tissue. The study however, had several limitations and used the 8-section multidetector scanner. The following three studies on the accuracy of PCT in characterizing the cerebral infarct were selected for critical appraisal: Murphy BD, Fox AJ, Lee DH, et al. Identification of penumbra and infarct in acute ischemic stroke using computed tomography perfusion-derived blood flow and blood volume measurements. *Stroke* 2006; 37:1771-1777. See [Evidence Table](#). Tan JC, Dillon WP, Liu S, et al. Systematic comparison of perfusion-CT and CT-angiography in acute stroke patients. *Ann Neuro*. 2007; 61:533-543. See [Evidence Table](#). Schramm P, Schellinger PD, Klotz E, et al. Comparison of perfusion computed tomography and computed tomography angiography source images with perfusion-weighted imaging and diffusion-weighted imaging in patients with acute stroke of less than 6 hours duration. *Stroke* 2004; 35:1652-1658. See [Evidence Table](#).

The use of Perfusion computed tomography (PCT) for the treatment of acute stroke does not meet the *Kaiser Permanente Medical Technology Assessment Criteria*.

For Non-Medicare Members

No Oncologic Diagnosis Confirmed

In the absence of a confirmed oncological diagnosis, PET results may be needed to determine the optimal location to perform an invasive diagnostic procedure due to difficulty accessing potential biopsy sites because of anatomical complexity as described in the medical records.

Solitary Pulmonary Nodule (SPN) Solid or Part Solid	Indications
	<ol style="list-style-type: none"> 1) Newly discovered, without known prior malignancy; and the following are met: <ol style="list-style-type: none"> a) A concurrent thoracic CT has been performed AND b) A single indeterminate or possibly malignant lesion more than 0.8 cm in diameter has been detected AND c) Not recommended for ground glass opacities/nodules 2) The purpose of the scan is to determine likelihood of malignancy in order to plan management of care

Oncological Diagnosis Confirmed

For patients with a biopsy proven or confirmed oncologic diagnosis (typically biopsy proven), PET scans may be medically necessary for any of the listed diagnoses below when standard staging/restaging diagnostic and imaging studies are inconclusive AND further characterization is needed to make management decisions. The expected change in clinical management must be documented in the clinical records. The grid below contains the letters TNM. T is for tumor and the number associated describes the tumor. N is for lymph node involvement. M is for extent of metastasis.

Oncological Diagnosis	Indications
Anal	<ol style="list-style-type: none"> 1) New diagnosis – consider PET scan for staging of T3 – T4, N0; or with any T, node positive
Breast Cancer	<ol style="list-style-type: none"> 1) Stage I, II: PET scan is not recommended 2) Stage III A or B: PET scan is not recommended for operable stage III. May be helpful in non operable stage III if equivocal findings on CT and bone scans 3) Stage IV: PET not routinely covered but may be indicated if conventional imaging is equivocal and results will change management 4) The following indications are not covered for PET scans <ol style="list-style-type: none"> a) Routine surveillance b) Initial diagnosis of breast cancer and the staging of axillary lymph nodes
Cervical	<p><u>Staging for Invasive Cervical Cancer as an Adjunct to Conventional Imaging:</u> An FDG PET scan is reasonable and necessary for the detection of metastases during the pre-treatment management phase (i.e., staging) in patients with newly diagnosed locally advanced cervical cancer with no extra-pelvic metastasis on conventional imaging tests, such as computed tomography (CT) or magnetic resonance imaging (MRI). Use of FDG PET as an adjunct may more accurately assist in the non-invasive detection of para-aortic, pelvic nodal involvement and other metastases in the pre-treatment phase of disease. The following conditions must be met:</p> <ol style="list-style-type: none"> 1) If stage is less than or equal to IB1: PET not routinely recommended 2) If stage is IB2 or greater: CT, PET scan or MRI as clinically indicated
Colorectal Cancer	<ol style="list-style-type: none"> 1) Initial staging Colon cancer appropriate for resection: Not routinely indicated and should not supplant contrast-enhanced CT. <ol style="list-style-type: none"> a) PET may be indicated for metastatic adeno carcinoma of the large bowel when there is potentially surgically curable metastatic disease 2) Restaging <ol style="list-style-type: none"> a) When the post-operative carcinoembryonic antigen (CEA) or liver function tests (LFTs) remain elevated and other attempts at imaging are negative OR

