Turner 2010	Prospective cohort study Patient enrollment: December 2004 to June 2006 Study location: Providers for the WA state workers' comp program; conducted by the Univ. of Washington	Length of f/u: 24 months Complete f/u rate: 87%†††††	<u>Total</u> N = 159 Mean age: 44.1 years Age range: NR 77% male	FBSS: 100% All patients had an open workers' compensation claim with the state of Washington Duration of chronic pain (median): 38 months	<u>Enrolled:</u> n = 52 <u>Crossover:</u> from UC: + 3 from PC: + 1 <u>Trial SCS*,†:</u> N = 51 (5 pts did not undergo trial) <u>Crossover:</u> to UC: + 2 to PC: + 3 <u>Permanent SCS‡:</u> N = 27 (52%) (n = 51 included in 24 month analysis, including crossovers)	<u>Enrolled:</u> n = 51 <u>Crossover:</u> to UC: -16 to SCS: -1 from UC: + 4 from SCS: + 2 <u>Pain clinic evaluation:</u> N = 39 <u>Pain clinic treatment:</u> N = 22 (n = 39 included in the 24 month analysis, including crossovers)	<u>Enrolled:</u> n = 56 <u>Crossover:</u> to PC: -4 to SCS: -3 from PC: + 16 from SCS: + 3 <u>Usual care treatment:</u> N = 68 (n = 68 included in the 24 month, including crossovers)	Study funded by Washington State Department of Labor and Industries, which administers the workers' comp provider for the enrolled patients (SCS would be a covered treatment only if patients enrolled in the study)

CRPS I: complex regional pain syndrome type I; previously referred to as reflex sympathetic dystrophy

f/u: follow-up

GPE: global perceived effect: evaluated on a seven-point scale (1 (“worst ever”) – 7 (“best ever”))

NR: not reported

PT: physical therapy

SCS: spinal cord stimulation

* Trial stimulation of SCS - devices used:

Kemler 2001, 2004, 2008: temporary electrode (model 3861, Medtronic, Minneapolis, MN): positioned in the in epidural space so the patient experienced paresthesia over the entire region of pain upon stimulation; external stimulator (model 3625, Medtronic).

Kumar 2007: device and length of trial stimulation NR.

North 2005: temporary electrode (3487A Pisces-Quad, Medtronic): placed in the percutaneous space, no other details given.

Turner 2010: device details NR, devices used determined by the treating physician.

† Trial stimulation of SCS – definition of success:

Kemler 2001: trial stimulation was considered successful if patients met either of the following criteria: (1) VAS score for the last four days of test stimulation was $\geq 50\%$ lower than the score prior to randomization, and/or (2) the GPE score was ≥ 6 (“much improved”).

Kumar 2007: trial stimulation was considered successful if patients met both of the following criteria: (1) $\geq 50\%$ reduction in leg pain, and (2) $\geq 80\%$ overlap of their pain with stimulation-induced paresthesia.

North 2005: trial stimulation was considered successful if patients met all of the following criteria: (1) $\geq 50\%$ reduction in pain “by standard pain rating methods”, (2) did not increase their analgesic medication dosage, and (3) had improved physical activity proportionate to their neurological status and age.

Turner 2010: success criteria NR, determined by the treating physician

‡ Permanent SCS implantation - devices used:

Kemler 2001, 2004, 2008: electrode (model 3487A, Medtronic): placed in thoracic (for hand) or lumbar (for foot) spine so the patient experienced paresthesia over the entire region of pain upon stimulation; pulse generator (Itrel III, model 7425, Medtronic): implanted in the left lower abdominal wall; tunneled extension lead (model 7495-51/66, Medtronic); programmer (model 7434-NL, Medtronic); generator specifications: rate: 85 Hz, pulse width: 210usec, amplitude (adjusted by patient): 0–10 V.

Kumar 2007: implantable neurostimulation system (Synergy System, Medtronic)

North 2005: electrode (3487A-56 or 3587A Resume Electrode, Medtronic): no details given regarding placement; generator (X-trel or Itrel pulse generator, Medtronic): no details given.

Turner 2010: device details NR, devices used determined by the treating physician.