Oncological Diagnosis	Indications
	b) Evaluation of a potentially resectable metastatic lesion in order to confirm that it is resectable and to confirm absence of other sites of disease OR c) Differentiating local tumor recurrence from post-operative and/or post-radiation scarring 3) Surveillance: not recommended 4) Monitoring therapy progress is not indicated
Esophageal	For staging and restaging 1) If no evidence of metastatic disease on chest/abdominal CT and 2) Individual is a candidate for aggressive therapy
Gastric/GE Junction	For staging and restaging (not necessary for T1 patients) 1) If no evidence of metastatic disease on chest/abdominal CT and 2) Individual is a candidate for aggressive therapy
Gastroenteropancreatic Neuroendocrine Tumors (GEP-NET)	Kaiser Permanente endorses the recommendations for PET imaging using somatostatin receptor (SSR)-PET* for neuroendocrine tumors from the National Comprehensive Cancer Network® (NCCN) Guideline for Neuroendocrine and Adrenal Tumors . (log-in required to access) *This service is available at multiple Kaiser Permanente facilities. Please click to view Lutathera criteria
Head and Neck Cancers	1) Staging indicated for: a) Stage III-IV disease of oral cavity, oropharynx, glottic larynx and supraglottic larynx, hypopharynx, ethmoid sinus b) Nasopharynx, Paranasal sinus, and Maxillary sinus: Imaging optional for evaluation of distant metastases (i.e. chest, liver, bone) for stage III-IV disease. Naso-pharyngeal cancer may be appropriate for PET for stage II disease if lymph node positive. 2) Restaging (only for stage III – IV cancers) a) Post-treatment evaluation of cancers of head and neck (minimum 12 weeks after radiation completed). If the study is negative, repeat PET not indicated for surveillance. 3) Lip: No PET is indicated in the absence of advanced stage disease (stage III) 4) Salivary: No PET is indicated; CT & MRI as needed 5) Unknown primary in the head and neck (squamous cell carcinoma, adenocarcinoma, or anaplastic/undifferentiated epithelial tumor on FNA) when no tumor is evident on initial eval: Initial evaluation should consist of a flexible fiberoptic laryngoscopy as well of CT of the neck For thyroid see below.
Lung Cancer – Non-small cell	1) A positive PET scan finding can be caused by infection or inflammation, including absence of lung cancer with localized infection, presence of lung cancer with associated infection, and presence of lung cancer with related inflammation. A false negative PET scan can be caused by a small nodule, low cellular density, or low tumor activity for FDG. Serial PET scans are not recommended to follow response to therapy; conventional imaging is preferred. No need for bone scan if PET scan already done. 2) Initial staging: Indicated for stages I-III A or B when active treatment is planned. Not typically recommended for known stage IV. Documentation must show how results will alter treatment for stage IV treatment 3) Radiation planning in patients with significant atelectasis, IV contrast is contraindicated and when improved targeting is sought. (if meets criteria 1 above) See Solitary Pulmonary Nodule Above

Oncological Diagnosis	Indications
Lung Cancer – Small Cell Recommended clinical trials only	<ol style="list-style-type: none"> 1) Initial staging small cell lung cancer (SCLC) when it has been determined to be of limited-stage (i.e. limited to the ipsilateral hemithorax and regional lymph nodes) after standard staging evaluation AND patient is a potential surgical candidate or for a combined modality approach with radiation and chemotherapy 2) Restaging – not recommended for routine follow-up after initial therapy See Solitary Pulmonary Nodule Above
Hodgkin Disease Lymphoma	<ol style="list-style-type: none"> 1) Initial staging <ol style="list-style-type: none"> a) Essential during initial work-up 2) Early/interim re-staging <ol style="list-style-type: none"> a) Prognostic value is seen with a PET after 2-4 cycles of standard dose chemotherapy, if change in treatment is anticipated 3) Restaging <ol style="list-style-type: none"> a) After completion of chemotherapy to assess treatment response and characterize residual mass at the end of treatment OR b) after radiation completion, typically at 3 months 4) Surveillance is not recommended due to risk of false positives 5) Pet Scan – field determination for radiation therapy planning
Melanoma	<ol style="list-style-type: none"> 1) Stage I & II not for routine staging, only to evaluate specific signs or symptoms (CT, MRI also options) 2) Stage III or IV; recommended for baseline staging and/or to address specific signs and symptoms (CT, MRI also options)
Multiple Myeloma	<p>Effective until 06/01/2023</p> <ol style="list-style-type: none"> 1) Skeletal survey with plain films is initial imaging of choice 2) Staging and restaging if standard imaging and lab tests cannot define extent of disease and results will change management <p>Effective 06/01/2023</p> <ol style="list-style-type: none"> 1) Whole-body imaging low-dose CT scan is preferred modality for patient initial workup for patients suspected of having MM, or Solitary Plasmacytoma. 2) FDG/PET CT is reserved for situations when initial whole-body low-dose CT or MRI is non diagnostic. 3) Whole-body imaging low dose CT is preferred for all Myeloma follow up.
Non-Hodgkin's Lymphoma	<p><u>Low grade lymphoma:</u> PET scan may be indicated for Stage I & II but not routinely for Stage III and IV unless management would be changed See Lymphoma Grade Table below</p> <p><u>Intermediate & High Grade Lymphoma:</u> PET scan is indicated for restaging after completion of therapy (chemotherapy or radiation); not for surveillance See Lymphoma Grade Table below</p> <ol style="list-style-type: none"> 1) Diffuse large B-cell lymphoma (intermediate) <ol style="list-style-type: none"> a) Initial staging is essential b) Restaging <ol style="list-style-type: none"> i) at completion of treatment (wait 8 weeks minimum) c) Early/interim restaging following 2-4 cycles of chemotherapy is controversial and should be done only if a planned change in management is documented. Biopsy of PET positive sites should be considered 2) AIDS-related B-cell lymphoma <ol style="list-style-type: none"> a) Initial staging is essential 3) Peripheral T-cell Lymphoma <ol style="list-style-type: none"> a) Initial staging is essential b) Interim restaging for all ALCL and ALK+ <ol style="list-style-type: none"> i) Repeat studies for all positive studies c) Restaging

Oncological Diagnosis	Indications
	i) at completion of treatment ii) Repeat studies for all positive studies 4) Extranodal NK/T-cell lymphoma nasal type a) Initial staging is essential b) Post-radiation therapy the role remains uncertain 5) Pet Scan – field determination for radiation therapy planning
Occult Primary	1) Not routinely recommended. Documentation must clearly identify the clinical reason for such testing.
Ovarian	1) PET scan not routinely indicated for initial staging 2) Restaging: may be covered if conventional imaging (CT, MRI) give indeterminate results and PET will alter management 3) May be approved if there is a solitary lymph node that is a possible candidate for surgical resection
Prostate	1) Use is unproven and should be provided within a clinical trial setting
Prostate – Axumin PET	<p>Effective until June 01, 2023</p> <p>Covered for:</p> <ul style="list-style-type: none"> Subsequent treatment strategy for individuals with prostate cancer who have a rising PSA (defined below) and have previously been treated with prostatectomy and/or radiation therapy. Both CT abdomen, CT pelvis, and bone scan must be negative for recurrence Patient must be a candidate for local therapy (such as removal of prostate after prior XRT, or removal of a local recurrence, or focal radiation) If the patient has diffuse metastatic disease already diagnosed, this imaging is not needed. Original clinical stage T1-T2, NX or NO and Life expectancy > 10 years and PSA now < 10ng/mL and PSA ≥ 1 or <1 with rapid PSA doubling time (doubled in less than 6 months) <p>Not covered for:</p> <ul style="list-style-type: none"> Initial treatment strategy for newly diagnosed prostate cancer Surveillance of individuals with localized/advanced prostate cancer, who have completed definitive therapy or are receiving maintenance therapy and whose PSA is not rising. <p>Effective June 01, 2023 Axumin no longer recommended; please see PSMA PET criteria here</p>
Prostate- PSMA PET	<p>Effective until June 01, 2023</p> <p>*PSMA PET currently being reviewed on a case-by-case basis based on medical necessity, until June 01, 2023: Gallium GA-68 PSMA-11 (PSMA PET – prostate) A9593, A9594, A9596 Piflufolastat F-18 (PSMA PET – prostate) A9595</p> <p>Effective June 01, 2023 Please see PSMA PET criteria here</p>
Soft Tissue Sarcoma	1) Not routinely recommended 2) Baseline staging, for cases when grade is uncertain or when conventional imaging has not conclusively evaluated the possibility of distant metastasis 3) Differentiation of suspected tumor from radiation or surgical fibrosis
Thyroid	1) Localization to plan treatment for papillary or follicular thyroid carcinoma with the following: <ul style="list-style-type: none"> a) Previously treated with thyroidectomy and radioiodine ablation AND b) Thyroid Globulin (TG-antibody) positive (stimulated or on suppression) greater than 10 AND c) Negative structural imaging i.e. ultrasound and CT negative