** Kemler 2001, 2004, 2008: continuation of physical therapy past 6 months was optional.

†† Kumar 2007: the primary (intention-to-treat) analysis was performed with data taken at 6 months follow-up due to the high rate of cross-over by 12 months.

‡‡ Kumar 2007: For the SCS group, the authors did not note which treatment patients lost to follow-up had received. At six months follow-up, 2/52 patients in the SCS group had withdrawn consent, however, the authors did not note whether these patients had had successful trial stimulation and received a permanent device or they had failed trial stimulation. At 12 months follow-up, 5/52 patients in the SCS group were lost (2/52 lost to f/u, 3/52 withdrew consent).

*** Kumar 2007: CMM for all patients was reviewed and actively managed at the discretion of the study investigatory and in accordance with local clinical practice and included oral medications (opioid, non-steroidal anti-inflammatory drug, antidepressant, anticonvulsant/antiepileptic and other analgesic

therapies), nerve blocks, epidural corticosteroids, physical and psychological rehabilitative therapy, and/or chiropractic care. No invasive treatments (including spinal surgery or implantation of an intrathecal drug delivery system) were permitted.

††† Sensitivity analysis:

Kumar 2007: excluded five patients in the SCS group who did not meet the screening criteria but requested an implant.

‡‡‡ Worst-case analysis:

Kumar 2007: considered patients unavailable at follow-up in SCS group “failures” and those in CMM group “successes”.

North 2005: “worst case” analysis was performed according to intention-to-treat, but patients unavailable at follow-up were considered “failures”.

**** North 2005: 10/60 patients (SCS: 6/30; reoperation: 4/30) were randomized but not treated: 9/10 due to failure to obtain insurance authorization and 1/10 due to a stroke; these patients are considered lost to follow-up in the complete follow-up calculation.

†††† North 2005: reoperation patients were treated with laminectomy and/or foraminotomy and/or discectomy with or without instrumentation; cross-over to SCS was permitted six months postoperatively.

‡‡‡‡ Turner 2010: patients paid for each evaluation completed: baseline, 24-months: \$40 per visit; 6- and 12-months: \$20 per visit.

***** Turner 2010: Patients distributed into treatment groups as follows:

SCS group: only those claimants who were potentially good candidates for SCS, met the study inclusion criteria, and had no contraindications for SCS were considered for trial stimulation. In order to be a candidate for SCS, Washington state workers’ compensation claimants must agree to be part of the trial, otherwise, SCS was not a covered treatment. All treatment protocols were determined by the treating physician (details NR). Patients in the SCS group had significantly longer workers’ compensation claim duration and work time loss compensation (vs PC only), more likely to have legal representation (vs PC or UC), longer leg pain duration (vs PC only) and greater leg pain intensity (vs UC only), as well as higher (worse) Roland-Morris Disability Questionnaire scores (vs PC and UC). These differences were not controlled for by multivariate analysis.

Pain Clinic group: claimants who met the inclusion criteria and had been approved for pain clinic evaluation were invited to participate in the study.

All treatment protocols were determined by the treating physician (details NR).

Usual Care group: claimants who met the inclusion criteria but had not been referred for SCS or pain clinic evaluation were randomly invited (8 patients per week) to participate in the study.

Supplemental Table 2. Inclusion and Exclusion Criteria: Spinal Cord Stimulation Comparative Studies

Author (Year)	Inclusion criteria	Exclusion criteria
Kemler 2001	<ul style="list-style-type: none"> • 18 – 65 years of age • Met the IASP diagnostic criteria for reflex sympathetic dystrophy (CRPS I) • Had impaired function and symptoms beyond the region of trauma* • Pain restricted to one hand or foot • Pain affected entire hand or foot • Pain lasting \geq 6 months that: <ul style="list-style-type: none"> • did not respond continuously to standard therapy† • had a mean intensity of 5 cm on a scale of 0 cm (no pain) to 10 cm (extreme pain) • Consent to randomization to either treatment group 	<ul style="list-style-type: none"> • Raynaud’s disease • History of unrelated neurologic abnormalities • Unrelated condition that affects the diseased hand or foot • Blood-clotting disorder or use of an anticoagulant • Cardiac pacemaker • Presence of serious psychiatric disorders‡: <ul style="list-style-type: none"> • did not respond continuously to standard therapy† • had a mean intensity of 5 cm on a scale of 0 cm (no pain) to 10 cm (extreme pain)
Kemler 2004, Kemler 2008	<ul style="list-style-type: none"> • patients randomized to SCS +PT who crossed over to PT due to failed trial stimulation 	<ul style="list-style-type: none"> • patients randomized to PT who crossed over to SCS (allowed after 6 months)

Author (Year)	Inclusion criteria	Exclusion criteria
Kumar 2007, Manca 2008	<ul style="list-style-type: none"> • ≥ 18 years of age • Neuropathic pain of radicular origin (predominantly legs) that exceeds back pain • Pain intensity ≥ 50 mm on VAS (0 – 100 mm) • Pain for ≥ 6 months after ≥ 1 anatomically successful surgery for herniated disc • Documented history of nerve injury (root compression by herniated disc) that would explain the radiating pain 	<ul style="list-style-type: none"> • Concurrent clinically significant or disabling chronic pain syndrome • Inability to receive or manage the SCS device • History of coagulation disorder, lupus erythematosus, diabetic neuropathy, rheumatoid arthritis, or ankylosing spondylitis • Active psychiatric disorder, any condition known to affect the perception of pain, or inability to evaluate treatment outcome • Life expectancy < 1 year • Existing or planned pregnancy

Author (Year)	Inclusion criteria	Exclusion criteria
North 2005	<ul style="list-style-type: none"> • Nerve root compression amenable to surgical treatment • Persistent or recurrent radicular pain (with or without low back pain) refractory to conservative care • At least one previous lumbosacral spine surgery • Consent to randomization to either treatment group 	<ul style="list-style-type: none"> • Conditions requiring immediate surgical treatment: <ul style="list-style-type: none"> • Disabling neurological deficit (such as foot drop, neurogenic bladder) in the distribution of a nerve root caused by surgically treatable compression • Critical cauda equina compression • Gross instability (spondylolisthesis or abnormal subluxation) requiring fusion • Untreated dependency on prescription narcotic analgesics or benzodiazapines • Untreated major psychiatric condition • Possibility of secondary gain • Concurrent clinically significant or disabling chronic pain condition • Primary complaint of axial (low back) pain that exceeds radicular (hip, buttock, leg) pain
Turner 2010	<ul style="list-style-type: none"> • Open Washington State workers' compensation claim (of any duration) for back injury • Receiving work time loss compensation as a result of temporary total inability to work due to the injury • Age 18–60 years • 1–3 prior open lumbar spine 	<ul style="list-style-type: none"> • Patients who did not meet the inclusion criteria

Author (Year)	Inclusion criteria	Exclusion criteria
	<p>operations during the claim</p> <ul style="list-style-type: none"> • Pain radiating into one or both legs for > 6 months • Radicular pain greater than axial pain • Average pain in the past month rated ≥ 6 on 0–10 scale • No prior SCS surgery • Ability to speak English or Spanish <p>SCS patients:</p> <ul style="list-style-type: none"> • No contraindications for surgery • No progressive motor deficit, bony deformity • SCS would be a covered treatment for the patients by workers' compensation if they participated in the study <p>Pain clinic (PC) patients:</p> <ul style="list-style-type: none"> • Identified from worker's compensation administrative databases when they were approved for PC evaluation <p>Usual care (UC) patients:</p> <ul style="list-style-type: none"> • Had not been referred for SCS or PC • Eight patients per week were randomly selected 	

CRPS I: complex regional pain syndrome type I; previously referred to as reflex sympathetic dystrophy

IASP: International Association for the Study of Pain

SCS: spinal cord stimulation

* These symptoms are not part of the IASP definition of reflex sympathetic dystrophy.

† Standard therapy consists of six months of physical therapy, sympathetic blockade, transcutaneous electrical nerve stimulation, and pain medication.

‡ The psychiatric health of all patients was evaluated using the 90-item Symptom Check List (score range: 90 – 450, higher scores indicate greater psychological distress); psychiatric examination was performed if the patient received a score of ≥ 200 and any patient with major psychiatric illness, substance abuse, or potential secondary gains from the treatment of the disease were excluded.