Oncological Diagnosis	Indications
	2) Initial staging OR follow-up for localization to monitor response to prior treatment (surgery, I131, radiation therapy, or tyrosine kinase inhibitor), for treatment planning or to predict prognosis for the following: <ul style="list-style-type: none"> a) Aggressive tumors confirmed by histology (Hurthle cell, poorly differentiated, anaplastic) OR b) Aggressive behavior i.e. any tumor with confirmed metastasis showing progression on structural imaging or by rising TG level despite prior treatment
All other cancers not listed above	1) Evaluated on a case by case basis, in conjunction with consultants and national guidelines

The Indolent Lymphomas**B Cell Neoplasms**

- Small lymphocytic lymphoma/B-cell chronic lymphocytic leukemia
- Lymphoplasmacytic lymphoma
- Plasma cell myeloma/plasmacytoma
- Hairy Cell leukemia
- Follicular lymphoma (grade I and II)
- Marginal zone B-cell lymphoma
- Mantle cell lymphoma

T Cell Neoplasms

- T-cell large granular lymphocyte leukemia (LGL disease)
- Mycosis fungoides
- T-cell prolymphocytic leukemia
- T-cell large granular lymphocyte leukemia

Natural Killer cell neoplasm

- Natural killer cell large granular lymphocyte leukemia

Low Grade

- A. Malignant lymphoma
Small lymphocytic
consistent with CLL
plasmacytoid
- B. Malignant Lymphoma, follicular
Predominantly small cleaved cell
- C. Malignant lymphoma, follicular
Mixed, small cleaved and large cell

The Aggressive Lymphomas**B Cell neoplasms**

- Follicular lymphoma (grade III)
- Diffuse large B-cell lymphoma
- Mantle cell lymphoma

T cell neoplasm

- Peripheral T-cell lymphoma
- Anaplastic large cell lymphoma, T/null cell

Intermediate Grade

- D. Malignant Lymphoma, follicular
Predominantly large cell
- E. Malignant lymphoma, diffuse
Small cleaved cell
- F. Malignant lymphoma, diffuse
Mixed, small and large cell
- G. Malignant lymphoma, diffuse
Large cell
cleaved cell
non-cleaved cell