						<ul style="list-style-type: none"> • PC: 24% (5/21) • $P = .37$ 	

EQ: EuroQol (European quality of life scoring tool)

GPE: Global Perceived Effect

NR: not reported

NRS: numerical rating scale

NS: not statistically significant

NSAID: non-steroidal anti-inflammatory drug

PC: pain clinic group

RDQ: Roland-Morris Disability Questionnaire

SCS: spinal cord stimulation

SD: standard deviation

TENS: transcutaneous electrical nerve stimulation

UC: usual care group

VAS: visual analogue scale

WCB: Worker’s Compensation Board

*GPE scores range from 1 to 7 and are defined as follows:

1 = worst ever

2 = much worse

3 = worse

4 = not improved and not worse

5 = improved

6 = much improved

7 = best ever

† Kemler 2000: HR-QoL measured using a VAS where 0 = death and 100 = perfect health.

‡ Kumar 2007: p-value adjusted for location of leg pain and may not exactly correspond to the unadjusted confidence intervals.

** Sensitivity analysis:

Kumar 2007: excluded five patients in the SCS group who did not meet the screening criteria but requested an implant.

†† Worst-case analysis:

Kumar 2007, 2008: considered patients unavailable at follow-up in SCS group “failures” and those in CMM group “successes”.

North 2005: “worst case” analysis categorized patients lost to follow-up (but presumably excluding the one patient in the SCS group who died) as “failures”.

‡‡ Kumar 2007: return to work analysis based on the number of people not working at baseline.

*** Kumar 2007: standard conversion tables were used to convert opioid dosages to morphine equivalents. Because a range was provided for some drugs, the authors calculated the “low” and “high” end of the range of morphine equivalent scores.

††† Manca 2008: using EQ-5D scores adjusted for differences in baseline EQ-5 scores between the groups.

‡‡‡ North 2005: The total number of available patients reported the SCS group for opiate use (n = 23 reported) does not correlate with the number of patients available for follow-up (SCS: 19/24 available for follow-up). No explanation was given in the text.

**** Modified per-protocol analysis was defined by the treatment received during the first year of the study: SCS (only trial stimulation was required); PC (pain clinic evaluation performed), and UC (patients did not undergo SCS trial or PC evaluation). Per-protocol analysis was used to compare SCS (patients underwent permanent implantation of SCS device) vs PC (some pain clinic treatment was received).

†††† Pain measured on a VAS (0 (no pain) to 10 (worst pain)).

‡‡‡‡ Adjusted for baseline differences between groups in the following characteristics: age, gender, RDQ score, leg pain intensity, duration of work time loss compensation, disability benefit other than workers’ compensation, unilateral vs bilateral leg pain, legal representation, and SF-36 mental health scores.

***** Adjusted for baseline value of the outcome measure being assessed

††††† Adjusted for work-related time loss compensation at baseline.

Supplemental Table 4. Safety Data: Spinal Cord Stimulation Comparative Studies

		months post-implantation) <ul style="list-style-type: none"> • seizures and ineffective pain relief (8 months post-implantation) • pain at pulse generator site and decreased effectiveness (17 months post-implantation) 	and a T2-L3 hemilaminotomy; one day following surgery, the patient had respiratory arrest and was placed on mechanical ventilation: 1 patient		

NR: not reported

SCS: spinal cord stimulation

IPG: implantable pulse generator

* Kemler (2000, 2004, 2008): Reported complications only for patients randomized to receive SCS. Thus, the final follow-up (60 months) excluded the 4 patients randomized to CMM alone who crossed over and received permanent implants; similarly, 2 CMM patients who had crossed over by 24 months were excluded.

† Kumar 2007, 2008: The number of revisions performed for each SCS component were not reported; many complications occurred requiring revision but the details of the procedure were not provided.

‡ Kumar 2007: Technique-related complications include: IPG cap not installed when only one lead was implanted; intermittent stimulation due to improper connection of extension to IPG; shocks caused by anteriorly implanted electrode; lead cut during implantation; and dural tear during implantation.

** Kumar 2008: Reported complications only for patients randomized to receive SCS. Thus, 32 CMM patients were excluded (28 crossed over, 4 underwent trial stimulation only).

†† Kumar 2008: Technique-related complications included intermittent stimulation due to improper connection of extension to IPG; shocks caused by anteriorly implanted electrode; and lead cut during implantation.

‡‡ North 2005: The authors did not report the denominator used for complication rates; we inferred it to be 31 based on one statement: “three SCS (9% of permanent implants) underwent hardware revisions...”. A total of 31 patients underwent permanent implantation, and 3/31 gives a rate of 9.6%. 29/31 patients were available for final follow-up, but we report the data using n = 31 as the denominator in accordance with the study.

** Turner 2010: study reported that 19% (5/27) of patients underwent total explantation of system, but another patient was apparently not included in this total and had explantation 20 months after the original implantation; our rate includes this additional patient.

f/u: follow-up

NR: not reported

SCS: spinal cord stimulation

* Trial stimulation device details for case-series are beyond the scope of this report. All patients reported here received a permanent SCS device; the number of patients reported that underwent trial stimulation is as follows:

Kay 2001: NR

Kumar & Wilson 2007: 424 patients enrolled; trial stimulation was successful in 80% (338/424) and a failure (not internalized) in 20% (86/424).

Kumar & Toth 1998: 221 patients enrolled, 39 either died or were lost to follow-up; 165 of the remaining 182 patients had successful trial stimulation and received permanent devices and an additional 5 who failed trial stimulation either died or were lost to follow-up.

Lanner 2007: NR

North 1993: 249 of 320 consecutive patients had successful trial SCS and received a permanent implant.

Sanchez-Ledesma 1989: 36 of 49 patients had successful trial SCS and received a permanent implant.

† Permanent SCS devices:

Kay 2001: Unipolar or quadripolar plate electrodes in the thoracic or cervical spine; stimulators included radiofrequency-coupled receiver transducer (14%) or total intracorporal pulse generators. Manufacturer information NR.

Kumar & Wilson 2007: Device details reported in Kumar 2006¹: Electrode systems (Medtronic); cylindrical electrodes (percutaneous implantation) (Pisces-Sigma, quadripolar Pisces, and octapolar Pisces electrodes) or paddle electrodes (small laminotomy required) (Resume and Specify electrodes).

Kumar & Toth 1998: electrodes placed percutaneously (Pisces-Sigma and Pisces-Quadripolar, Medtronic) or via small laminotomy (Resume, Medtronic); pulse generators with internal batteries and external programmers (Itrel I, II, III; X-trel, Medtronic).

Lanner 2007: devices NR.

North 1993: Of the 298 total devices implanted in 249 patients, 76% (226/298) were implanted percutaneously and 24% (72/298) were implanted by laminectomy; 44% (131/298) were either monopolar or bipolar, and 56% were multipolar (4 or 8 contacts). The generators were single-channel radiofrequency-coupled in 48% (144/298) and multichannel programmable radiofrequency-coupled in 52% (154/298). Device manufacturers were Medtronic and Neuromed, Inc. (Ft. Lauderdale, Florida).

Sanchez-Ledesma 1989: Electrodes implanted percutaneously and connected to a subcutaneous radiofrequency receiver (Medtronic) or to a total implantable system (Medtronic).

‡ *Kay 2001*: authors explicitly stated that they received no financial contribution from Medtronic for the study.

** *Kumar & Wilson 2007*: although the study suggests a complete follow-up rate of 99.4% (336/338), Kumar 2006¹ (which is an earlier follow-up of a subset of patients) noted that 42 patients had been excluded with < 1 year follow-up available; whether these patients had undergone permanent SCS implantation was not noted. *Kumar & Wilson 2007* did not provide any additional information, though it is clear that at least 42 patients were excluded.

†† *Kumar & Wilson 2007*: patient demographics are for the total number of patients enrolled, only 338/424 underwent permanent SCS implantation.

‡‡ *Kumar & Toth 1998*: patient demographics are for the 182 patients enrolled and available for follow-up; only 165 underwent permanent SCS implantation.

*** *Lanner 2007*: In the period between 1999–2005, 145 patients with chronic pain were treated with SCS, yet only 88/145 (61%) were included in the study. No information was provided regarding the selection of these 88 patients from the larger pool.

††† *North 1993*: It is not clear which subset of patients the demographic data pertains to (ie., all 320 patients; the 249 that underwent implantation, or the 171 of the latter group available at follow-up).