The Highly Aggressive Lymphomas**B cell neoplasms**

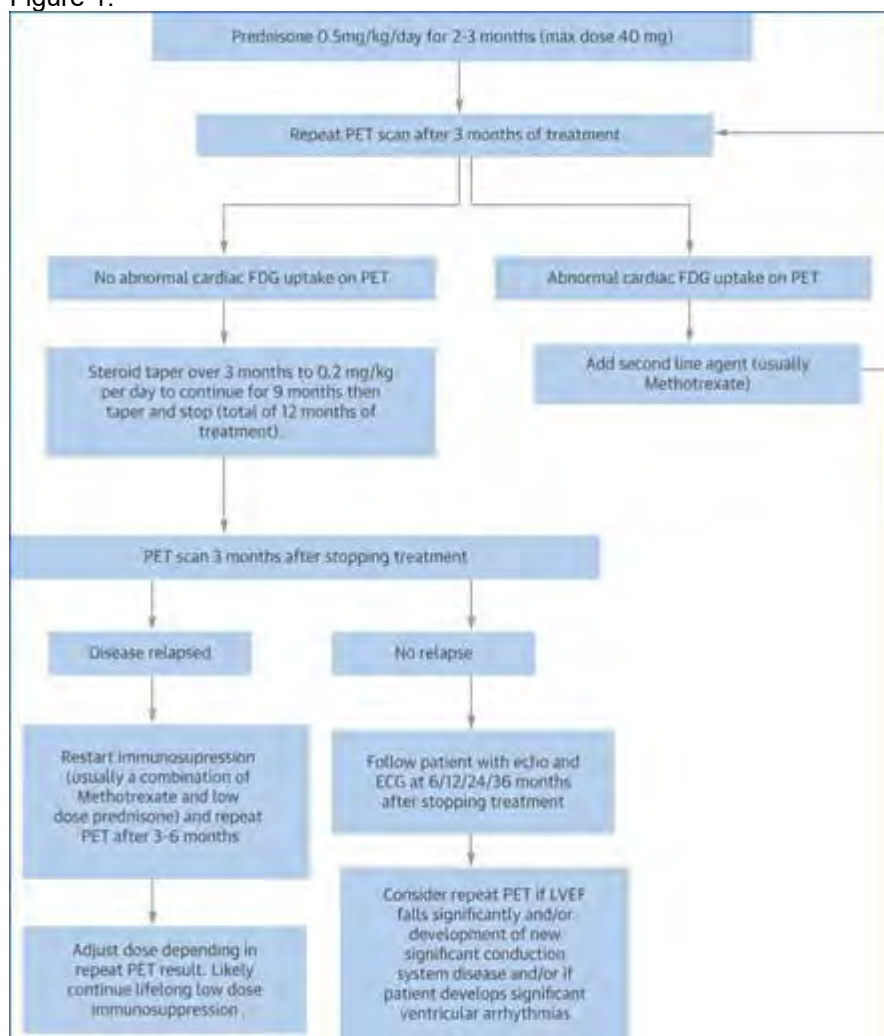

- Burkitt's lymphoma
- Precursor B lymphoblastic leukemia/lymphoma

High Grade

- H. Malignant Lymphoma
Large cell, immunoblastic
- I. Malignant lymphoma
Lymphoblastic
- J. Malignant lymphoma
Small non-cleaved cell
Burkitt's
Non-Burkitt's

Non-oncological conditions	Indications
Heart For myocardial Viability Using Fluorodeoxy-D-glucose (FDG)	<ol style="list-style-type: none"> 1. Determine myocardial viability prior to revascularization for patients who are potential candidates for CABG or stent if alternate diagnostic testing are not suitable or non-diagnostic <ol style="list-style-type: none"> a. SPECT is inconclusive or contraindicated due to BMI greater than 40 AND b. dobutamine stress echocardiogram is inconclusive or contraindicated AND c. cardiac MRI is contraindicated or non-diagnostic 2. Sarcoidosis with suspected/known cardiac involvement <ol style="list-style-type: none"> a. For initial diagnosis to evaluate active cardiac sarcoidosis <ol style="list-style-type: none"> a. if MRI cannot be performed b. if MRI is non-diagnostic or inconclusive, and high clinical suspicion for cardiac sarcoidosis remains c. if MRI is positive for cardiac sarcoidosis, a subsequent PET can be done for assessment of active myocardial inflammation b. Repeat PET study as per the algorithm below (Figure 1: Birnie, D. H., Nery, P. B., Ha, A. C., & Beanlands, R. S. B. (2016, July 26). Cardiac Sarcoidosis. Retrieved March 20, 2020, from http://www.onlinejacc.org/content/68/4/411) c. Routine surveillance with PET without a known diagnosis of cardiac sarcoidosis is not medically indicated. Serial evaluation while on

Figure 1:

Non-oncological conditions	Indications
	treatment for cardiac sarcoidosis should not be more frequent than 3 months. If there is a request in a shorter time frame, Kaiser Permanente Medical Director review is required.
Perfusion of the Heart Using Ammonia N-13 or Using Rubidium 82	1) Following inconclusive SPECT prior to revascularization (other diagnostic tests or alternative test are contraindicated or not suitable).
Epilepsy refractory Seizures	1) pre-surgical evaluation of refractory seizures

Other forms of PET Scans	Indications
¹⁸ F-florbetapir (Amyvid) PET for Alzheimer's Disease Flortaucipir F 18 injection PET for Alzheimer's Disease FDG Alzheimer's Disease and Dementia C-11 Acetate PET for Diagnosing Primary and Metastatic Prostate Cancer ¹⁸ F Fluoro-Estradiol PET (FES-PET) to Measure Estrogen Receptor Expression - Breast Cancer ¹⁸ F-NaF PET for the Detection of Bone Metastases Fluorodopa F-18 injection PET for Parkinsonian syndrome	There is insufficient evidence in the published medical literature to show that this service/therapy is as safe as standard services/therapies and/or will provide better long term outcomes than current standard services/therapies.

If requesting these services, please send the following documentation to support medical necessity:

- Last 6 months of clinical notes from requesting provider &/or specialist
- Last 6 months of radiology notes if applicable

[Positron Emission Mammography \(PEM\)](#) (Click here for link)

The following information was used in the development of this document and is provided as background only. It is provided for historical purposes and does not necessarily reflect the most current published literature. When significant new articles are published that impact treatment option, Kaiser Permanente will review as needed. This information is not to be used as coverage criteria. Please only refer to the criteria listed above for coverage determinations.

Background

Positron Emission Tomography has been studied over the past few years at the University of Washington as well as other academic centers. The efficacy of this scan is still being evaluated. Because medical staff members have asked to have this study covered for cancer detection, a criteria set for medical necessity has been developed which involves review by the Medical Director of the radiology department and maintenance of a request log with determination outcomes.

Positron emission tomography (PET) also known as positron emission transverse tomography (PETT), or positron emission coincident imaging (PECI), is a noninvasive imaging procedure that assesses perfusion and the level of metabolic activity in various organ systems of the human body. A positron camera (tomograph) is used to produce cross-sectional tomographic images by detecting radioactivity from a radioactive tracer substance (radiopharmaceutical) that is injected into the patient.

Positron Emission Tomography (PET) is a non-invasive nuclear medicine scanning technique that provides unique diagnostic information that cannot be obtained by other imaging modalities. While CT and MRI provide detailed images of the patient's anatomy; PET scanning reveals vital information concerning cellular function. This functional information can be critical in the evaluation of a variety of common and serious diseases. PET has shown utility in the management of a wide range of malignancies including lung cancer, colon cancer, lymphoma and melanoma. PET scanning also plays an important role in the evaluation of certain neurologic and cardiac diseases and the applications of this unique imaging modality continue to expand.

Recent developments in the field of PET scanning are certain to lead to a rapid expansion in the utilization of this powerful technique. There have been improvements in the resolution of the cameras allowing for higher diagnostic yield. Reimbursement issues are being worked out and HCFA has approved payment for several indications in the area of oncology. Additional indications may be approved in the near future. The problems surrounding the delivery of the radioisotopes are also being solved. This is particularly true for the Puget Sound area where a production facility (cyclotron) has recently been built in Kent.

Several careful studies have shown that there is a cost benefit associated with PET. In many cases PET will reveal findings not identified by CT or MRI, resulting in a more appropriate and timely diagnostic evaluation. Costs for unnecessary procedures are avoided. This results in an overall cost saving, despite the initial cost of performing the PET study.

Interest in PET scanning continues to grow rapidly in both the national and local medical community. Several local hospitals already have PET capability and the number of facilities offering this important diagnostic capability is certain to expand quickly. Many facilities are beginning their PET program by utilizing a mobile service. There are a number of mobile PET companies that are already providing or will soon be providing service to our area. This approach would allow for a minimal initial investment with low risk and could provide the opportunity to provide PET scanning at a number of different GH facilities on a rotating basis. In the future, depending on patient volume, consideration may be given to installing a permanent facility.