‡‡‡ *Sanchez-Ledesma 1989*: patient demographics are for the total number of patients enrolled, only 36/49 underwent permanent SCS implantation.

f/u: follow-up

NR: not reported

SCS: spinal cord stimulation

* Kumar & Wilson 2007: complete f/u rate was not explicitly stated; we obtained a 99% f/u based on the data provided.

† Kumar & Wilson 2007: the authors used all 424 patients to calculate the complication rates even though only 338/424 underwent permanent implantation of SCS. For our reported complication rates, we used the 336/338 patients who underwent permanent implantation of SCS and were available at long-term follow-up.

‡ North 1993: data not reported separately for electrode and lead failures.

Supplemental Table 7. Demographic Table: Spinal Cord Stimulation Prognostic Studies

Author (Year)	Study Type Study Period Study Location	Follow-up Complete f/u rate (%)	# Patients (perm. SCS) Age (mean, range) Sex	Preop diagnosis (%), N) Duration of chronic pain or disease	Intervention	Conflict of Interest

None of the authors had a financial interest in Medtronic or Neuromed.
Turner 2010	See Table 1					

Author (Year)	Study Type Study Period Study Location	Follow-up Complete f/u rate (%)	# Patients (perm. SCS) Age (mean, range) Sex	Preop diagnosis (% , N) Duration of chronic pain or disease	Intervention	Conflict of Interest
Van Eijs 2010	Retrospective cohort Study period NR; recruitment period: March 1997 to July 1998 Maastricht University Hospital; Maastricht, Netherlands	Length of f/u: 12 months Complete f/u rate: 94%††† (35/36)	N = 36†††, but only 24/36 underwent permanent SCS implantation Mean age: 40 years**** Age range: 21–65 years**** 61% female****	Chronic CRPS type I: 100%, affecting the: • hand: 61% (22/36)**** • foot: 39% (14/36)**** Duration of chronic pain (mean): 3.33 years (range, 0.75–10 years)****	<u>Enrolled:</u> N = 36 <u>Received permanent SCS device*:</u> N = 24 (51%) (see Kemler 2000 in Table 1 for details)	None (study supported by a grant from the Dutch Health Insurance Council)

CRPS: complex regional pain syndrome

FBSS: failed back surgery syndrome

f/u: follow-up

NR: not reported

SCS: spinal cord stimulation

SD: standard deviation

* Permanent SCS devices:

Burchiel 1995: 37/40 patients had implantation of a quadripolar electrode (PISCES-Quad Model 3487A or PISCES-Quad Plus Model 3888, Medtronic) via the epidural space; 3/40 had a laminectomy and implantation of the RESUME electrode (Medtronic); pulse generators (ITREL I or II, Medtronic) were implanted in patients who had successful trial stimulation with a handheld programmer for 2 days.

Lame 2009: device details NR.

North 1991: electrodes were placed percutaneously in 64% of patients (Model 1980 JF, Neuromed, Inc.; Pisces Quad, Medtronic) and by laminectomy in 36% of patients (Medtronic Myelostat and Resume). Quadruple electrode arrays used in 76% of patients (Medtronic Pisces Quad or Resume; Neuromed 1980

JF) which utilized implanted radiofrequency-coupled programmable stimulators (Medtronic SE-4; Neuromed MNR-4); bipolar electrodes were used in 24% of patients and were connected to single-channel radiofrequency coupled stimulators (Medtronic Pisces). Electrodes were typically placed within T9–T12 segments to achieve the most overlap of parasthesias with pain.

North 1996: device details NR.

Van Eijs 2010: electrode (model 3487A, Medtronic): placed in thoracic (for hand) or lumbar (for foot) spine so the patient experienced paresthesia over the entire region of pain upon stimulation; pulse generator (Itrell III, model 7425, Medtronic): implanted in the left lower abdominal wall; tunneled extension lead (model 7495-51/66, Medtronic); programmer (model 7434-NL, Medtronic); generator specifications: rate: 85 Hz, pulse width: 210usec, amplitude (adjusted by patient): 0–10 V.

† Burchiel 1995: N = 79 enrolled; 57/79 had successful trial stimulation and received permanent device, 45/57 available at 3 months (2/57 excluded after explantation of SCS system (hardware malfunction, ineffective stimulation); 1/57 discontinued use (ineffective stimulation); 9/57 lost to f/u or did not provide f/u data); 40/45 met the diagnostic inclusion criteria. Complete follow-up rate determined by the number of patients included at follow-up who underwent permanent SCS implantation (34/57).

‡ Lame 2009: Demographic information provided for 32/35 patients who received permanent implantation of SCS that were available for follow-up.

** North 1991: Demographic information provided for 50/53 patients available at follow-up.

†† North 1996: Demographic information provided for the 58 patients enrolled in the study, only 35 of whom underwent permanent SCS implantation.

‡‡ North 1996: 42 of the 58 patients were also reported in North 1993

*** North 1996: No conflict of interest was reported, however, North 1993 (which included 42/58 patients included here) was supported by a grant from Medtronic, and Medtronic was not involved in data collection or analysis. None of the authors had any financial interest in Medtronic or Neuromed.

††† Van Eijs 2010: complete f/u rate NR in this study, but the complete f/u rate for these patients (the 36 patients in the SCS group) was 94% (35/36) in Kemler 2004.

‡‡‡ Van Eijs 2010: patient population was taken from an RCT (Kemler 2000) in which the authors participated.

**** Van Eijs: demographic data provided for the 36 patients included in the study; only 24/36 underwent permanent device implantation.

CRPS: complex regional pain syndrome

DABS: Derogatis Affects Balance Scale

FBSS: failed back surgery syndrome

f/u: follow-up

GPE: global perceived effect

MMPI: Minnesota Multiphasic Personality Inventory

NR: not reported

NRS: numerical rating scale

PCS: pain catastrophizing score

PGIC: patients global impression of change

RDQ: Roland-Morris Disability Questionnaire

RSD: reflex sympathetic dystrophy

SCS: spinal cord stimulation

SD: standard deviation

SF-36: Short-Form 36

WCB: Worker’s Compensation Board

* Pain outcome measures:

Burchiel 1995: 10-cm VAS scale used.

Lamé 2009: the VAS was recorded three times a day for four days and the mean score was used to determine pain intensity and compared to the VAS at baseline.

North 1991: “success” was achieved if a patient had $\geq 50\%$ pain relief at last available follow-up and patient satisfaction (patient would repeat treatment for the result obtained).

North 1996: “success” was defined as continuous pain relief of $\geq 50\%$ by VAS and patient satisfaction (patient would repeat treatment for the result obtained).

- Van Eijs 2010*: “success”: patients with SCS were considered successful at the 12-month f/u if they had sustained pain reduction, as defined by a reduction in their VAS by ≥ 2.5 and/or a PGIC score of “much improved” or “very much improved” at 3 of the 4 follow-up visits.
- † Burchiel 1995: A prediction equation was generated using forward, stepwise linear regression analysis of all the prognostic variables listed above; age, the McGill Pain Questionnaire evaluative subscale (MPQe), and depression (D) subscale scores were found to be significant predictors of outcome. The predictive equation generated is: $\% \Delta \text{VAS} = 112.57 - 1.98(D) - 1.68(\text{Age}) + 35.54(\text{MPQe})$.
- ‡ Lame 2009: Multivariate regression analysis done for the domains of the SF-36; pain duration and the corresponding baseline score of each SF-36 domain were both used as control variables; pain catastrophizing was used as the crucial variable. *Post hoc* analysis was additionally performed by substituting the remaining variables for pain catastrophizing.
- ** Lame 2009: Education classified as “low” (lower vocational education) or “high” (secondary education).
- †† Turner 2010: Adjusted for baseline differences between groups in the following characteristics: age, gender, RDQ score, leg pain intensity, duration of work time loss compensation, disability benefit other than workers’ compensation, unilateral vs bilateral leg pain, legal representation, and SF-36 mental health scores.
- ‡‡ Van Eijs 2010: Although only 24/36 of the patients had a successful trial stimulation and received permanent SCS implants, prognostic data was reported for all 36 patients. “Successful” patients consisted of 20/24 of those who underwent permanent implantation, while “unsuccessful” patients consisted of 4/24 of those with permanent implants as well as the 12 who did not receive permanent implants (failed trial stimulation).
- *** Van Eijs 2010: Absent or light hypoesthesia was defined as normal or diminished sensibility to light touch; severe hypoesthesia was defined as diminished sensibility or loss of protective sensation.
